THE CRITICS HAVE RAVED, AND I’M SURE THEY MUST HAVE BEEN TALKING ABOUT THIS BOOK:

THE PHENOMENAL #1 BEST SELLER!

THE BOOK EVERYBODY’S TALKING ABOUT!

NOW A MAJOR MOTION PICTURE

“Taut, fast, and relentless . . . A ride worth taking. Keeps the reader hooked . . . from the gripping first chapters . . . to the vise-tightening midsection and on to the sensational finale.”

Name withheld by request
.1. Preface

This manuscript represents my effort to produce a comprehensive text on real analysis, in a new organizational format possible only in an online book. The project is far from complete; indeed, it could be described as still being in its infancy. It will continue to evolve and grow in the future.

I have tried to take advantage of the increased organizational flexibility available for an online manuscript. A printed book must be organized linearly, but an online book need not be. Hyperlinks can make it possible to navigate through the various sections in a complicated and organic way. Supplemental material can be included without interfering with the flow of the core material (which can itself be varied according to the interests of the reader). While I am certainly not the first author to think of trying to take advantage of this flexibility in organizing an online book, I have been surprised to find that the possibilities have been largely unexplored so far, and the potentially revolutionary benefits of flexible organization online have been little exploited. Even \( \LaTeX \) (or at least \( \LaTeX \)), which has become the universally-used text editing system for mathematics and related fields (and which I have used for this manuscript), is too inflexibly oriented toward producing linearly-organized printed documents. I hope my approach to organization of this manuscript will help encourage other attempts to develop the possibilities. See () for more detailed comments about organization.

This book is intended as a supplement, not a replacement, for the many fine books on this subject already available. I have consulted existing texts and references extensively, and they have collectively been very influential in both the general approach and specific details of my treatment. I have tried to be careful in giving credit where credit is due; however, in a subject as generally mature as real analysis, there is little originality in the actual mathematics of most books (including this one) – the primary contributions of each author are the exposition and organization, and decisions on what material to emphasize and what to leave out (the online organization of this book has made the decision criteria considerably different for me than for authors of printed books).

No part of this manuscript should be regarded as the last word, or even my last word, on the subject. My approach on many topics is pretty standard, and in a lot of cases will probably remain so; much of this subject has been quite refined for a long time. But my approach to some parts of the subject has changed already during the project (frankly, I have been forced to think critically about the treatment of some topics for the first time in my career), and this process will surely continue.

I regard myself as a competent mathematician who is reasonably qualified for a project of this sort, and I think I have learned something about the right way to present this subject in my 35 years of experience in teaching analysis at the university level. But I am in no way uniquely or even especially well qualified; I think there are many other mathematicians who could do at least as good a job, in some cases much better, on all or parts of the project. The only difference is that I actually have done it.

I expect and welcome comment and criticism concerning my efforts, either through personal communication or public statements. I will take all (informed) criticism to heart, and it will perhaps result in improvements in the manuscript. Certainly simple corrections to errors and misstatements (of which there are likely to be a substantial number despite my best efforts to be careful) will be greatly appreciated and quickly acted on. Broader criticism of the text is also welcome. However, I issue the following challenge to anyone who is dissatisfied with what is here: don’t just criticize me, try to do better yourself. I do not regard myself as being in competition with anyone; my goal is simply to have the best treatment of this subject available to the community at large. Criticism of my manuscript makes a small contribution to this goal, but anything you write which is better than what I write benefits us all much more.

Chapter I

Introduction

“I regard as quite useless the reading of large treatises of pure analysis: too large a number of methods pass at once before the eyes.”

*Joseph Louis Lagrange*

This chapter is intended as an informal overview of the subject developed in this book. We will describe in general terms what the theory of real analysis is all about, and how it relates to the rest of mathematics.

I.1. Calculus and Analysis

“By 1800 mathematicians and physicists had developed calculus into an indispensable tool for the study of the natural world, and the problems that arose from this connection led to a wealth of new concepts and methods – for example, ways to solve differential equations – that made calculus one of the richest and hottest research areas in the whole of mathematics. The beauty and power of calculus had become undeniable. However, Bishop Berkeley’s criticisms of its logical basis remained unanswered, and as people began to tackle more sophisticated topics, the whole edifice started to look decidedly wobbly. The early cavalier use of infinite series, without regard to their meaning, produced nonsense as well as insights. The foundations of Fourier analysis were non-existent, and different mathematicians were claiming proofs of contradictory theorems. Words like ‘infinitesimal’ were being bandied about without being defined; logical paradoxes abounded; even the meaning of the word ‘function’ was in dispute. Clearly these unsatisfactory circumstances could not go on indefinitely.

Sorting it all out took a clear head, and a willingness to replace intuition by precision, even if there was a cost in comprehensibility. The main players were Bernard Bolzano, Cauchy, Niels Abel, Peter Dirichlet, and, above all, Weierstrass. Thanks to their efforts, by 1900 even the most complicated manipulations of series, limits, derivatives and integrals could be carried out safely, accurately and without paradoxes. A new subject was created: analysis. Calculus became one core aspect of analysis, but more subtle and more basic concepts, such as continuity and

\[^{1}\text{http://www.math.okstate.edu/~wli/teach/fmq.html}\]
limits, took logical precedence, underpinning the ideas of calculus. Infinitesimals were banned, completely.”

Ian Stewart

Calculus, as learned by undergraduates, roughly develops into two distinct, but interconnected, branches of mathematics. One branch, differential calculus, leads to the subject of differential geometry; the other, integral calculus, is the starting point for the subject of measure and integration. Subjects such as Complex Analysis and Ordinary and Partial Differential Equations are also based on calculus, but cannot be cleanly categorized in either branch. The catchall term analysis is used in mathematics to loosely include all subjects which are outgrowths of calculus, covering such a broad and diverse spectrum of mathematics as to defy a good definition, although it roughly means those parts of mathematics which involve infinite processes and limits; it is also often described as the mathematics of change or of continuous processes. (The word “analysis” in nontechnical English has a different and even broader meaning, which would include most of mathematics.)

I.2. Differential Calculus

I.3. Measure and Integration

Measure and integration, besides being a rich and beautiful theory in its own right, is an indispensable tool in most parts of pure and applied mathematics. To the working mathematician, measure and integration are as fundamental a tool as calculus and linear and abstract algebra. Whole parts of mathematics, including Probability Theory and Functional Analysis, are based primarily on the theory of measure and integration; other subjects, such as the modern theory of Ordinary and Partial Differential Equations, also owe their foundations to this theory.

Either measure or integration can be taken as the fundamental concept, and the other developed from it. It is somewhat a matter of taste which way to do this, but it is valuable to be able to think both ways since each approach is natural in some important contexts.

I.3.1. Measure

I.3.1.1. Measure theory, developed in the early twentieth century, gave the first mathematically satisfactory resolution to two foundational problems of analysis and geometry, one which caused great controversy especially in the sixteenth and seventeenth centuries in Europe (see [Ale13] for a study), and one which was only realized much later. (Measure theory later turned out to be good for a lot of other things too, such as formulating a rigorous theory of probability.)

The Paradox of Indivisibles

I.3.1.2. Should a line be regarded as a set of points? Any discussion of two lines intersecting at a point, drawing line through two given points, or especially considering the points between two given points on a line, all basic notions of Euclidean geometry, would seem to implicitly entail that certain points are at least “located” on a given line, almost (but not necessarily quite the same thing as) saying that the line is

\[?, \text{p. 149}\]
composed of a collection of points. Thus it is hard to imagine that it could be controversial that a line is (or can be thought of as) a collection of points, but it was.

I.3.1.3. Actually, we must first consider a more basic question: is a mathematical line (or plane, or three-dimensional space) something which exists in a well-defined and uniquely determined form, reflecting properties of physical space, as apparently believed by everyone until the nineteenth century, or is it a human mental construct which can be made in various ways, with properties depending on the way it is defined? If one believes the former, then observed properties of physical space place limits on what can be believed or contemplated about mathematical space.

I.3.1.4. The first problem to be considered is whether the number of points (“indivisibles”) on a line segment is finite or infinite. If there are only finitely many points on a line segment, either the points must have a positive diameter and touch each other, or there must be gaps between them. Either hypothesis seems untenable, and few mathematicians or even nonmathematicians have taken this possibility seriously; a mathematical line, or mathematical space, is very different in character from physical objects made up of a large but finite number of atoms. And nowadays (and gradually since DESCARTES) we identify points on a line with (real) numbers, and it is easily seen that between any two numbers there are infinitely many more, and in particular, there is no such thing as two consecutive numbers. In fact, in this picture of a line, every subinterval of a line segment, no matter how tiny, looks just like the whole segment, so a line is “infinitely divisible”; but contrary to what most if not all people from the sixteenth century believed, there is no logical contradiction in saying a line is infinitely divisible but that it is made up of points which are indivisible.

I.3.1.5. The other possibility is that a line segment is made up of infinitely many points (indivisibles). The next question then is whether for each point there is a “next” point, and if so whether the points “touch” or whether there is a gap between them. GALILEO thought there were infinitely many points, each of infinitesimal size, with gaps of infinitesimal length between them (he did not attempt to define what he meant by “infinitesimal”). In our picture of a line as the set of (real) numbers, there are clearly not consecutive points, and the questions of whether points on a line “touch” or whether there are “gaps” become very subtle if not meaningless (see (1)).

I.3.1.6. Whether or not there are consecutive points, if it is assumed that a line segment contains infinitely many points there is a basic paradox, which was one of the roots of the controversy over the theory of indivisibles. The length of the interval should be the sum of the sizes (diameters) of the points. Presumably all the points have the same character, and in particular have the same size. If the diameter of each is positive, the length of the interval is the sum of infinitely many equal positive numbers, which is infinite. And if the diameter of each is zero, then the length of the interval is the sum of infinitely many 0’s, so should be zero. How can the length be a finite positive number?

I.3.1.7. Mathematicians (and nonmathematicians) worried about this paradox for a long time, but through the development of Calculus it was glossed over, or if considered was resolved using the vague (at the time) notion of “infinitesimal numbers,” numbers which were positive but equal to 0 for practical purposes. It was not until measure theory was developed in the twentieth century that a satisfactory and rigorous solution to the paradox was found.
The key idea was the sensational discovery by Cantor in the late nineteenth century that there were different sizes of infinity, i.e. infinite sets could have different sizes. The smallest infinity is “countable infinity”: a set is countably infinite if its elements can be listed in a sequence. There are also “uncountable infinities” (actually many different ones!): a set is uncountable if it has “too many” elements to be listed in a sequence, i.e. any sequence of elements from the set necessarily leaves out some (“most”) elements of the set. Cantor showed not only that uncountable sets exist, but even that every interval of numbers is uncountable, i.e. every line segment contains uncountably many points. The resolution of the paradox is that while a sensible definition of the sum of countably many numbers can be made (this is the theory of infinite series), no sensible definition of the sum of uncountably many numbers is possible. Thus it cannot be sensibly said that the length of an interval is the (uncountable) sum of the (zero) diameters of the points.

The theory of Lebesgue measure is built on this resolution. A notion of “size” of subsets of $\mathbb{R}$ is defined, which has the property that the size of an interval is its length, and in particular the size of a point (singleton) is zero, and the size of a countable disjoint union of sets is the sum of the sizes of the sets. There is no strict numerical relationship between the size of an uncountable union of disjoint sets and the sizes of the sets themselves, so in particular there is no inconsistency between the size of an interval, which is an uncountable disjoint union of single points, and the sizes of the points. (Actually, it turns out that not all subsets of $\mathbb{R}$ have a well-defined “size” (Lebesgue measure), but the ones which do not are so bizarre they cannot even be explicitly described, and never come up in practice.)

A variation of the theory of indivisibles is to regard a plane figure as being “made up” of a collection of parallel line segments, or a solid region in $\mathbb{R}^3$ being made up of a collection of parallel slices, each a plane figure, although these line segments or slices are technically not “indivisible.” One has the same paradox as in the one-dimensional case: the area of the plane figure should be the sum of the areas of the line segments, and similarly in the solid case. The paradox is resolved in the same way via measure theory. But even before this can be done, another foundational problem must be resolved.

What Do Area and Volume Mean?

The area of a plane region, or the volume of a solid, seem to have a self-evident meaning. It apparently did not occur to anyone before the twentieth (or perhaps late nineteenth) century — not Euclid, not Archimedes, not Newton, not Euler, not Gauss, not Cauchy — that area or volume had to be defined: they were just there, and merely needed to be calculated. (This issue is on top of the more basic question discussed earlier of whether lines, planes, or space are themselves well defined.) Not only was it implicitly assumed that area (volume) was a meaningful concept, it was also assumed that it had some “obvious” properties: congruent regions have the same area, the area of a disjoint union is the sum of the areas of the components, the area of a rectangle is $\text{length} \times \text{width}$, the area of a curve is 0, and hence the area of the boundary of a region is 0, so the area of the union of “nonoverlapping” regions is the sum of the areas, etc. See I.5.1.1. for a more extensive discussion of the issue.

So how do we define the area of a region, and how do we show that area has the expected properties? Measure theory gives a satisfactory answer. We first define the area of a rectangle to be $\text{length} \times \text{width}$, and then by a somewhat involved process extend the definition to sets which can be built up from rectangles by countably many set operations. As in the case of Lebesgue measure on the line, not every subset of the plane has a well-defined area by this process, but all “reasonable” subsets do, and in
particular all the sets considered during the long development of geometry and calculus (going back at least to Euclid and Archimedes) have an area by this definition, which agrees with the intuitive areas already calculated by algebraic and calculus methods. The same procedure gives a rigorous definition of volume for subsets of \( \mathbb{R}^3 \), agreeing numerically with the informal or assumed “volume” calculated by earlier methods. The expected properties of area must be proved from the definition, but can be shown to hold (although there are some subtleties, e.g. the area of the boundary of a region is not necessarily zero if the boundary is sufficiently complicated).

The Nature of Measure Theory

I.3.1.13. The goal of the subject of measure theory is to associate a numerical “size” to subsets of a set \( X \) in a precise, consistent, and well-behaved manner. The principal property that such a notion of “size” should have is that the “size” of a union of disjoint subsets should be the sum of the sizes of the sets.

I.3.1.14. It turns out that in most applications it is both natural and necessary to restrict attention only to certain well-behaved subsets of \( X \); frequently some subsets are too bizarre to allow a reasonable notion of “size.” In addition, to get a reasonable theory one must only allow countably many operations. The technical term is that the collection of “measurable sets” (subsets with a “size” or measure) form a \( \sigma \)-algebra (see () for a precise definition.)

I.3.1.15. In many instances there is a natural notion of size for a collection of subsets which is not large enough to form a \( \sigma \)-algebra, and the task is then to extend this size notion to a larger \( \sigma \)-algebra of sets.

There are two fundamental examples of this process, which have motivated most of the development of the theory:

I.3.1.16. Example. As discussed above, let \( X \) be the real numbers \( \mathbb{R} \). There is a natural size for certain nice subsets, the intervals: if \( I \) is the interval from \( a \) to \( b \) (with or without endpoints), the measure of \( I \) should be the length \( b - a \). It turns out that this measure can be extended to a \( \sigma \)-algebra of subsets of \( \mathbb{R} \) in such a way that congruent sets have the same measure. The resulting measure is called Lebesgue measure on \( \mathbb{R} \), and gives by far the most natural and important example of a measure space. It turns out that not every subset of \( \mathbb{R} \) can be Lebesgue measurable, but every subset which can be explicitly described, and in particular any set which arises in any reasonable way in applications, is measurable.

Similarly, the plane \( \mathbb{R}^2 \) has a size notion (“area”), as does three-dimensional Euclidean space \( \mathbb{R}^3 \) (“volume”), and more generally \( \mathbb{R}^n \) for any \( n \). These size notions are only defined at first for nice subsets such as rectangular solids, but can be extended in the same manner as in \( \mathbb{R} \). These cases are a little harder intuitively than the one-dimensional case: for example, even finding the area of a set like a disk requires a nontrivial limiting process. However, the general theory applies in just the same manner as in the one-dimensional case to give \( n \)-dimensional Lebesgue measure.

There are other natural measures on Euclidean space. For example, there is a measure on \( \mathbb{R}^2 \) which assigns to a smooth curve its arc length. This measure, called one-dimensional Hausdorff measure, would give infinite size to any two-dimensional set. Hausdorff measures giving fractional dimensions to fractal sets can also be defined. In fact, measure theory underlies the whole study of fractals.
I.3.1.17. Example. The basic setup of probability theory is to analyze a process or “experiment” to numerically describe the possible results. The set of all possible outcomes is called the sample space, which we will denote \( \Omega \). A subset \( E \) of \( \Omega \) is called an event. In the simplest situation, \( \Omega \) is just a finite set, and each point has a certain probability of occurring; the sum of all the individual probabilities is 1. The probability that an event \( E \) occurs is the sum of the probabilities of the points in \( E \).

However, the set \( \Omega \) is often infinite, and individual points have probability 0, but infinite events may have positive probability. For example, suppose the process is to choose a number \( x \) randomly from \([0, 1]\). The sample space \( \Omega \) is thus \([0, 1]\). If \( x_0 \) is any fixed number, the probability that the chosen \( x \) is exactly equal to \( x_0 \) is 0. However, the probability that \( 0 \leq x \leq 1/2 \) (\( E = [0, 1/2] \)) is 1/2. More generally, the probability that \( a \leq x \leq b \) is \( b - a \).

The proper setup for probability theory is to take the set of allowable events to be a \( \sigma \)-algebra of subsets of \( \Omega \), and the probability of events is given by a measure on this \( \sigma \)-algebra with the measure of the whole space \( \Omega \) equal to 1. In the above example, the probability is given by Lebesgue measure on \([0, 1]\).

In fact, most of the elementary concepts of probability theory are measure theory concepts with different terminology. A simple dictionary is all that is needed to make the translation.

I.3.2. Integration

I.3.2.1. Integration is the other basic component of this part of real analysis. The goal of integration is to systematically assign to a real-valued function \( f \) on a set \( X \), and a subset \( A \) of \( X \), a number \( \mathcal{I}_A(f) \) called the integral of \( f \) over \( A \) (the notation \( \int_A f \), or some variation, is usually used; the symbol \( \int \) is called the integral sign), which is usually thought of as a “normalized sum” of the values of \( f \) on the points of the subset \( A \). This number has various interpretations in applied situations as total distance (regarding \( f \) as giving instantaneous velocity), total mass (regarding \( f \) as giving density), etc. Integration in analysis is thus almost always (and always in this book) a generalization or analog of what in elementary calculus is called the “definite integral.” (We will also have occasion to consider analogs of the “indefinite integral” of calculus, but these will have different names and will not be called integrals.)

I.3.2.2. All modern theories of integration are in a sense outgrowths of the so-called Riemann integral (actually developed first by Cauchy for continuous functions and generalized by Riemann to also handle moderately discontinuous functions), the type of integration treated in elementary calculus. The Riemann integral was the first reasonably satisfactory theory of integration, and is still by far the theory most widely used in applications; Riemann integrals can in many cases be exactly and efficiently computed using antiderivatives and the Fundamental Theorem of Calculus, and there are good numerical techniques for approximating Riemann integrals that cannot be computed exactly. In fact, more general integrals are rarely actually computed directly; in practice they are usually approximated by Riemann integrals which are then computed or estimated using standard techniques.

For theoretical purposes, Riemann integration has two serious inadequacies:

1. The class of Riemann integrable functions is too small. For a function to be Riemann integrable on an interval, it must be bounded and “almost continuous” (see () for a precise statement). It is particularly useful to be able to integrate certain unbounded functions. This is reasonably, but not entirely, satisfactorily achieved by using various notions of improper Riemann integrals and principal values. It is also important to be able to integrate over unbounded intervals, which can be done through other types of improper integrals, although not in an entirely satisfactory way. At least for theoretical purposes, it is also important to be able
to integrate functions which are too discontinuous to be Riemann integrable, and to be able to integrate functions over subsets of the real numbers more general than intervals or finite unions of intervals (although the practical value of this type of integration is sometimes somewhat overemphasized as an inadequacy of Riemann integration).

2. It is crucial in many settings to have limit and approximation theorems, i.e. to know that under reasonable conditions, if \( f_n \to f \) in some sense, we have \( I_A(f_n) \to I_A(f) \). It is quite difficult to establish good theorems of this sort for Riemann integration which are applicable even if we know that the limit function is Riemann integrable (which is often not the case due to the limitations described above). It turns out that to get reasonable convergence theorems, more general integration theories are needed.

Another limitation of Riemann integration is that it only (directly) works on \( \mathbb{R} \), or on \( \mathbb{R}^n \). It is very important to have integration theories which work on more general spaces, and it turns out that modern approaches give this flexibility with essentially no additional work.

“Lebesgue’s definition enables us to integrate functions for which Riemann’s method fails; but this is only one of its advantages. The new theory gives us a command over the whole subject which was previously lacking. It deals, so to speak, automatically with many of the limiting processes which present difficulties in the Riemann theory.”

\[ E. \ C. \ Titchmarsh^{3}\]

There are three principal modern approaches to integration, each with many variations. We first discuss the basics of Riemann integration in a form allowing the various generalizations to be made naturally.

I.4. Other Topics

“The object to be attained by the theory of functions of a real variable consists then largely in the precise formulation of necessary and sufficient conditions for the validity of the limiting processes of Analysis. . . . In the literature of the subject, errors are not infrequent, largely owing to the fact that spatial intuition affords an inadequate corrective of the theories involved, and is indeed in some cases almost misleading.”

\[ E. \ W. \ Hobson^{4}\]

“If you have an apple and I have an apple and we exchange apples then you and I will still each have one apple. But if you have an idea and I have an idea and we exchange these ideas, then each of us will have two ideas.”

\[ George \ Bernard \ Shaw\]
I.5. Rigor in Mathematics

“A simple man believes every word he hears; a clever man understands the need for proof.”  
Proverbs 14:15\(^5\)

“After deserting for a time the old Euclidean standards of rigour, mathematics is now returning to them, and even making efforts to go beyond them. . . . Later developments . . . have shown more and more clearly that in mathematics a mere moral conviction, supported by a mass of successful applications, is not good enough. Proof is now demanded of many things that formerly passed as self-evident. Again and again the limits to the validity of a proposition have been in this way established for the first time. . . . In all directions these same ideals can be seen at work – rigour of proof, precise delimitation of extent of validity, and as a means to this, sharp definition of concepts.”

Gottlob Frege, 1884\(^6\)

A student, particularly a nonmathematics student, may well wonder about two questions:

1. Why is it necessary to spend the time and effort to develop a precise, rigorous, and complete theory of measure and integration (or any other mathematical topic)? Isn’t this just an idle intellectual exercise for mathematicians with nothing better to do, without practical benefit to those using the theory? Does there have to be an elegant general theory behind every useful piece of mathematics?

2. Even given that someone ought to carefully work out the details, isn’t it enough that someone already has? Why can’t we just use the theory without having to immerse ourselves in the details?

Both questions are legitimate ones, and deserve serious answers.

Let us discuss the second question first. Here there is a good analogy. It is quite possible for a person to use a machine without understanding all the technical details of its construction and operation. However, it is quite important that the user, in addition to simply knowing how to operate the machine, understand enough about it to know what it can and cannot do, and what dangers it may pose; failure and even disaster can result from careless operation or trying to use the machine beyond its capabilities. Also, the user might eventually want to have the machine do something it was not designed for, and the machine may have to be modified to accomplish the new task. It would likely be impossible to figure out how to adapt the machine to a new task without a good understanding of its construction.

In addition, the existing theory is so vast that it is often easier to work out what is needed in a particular situation instead of doing a possibly long and involved search for exactly the right “off-the-shelf” result that applies. One needs a good understanding of the theory to do this (and indeed even to recognize when an off-the-shelf result applies and suffices!)

“The problem may be viewed as one of information retrieval; we wish to find a particular piece of information, not knowing for sure that it has ever been recorded, and instead of trying to provide a catalog of known results (which would necessarily be finite and to a great extent represent past

---

\(^5\)New English Bible

interests), we prefer a method of creating it as needed. Instead of information retrieval we prefer information regeneration. Of course this attitude will not work in all areas of knowledge, but in a mature science the principles should show how to recreate the information on demand.”

R. W. Hamming

The first question is almost asking: What is mathematics? To begin with the last part of Question 1, it is certainly not true that every bit of mathematics has to be backed by a rigorous general theory to be useful. For example, a lot of analysis beginning with calculus was developed and extensively used for about 200 years before its logical underpinnings were carefully worked out in the nineteenth century. Even today, where standards of rigor are high and mathematicians rarely if ever use techniques and results whose validity has not been carefully established, there are many heuristic and ad hoc methods not backed up by general theory, especially in applied mathematics. This is in no way a criticism of this work, or of applied mathematics in general; if applied mathematicians had to wait for general theories underlying their techniques before using them, progress would grind nearly to a halt (and the general theories might never come.)

A good example is fractal geometry. Some mathematicians question whether this subject should even be regarded as part of mathematics, since there are almost no theorems and the work is almost entirely descriptive rather than analytical. I personally do not take such a narrow view of mathematics, and I think this subject is unquestionably part of mathematics; after all, did calculus only become part of mathematics after Weierstrass?

Perhaps an even more striking example is the “theory” of quantum groups. Mathematicians seem to know a quantum group when they see one, and there has been a great deal of work on quantum groups over the last several decades, some of which is widely regarded as important, first-rate mathematics. But there is still as yet no generally accepted definition of a quantum group!

Nonetheless, the usefulness and even necessity of rigorous general theories is not diminished by such work, and indeed the desirability and urgency of a general theory explaining and connecting specific results and techniques is greatly enhanced by the applications.

**Authority in Mathematics**

“Mathematics is fundamentally an egalitarian subject. It should in principle be possible for anyone to check the correctness of any argument; nothing needs to be taken on trust.”

J. K. Truss

(See III.1. for a continuation of this quote.)

“Believe nothing on hearsay. Do not believe in traditions because they are old, or in anything on the mere authority of myself or any other teacher.”

Buddha

---

7[T, p. 244]
8[Tru97, p. v]
9[Bel92, p. xi].
“No man can worthily praise Ptolemye... yet muste ye and all men take heed, that both in him and in all mennes workes, you be not abused by their autoritye, but evermore attend to their reasons, and examine them well, ever regarding more what is saiide, and how it is proved, than who saieth it, for autorite often times deceaveth many menne.”

*Robert Recorde, 1556*

“In questions of science the authority of a thousand is not worth the humble reasoning of a single individual.”

*Galileo*

We should never rely entirely on an “authority” to tell us what is true in mathematics, although we should give credence to the guidance of knowledgable people. For one thing, any “authority” can be wrong. Nobody has a corner on the truth in mathematics; some just have a somewhat better handle on it than others.

A simple illustration is the story told [?, p. 73] by JOHN PAULOS, a mathematician and author of the popular book *Innumeracy*, who at age ten calculated the earned run average of a certain baseball pitcher to be 135 (a pitcher’s earned run average, or ERA, is the average number of earned runs allowed per nine innings pitched, calculated by the formula

\[
\text{ERA} = \frac{9 \cdot \text{(number of earned runs allowed)}}{\text{innings pitched}}
\]

This pitcher had allowed 5 earned runs in 1/3 inning pitched.) He showed his calculation to his teacher, who authoritatively replied that he was wrong, that an ERA could never be higher than 27 (the number of outs in 9 innings). When the published official statistics confirmed his calculation, he felt vindicated, and recalls:

“I remember thinking of mathematics as an omnipotent protector. You could prove things to people and they would have to believe you whether they liked you or not.”

Unfortunately, his teacher still did not believe him even when presented with the published proof!

Students, particularly at lower levels, are often far too willing to defer to the “authority” of instructors in mathematics. I once had a calculus student who came to my office because he could not get his answer to an online homework problem to match what the computer demanded (a serious ongoing problem with online homework, although things are slowly improving). Instead of the “right” answer of 2, he kept getting \(\frac{3+\sqrt{1}}{2}\). I told him to simplify the square root to 1. He thought a minute, then said, “Wait a minute. Is \(\sqrt{1}\) 1?” When I assured him it was, he thought a minute more, then said, “Wait a minute. Is \(\sqrt{1}\) always 1, or just in this course?” I refrained from suggesting he ask his Calculus II instructor the next semester what \(\sqrt{1}\) is in that course.

Abstraction, Interpretation, and Point of View

“The more comprehensive the subject is they treat, and the more general and abstract the manner is in which they are considered, the more are [mathematical] principles free of darkness and the easier it is to grasp them.”

Jean d’Alembert, 1743

“The purpose of axiomatization in mathematics is to reduce to a minimum the presuppositions on which a given theory depends, and at the same time to make every presupposition fully explicit.”

B. Rotman and G. T. Kneebone

“The most striking characteristic of the written language of algebra and of the higher form of the calculus is the sharpness of definition, by which we are enabled to reason upon the symbols by the mere laws of verbal logic, discharging our minds entirely of the meaning of the symbols, until we have reached a stage of the process where we desire to interpret our results. The ability to attend to the symbols, and to perform the verbal, visible changes in the position of them permitted by the logical rules of the science, without allowing the mind to be perplexed with the meaning of the symbols until the result is reached which you wish to interpret, is a fundamental part of what is called analytical power. Many students find themselves perplexed by a perpetual attempt to interpret not only the result, but each step of the process. They thus lose much of the benefit of the labor-saving machinery of the calculus and are, indeed, frequently incapacitated for using it.”

Thomas Hill

“Mathematics is a way of thinking that can help make muddy relationships clear. It is a language that allows us to translate the complexity of the world into manageable patterns. In a sense, it works like turning off the houselights in a theater the better to see a movie. Certainly, something is lost when the lights go down; you can no longer see the faces of those around you or the inlaid patterns on the ceiling. But you gain a far better view of the subject at hand.”

K. C. Cole

One of the characteristic and essential features of mathematics is the fact that most parts of the subject can be approached or interpreted from various points of view. Not only does this variety of viewpoints increase the usefulness of mathematical theories, but the very progress of mathematics often depends on this flexibility: problems which appear obscure or difficult from one point of view often have obvious solutions when viewed in a different way.

In fact, modern mathematicians deliberately try to create theories which have flexibility and variety of viewpoints built in. This is one of the principal reasons for the abstraction of today’s mathematics. The usual procedure is to base the entire theory on a few basic and generally abstract assumptions called axioms, and logically deduce all features of the theory from the axioms without making additional assumptions about the “meaning” of the axioms or the terminology used in them. Abstraction serves several purposes:

---

12J. d’Alembert, Traité de dynamique, Paris, 1743.
1. It simplifies the range of information which must be simultaneously considered and used in developing
the theory, including the notation and terminology, to a manageable level.

2. It allows mathematicians to focus their thinking on the essential structural features of the theory
without being tied to one particular interpretation of the theory which may constrain creative thought
by introducing unimportant or even extraneous elements.

3. It allows the precise limits of the validity of the theory to be described.

4. It allows, even invites, new interpretations of the theory to be identified, leading not only to broader
applicability of the theory and results already obtained, but also to new ways of looking at and solving
problems arising in the development of the theory.

5. It makes it easier to notice similarities and connections with other parts of mathematics, leading both
to a better understanding of the big picture of mathematics, and to cross-fertilization: importation of
ideas and techniques from one part of mathematics into another.

“Abstraction gives us the ‘less is more’ approach – fewer assumptions leave us in touch with
more mathematical objects (and thus the theorems we prove apply in more instances). More
importantly, however, it gives us the ‘less is clearer’ approach. Because we haven’t made a myriad
of assumptions, our mathematical choices are more clearly defined, our mathematical arguments
are cleaner, and the conclusions we draw are less likely to be cluttered up by irrelevant issues.
We can, therefore, sort out the essential mathematical ingredients that support a particular fact.”

*Carol Schumacher*\(^{16}\)

“[A] single simple principle can masquerade as several difficult results; the proofs of many theo-
rems involve merely stripping away the disguise.”

*M. Spivak*\(^{17}\)

The Greek word “axiom”, as used in mathematics, originally meant “self-evident truth.” In formalist
mathematics, axioms are regarded as “arbitrary assumptions.” To most modern mathematicians, they are
neither. The axioms used in a theory are a matter of choice and are not necessarily obvious. But they
are not arbitrary; they are chosen to be a reasonable general starting point for a theory with at least one
interpretation or application of interest. The terminology used in the axioms and throughout the theory is
often, but not always, suggestive of a particular interpretation; such suggestive terminology can be beneficial
in guiding a mathematician’s thoughts, but also confining by restricting the mathematician’s ability to
“think outside the box” and to find and use other interpretations of the concepts. Sometimes an entirely
equivalent theory can be developed from a completely different set of equally reasonable axioms, often
using different terminology; when this occurs, the theory tends to be richer because different results can
be more easily or naturally obtained in the two setups (and the different axiom schemes are also evidence
of broader applicability of the theory). Measure theory is an excellent example of this; various approaches
beginning with measure, probability, and integration lead to essentially the same theory, with many varied
tools available from the different approaches.

\(^{16}\)[?, p. 5].

\(^{17}\)[?, p. ix].
“Mathematics is the art of giving the same name to different things. It is enough that these things, though differing in matter, should be similar in form, to permit of their being run in the same mould. When language has been well chosen, one is astonished to find that all demonstrations made for a known object apply immediately to many new objects: nothing requires to be changed, not even the terms, since the names have become the same.”

H. Poincaré

Abstraction for its own sake is rarely worthwhile in mathematics. Even though it is usually impossible to foresee the full implications of a new theory, significant mathematical developments almost always occur when mathematicians have some interpretation or use in mind for the new theory; these can range from direct applications to important problems outside mathematics to simple curiosity about a specific mathematical problem that just seems interesting.

“The axiomatic method has provided deep insights into mathematics, disclosing identities where none had been suspected. In the hands of mathematicians of genius this method has been used to strip away exterior details that seem to distinguish two subjects and to disclose an identical structure whose properties can be studied once for all and applied to the separate subjects.”

Mina Rees

“[T]he users of [mathematics] naturally enough take a somewhat skeptical view of this development [abstraction and generalization] and complain that the mathematicians now are doing mathematics for its own sake. As a mathematician my reply must be that the abstraction process that goes into functional analysis [and other parts of mathematics] is necessary to survey and to master the enormous material we have to handle. . . . Our critics, especially those well-meaning pedagogues, should come to realize that mathematics becomes simpler only through abstraction. The mathematics that represented the conceptual limit for Newton and Leibniz is taught regularly in our high schools, because we now have a clear (i.e. abstract) notion of a function and of the real numbers.”

G. Pedersen

I.5.1. Semantics: What is Obvious?

“‘Obvious’ is the most dangerous word in mathematics.”

E. T. Bell

“Since people have tried to prove obvious propositions, they have found that many of them are false.”

Bertrand Russell

“Being a mathematician means that you don’t take ‘obvious’ things for granted but try to reason. Very often you’ll be surprised that the most obvious answer is actually wrong.”

Evgeny Evgenievich

“It ain’t what you don’t know that gets you into trouble. It’s what you know for sure that just ain’t so.”

Mark Twain

“Science is always in need of those who are willing, and able, to say ‘Hold on a minute, isn’t there a problem with . . . ?’ ”

Peter R. Law

It is a surprisingly delicate matter, which can confuse not only students but even professional mathematicians, to decide what in mathematics is “obvious” and can simply be asserted, and what must be carefully spelled out. Often the difficulty is a semantic one, stemming from misuse, or at least careless use, of language: language can be subtly suggestive in a misleading way. We will discuss a few such examples related to the foundations of analysis.

Areas in the Plane

I.5.1.1. The first example concerns areas of sets in the plane. Consider the following two statements:

Statement 1. If \( R \) is a rectangle with length \( x \) and width \( y \), then the area \( A(R) \) is \( xy \).

Statement 2. If a rectangle \( R \) is subdivided into a finite number \( R_1, \ldots, R_n \) of nonoverlapping subrectangles (nonoverlapping means two of the subrectangles can have only boundary points in common), then

\[
A(R) = \sum_{k=1}^{n} A(R_k)
\]

(See Figure I.1; the area of the black rectangle is the sum of the areas of the green rectangles.)

---

21[Bel87, p. 16].
22[?].
23[Fre13, p. 16].
24This is one of many quotes often attributed to Twain for which there is no documentation. The first version published of this statement appears to be due to Josh Billings in 1874.
25MathSciNet review of [Pen05].
Let us set Statement 1 aside for the moment, and consider Statement 2. The question we want to discuss is: Is Statement 2 obvious?

Many people would say that Statement 2 is “geometrically obvious.” And not just people untrained in mathematics: for example, on p. 7 (the first page of actual text) of the otherwise carefully written book [SG77], it is asserted without comment that Statement 2, and even its higher-dimensional version, is true, and this assertion is then used as the basis for the whole development of Riemann integration in Euclidean space. The same assertion is made in [KF75, p. 255] (where it is called “obvious”) and in [Sak64]; essentially the same statement (including the “obvious” assertion) occurs in [Bog07, p. 180]. (Is this an Eastern European thing? Note, however, that [Nat61] does not have this problem – see p. 64-65 of Volume 2.)

The real issue is whether Statement 1 is a definition or a proposition. If it is a proposition, then what is the definition of the area of a rectangle, or other plane figure? Are we using some intuitive “definition” of area, along with its accompanying list of “natural” properties, among which would be some general version of Statement 2? What justification do we have that there is a notion at all of area having the geometric properties we would expect? (There is, but it takes some work to show it, even for polygons; cf. [Har00, §23]. For more complicated regions, even a circle, it is still more difficult, requiring limits.) We can bypass these difficulties by taking Statement 1 as the definition of the area of a rectangle; but then we are not justified in assuming that “area” so defined has the expected geometric properties. In particular, Statement 2 is then not obvious, and requires proof. (The proof, while not difficult when the right “trick” is seen, is nontrivial: see XIV.3.1.6. Note that it cannot simply be proved by induction on \( n \): the cases \( n = 3 \) and \( n = 4 \) can be easily reduced to the case \( n = 2 \), which is obvious, but even the case \( n = 5 \) is not entirely obvious and cannot be simply reduced to applications of the smaller cases, since a rectangle can be divided into five subrectangles in such a way that the union of no two, three, or four subrectangles is a rectangle.)
Some references such as [Wyl64] try to define area axiomatically; Statements 1 and 2 are then among the axioms, or at least theorems, of the theory. But this approach does not eliminate the problem: the difficulty then simply becomes showing that the axioms are consistent, a question not really discussed in [Wyl64].

The semantic problem is use of the word “area” without specification of its meaning; it is suggestive to the reader of an intuitive interpretation which was perhaps reinforced by informal discussions of the subject in school, even though the informal or intuitive interpretation may not be appropriate in careful mathematics.

I.5.1.2. Anyone who thinks it is obvious that when a figure is cut up and rearranged, the area stays the same, should try the following example (photo from the website [http://www.moillusions.com/2006/03/impossible-triangle-illusion-no2.html](http://www.moillusions.com/2006/03/impossible-triangle-illusion-no2.html)):

![Image of a triangle cut into pieces and rearranged](http://www.moillusions.com/2006/03/impossible-triangle-illusion-no2.html)

Figure I.2: Where did the extra square come from?

A triangle of area $\frac{65}{2}$ is cut up and rearranged into a figure of area $\frac{63}{2}$ (or is it?) For a great visual version, see [http://www.moillusions.com/2013/04/video-missing-cubes-optical-illusion.html?utm_source=feedburner&utm_medium=feed&utm_campaign=Feed%3A+OpticalIllusions+%28OpticalIllusions%29&utm_content=Google+International](http://www.moillusions.com/2013/04/video-missing-cubes-optical-illusion.html?utm_source=feedburner&utm_medium=feed&utm_campaign=Feed%3A+OpticalIllusions+%28OpticalIllusions%29&utm_content=Google+International).

A much more sophisticated case (which is a real counterexample, not just an illusion) is the Banach-Tarski Paradox (): a ball in $\mathbb{R}^3$ can be dissected into five pieces which can be rearranged to form two balls of the same size as the original. The paradox is resolved by the fact that the pieces are nonmeasurable: they are so bizarre that no “volume” can be assigned to them. (In fact, area in $\mathbb{R}^2$, when defined, is preserved under arbitrary finite dissection and rearrangement, but this is quite nontrivial and nonobvious and, as the Banach-Tarski Paradox shows, does not hold for either volume or surface area in $\mathbb{R}^3$. See e.g. [Wag93].)
Circumference of a Circle and the Number $\pi$

I.5.1.3. Area, at least for a rectangle, is easy and elementary to define (or calculate). But here is an example where making a careful definition of an intuitive concept is quite complicated.

How do we define the number $\pi$? It is usually defined as the ratio of the circumference of a circle to its diameter (for this to make sense, it must be shown that the ratio is always the same for all circles, which is not really so obvious; in fact, it is false in noneuclidean geometry!) Slightly more precisely:

**DEFINITION.** The number $\pi$ is the circumference of a circle of diameter 1.

Several things must be made precise before this can be accepted as a real definition: the terms *circumference*, *circle*, and *diameter* (and I suppose even the number 1) must be defined. To get to the heart of the matter, let us tighten up the definition to

**DEFINITION.** The number $\pi$ is half the circumference of the circle

$$\{(x, y) : x^2 + y^2 = 1\} \subseteq \mathbb{R}^2.$$  

The real issue is the definition of the term *circumference* (or *perimeter*). Although people have a (fairly) good intuition as to what this term means, and one could be led to say the meaning is “obvious”, it is not at all easy to give a precise definition, and the meaning of the word is finessed throughout precalculus mathematics (e.g. to paraphrase MANDELBROT, what is the circumference of Britain?) Using calculus, it can be defined as a special case of arc length, which can itself be defined as the supremum of a set of sums (and in good cases exactly calculated as a definite integral). It is then not entirely obvious that a circle even can be defined as a special case of arc length, which can itself be defined as the supremum of a set of sums.

To elaborate on the difficulties, let us consider the traditional (at least since ARCHIMEDES) way circumference is defined and estimated. Fix a circle. We consider inscribed and circumscribed regular polygons. For a fixed $n$, the perimeter $p_n$ of all inscribed regular $n$-gons is the same by symmetry, and similarly for the perimeter $P_n$ of circumscribed regular $n$-gons, and obviously $p_n < P_n$. It is not obvious that $p_n$ increases monotonically as $n$ increases (although this can be shown), but it is obvious, and easily proved, that $p_n < p_m$ if $n$ divides $m$. It is less obvious, but not difficult to prove, that $P_m < P_n$ if $n$ divides $m$. Thus, if $n$ divides $m$, $p_n < p_m < P_m < P_n$. The circumference $p$ of the circle is generally defined to be the supremum (or limit) of the $p_n$ as $n \to \infty$. It is not hard to show that $P_n - p_n \to 0$ as $n \to \infty$ (cf. I.5.1.16.(v)), so $p$ is also the infimum (or limit) of the $P_n$. By explicitly calculating $p_n$ and $P_n$ for large $n$, decent upper and lower estimates for $p$ can be obtained.

Incidentally, some references assert that it is “obvious” that $p < P_n$ for any $n$. I’m sorry, but it is not at all obvious to me. Intuitive arguments for this fact seem to be based on some type of belief in the continuity of arc length (I.5.1.11.). It does follow (using that $P_m < P_n$ if $n$ divides $m$) from the lower semicontinuity of arc length (VI.4.1.30.), but I don’t think that is intuitively obvious. It is intuitively plausible that $p_n < p$ for all $n$, based on the principle that “a straight line is the shortest distance between two points,” and it is not unreasonable to define $p$ as sup $p_n$. The above arguments which show that $\inf P_n$ is equal to $\sup p_n$ imply that $\inf P_n = p$ and hence $p < P_n$ for all $n$ (this follows more easily directly from the fact that $p_m < P_n$ if $n$ divides $m$, which implies that $P_n$ is an upper bound for the $p_m$ for any $n$).

So what is the difficulty with this argument? For one thing, many seemingly small details must be made precise; all the statements above need to be proved, and along the way some terms need to be carefully defined, which is sometimes not as easy as one might think. In addition, one needs to show:
There exist inscribed and circumscribed regular \( n \)-gons. Note that this cannot be done simply by using angle measure since angle measure cannot be carefully defined until concepts from trigonometry are developed, which already requires knowledge about the perimeter of a circle and its subarcs. Instead, either geometric or analytic arguments must be used. (Certain regular polygons inscribed in a circle like a square or hexagon can be constructed by straightedge and compass, and their sides repeatedly bisected to obtain regular polygons with arbitrarily large numbers of sides, but not all regular polygons can be constructed this way, although enough can to make the argument work with additional justification.)

The perimeter of an inscribed polygon must be defined. In order to do this, it must be said what is meant by a finite sequence of points on a circle being listed in cyclic order. It is “obvious” geometrically what this means, but not so simple to explicitly state in words (if angle measure cannot be used). Two (equivalent) ways are: (1) interiors of edges between two pairs of consecutive points never intersect or (2) the sum of the distances between consecutive points (the perimeter) is minimum among all possible orderings of the given points. (The second characterization may be preferable, since it is not obvious that a given finite subset of the circle has any ordering satisfying (1).)

The Completeness Property of \( \mathbb{R} \) is needed to insure that the supremum or limit of the \( p_n \) exists.

In addition, there is another technical difficulty. The arc length of a circle, as defined in calculus, would be the supremum of the perimeters of all inscribed polygons, regular or not. It is not obvious that the same supremum is obtained for all inscribed polygons as for inscribed regular polygons, i.e. that there could not be a nonregular inscribed polygon whose perimeter is greater than the perimeters of all inscribed regular polygons. A way of showing that the two suprema are the same is to fix a point \( a \) on the circle, and show that the vertices of regular inscribed polygons with one vertex at \( a \) are dense in the circle; by continuity it suffices to consider only inscribed polygons with vertices in this set, and any finite number of points in this set are among the vertices of a single inscribed regular polygon. The density of this set of vertices, while “geometrically obvious”, takes some work to prove. As an alternate approach, it can be shown using a compactness argument (based on the Completeness Property) that for any fixed \( n \), there is an inscribed \( n \)-gon of maximum perimeter, and it is fairly easy to show that it must be a regular \( n \)-gon. Or the arguments of [Pó90a, Chapter X] can be adapted to give an “elementary” proof of this fact, although a careful and complete argument involves much more than is discussed in [Pó90a] (cf. I.5.1.5.).

All in all, it is a quite involved matter to make this approach completely rigorous.

I.5.1.5. There are a number of closely related arguments in [Pó90a]. Let us confine the discussion to the topics in Chapters VIII and X, where max-min problems and the Isoperimetric Problem are considered. The arguments in [Pó90a] are clever and elementary, and at first reading seem convincing, but there are serious logical gaps in the arguments which the author seemingly tries to obscure by his choice of language. Among these are:

(i) It is often implicitly assumed, or even explicitly asserted without explanation, that the desired maximum or minimum exists. To justify the existence requires at least an application of the Completeness Property of \( \mathbb{R} \), and in some cases additional continuity or compactness arguments are needed.

This point of justifying existence of a maximum/minimum is not just a pedantic technicality: there are seemingly similar problems, e.g. the Dirichlet principle (), where it turned out that no max/min exists in general, much to the surprise of mathematicians who assumed the contrary as “obvious.”

(ii) In some arguments, it is assumed without discussion that there is a notion of area of regions of the plane bounded by various types of curves, which is additive on “nonoverlapping” regions and invariant under rigid motions, leading to more complicated versions of the difficulties discussed in I.5.1.1..
(iii) In several arguments, use is made of “tangent lines” to various curves without defining what this means, much less discussing whether such lines exist and what properties they must have. When the curve is a circle, tangent lines can be defined and found without any explicit use of calculus (but there is still some nontrivial work to be done for a careful treatment), but for more general curves calculus cannot be avoided.

(iv) Several other similar difficulties are dismissed using a comment like “remembering some elementary geometry . . .” and some of these are theorems that take some work to prove or even to carefully state.

See [Oss78], [BZ88], or [Ber03, p. 26-29] for much more careful and complete discussions of the Isoperimetric Inequality.
The Area of a Circle

I.5.1.6. The circumference of a circle of radius \( r \) is \( 2\pi r \), and the area is \( \pi r^2 \). Even a casual observer would notice a similarity between these two formulas, and a calculus student would observe that the circumference is the derivative of the area (this is of course no accident, and is the basis for a quick calculus proof of the area formula). Explaining to a layman why the formulas are similar, and why one follows from the other, is a challenge, though.\(^{26}\) Since the circumference formula is essentially just true by the definition of \( \pi \), the task amounts to proving the area formula from the circumference formula.

I.5.1.7. The area formula requires calculus in some form for its proof, since some type of limit is necessarily involved. (As explained earlier, limits are involved in even making a careful definition of either area or circumference.) ARCHIMEDES described a beautiful argument which seems to make the area formula “obvious” once the informal limiting operations are made rigorous. This argument has recently been again popularized by S. STROGATZ in his New York Times series ([http://opinionator.blogs.nytimes.com/2010/04/04/take-it-to-the-limit/](http://opinionator.blogs.nytimes.com/2010/04/04/take-it-to-the-limit/)), from which the following pictures are taken.

I.5.1.8. The argument goes like this. Divide the circle (actually disk) into a large number of congruent wedges, say \( 2^n \), and rearrange them into a strip:

![Figure I.3: Rearrangement with 4 wedges](http://opinionator.blogs.nytimes.com/2010/04/04/take-it-to-the-limit/)

For any \( n \), the wavy strip has the same area as the circle, the top and bottom have arc length \( \pi r \), and the sides are line segments of length \( r \).

I.5.1.9. As \( n \to \infty \), the top and bottom wavy curves flatten out into straight line segments, and the end segments become more and more vertical; thus in the limit the figure becomes a rectangle.

This rectangle has area \( \pi r^2 \), so the area of the circle is also \( \pi r^2 \).

\(^{26}\) Teachers don’t always try. PETR BECKMANN [Bec71, p. 17] says: “Most of us first learned this formula [for the area of a circle] in school with the justification that the teacher said so, take it or leave it, but you better take it and learn it by heart; the formula is, in fact, an example of the brutality with which mathematics is often taught to the innocent.”
I.5.1.10. This argument is sometimes represented as a “proof” of the area formula. But it is not (yet) since it has some gaps, one of which is quite serious. The obvious gaps are that

(i) The limiting operations must be made precise.

(ii) It must be shown that area is well defined for the types of regions considered, and that it has the subdivision property discussed in I.5.1.1.

(Actually, (ii) may not be obvious to most observers!) However, there are two more gaps which may not be as obvious:

(iii) It must be shown that such a decomposition into wedges is possible, discussed in I.5.1.4.(i).

(iv) It must be shown that both area and arc length are preserved under the limiting operations of (i).

I.5.1.11. The preservation of area under the limiting operation of passing from the wavy strips to the limiting rectangle takes some work to prove rigorously, but is at least true in great generality, and it is possibly justifiable to regard the proof as simply a technical justification for an “obvious” geometric assertion.

However, the arc length assertion is definitely not “obvious.” It is not even true in general. Actually, to even formulate it carefully it must be said what the limiting operation is. One reasonable way to state it formally is: regard the bottom curve as the graph of a function $f_n$, and the limiting curve the graph of a
(constant) function \( f \). Then \( f_n \to f \) uniformly. (One could alternately think of them as parametrized curves and consider uniform convergence of the parametrizing functions.) However, arc length is not preserved under such a limiting operation (it is only lower semicontinuous (VI.4.1.30.), not continuous):

**I.5.1.12. Example.** On the interval \([0, \pi]\), define a sequence of functions by

\[
f_n(t) = 2^{-n} \sin(2^n t)
\]

and a limit function \( f = 0 \). Then \( f_n \to f \) uniformly on \([0, \pi]\), i.e. the curves \( y = f_n(x) \) approach the straight line from 0 to \( \pi \) on the \( x \)-axis (in the uniform sense). However, the arc lengths of the curves are all the same, as can be seen easily from a geometric argument (the graph of \( f_{n+1} \) consists of two pieces, each similar to the graph of \( f_n \) scaled by a factor of \( \frac{1}{2} \)), and this arc length can be computed by calculus () to be

\[
\int_0^\pi \sqrt{1 + [f_n'(t)]^2} \, dt = \int_0^\pi \sqrt{1 + \cos^2(2t)} \, dt \approx 3.82
\]

which is not the same as the arc length \( \pi \approx 3.14 \) of the limiting curve.

One can do much worse: set

\[
g_n(t) = 2^{-n} \sin(4^n t)
\]

on \([0, \pi]\). Then \( g_n \to 0 \) uniformly, so the graphs again approach the straight line segment from 0 to \( \pi \), but the arc lengths of the graphs of the \( g_n \) go to \( +\infty \).

**I.5.1.13.** A similar example is given in [LN00] (“le trou normand”), where it is regarded as a “paradox.” Someone with a reasonable level of mathematical sophistication (unlike the authors of that book) would realize that this is not a paradox at all: the problem is simply that if \( f_n \to f \) uniformly, then it is generally not true that \( f_n' \to f' \) in any sense (even if the derivatives all exist, which need not be the case).

In fact, with a little more reflection this disconnect should be expected. The absolute value of the derivative of a function says how rapidly the function is changing, not how much. A function can change rapidly, i.e. briefly have a large derivative, even if it is almost constant, if the changes are small enough. The derivative can even be large (in absolute value) most of the time, if it oscillates rapidly between positive and negative.

**I.5.1.14.** Here is perhaps the simplest example of this phenomenon (I am indebted to S. Strogatz for pointing it out). The diagonal of the unit square in \( \mathbb{R}^2 \) can be arbitrarily approximated uniformly by a “staircase” curve consisting of short alternating horizontal and vertical segments. Such a staircase curve clearly has arc length 2. So why doesn’t the diagonal also have length 2?

**I.5.1.15.** The nontrivial extra feature in the case of Archimedes’ argument (which incidentally was not his standard proof, which was a rigorous argument by double reductio ad absurdum, cf. ()) is that if \( f_n \) is the function whose graph is the lower wavy curve at the \( n \)'th stage, then not only does \( f_n \to 0 \) uniformly, but the derivatives of the \( f_n \) (actually the one-sided derivatives since \( f_n \) is not differentiable everywhere) also converge uniformly to 0, which is sufficient to conclude continuity of the arc lengths. To make the argument into a rigorous proof, some version of this additional argument is necessary.
I.5.1.16. There is an alternate way to phrase the argument which reduces (but does not eliminate) the technicalities, once the previous arguments about circumference have been done, necessary in any event for a full logical treatment. Inscribe a regular polygon with \( n \) sides in a circle of radius \( r \), and connect each vertex to the center of the circle by a line segment (see Figure I.6, from http://www.amsi.org.au/teacher_modules/the_circle.html).

![Figure I.6: Inscribed regular polygon with \( n = 12 \), divided into triangles.](image)

This divides the polygon into \( n \) congruent isosceles triangles of short side \( b_n \) and height \( h_n \). Each of these triangles thus has area \( \frac{1}{2}b_nh_n \). We have that \( nb_n = p_n \), the perimeter of the polygon, so the area of the polygon is

\[
A_n = n \cdot \frac{1}{2}b_nh_n = \frac{1}{2}p_nh_n.
\]

As \( n \to \infty \), \( p_n \to 2\pi r \) and \( h_n \to r \), so the area \( A \) of the circle is

\[
A = \lim_{n \to \infty} A_n = \lim_{n \to \infty} \frac{1}{2}p_nh_n = \frac{1}{2} \cdot 2\pi r \cdot r = \pi r^2.
\]

For this argument, we need to verify:

(i) Such a decomposition into triangles is possible, discussed in I.5.1.4 (i).

(ii) The area of the polygon is indeed the sum of the areas of the triangles, i.e. area is additive.

(iii) The area of a triangle with base \( b \) and height \( h \) is \( \frac{1}{2}bh \), which has an elementary proof by dissection once the area of a rectangle is known (in some approaches such as in [Har00], areas of triangles are the primitive data and no proof of this is necessary).

(iv) \( p_n \to 2\pi r \), the circumference argument already done.

(v) \( h_n \to r \), which takes some work to do carefully but is relatively easy. Indeed, by the Pythagorean Theorem,

\[
0 < r - h_n = \sqrt{\left(\frac{p_{2n}}{2n}\right)^2 - \left(\frac{p_n}{2n}\right)^2} = \sqrt{\frac{(p_{2n} + p_n)(p_{2n} - p_n)}{4n^2}} < \sqrt{\frac{4\pi r (2\pi r - p_n)}{4n^2}} < \frac{\sqrt{4\pi r (2\pi r)}}{2n} = \frac{\pi r \sqrt{2}}{n}
\]

which can be made arbitrarily small by choosing \( n \) large enough.
(vi) $A_n \to A$, one of the same difficulties as in Archimedes’ argument, but easier since it is essentially a monotone argument, traditionally called exhaustion (cf. XIII.1.2.7.).

(vii) The elementary limit fact (IV.1.3.21.(ii)) that a limit of a product is the product of the limits.

I.5.1.17. If $n$ is even, the triangles can be rearranged into a true parallelogram of length $p_n/2$ and slant height $r$ sitting inside the wavy parallelogram of Figure I.5. As $n \to \infty$, by (iv) the length of the base approaches $\pi r$, so the arc length difficulty in Archimedes’ argument is avoided (or, really, converted into the previous circumference argument). But the other difficulties remain.

Equal Division

I.5.1.18. On the subject of area, here is a problem which is described in some popular books as having an “obvious” solution. Let $E$ be a (bounded) region in the plane, and $L$ a line in the plane. Then there is a line parallel to $L$ which cuts $E$ into two regions of equal area.

The “obvious” solution is to begin with a line parallel to $L$ with $E$ entirely on one side. Then move this line “continuously” toward and past $E$ until it lies entirely on the other side of $E$. Since the area on the back side of the line begins at 0 and increases continuously to the area $A(E)$ of $E$, there must have been some point where this area is exactly $\frac{1}{2}A(E)$.

I.5.1.19. What is the difficulty? Some of these references gloss over this question entirely, suggesting there is none at all. But some acknowledge that the result depends on the Intermediate Value Theorem, which is a nontrivial (but perhaps geometrically “obvious”) fact. And there is another difficulty which never seems to be mentioned: if $A(t)$ is the area of the part $E_t$ of $E$ behind the line moved a distance $t$, why is $A(t)$ a continuous function of $t$? It is, but this fact is essentially the upward and downward continuity of Lebesgue measure in the plane (.), again a nontrivial fact, although if $E$ is bounded, continuity of $A(t)$ can be proved more easily by bounding $E_t \setminus E_s$ in a rectangle of fixed length and small width if $s$ is slightly less than $t$. These difficulties are, of course, in addition to the question of whether $A(E)$ and the $A(t)$ are even well defined and whether $A(E) = A(E_t) + A(E \setminus E_t)$ for all $t$, discussed earlier.

I.5.1.20. Some popular books go on to discuss the next version (the two-dimensional version of the ham sandwich theorem ()): if $D$ and $E$ are (bounded) regions of the plane, then there is a line which simultaneously cuts both $D$ and $E$ into regions of equal area. The “obvious” argument goes as follows: by the first part of the argument, for each $\theta$ there is a line $L(\theta)$ making an angle $\theta$ with the horizontal which cuts $E$ into two equal parts. If $\theta$ is varied from 0 to $\pi$, the line $L(\theta)$ passes across $D$ as before, and the division is reversed for $\theta = \pi$ from the division at $\theta = 0$, so there must be a $\theta$ for which the division of $D$ is equal.

There is an additional difficulty in this version, rarely if ever identified in popular references: the line $L(\theta)$ is not necessarily unique, e.g. if $E$ is not connected, so an $L(\theta)$ must be chosen for each $\theta$. It is not obvious, and is rather tricky to prove even in the case where the $L(\theta)$ are unique, that the lines $L(\theta)$ can be chosen to vary “continuously” with $\theta$. However, it is easier to show (although still a little tricky to prove rigorously) that if $D$ and $E$ are bounded, the area of the part of $D$ on the one side of $L(\theta)$ can be chosen to be a continuous function of $\theta$.
Sequences and Pattern Recognition

I.5.1.21. What is the next term in the sequence \((0, 1, 2, \ldots)\)? Most people would immediately answer "3". The "simplest" formula for the \(n\)th term \(x_n\) giving these values for \(n \leq 3\) would be \(x_n = n - 1\), so this is the “obvious” answer. However, there are many other possible formulas, and the “correct” answer depends on guessing what the poser of the problem had in mind. For example, if \(r\) is any real number \(\neq 3\), it is a simple exercise (solving a system of four linear equations in four unknowns) to find a cubic polynomial \(f\) such that \(f(1) = 0, f(2) = 1, f(3) = 2,\) and \(f(4) = r\).

I.5.1.22. There are other possible rules: for example, \(x_n\) could consist of \(n - 1\) followed by \(n - 1\) factorial signs (I am indebted to Vaughan Jones for this example.) Then

\[
\begin{align*}
  x_1 &= 0 \\
  x_2 &= 1! = 1 \\
  x_3 &= 2!! = (2!)! = 2 \\
  x_4 &= 3!!! = 720! \approx 2.6 \times 10^{1746}.
\end{align*}
\]

I.5.1.23. Here is another example. It appears different since it is not stated in purely mathematical terms, but in fact it is essentially identical. Suppose at 6 AM the temperature is 0°, at 9 AM it is 10°, and at noon it is 20°. What will the temperature be at 3 PM? 6 PM? 9 PM? Does anyone believe the temperature will be 50° at 9 PM? I suppose it’s not impossible, but it’s certainly not likely!

Actually, the only difference between this problem and the previous one is that there is more information: how do you know in the first problem that the terms of the sequence aren’t the temperatures (measured in 10° units) at three-hour intervals starting at 6 AM a certain day and location? Or maybe the \(n\)th term is the number of hits a certain baseball player gets in his first \(n\) at bats of the season, or the number of Heads in the first \(n\) tosses of a coin, or \(\ldots\). How do we know there is any rule or pattern at all - why couldn’t it just be a random sequence?

In the second problem meteorologists could predict with considerable accuracy what these temperatures will be, but they would need more information than is stated in the problem. However, in none of the problems can anyone figure out definitively what the next term will be without more information than is given in the problem (and in the coin tossing case no one could determine the next term even with more information).

I.5.1.24. The situation seems to be similar to a television comedy sketch which once appeared on Saturday Night Live, about a game show. The final question was: “I’m thinking of a color. What is it?”

I.5.1.25. But is it really similar? Being able to recognize a pattern in a sequence is an important mathematical skill. The above example is too easy to properly illustrate the point. A better example is the following sequence:

\[(2, 5, 10, 17, \ldots)\]

It is a bit more challenging, although not difficult, to come up with a pattern here. In fact, there are several natural ways to generate a sequence beginning with these terms, and it is not obvious what rule is “simplest” in this case.
I.5.1.26. This sequence appeared on a TerraNova standardized test for high school students. Unfortunately, it was phrased as a multiple choice question, asking for the next term; three of the choices for the answer were 24, 26, and 28.

The solution, as described in the Reno Gazette-Journal, is that the difference between successive terms increases by 2 at each step. The “correct” answer is thus 26.

I.5.1.27. Equivalently, this rule can be phrased as an algebraic formula giving the terms rather than a way of obtaining each new term from the last one. Use the function $f(x) = x^2 + 1$; then the $n$’th term of the sequence is the value of $f(x)$ for $x = n$. This formula gives the same fifth term, 26, as the published rule (in fact, all the terms of the sequences are the same.)

I.5.1.28. One can give a completely different rule. Let the $n$’th term be the sum of the first $n$ prime numbers. We then obtain the sequence $(2, 5, 10, 17, 28, 41, 58, \ldots )$, so the fifth term is one of the “incorrect” answers.

I.5.1.29. One can, of course, play the polynomial game here too. For example, let

$$f(x) = x^4 - 10x^3 + 36x^2 - 50x + 25.$$  

We then have $f(1) = 2$, $f(2) = 5$, $f(3) = 10$, $f(4) = 17$, and $f(5) = 50$. For another example,

$$g(x) = -\frac{1}{12} x^4 + \frac{5}{6} x^3 - \frac{23}{12} x^2 + \frac{25}{6} x - 1$$

has $g(1) = 2$, $g(2) = 5$, $g(3) = 10$, $g(4) = 17$, and $g(5) = 24$, another of the “incorrect” answers from the problem.

I.5.1.30. Most mathematicians are very critical of problems like this one. The objection is not to the problem itself, but the way it is phrased: as written, it is a psychology problem, not a mathematics problem; it is almost like asking, “In what country are the Alps located?” A much preferable way to phrase the problem is: “Describe a rule or pattern giving a sequence of numbers whose first four terms are 2, 5, 10, 17, and find the fifth term in the sequence according to your rule.” Unfortunately, there does not seem to be any reasonable way to phrase this type of problem as a multiple-choice question; the only acceptable multiple-choice version would be one with a choice (the correct answer!) “Cannot be determined from the information given.”

Questions like this are really very much like questions where letters must be unscrambled to form a word, if only one answer is “right”; see figure I.7.27

I.5.1.31. The widespread acceptance of the legitimacy of this type of question is symptomatic of a general human problem: there is often more than one explanation for a phenomenon, but an individual or community often settles on one explanation as the “right” one and rejects any alternatives or even the

---

27The company which produced the instructional software we use in calculus classes was bought out by another company. To use the software, I needed an account with the new company. When I tried to create one, I found that one had already been set up automatically, without anyone telling me. To log in, I needed the password which no one had told me either. When I clicked on “forgot password,” I was required to give the answer to my “Secret Question.” It would not tell me what the question was, presumably because it was secret.
possibility of an alternative, even sometimes in light of new evidence. Scientific theories which contradict, or appear to contradict, established religious beliefs are a notorious example. In the sequence problem case, people untrained in mathematics may have the excuse that they think such ambiguity cannot happen in mathematics and that any mathematically phrased problem has a definitive answer; mathematicians know better!

I.5.1.32. The question remains, however, whether it makes sense in general to try to make precise the notion of the “simplest” rule for a given initial sequence segment. This notion would appear to be highly subjective and mathematically imprecise; however, we should not reject out of hand the possibility that it could have some meaning and that the ability to recognize simple patterns is indicative of general mathematical ability. Thus the proper formulation and use of this type of question on standardized tests is a matter for legitimate debate and study.

I.5.1.33. One possible “simplest” formula for a sequence in which \( n \) terms are given is the unique polynomial of degree \( \leq n - 1 \) giving these values at 1, \ldots, \( n \) (cf. V.11.1.1.), especially if (as in the above cases) the degree of this polynomial is smaller than \( n - 1 \). However, this type of definition excludes simple and natural recursive rules which can be found for certain sequences. A good example is the famous Fibonacci sequence, which arises naturally in many applied problems such as in biology. The first few terms are (1, 1, 2, 3, 5, 8, \ldots), and each term, beginning with the third, is the sum of the two previous terms.

I.5.1.34. Here is another example, taken from [CG96, p. 76-79], where the “simplest” formula is not a polynomial. What is the next term in the sequence (1, 2, 4, 8, 16, \ldots)? The “obvious” answer is 32, which is correct if each term is twice the preceding term (i.e. the \( n \)'th term is \( 2^{n-1} \)). But here is another natural
(but somewhat more complicated) sequence beginning with the same terms. To get the $n$’th term $x_n$, place $n$ points on a circle and connect each pair of points with a line segment (chord), and count the number of regions the disk bounded by the circle is divided into. It is not too hard to see that the answer does not depend on how the points are arranged on the circle, as long as no three of the chords pass through the same interior point (so, for example, the points could not be evenly spaced around the circle if $n$ is even and more than 4). It is easy to check that $x_1 = 1$, $x_2 = 2$, $x_3 = 4$, $x_4 = 8$, and $x_5 = 16$. But $x_6 = 31$, not 32, and the difference between $x_n$ and $2^{n-1}$ becomes more dramatic as $n$ increases (it is easily seen that $2^{n-1}$ is far too large if $n$ is, say, 20 or 30). In fact, it can be shown that

$$x_n = \binom{n-1}{0} + \binom{n-1}{1} + \binom{n-1}{2} + \binom{n-1}{3} + \binom{n-1}{4}$$

(where $\binom{n}{k}$ is the binomial coefficient (V.17.7.1.), the number of ways of choosing $k$ elements from a set of $m$ elements), which is a fourth-degree polynomial

$$x_n = \frac{1}{24}(n^4 - 6n^3 + 23n^2 - 18n + 24)$$

This is the unique polynomial of degree $\leq 4$ giving the specified terms for $n \leq 5$, and for the circle division rule gives $x_n$ for all $n$.

**I.5.1.35.** Here is yet another example. Consider the sequence $(1, 4, 6, 13, \ldots)$. These are the first terms of the busy beaver function $\Sigma$, where $\Sigma(n)$ is the maximum number of 1’s an $n$-state Turing machine with alphabet \{0, 1\} can write on a blank tape (all 0’s) and then halt (there are only finitely many such Turing machines, so the maximum exists). $\Sigma$ is an uncomputable function since there is no algorithm for determining whether a Turing machine halts, and in fact grows faster than any computable function. No values of $\Sigma(n)$ are known for $n > 4$; $\Sigma(5)$ is known to be at least 4098, $\Sigma(6)$ is at least $3.5 \times 10^{18267}$, and

$$\Sigma(7) \geq 10^{10^{10^{18705352}}}$$

(probably much larger). In general, $\Sigma(2k) > 3^{4k-2}$ (II.8.6.16.), and is asymptotically much larger.

Not only is the whole function $\Sigma$ uncomputable\(^{28}\), but there are even specific $n$’s for which $\Sigma(n)$ is in principle uncomputable (the smallest $n$ known to have this property is 1919, since a Turing machine of this size which just writes 1’s can be constructed which halts if and only if ZF set theory is inconsistent; but it is generally believed there are much smaller such $n$, perhaps as small as 10).

**I.5.1.36.** Readers interested in exploring mathematical sequences should check out the website

http://oeis.org

This site lets the user search for naturally-occurring sequences beginning with any specified terms. For example, the search gives more than 70 mathematical sequences beginning with (or including as a segment) 2,5,10,17. For example, if $x_n$ is the length of the longest uncrossed knight’s path on an $(n + 2) \times (n + 2)$ chessboard, then the first few terms are $(2, 5, 10, 17, 24, 35, \ldots)$.

---

\(^{28}\)There is no universally accepted definition of a computable function, but we can take this to mean Turing computable. A function $f : N \to N$ is Turing computable if there is a Turing machine with alphabet \{0, 1\} such that, for any $n \in N$, if the machine is given an input tape with $n$ 1’s it outputs $f(n)$ 1’s on the tape and then halts. This is equivalent to several other natural notions of computability for functions. Computability of $f(n)$ for a fixed $n$ is more difficult to define precisely, but means there is a definite finite procedure (perhaps dependent on $n$) for calculating the numerical value from the definition of the function, or a finite proof that a specific number $m$ (specified by a particular algorithmic or inductive numerical notation, e.g. II.8.7.4.) is equal to $f(n)$. 

28
Euclid’s Parallel Postulate

I.5.1.37. Next, we consider an issue which vexed mathematicians for centuries: Euclid’s Parallel Postulate. I believe one of the important reasons it took so long to understand this situation was that mathematicians were misled and constrained in their thoughts by subtle implications of the terms Euclid used in the formulation. (Euclid himself was misled: in some of his proofs he used additional assertions which must have seemed “obvious” to him, but which do not follow from his axioms.)

I.5.1.38. One of Euclid’s postulates (or axioms) for geometry, called the Parallel Postulate, states that “if \( L \) is a line and \( p \) a point not on \( L \), there is one and only one line through \( p \) parallel to \( L \).” (Actually Euclid stated this postulate in a rather different and more complicated way; the version we have stated is often called Playfair’s axiom, although it was known and used at least as far back as Proclus. See [Wil, I.1] for a discussion of the origin and demise of the distinction between axioms and postulates.) In Euclid’s time, and for a very long time afterwards, axioms were supposed to be “self-evident truths,” and the Parallel Postulate is indeed true in ordinary (\( \mathbb{R}^2 \)) geometry. Mathematicians long wondered not whether the Parallel Postulate was “true”, but whether it could be proved from Euclid’s other axioms (since the actual statement was sufficiently complicated as not to be “self-evident.”)

I.5.1.39. Although over the centuries various mathematicians assumed the Parallel Postulate was false, and even proved what are now regarded as theorems of noneuclidean geometry, it was always done with the goal of obtaining a contradiction; it apparently never occurred to mathematicians until the nineteenth century (with the possible exception of J. Lambert in the eighteenth) that there really could be “geometries” satisfying the rest of Euclid’s axioms but not the Parallel Postulate, or, in modern language, models for Euclidean geometry with the Parallel Postulate replaced by its negation. Once the possibility was contemplated, it did not take long for such geometries to be found, in fact independently by several mathematicians: Gauss, Bolyai, and Lobachevskii for hyperbolic geometry, and Riemann for elliptic (some of Euclid’s other postulates arguably have to be modified a little in this case – see below); an actual model of hyperbolic geometry was not constructed until later in the century, by Beltrami. It follows immediately that the Parallel Postulate is independent of the other axioms of Euclidean geometry, i.e. cannot be proved (or disproved!) from them. (In fact, we know now, via model theory, that the converse is also true: if a statement such as the Parallel Postulate is independent of the other axioms, then there is a model for the other axioms in which the statement is false, although this was far from clear in the nineteenth century.)

I.5.1.40. While the mathematical atmosphere in the nineteenth century was much more conducive to the thought processes leading to these examples than in earlier times, I cannot help but think that the language used by Euclid had a stifling effect on creative thought about geometry. Euclid used the terms “point” and “line” as essentially undefined objects (he did give “definitions” which would not be considered true definitions today, e.g. “defining” a point to be “that which has no part” and a line to be “that which has length but no breadth”), but the terms used were strongly suggestive of a particular interpretation in which the Parallel Postulate is rather “obviously” true. It finally took some very smart and creative thinkers to realize that the terms “point” and “line” could be interpreted to mean something other than what Euclid evidently had in mind, e.g. what we would now call geodesics on surfaces could play the role of lines. This thinking has evolved further (pioneered by Poincaré, and culminating in Hilbert’s treatment of the Foundations of Geometry), to the degree that we now realize that “point” and “line” can refer to any kind of mathematical objects at all, so long as the axioms (with suitable interpretation) hold for them.
I.5.1.41. I wonder what would have happened if Euclid had used some non-suggestive terms (such as “bxptq” and “zkmr”) instead of “point” and “line.” One of two things would probably have happened: either models of non-Euclidean geometry would have been discovered sooner, or (more probably) no one would have continued to study Euclid at all since his work would not have seemed to be “about” anything! Suggestive terminology has undeniable advantages so long as the pitfalls are understood.

I.5.1.42. Incidentally, I am pretty tired of reading uninformed nonsense about how the development of non-Euclidean geometry somehow divorced geometry from physical reality and precipitated a “crisis” in mathematics, especially in its foundations. Such an argument is more worthy of Alfred E. Neuman than John von Neumann, and is based on a very simplistic view of “reality.” Although for a brief time the new ideas were evidently unsettling to some mathematicians, I do not think it was a prevalent attitude among mathematicians to be upset by the developments and fear that mathematics might be a house of cards which was about to collapse; in fact, it seems that most good mathematicians thought it was an exciting time in mathematics when the frontiers of knowledge and understanding were expanding rapidly. (There was a controversy in the German mathematical community in the 1920s called the “foundational crisis,” but this was really a dispute over which parts of mathematics, if any, could be considered “true” or “meaningful” and not whether mathematics held together logically.) It is certainly true that the geometric discoveries, along with the roughly simultaneous “arithmetization” of analysis, led to a profound revolution in the nature and conception of mathematics. But even before Einstein came along to definitively discredit the idea that the geometry of physical space is Euclidean (Poincaré, Hilbert, and Minkowski played important roles too), it could be seen that Riemann’s spherical (elliptic) geometry was in fact the geometry of the surface of the earth, physical geometry of the most basic sort (recall that the very word geometry comes from Greek meaning “measuring the earth”). Hyperbolic geometry has less immediate direct application to the familiar world, but it cannot be reasonably argued that it has no connection with physical reality. Indeed, general relativity could not have been developed without geometric ideas which were outgrowths of the discovery of non-Euclidean geometry.

“The value of non-Euclidean geometry lies in its ability to liberate us from preconceived ideas in preparation for the time when exploration of physical laws might demand some geometry other than the Euclidean.”

B. Riemann

Anyone who thinks non-Euclidean geometry is divorced from reality should read [Pen05] and [MTW73]. See [Gra08] for a thorough and intelligent study of the “modernist” revolution in mathematics without resort to the “crisis” characterization.

“[T]he development of mathematics may seem to diverge from what it had been set up to achieve, namely to simply reflect physical behaviour. Yet, in many instances, this drive for mathematical consistency and elegance takes us to mathematical structures and concepts which turn out to mirror the physical world in a much deeper and broad-ranging way than those that we started with.”

Roger Penrose

29 cf. [Gre93, p. 371].
30 [Pen05, p. 60].
Euclid’s Postulates

I.5.1.43. Here are EUCLID’s five postulates, according to [Euc02]31 (other sources give slightly different wording):

1. To draw a straight line from any point to any point.
2. To produce a finite straight line continuously in a straight line.
3. To describe a circle with any center and distance.
4. That all right angles are equal to one another.
5. That, if a straight line falling on two straight lines make the interior angles on the same side less than two right angles, the two straight lines, if produced indefinitely, meet on that side on which are the angles less than the two right angles.

Postulate 5 is EUCLID’s version of the Parallel Postulate (note that EUCLID neglected to specify that the two lines not both pass through the same point of the line falling on them! Maybe this is implicit in the “interior angle” term which is actually not defined.) It is conventional wisdom, stated in many references, that Playfair’s Axiom is equivalent to EUCLID’s Postulate 5, in the presence of Postulates 1–4; however, as we shall see, this equivalence requires that some things be read into Postulates 1–3 which are (arguably) not really there. These additional assertions evidently seemed “obvious” to everyone from EUCLID’s time until the nineteenth century (M. PASCH seems to have been the first to notice) and apparently escaped the notice of everyone who tried to deduce Postulate 5 or its believed equivalent Playfair’s Axiom from the other postulates (some seem to escape the notice of even some contemporary writers!)

Does Spherical Geometry Satisfy Euclid’s Postulates?

A good case study to illustrate the principles is spherical geometry. Whether spherical geometry satisfies EUCLID’s postulates is a matter of interpretation which also illustrates how unwarranted consequences can be read into statements.

I.5.1.44. In spherical geometry, a sphere $S$ is fixed. “Points” of the geometry are just points of $S$. “Lines” (“straight lines”) of the geometry are great circles. “Line segments” (“finite straight lines”) are (usually minor) arcs of great circles. “Circles” are ordinary circles on $S$, not necessarily great circles; we will also call singleton sets circles. The center of a circle has its usual interpretation (a circle actually has two antipodal centers!); the center of a singleton circle is the point itself (or the antipodal point). “Angles,” particularly “right angles,” are interpreted in the usual way using tangent lines.

Note that it does not actually contradict the postulates that certain circles are also “straight lines” (or single points), or that circles with different centers can coincide – it only contradicts our intuition about what these terms should “mean.” (Note that there is an ambiguity in EUCLID’s definitions between “circle” and “disk”; in spherical geometry, distinct disks can have the same boundary circle.)

---

I.5.1.45. The first observation is that spherical geometry actually satisfies Postulate 5 as Euclid stated it. Since it obviously does not satisfy Playfair’s Axiom (according to Euclid’s definition, “parallel” means “nonintersecting,” so there are no parallel lines in spherical geometry), either spherical geometry fails to satisfy all of the other four postulates or Playfair’s Axiom is not really equivalent to Postulate 5.

I.5.1.46. Next look at Postulate 4. What this postulate evidently means is that there is an assumed notion of congruence. An easy way to accomplish this (although not the most general way) is to assume there is a set (group) of sufficiently many “rigid motions” available to translate and rotate figures (specifically, which is transitive on points and lines). There is such a group (SO(3)) for the sphere.

I.5.1.47. The suspect postulates in spherical geometry are 1–3. First consider 1. If \( p \) and \( q \) are distinct points on a sphere, there is clearly a line through \( p \) and \( q \), so if Postulate 1 is read strictly as Euclid stated it, it is satisfied in spherical geometry. However, most readers, beginning with Euclid himself, include into Postulate 1 an implicit requirement that the line be unique, which fails on the sphere if \( p \) and \( q \) are antipodal points. So whether spherical geometry satisfies Postulate 1 is a matter of interpretation. (In the projective plane, the quotient of the sphere by the antipodal map, the line through two given points is unique, although the line segment between two points is not necessarily unique. Euclid does not explicitly distinguish in his postulates between lines and line segments, but there is a clear distinction between the two in Postulate 2 and perhaps implicitly in Postulate 1.)

I.5.1.48. Now look at Postulate 2, which leads to similar but more interesting interpretation questions. The statement is somewhat vague, and can be interpreted in several reasonable ways. It might mean simply that every line segment is contained in a line (which may even be equal to the line segment). But the word produce might implicitly mean that the line is larger than the segment. We might expect that it means that the line segment between, say, \( p \) and \( q \) can be “extended beyond \( q \),” whatever that means from the Postulates, and similarly beyond \( p \). It might then mean that a line segment from \( p \) to \( q \) could always be continued to a point \( r \) giving a line segment from \( p \) to \( r \) containing \( q \), with the line segment from \( q \) to \( r \) the magnitude of a fixed reference segment, and similarly beyond \( p \). With this interpretation, “lines” in spherical geometry, i.e. great circles, satisfy the postulate. But someone thinking about ordinary Euclidean geometry reading the postulate would probably interpret it as meaning that the extension of the line segment consists entirely of distinct points, i.e. the extension beyond \( q \) does not intersect the extension beyond \( p \), which fails on the sphere. Euclid himself made and used this assumption, sometimes called the “infinitude of lines,” without mentioning it in his postulates. The “infinitude of lines” interpretation is necessary if one wants to have a notion of one point being “between” two others on a line, which is important in Euclidean geometry; there is no such notion in spherical geometry. “Betweenness” is not mentioned in Euclid’s postulates, but is a fundamental concept in Hilbert’s more careful axioms for Euclidean geometry. Actually, “betweenness” is implicit in the notion of line segment with endpoints; in the presence of Postulates 1 and 2, along with a weak uniqueness statement that three distinct points can lie on at most one line (which does not follow from Euclid’s postulates as stated), the “infinitude of lines” is equivalent to the statement that if three distinct points are on a line, exactly one is “between” the other two.

The “infinitude of lines” is distinct from the question of whether the extension in Postulate 2 is unique, i.e. whether two different lines can have a segment in common, another assumption made by Euclid not included, but arguably implicit, in the postulate; extensions are unique in spherical geometry. (There is another interpretation ambiguity: what does the word “continuously” mean in this postulate? Any reasonable interpretation would seem to be satisfied in spherical geometry, although some authors have suggested that
"continuously" refers to the infinitude of lines, which seems doubtful to me.) I think it is somewhat harder to argue that the “infinitude of lines” is implicit in Postulate 2 than that extensions are unique. Thus whether spherical geometry satisfies Postulate 2 is again a matter of interpretation.

I.5.1.49. Postulate 3 appears to be false in spherical geometry; there is a limit to the radius of circles on a sphere. But this conclusion depends on a modern interpretation of the phrase “any distance.” Euclid did not use the notion of numerical distance between points; in fact, in ancient Greece a clean distinction was made between numbers (natural numbers), which denoted quantity, and “magnitudes,” which denoted size. To Euclid, a “distance” would have meant the “magnitude” of a line segment between two points. Thus he arguably would have agreed that Postulate 3 could have been equivalently phrased:

3’. Given points \( p \) and \( q \), a circle can be drawn with center \( p \) passing through \( q \).

In fact, this is the form of Postulate 3 always used in his proofs (and in straightedge-and-compass constructions); cf. [Gre93]. With this interpretation, spherical geometry does indeed satisfy Postulate 3. There is a slight problem if \( p \) and \( q \) are antipodal points on the sphere; but this problem evaporates if we allow a circle to be a single point, or if we pass to the projective plane, although this could cause (slight) difficulties with Postulate 5 since a line does not divide the projective plane.

I.5.1.50. Note also that the notion of “magnitude” of a line segment, as well as Postulate 4, only make sense if there is an assumed notion of congruence. As previously noted, there is such a notion for the sphere (and for the projective plane).

I.5.1.51. Thus it can be argued, although perhaps somewhat weakly, that spherical geometry satisfies all of Euclid’s postulates (it can be argued somewhat less weakly that the projective plane satisfies all the postulates), and also that the equivalence of Playfair’s Axiom with Postulate 5 depends on reading extra assertions into the other postulates.

Other Interpretations of Euclid’s Postulates

I.5.1.52. One could also consider the set \( P \) of points in \( \mathbb{R}^2 \) with rational coordinates (rational points). Lines in \( P \) will consist of all rational points on an ordinary line through two rational points, and circles in \( P \) will consist of rational points on an ordinary circle with rational center passing through a rational point. (There is a dense set of rational points on any such line or circle.) Then Postulates 1, 2, and 5 hold in \( P \), including uniqueness and the “infinitude of lines,” and Postulate 3 holds in the form of 3’, with no bound on the radii of circles. The (slight) difficulty this time is with Postulate 4, since the group of rigid motions is too small to allow comparison of all pairs of right angles; but the group of similarities is large enough to allow such comparison in a well-defined way, so Postulate 4 can be said to be satisfied in \( P \). (Comparison of magnitudes in \( P \) is also not possible in general for the same reason.) But in this geometry Euclid’s first proposition, construction of an equilateral triangle with two given vertices, fails since the circle with center \( p \) passing through \( q \) and the circle with center \( q \) passing through \( p \) do not intersect even though they “overlap.” Euclid assumed in his proof that such circles intersect, an assumption which does not follow from his postulates. (The assumption also fails in spherical geometry if \( p \) and \( q \) are too far apart.) In fact, \( P \) contains no equilateral triangles.
Consider also the following simple system. The space consists of exactly four points. Lines are defined to be sets containing exactly two points. A circle is a set of exactly three points; the fourth point is called the center of the circle. A right angle is a set of three points with one of them designated as the vertex. Two lines are parallel if they are disjoint. The angle between two nonparallel lines is defined to be the right angle consisting of the union of the lines with the intersection as vertex. Euclid’s postulates 1, 2, and 3’ are satisfied (except possibly for the word “continuously” in Postulate 2, whatever it is supposed to mean), including uniqueness in 1 and 2 (and in 3’); the “infinitude of lines” is also trivially satisfied since the extension of a line segment is just the segment itself. If the group of rigid motions is taken to be the group of all permutations of the space, Postulate 4 is also satisfied. And Postulate 5 is vacuously satisfied since the angle between any two nonparallel lines is always a right angle. Playfair’s Axiom also holds in this space. This example and the previous one show that Euclid’s postulates do not uniquely determine a geometry.

Note that it is also consistent with the postulates that there be no points, and any number of lines (including none), or that there be exactly one point and any number of lines, or that there be any number of points and exactly one line containing all of them. In these cases, some or all of the postulates will hold vacuously. These situations could be ruled out by assuming that there exist three points not all on the same line, another assumption Euclid made in many places.

There was a counterexample staring everyone in the face who tried to deduce Euclid’s Parallel Postulate from the other postulates, if they had been open-minded enough to realize it! (To be fair, it would be unreasonable to expect them to have recognized it before the abstraction of the nineteenth or even twentieth century.) Just take \( \mathbb{R}^3 \) with the usual points, lines, and line segments, and interpret a “circle” to be a sphere. Euclid’s first four postulates hold, even with the extra uniqueness provisions added. But if we use Euclid’s definition that “parallel” means not intersecting, Playfair’s Axiom fails. There is a semantic problem with Euclid’s fifth postulate because it refers to a “side” of a line, but this can be bypassed simply by declaring that a line has only one side (i.e. the side of the line consists of all points not on the line); with this interpretation, the fifth postulate also fails.

This example would surely have been regarded as cheating (even if abstract interpretations were accepted allowing a sphere to be called a “circle”), since Euclid’s postulates were clearly designed to define plane geometry. But there is nothing in any of Euclid’s postulates or common notions which would force two-dimensionality or rule out examples of this sort (he could have easily done so with an additional postulate). From modern hindsight, this example would immediately show that neither Euclid’s fifth postulate nor Playfair’s Axiom can be proved from the other assumptions Euclid spelled out.

If Euclid’s definitions, imperfect as they are, are closely examined, it could be argued that they include implicit additional postulates which rule out examples such as I.5.1.52–I.5.1.55, and even force the space considered to be at least what we would call a surface or 2-manifold. He defines a “line” (meaning what we would call a “curve”; he goes on to define a “straight line” to be a line satisfying a condition I find incomprehensible) to be “that which has length but no breadth.” Length and breadth are not defined, but one could argue that this definition means that lines must be topologically one-dimensional, an interpretation reinforced by the word “continuously” in Postulate 2 which is otherwise mysterious, and must have a well-defined arc length. In particular, lines (curves) must be isometric to intervals in \( \mathbb{R} \), anticipating modern
principles of completeness and measure which were far in the future in ancient Greece.

Euclid’s definition of a circle is “a plane figure contained by one line such that all the straight lines falling upon it from one point among those lying within the figure equal one another.” This actually defines what we would call a disk, but if we take the term “circle” to mean the boundary of such a figure, it must be a line or curve in the above sense, and must implicitly have an interior and exterior as well as a center. (Note though that this definition, like some of his others, is circular in that it refers to a “plane figure” although the whole theory is intended to establish what a “plane figure” is.)

I.5.1.57. Thus, although Euclid’s postulates and axioms themselves fall far short of adequacy to describe plane geometry, when the additional postulates arguably implicit in his definitions are added, as most interpretations over the centuries have done, they come remarkably close.

“Proclus shared the human problem of distinguishing between the obvious and that which only appears to be obvious.”

George E. Martin^{32}

“One of the pitfalls of working with a deductive system is too great familiarity with the subject matter of the system. It is this pitfall that accounts for most of the blemishes in Euclid’s Elements.”

Howard Eves^{33}

I.5.1.58. My purpose in discussing these matters is not to find fault with Euclid, but simply to illustrate how easy it is to jump to conclusions not supported rigorously. (In [?] it is stated that only “little people” like to point out flaws in Euclid; then the author himself describes some of the flaws over the next several pages!) Although we may find flaws in it, Euclid’s Elements was a remarkable intellectual achievement (not just by Euclid, but also by his predecessors who developed much of the theory) which is a leading candidate for the greatest mathematical work of all time, and remains the most widely read, studied, and influential non-religious book ever written on any subject. No mathematical work, with the arguable exception of Archimedes’ writings, rivaled it in importance at least until Newton’s Principia two thousand years later (and to call Principia a mathematical work might be a bit of a stretch), and the Elements was more “modern” and rigorous than anything else written before about the nineteenth century.

“If mathematics does not teach us how to think correctly, it at least teaches us how easy it is to think incorrectly.”

Harald Bohr^{34}

“The genius of Euclid is insufficiently celebrated. When he sat down to write his Elements of Geometry, he probably did not know that he was going to create a work that would last for centuries and would forever change how the human race thought, not just about geometry but about truth and how to get at it. He probably did not realize that he was one of the chief figures

---

^{32}Ped89, p. 138.
^{33}Ped89, p. ix.

in a revolution that, in a mere three hundred years or so, made our world possible by elevating reason to its proper place. Probably he was thinking only that it would be a good idea to gather up all the pieces of mathematics that were scattered around (some of them, he may have thought, shockingly badly written) and put them in one place, neatly and logically organized. After all, Euclid worked in a library and may have had some of the habits of mind that librarians are either born with or quickly absorb from the atmosphere of libraries. But whatever his motives, Euclid deserves to be remembered.

Euclid’s book has been a model of deductive reasoning ever since it appeared. Deductive reasoning is highly prized as a method of getting at truth, since from truth only truth can follow by deduction. Science is based on it, and even lawyers and politicians attempt to use it at times. It is such a part of our civilization that we cannot imagine a real civilization without it. Deductive reasoning has made us what we are. That is why we insist that high-school students be exposed to a version of Euclid: it is not that any of them will ever have to prove a theorem about triangles, it is just our way of acknowledging our debt to deductive reasoning.”

_Underwood Dudley_\textsuperscript{35}

\textsuperscript{35}[Dud92, p. 78].
“Obvious” is Subjective

I.5.1.59. Finally, we turn to a somewhat different issue: it is a highly subjective matter what details of an argument an author or lecturer feels need to be explained and justified, and which ones can be safely considered “obvious.” Opinions about this can vary widely from person to person, and even from time to time with the same person, and are not always justifiable. Rather than discuss this issue further, let us just recall a standard joke which illustrates it nicely:

A mathematician was giving a lecture, and at one point he said, “It is obvious that . . .” He then paused in mid-sentence, a concerned look came over his face, and he paced back and forth, scratching his head and stroking his chin, deep in thought. After about five minutes, his face suddenly brightened and he exclaimed, “Ah, yes! It is obvious.”

If an instructor ever tells you something is obvious and you aren’t so sure, or it is not obvious to you, don’t be reluctant or embarrassed to ask for an explanation. It may turn out that it is not so obvious to the instructor either!

Does Familiarity Breed Contempt?

“I thought at first you had done something clever. But [after Holmes’s explanation] I see that there was nothing in it after all.”

_Jabez Wilson (to Sherlock Holmes)_

I.5.1.60. It is a pervasive human characteristic to be more in awe of things we do not understand. Once we see a rational explanation of something, the wonder of it tends to fade and it becomes more mundane or commonplace. We, like Jabez Wilson, may even be fooled into thinking it is obvious or easy, and we often underappreciate the effort and/or genius required to find the phenomenon or its explanation in the first place.

Mathematicians are not immune from this tendency. Consider, for example, the wonderful (possibly apocryphal) description by William Lilly of the first encounter between Henry Briggs, one of the principal developers of the theory of logarithms, and John Napier, their inventor, at Napier’s home in 1615:

“At first, when the Lord Napier, or Marchiston, made publick his Logarithms, Mr. Briggs, then reader of the astronomy lecture at Gresham-College in London, was so surprized with admiration of them, that he could have no quietness in himself, until he had seen that noble person the Lord Marchiston, whose only invention they were: he acquaints John Marr herewith, who went into Scotland before Mr. Briggs, purposely to be there when these two so learned persons should meet. Mr. Briggs appoints a certain day when to meet at Edinburgh: but failing thereof, the Lord Napier was doubtful he would not come. It happened one day as John Marr and the Lord Napier were speaking of Mr. Briggs: ‘Ah, John,’ saith Marchiston, ‘Mr. Briggs will not now come:’ at the very instant one knocks at the gate; John Marr hasted down, and it proved Mr. Briggs, to his great contentment. He brings Mr. Briggs up into my Lord’s chamber, where almost one

---

37 _History of his Life and Times._
quarter of an hour was spent, each beholding the other almost with admiration, before one word was spoke: at last Mr. Briggs began.

‘My Lord, I have undertaken this long journey purposely to see your person, and to know by what engine of wit or ingenuity you came first to think of this most excellent help unto astronomy, viz. the Logarithms; but, my Lord, being by you found out, I wonder no body else found it out before, when, now known, it is so easy.’

Mathematicians tend to become particularly blasé about parts of elementary mathematics as they attain higher levels of knowledge and sophistication in the subject (perhaps including some of the mathematics we discuss in this book). The fact that in the not-too-distant past some of this mathematics represented the pinnacle of human thought can be overlooked in its familiarity to us.

“A mathematician’s first steps into unknown territory constitute the first phase of a familiar cycle.

After the darkness comes a faint, faint glimmer of light, just enough to make you think that something is there, almost within reach, waiting to be discovered. . . . Then, after the faint, faint glimmer, if all goes well, you unravel the thread – and suddenly it’s broad daylight! You’re full of confidence, you want to tell anyone who will listen about what you’ve found.

And then, after day has broken, after the sun has climbed high into the sky, a phase of depression inevitably follows. You lose all faith in the importance of what you’ve achieved. Any idiot could have done what you’ve done, go find yourself a more worthwhile problem and make something of your life. Thus the cycle of mathematical research . . .” [Emphasis original]

C. Villani38

I.5.1.61. There is also a human tendency to need some sort of explanation of mysterious phenomena. This is the origin of most religion; many people are satisfied and comforted with religious explanations for things with no apparent rational explanation. However, I have observed that mathematicians often have quite the opposite instinct: they demand a rational explanation, and do not properly appreciate something, especially a mathematical result, until they understand it. (I do not mean to suggest that mathematics and religion are incompatible; indeed, many mathematicians, including great ones, have been deeply religious.) In fact, the drive to understand phenomena and revel in the understanding might tend to be one characteristic of people with a predilection towards mathematics, although I do not want to attempt a universal generalization here; this tendency may more be characteristic in distinguishing people who are intellectually capable and energetic, whatever their academic interests. In any event, a healthy curiosity about the world, both concrete and abstract, seems to be an almost necessary attribute of anyone who is successful in mathematics.

I.5.2. Set Theory and Logic

One of the main goals of many (but not all) mathematicians in the early 20th century was to carefully axiomatize all of mathematics, beginning with set theory. The hope was that a complete list of all theorems of mathematics could be generated, and there would be a mechanical process by which the truth or falsity of any mathematical statement could be determined. This hope turned out to be impossible, but at least set theory has been put on a generally accepted axiomatic footing.

38[Vil16, p. 243].
*****Rewrite*****: Through the early 20th century, and to a small extent even today, a debate raged between two schools of mathematics, the “intuitionists” and the “formalists”. The current consensus is that the truth lies somewhere between the two camps. On the one hand, the intuitionists’ belief that Cantor’s theory of the transfinite, and the subsequent formalizations of set theory and mathematical logic, are unsound and have no place in real mathematics has been thoroughly discredited; it is now almost universally accepted that these theories have a legitimate and even central place in the world of mathematics. On the other hand, the intuitionists’ main point seems valid: many (perhaps most) mathematical concepts appear to have an intrinsic meaning within the human intellect quite beyond just being a collection of symbols.

Gödel’s Incompleteness Theorem (1931) showed that it is not possible to completely carry out the program described in the first paragraph of this section. Perhaps it is just as well: while it is certainly a worthwhile endeavor to try to put the foundations of mathematics on a sound logical footing, attempting to reduce all of mathematics to mechanical symbol manipulation would rob mathematics of much of its richness, beauty, and usefulness. As Ian Stewart puts it in his book, Nature’s Numbers [?]:

“Textbooks of mathematical logic say that a proof is a sequence of statements, each of which either follows from previous statements in the sequence or from agreed axioms – unproved but explicitly stated assumptions that in effect define the area of mathematics being studied. This is about as informative as describing a novel as a sequence of sentences, each of which either sets up an agreed context or follows credibly from previous sentences. Both definitions miss the essential point: that both a proof and a novel must tell an interesting story. They do capture a secondary point, that the story must be convincing, and they also describe the overall format to be used, but a good story line is the most important feature of all.”

Here are other trenchant observations on the role of proof in mathematics:

“If a mathematical statement is false, there will be no proofs, but if it is true, there will be an endless variety of proofs, not just one! Proofs are not impersonal, they express the personality of their creator/discoverer just as much as literary efforts do. If something important is true, there will be many reasons that it is true, many proofs of that fact. ... And each proof will emphasize different aspects of the problem, each proof will lead in different directions. Each one will have different corollaries, different generalizations ... Mathematical facts are not isolated, they are woven into a vast spider’s web of interconnections.”

Gregory Chaitin\textsuperscript{39}

“Appreciating a theorem in mathematics is rather like watching an episode of Columbo: the line of reasoning by which the detective solves the mystery is more important than the identity of the murderer.”

C. Villani\textsuperscript{40}

\textsuperscript{39}[Cha05, p. 23-24].
\textsuperscript{40}[Vil16, p. 32].
I.5.3. Proofs vs. Formal Proofs (or, How Mathematics Really Works)

“A proof is a proof. What kind of a proof? It’s a proof. A proof is a proof. And when you have a good proof, it’s because it’s proven.”

Jean Chrétien, Prime Minister of Canada

I.5.3.1. The standard logical foundation of mathematics is that everything is defined within set theory, beginning with a set of axioms, and that all arguments and proofs are done using the standard rules of logic. Every mathematical statement can be phrased in this way, and every theorem or proposition needs to have a formal proof from the axioms in which every statement follows from the previous ones by an application of one of the rules of formal logic. Free use can be made of previously proved statements (whose proofs technically then become pieces of the proof of the new statement, in the nature of a “subroutine”). In this way, a large edifice is gradually created.

In practice, it is impossibly complicated and tedious to translate all but the simplest mathematical statements into foundational form and write out formal proofs, and most working mathematicians rarely if ever contemplate doing this with their mathematics. In fact, one can say that much of mathematics consists of developing efficient notation and terminology to allow rigorous analysis of complex mathematical ideas without reducing to the foundational level.

“By relieving the brain of all unnecessary work, a good notation sets it free to concentrate on more advanced problems, and, in effect, increases the mental power of the race.”

A. N. Whitehead

I.5.3.2. Mathematicians understand the term “proof” to mean something different from “formal proof”. Mathematical proofs are in essence outlines of formal proofs, and the usual (although not universal) unwritten rule is that the proof should be written in sufficient detail that a competent (and perhaps masochistic) reader, with sufficient time and effort, could translate it into a formal proof. As in the case of formal proofs, free use can be made of other results whose proofs have already been accepted. (It is a gray area whether the author of a new proof is expected to carefully check the validity of the proofs of other results used.) This standard is, of course, subjective, and also depends in part on the audience; a proof written by a specialist to be read by other specialists can be written more concisely than would be possible if intended for nonspecialists or students. The standard for acceptance of a proof of a new result is generally a consensus of experts that the proof is correct and complete enough to meet the formal translation criterion.

“The essence of a proof is that it compels belief.”

Pierre de Fermat

43 [Wei07, p. 50].
I.5.3.3. It should be noted, however, that mathematicians sometimes use and accept arguments of a type for which there does not seem to be any possibility of a formal translation, so the question of what a mathematical proof really is is more complicated than we have suggested here. J. R. Lucas [Luc00] regards a proof as a dialog (the view of a mathematical argument as a dialog goes back at least to Plato; a notable recent proponent was IMRE LAKATOS [Lak76]. Indeed, the very term “argument” suggests a dialog.) Lucas then considers a formal proof to be the extreme special case when the dialog is held with a “recalcitrant fool,” and adds:

“An argument is not really cogent unless it works even on morons and skeptics.”

Even cogency may not suffice in such a situation! In the more common case where the discussion is with an intelligent and reasonable fellow truth-seeker, an argument of a different type or level of detail may suffice. See [?] and [?] for further discussion of the nature of mathematical proofs.

I.5.3.4. There are two types of flaws a purported proof can have. The first is actual errors. An error in an argument is a step which is demonstrably false. One error in one step invalidates the entire argument. An argument with an error can be repaired in either of two ways:

(1) By finding a correct logical path around the error, a valid justification for the conclusions drawn from the erroneous assertion.

(2) By adding extra hypotheses to the statement of the result, in effect restricting to a special case where the erroneous statement is valid.

The first type of repair is preferable when it is possible. Both types of repair must sometimes be used together.

I.5.3.5. A more common flaw in “proofs” offered by mathematicians is a gap. A gap is a step in the argument which the reader is unable to bridge. Gaps are often in the eye of the beholder: what constitutes a gap for one reader may not be a gap for the author or other readers.

“I never come across one of Laplace’s ‘Thus it plainly appears’ without feeling sure that I have hours of hard work before me to fill up the chasm and find out and show how it plainly appears.”

N. Bowditch

The most serious gaps are ones which, once identified, cannot be quickly bridged by either the author or other readers. The gap then must be repaired before the argument can be accepted as a valid proof. A gap can be repaired in either of the two ways described above, or by simply finding an argument which bridges the gap directly (the word “simply” must be taken with a grain of salt; it is often not simple at all to do this!)

Purported formal proofs can also contain errors or gaps, but these are rather easy to identify. In fact, a computer can be programmed to check the correctness of a formal proof. There is no such definite procedure for mathematical proofs.

---

44Quoted in Cajori, *Teaching and History of Mathematics in the U.S.* (Washington, 1896); cf. [Mor93, 985]. According to W. W. R. Ball [Mor93, 986], “Biot, who assisted Laplace in revising [the Mécanique Céleste] for the press, says that Laplace himself was frequently unable to recover the details in the chain of reasoning, and if satisfied that the conclusions were correct, he was content to insert the constantly recurring formula, ‘Il est aisè à voir.’ ”
For a proof to be accepted as valid, there must be general agreement among specialists that it contains no errors or gaps. The process of accepting a proof is thus a somewhat subjective one which is not entirely rigorous; it can happen (but, fortunately, is very rare) that an error or gap is noticed in an argument long after it has been generally accepted as valid. In defense of mathematicians, it must be said that the process almost always works well, and acceptance of a mathematical result is much less dependent on the reputation or force of personality of the author than is the situation in most other academic subjects. And no interesting or useful result can stand the test of time for very long unless it is fully and correctly established. Standards of rigor have evolved over time: many arguments accepted as proofs as late as the early nineteenth century would not pass muster today, although the statements of the results were rarely wrong (but sometimes exact technical hypotheses were not carefully spelled out, or even understood), and the arguments can usually be filled out to be acceptable as proofs today. Mathematicians as a group are very careful and critical in testing the validity of proofs, especially since a proved statement becomes a “building block” in the “edifice of mathematics” ( ), and a flawed block could cause a whole section of the building to collapse. Besides, once something in mathematics is really proved \footnote{I do not just mean here that a proof has been accepted; mathematicians’ opinions about what constitutes a proof can be fallible! For contrary views about the sentiment expressed here, see J. Crowe, Ten Misconceptions about Mathematics, in [AK88], p. 267-271.} it stays proved forever; it can never be invalidated by new theories or points of view. Proofs found by ancient Greeks, when written carefully according to modern standards, are just as good today as they were 2500 years ago!

“I sometimes think that we worry ourselves overmuch about the enduring consequences of our errors. They may work a little confusion for a time. In the end, they will be modified or corrected or their teachings ignored. The future takes care of such things. In the endless process of testing and retesting, there is a constant rejection of the dross, and a constant retention of whatever is pure and sound and fine.”

Benjamin N. Cardozo\footnote{The Nature of the Judicial Process, p. 179.}

“We must not be surprised, however, that many minds apply themselves to other studies [than arithmetic and geometry], or to philosophy. Indeed everyone allows himself more freely the right to make his guess if the matter be dark than if it be clear, and it is much easier to have on any question some vague ideas than to arrive at the truth itself on the simplest of all.”

Descartes\footnote{Rules for the Direction of the Mind: Torrey’s Philosophy of Descartes (New York, 1892), p. 63; cf. [Mor93, 1628].}

“It has long been a complaint against mathematicians that they are hard to convince: but it is a far greater disqualification both for philosophy, and for the affairs of life, to be too easily convinced; to have too low a standard of proof. The only sound intellects are those which, in the first instance, set their standards of proof high. Practice in concrete affairs soon teaches them to make the necessary abatement: but they retain the consciousness, without which there is no sound practical reasoning, that in accepting inferior evidence because there is no better to be had, they do not by that acceptance raise it to completeness.”

J. S. Mill\footnote{An Examination of Sir William Hamilton’s Philosophy (London, 1878), p. 611; cf. [Mor93, 811].}
I.5.4. How to Understand a Proof

I believe I am fairly typical of mathematicians in my approach to understanding a proof I try to read. After reading through any previous explanatory material to be sure I understand the setup, context, notation, and terminology, I first read the statement of the result and try to think of my own proof. I usually fail, especially if it is a research-level result in my field or a result outside my specialty, and I often do not spend a great deal of time trying. If I do succeed, or if I think I have succeeded, I read through the written argument to see if it is the same as mine. Sometimes it is, and I then understand the proof because I have internalized it. Sometimes it is a different argument, and after seeing the general form of the author’s argument I put the written proof down and again try to come up with my own argument along those lines (and I also rethink my first argument to see if it is really correct, especially if it is simpler than the written proof.) Sometimes the written argument is basically the same as mine, but treats a technical point which I have overlooked. Occasionally I find that the author has overlooked a technical point which I noticed, and if so I have found a gap or error in the written proof.

It frequently happens that I can identify an overall strategy for proving the result, but there is a crucial step in the proof that I cannot figure out, or I can reduce the statement of the result to another apparently simpler or more elementary statement which I cannot see how to prove. Sometimes, especially if it is a known problem within my specialty, there may even be a well-known strategy or reduction of the problem that I am aware of. In these cases, I hone in on the author’s treatment of the step I regard as the essential difficulty, or look to see if the author has taken a new or different approach entirely.

In the more common case where I have not been able to get very far in finding my own proof, I look at the written proof and try to identify its overall outline, and then using that I again look for my own proof. There are usually several iterations of this process (each of which can take anywhere from a few minutes to several hours). After a couple of rounds I frequently have most of the argument down, but I am still puzzled by one part (or more) of the argument; I then concentrate the process on the part(s) of the argument I am having difficulty with. At the end of the process I (hopefully) really understand the proof, and the test I use to make sure is whether I can explain the whole argument to someone else with reference to notes only for technical items like formulas or calculations.

I.5.5. Proof by Contradiction

“When you have excluded the impossible, whatever remains, however improbable, must be the truth.”

*Sherlock Holmes*49

One of the commonly used schemes of proof is proof by contradiction, sometimes called *reductio ad absurdum*. If one is trying to prove a statement $P$, it is assumed that $P$ is false and from this a contradiction or absurdity is obtained; thus $P$ cannot be false and is therefore true. This technique is a variant of proving an implication $P \Rightarrow Q$ by assuming the conclusion $Q$ is false and proving that at least one hypothesis cannot hold, i.e. that $P$ is also false (that is, proving the implication $P \Rightarrow Q$ by proving the contrapositive $(not Q) \Rightarrow (not P)$); however, a proof by contradiction does not necessarily involve a proof of a contrapositive, at least explicitly.

A good example of a proof by contradiction is the famous ancient proof that $\sqrt{2}$ is irrational, which dates from about 500 BCE. The proof is often attributed to Pythagoras, but is likely due to one of his

followers (Hippasus is frequently credited; some attribute this proof to Aristotle). We will write the proof in modern algebraic notation, which did not exist in ancient Greece.

**Theorem.** $\sqrt{2}$ is irrational: there is no rational number $r$ such that $r^2 = 2$.

**Proof:** Suppose there is such an $r$. Then $r = \frac{a}{b}$ with $a, b \in \mathbb{N}$ (the natural numbers, or positive integers). By repeatedly dividing out common factors of 2, we may assume $a$ and $b$ are not both even. We have

$$\frac{a^2}{b^2} = 2$$

so $a^2$ and hence $a$, is even. Then $a = 2c$ for some $c \in \mathbb{N}$, so

$$a^2 = 4c^2 = 2b^2$$

and $b^2$, hence also $b$, is even, contradicting our assumption that $a$ and $b$ are not both even. The actual contradiction is to the assumption that $r$ exists, i.e. that $a$ and $b$ exist, since if they do the reduction to the case where they are not both even follows from basic properties of $\mathbb{N}$ (cf. III.1.7.4.).

See III.1.12.6. and III.1.13.6. for other elementary proofs by contradiction of the irrationality of $\sqrt{2}$.

It should be noted that intuitionist mathematicians of the Brouwer school do not accept the Principle of the Excluded Middle, i.e. that $(P \text{ or } \neg P)$ is a tautology for every statement $P$, and hence generally reject the validity of proof by contradiction (they do not entirely reject *reductio ad absurdum*, however: for example, the above proof of the irrationality of $\sqrt{2}$ is acceptable to most intuitionists). But almost all mathematicians embrace proof by contradiction as a legitimate method of proof, and agree with the sentiment in the famous statement of G. H. Hardy:

“*Reductio ad absurdum*, which Euclid loved so much, is one of a mathematician’s finest weapons.

It is a far finer gambit than any chess play: a chess player may offer the sacrifice of a pawn or even a piece, but a mathematician offers the game.”

A careful distinction must be made between proof by contradiction and an *impossibility proof*, a proof that a certain mathematical object does not exist. (Theorem I.5.5. is an impossibility theorem: “There does not exist a rational number $r$ with $r^2 = 2$.”) Proof by contradiction is a technique of proof which can be used to prove any sort of mathematical statement. Impossibility results (of which there are many) are commonly proved by contradiction, but not necessarily so: for example, the standard abstract algebra proof that a general fifth-degree polynomial is not solvable by radicals is usually expressed as a direct argument, not a proof by contradiction. Fermat’s Last Theorem is another example (although the proof there is very deep). See I.5.6.10. for more on impossibility results.

Most, if not all, proofs by contradiction can in principle be converted into direct proofs, but it may be very clumsy and unnatural to do so in practice. It is also true that almost any direct mathematical statement can be converted into an impossibility statement, but also often in a clumsy and unnatural way.

My experience is that beginning students tend to overuse proof by contradiction. It is usually good advice to look for a direct proof first and only use proof by contradiction as a last resort, unless one happens to notice an obvious and simple contradiction argument. As a rule, the only types of mathematical statements where it is worthwhile to begin by looking for a proof by contradiction are impossibility statements.

---

I.5.6. Proofs and Counterexamples: Mathematics as Creative Activity

“All truths are easy to understand once they are discovered; the point is to discover them.”

Galileo

I.5.6.1. As important as it is to be able to understand proofs written by other mathematicians, the true essence of mathematics is the ability to solve problems. Mathematical problems range from very specific to completely general and open-ended, and from straightforward to intractable (the two scales, by the way, are largely uncorrelated; very specific problems can be, or seem, intractable). Solutions to mathematical problems can range from simple numerical calculations or straightforward applications of standard mathematical results up to remarkably intricate, clever, and ingenious creative new arguments which can spawn entire new areas of mathematics. The best solutions to even simple problems are ones which are stimulating and thought-provoking beyond the problem at hand.

“In mathematics resolving of important specific questions and development of an abstract general theory are processes as inseparable as inhaling and exhaling.”

V. Zorich\textsuperscript{51}

“A naive non-mathematician ... understandably concludes [from formal presentations] that in mathematics, axioms come first. ... But anyone who has done mathematics knows what comes first – a problem. Mathematics is a vast network of interconnected problems and solutions. ... Sometimes a solution is a set of axioms! ... When a piece of mathematics gets big and complicated, we may want to systematize and organize it, for esthetics and for convenience. The way we do that is to axiomatize it. Thus a new type of problem (or ‘meta-problem’) arises:

‘Given some specific mathematical subject, to find an attractive set of axioms from which the facts of the subject can conveniently be derived.’

Any proposed axiom set is a proposed solution to this problem. The solution will not be unique. ... In developing and understanding a subject, axioms come late. Then in the formal presentations, they come early.”

Reuben Hersh\textsuperscript{52}

“Mathematical statements, mathematical theorems, are answers to questions. ... The mystery of how mathematics grows is in part caused by looking at mathematics as answers without questions. That mistake is made only by people who have had no contact with mathematical life. It’s the questions that drive mathematics. Solving problems and making up new ones is the essence of mathematical life.”

Reuben Hersh\textsuperscript{53}

\textsuperscript{51}[Zor09, p. V]
\textsuperscript{52}What is Mathematics, Really?, p. 6.
\textsuperscript{53}What is Mathematics, Really?, p. 18.
I.5.6.2. One of the most common kinds of mathematical problems is: Is statement $P$ true? True, of course, means always true: the conclusion holds in every situation in which the hypotheses are satisfied. A solution to a problem of this sort consists of a proof or a disproof of the statement. Note that a statement cannot be proved by verifying that it is true in one or more examples unless every example in which the hypotheses hold is checked (which is indeed sometimes feasible in specific problems); at best, verifying the statement in some examples provides evidence that the statement may be true in general. However, one example where the hypotheses are satisfied but the conclusion does not hold disproves the statement (proves that the statement is false). Such an example is called a counterexample for the statement. It is possible in theory, and occasionally in practice, to disprove a statement without finding a specific counterexample; but a “smoking gun” counterexample is usually the simplest, and often the most satisfying, way to disprove a statement.

“The mathematician as the naturalist, in testing some consequence of a conjectural general law by a new observation, addresses a question to Nature: ‘I suspect that this law is true. Is it true?’ If the consequence is clearly refuted, the law cannot be true. If the consequence is clearly verified, there is some indication that the law may be true. Nature may answer Yes or No, but it whispers one answer and thunders the other, its Yes is provisional, its No is definitive.”

G. Polya

Finding a Solution

“It will seem not a little paradoxical to ascribe a great importance to observations even in that part of the mathematical sciences which is usually called Pure Mathematics, since the current opinion is that observations are restricted to physical objects that make impression on the senses. As we must refer the numbers to the pure intellect alone, we can hardly understand how observations and quasi-experiments can be of use in investigating the nature of the numbers. Yet, in fact, as I shall show here with very good reasons, the properties of the numbers known today have been mostly discovered by observation, and discovered long before their truth has been confirmed by rigid demonstrations. There are even many properties of the numbers with which we are well acquainted, but which we are not yet able to prove; only observations have led us to their knowledge. Hence we see that in the theory of numbers, which is still very imperfect, we can place our highest hopes in observations; they will lead us continually to new properties which we shall endeavor to prove afterwards. The kind of knowledge which is supported only by observations and is not yet proved must be carefully distinguished from the truth; it is gained by induction, as we usually say. Yet we have seen cases in which mere induction led to error. Therefore, we should take great care not to accept as true such properties of the numbers which we have discovered by observation and which are supported by induction alone. Indeed, we should use such a discovery as an opportunity to investigate more exactly the properties discovered and to prove or disprove them; in both cases we may learn something useful.”

L. Euler

54 [Pol90a, p. 10];
55 Opera Omnia, ser. 1, vol. 2, p. 459; cf. [Pol90a, p. 3].
I.5.6.3. In order to solve the problem of whether statement $P$ is true or not, one must usually first form an opinion about the answer, which when firmly held and/or communicated to others is called a conjecture. The next step is to try to verify the conjecture by either looking for a proof (if the conjecture is that $P$ is true) or a counterexample (if the conjecture is that $P$ is false). The search often involves doing both things to some extent: obstacles encountered in trying to prove $P$ may suggest a possible counterexample, and on the other hand inability to construct a counterexample can sometimes suggest a method of proof of $P$.

I.5.6.4. Although mathematics is (for the most part) not an experimental science, there is a good analogy with experimental sciences: in both mathematics and experimental sciences, people form a conjecture (called a “theory” in sciences) based at least in part on evidence from observations or experiments. Then either the creator of the conjecture (theory) or someone else “tests” the conjecture (theory) with “experiments.” A well-designed set of experiments, or candidates for counterexamples in mathematics, provide the most critical tests for consequences or predictions of the conjecture (theory): if the conjecture (theory) “passes the test”, it can be deemed worthy of being taken seriously. Of course, the biggest difference between mathematics and experimental sciences is that theories can never be proved in science (at least not in the same sense as proofs in mathematics), and acceptance of a theory in science is based only on believability, observational or experimental evidence, accuracy of prediction, and/or lack of experimental refutation; such acceptance is always subject to revision in light of new evidence.

I.5.6.5. One need not, and often should not, stop when the problem at hand is solved. It is a much more significant accomplishment to come up with a general scheme for solving a class of related problems, so that new problems as they arise can also be solved more or less mechanically without a similar investment of time and effort. This is the origin of new subdisciplines in mathematics. (One should not be under the illusion, however, that all of mathematics can eventually be reduced to a set of mechanical processes or algorithms; there will always be room for creative genius in mathematics.)

“...In general the position as regards all such new calculi is this – That one cannot accomplish by them anything that could not be accomplished without them. However, the advantage is, that, provided such a calculus corresponds to the inmost nature of frequent needs, anyone who masters it thoroughly is able – without the unconscious inspiration of genius which no one can command – to solve the respective problems, yea, to solve them mechanically in complicated cases in which, without such aid, even genius becomes powerless. Such is the case with the invention of general algebra, with the differential calculus, and in a more limited region Lagrange’s calculus of variations, with my calculus of congruences, and with Möbius’s calculus. Such conceptions unite, as it were, into an organic whole countless problems which would otherwise remain isolated and require for their separate solution more or less application of inventive genius.”

C. F. Gauss\(^{57}\)

---

\(^{57}\)Werke, Bd. 8, p. 298; cf. R. Moritz, Memorabilia Mathematica, 1215.
“How thoroughly it is ingrained in mathematical science that every real advance goes hand in hand with the invention of sharper tools and simpler methods which, at the same time, assist in understanding earlier theories and in casting aside some more complicated developments.”

D. Hilbert

“... [M]ath isn’t the art of answering mathematical questions, it is the art of asking the right questions, the questions that give you insight, the ones that lead you in interesting directions, the ones that connect with lots of other interesting questions – the ones with beautiful answers!”

Gregory Chaitin

“The outcome of any serious research can only be to make two questions grow where only one grew before.”

Thorstein Veblen

Is There a Solution?

I.5.6.6. One question which must be faced, at least in passing, in any mathematical problem is: does the problem have a solution at all? Indeed, in some mathematical problems it is not entirely clear what one would exactly mean by a “solution,” and part of formulating such a problem well is deciding what this should mean.

I.5.6.7. Even if the problem is well-formed and it is obvious what a “solution” would be, it is often not obvious whether there is one. In fact, in many problems the most difficult part of the problem is establishing that there is a solution: if a solution is known to exist, it can sometimes be found relatively easily from the properties it must have. And sometimes knowing the mere existence of a solution can itself have important consequences. Thus considerable mechanisms have been developed in mathematics to establish the existence of solutions to certain kinds of problems:

The notions of completeness and compactness can be thought of as properties insuring the existence of solutions to problems involving limits, maxima, and minima (although not all such problems!)

The Axiom of Choice is a set-theoretic assumption insuring the existence of certain kinds of sets and functions.

I.5.6.8. On the other hand, it can sometimes be shown that a certain problem has no solution. This can also have important consequences quite beyond simply letting mathematicians avoid wasting time and effort looking for one. Proving that a problem has no solution is a type of impossibility result ( ). Actually, though, establishing nonexistence of a solution is often not the end of the story: such results sometimes lead to important expanded theories in which there is a solution. Here are some examples where the absence of a solution led to important advances:

58[Cha05, p. 24].
59The Place of Science in Modern Civilization and Other Essays.
(i) The equation $x^2 = 2$ has no solution in the set of rational numbers. This is one of the examples which eventually led to the study of irrational numbers and formulation of the theory of real numbers, which underlies all of analysis.

(ii) The equation $x^2 = -1$ has no solution in the set of real numbers. The complex numbers were developed specifically to provide a solution to this equation; they then turned out to be important and useful beyond the wildest dreams of the mathematicians who first considered them.

(iii) The “Dirac delta function” is a function $\delta$ on the real numbers $\mathbb{R}$ such that $\delta(x) = 0$ for all $x \neq 0$ and such that $\int_{-\infty}^{+\infty} \delta(x) \, dx = 1$. Such a “function” would have many uses in both pure and applied mathematics. But it is easily proved that there is no such function. This example led to the theory of generalized functions and distributions, where $\delta$ exists as a generalized function and, with care, can be used in many of the applications.

“Remember that when the usual road does not lead to success, one should not be content with this determination of impossibility, but should bestir oneself to find a new and more promising route. Mathematical thought, as such, has no end. If someone says to you that mathematical reasoning cannot be carried beyond a certain point, you may be sure that the really interesting problem begins precisely there.”

F. Klein

I.5.6.9. One must be careful about assuming that simply stated problems either have relatively simple solutions or none at all. For example, does the equation

$$x^2 - 1141y^2 = 1$$

have any solutions in positive integers? An exhaustive search through reasonably, semi-reasonably, and even not-so-reasonably sized pairs of positive integers would not turn up a solution, so one could be led to believe there is no solution. However, it turns out that there is a solution, in fact infinitely many, the smallest of which is

$$x = 1,036,782,394,157,223,963,237,125,215 \approx 10^{27}$$

$$y = 30,693,385,322,765,657,197,397,208 \approx 3 \times 10^{25}.$$  

This is an example of Pell’s equation; see e.g. [Sta78] for a discussion.

Another example is Archimedes’ cattle problem (see [Var98] for a formulation and nice discussion). This is a problem which can be expressed in words without use of mathematical symbols, yet the smallest solution is approximately $7.76 \times 10^{206544}$.

“At any moment there is only a fine layer between the ‘trivial’ and the impossible. Mathematical discoveries are made in this layer.”

A. Kolmogorov

---

60[Kle04, p. 143]. Note that this was written before Gödel; nonetheless Klein’s point is well taken.

61[?, p. 83].
I.5.6.10. It is worth a digression to discuss an endemic problem in mathematics which continues to plague mathematicians: misunderstanding the difference between unsolved and unsolvable.

Many mathematical problems are unsolved; some mathematical problems are unsolvable. The classes are quite distinct. (There is a nonempty overlap: some unsolved problems will undoubtedly turn out to be unsolvable, although “most” will not.) What many nonmathematicians do not understand is that many mathematical problems, including some famous ones, have been proved to be unsolvable; thus they cannot be described as “unsolved.” In fact, impossibility theorems are precisely solutions to “unsolvable” problems. Probably the most famous such problem is trisecting an angle, or more precisely giving a general procedure for trisecting a given angle with straightedge and compass, one of the “big three” problems from ancient Greece. The other two ancient Greek problems, almost as famous, are “squaring the circle” (constructing with straightedge and compass a square with the same area as a given circle, cf. [Bla97]) and “doubling the cube” (constructing with straightedge and compass a cube whose volume is twice the volume of a given cube). These problems were unsolved until the nineteenth century, when some abstract algebra now regarded as elementary (covered in undergraduate abstract algebra courses) was developed which proved that the problems are unsolvable, i.e. there can be no such procedure (the transcendence of $\pi$ is also needed for the circle squaring problem, cf. III.9.3.2.).

Mathematicians and mathematics departments regularly receive purported “solutions” to these problems, especially angle trisection. These arguments are often complicated and clever, but of course must necessarily contain a mistake. Mathematicians are understandably extremely reluctant to make the effort to find the inevitable mistakes, and thus tend to ignore or summarily dismiss such communications, leading to bad public relations and charges that mathematicians are closed-minded. Some mathematics departments have actually assigned a faculty member to respond to them for public relations purposes. The people who submit such attempted solutions are generally not crackpots (although there are some of those – see [Dud92] and Figure I.8), but intelligent people who know enough mathematics to be able to formulate the problems and discuss them but not enough to really understand them. In mathematics, a little knowledge can be a dangerous thing.

The most widespread source of confusion is that the problems are often slightly misstated so they sound unsolved, such as: “No one has ever found a procedure to trisect an angle with straightedge and compass.” This is a true statement. But it does not mean the problem is unsolved! It is also a true statement that “No one has ever found a rational number $x$ such that $x^2 = 2.$” And on a simpler level: “No one has ever found an integer $x$ such that $2x = 5.$” No intelligent person would waste time trying to find such an integer, as it is elementary to see there is none. The problem is solved, proved to be unsolvable. Understanding why the trisection problem has no solution is not elementary enough that a person without the requisite knowledge of field theory could be expected to come up with it (even Euler could not), but to a modern mathematician it is quite as impossible to trisect angles as it is to solve the $2x = 5$ problem.

Here are some examples, in roughly increased order of sophistication. These are unsolvable problems, not unsolved problems (the last two were solved in the twentieth century):

There is no integer $x$ with $2x = 5.$

There is no rational number $x$ with $x^2 = 2.$

There is no procedure to trisect angles with straightedge and compass.

There is no procedure to double a cube with straightedge and compass.
There is no procedure to square a circle with straightedge and compass.

There is no algebraic formula for the roots of a general fifth-degree polynomial.

There is no elementary formula for \( \int e^{-x^2} \, dx \) (X.9.3.18.). [But this does not mean there is no antiderivative!]

The Axiom of Choice and the Continuum Hypothesis are neither provable nor disprovable in ZF set theory.

There are no natural numbers \( x, y, z, n \) with \( n > 2 \) for which \( x^n + y^n = z^n \).

Figure I.8: A famous crackpot publication. The author claims that \( \pi = \left( \frac{\sqrt{2}}{2} \right)^4 = \frac{3}{2} \approx 3.16 \). (Is it a coincidence that HEISEL and FABER were both named “Carl Theodore”?)

The assertion that \( \pi = \left( \frac{\sqrt{2}}{2} \right)^4 = 4 \left( \frac{\sqrt{2}}{2} \right)^2 \) was obtained in ancient Egypt (Rhind Papyrus, circa 1650 BCE); cf. e.g. [Bec71, p. 22–25] or [Bla97]. Things could be worse: there are passages in the Bible (I Kings 7:23 and II Chronicles 4:2) which can be interpreted to say that \( \pi = 3 \), so mathematicians could be up against religious dogma as much as evolutionary biologists are. (I have an opinion why this has not happened, which I think I will not commit to print.) Note that mathematics is not immune from religious dogma: the theory that a line is composed of a collection of indivisible points came under withering attack by the Jesuits in the sixteenth century as contradicting the Eucharistic doctrine of transubstantiation (cf. I.3.1.2., [She18]).
Determination and Hard Work

“It would be a mistake to think that solving problems is a purely ‘intellectual affair’; determination and emotions play an important role. Lukewarm determination and sleepy consent to do a little something may be enough for a routine problem in the classroom. But, to solve a serious scientific problem, will power is needed that can outlast years of toil and bitter disappointment.”

G. Polya

I.5.6.11. One psychologically difficult characteristic of the process of solving mathematical problems is that one can work hard for a long time without apparent progress, and even disappointing regress when mistakes are discovered in previous work. But eventually (not always, but often enough), everything suddenly comes together in an “aha!” moment. This moment can even occur while not actively thinking about the problem: after a lot of thought and concentration on a problem the mind continues to mull it over subconsciously even during other activities. When the moment occurs, we can be fooled into thinking that all the previous effort without progress was wasted and could have been avoided if we had just been smarter about the problem, but the fact is that we would have been extremely unlikely to come up with the right idea without all the preceding thought and effort. Edison’s famous statement that “genius is 1% inspiration and 99% perspiration” may be an exaggeration, but contains a good deal of truth. And there is nothing more uplifting for a mathematician than that moment of understanding, which makes (or should make) all the previous work worthwhile.

“Every mathematician worthy of the name has experienced … the state of lucid exaltation in which one thought succeeds another as if miraculously … this feeling may last for hours at a time, even for days. Once you have experienced it, you are eager to repeat it but unable to do it at will, unless perhaps by dogged work …”

André Weil

This does not just happen in mathematics: for example, athletes often describe being “in the zone” and experiencing something similar. But long hours of previous training are necessary preparation.

I.5.6.12. One song I can really relate to is John Denver’s “Looking for Space.” Although he was not a mathematician, and probably knew little about mathematics or the process of doing it, he beautifully captured the emotional roller-coaster mathematicians can deal with in their work:

“On the road of experience, I’m trying to find my own way. Sometimes I wish that I could fly away When I think that I’m moving, suddenly things stand still I’m afraid ’cause I think they always will

And I’m looking for space And to find out who I am And I’m looking to know and understand

---

62 How to Solve It, p. 93.
63 The Apprenticeship of a Mathematician.
It’s a sweet, sweet dream
Sometimes I’m almost there
Sometimes I fly like an eagle
And sometimes I’m deep in despair

All alone in the universe, sometimes that’s how it seems
I get lost in the sadness and the screams
Then I look in the center, suddenly everything’s clear
I find myself in the sunshine and my dreams

And I’m looking for space
And to find out who I am
And I’m looking to know and understand
It’s a sweet, sweet dream
Sometimes I’m almost there
Sometimes I fly like an eagle
And sometimes I’m deep in despair

On the road of experience, join in the living day
If there’s an answer, it’s just that it’s just that way
When you’re looking for space
And to find out who you are
When you’re looking to try and reach the stars
It’s a sweet, sweet sweet dream
Sometimes I’m almost there
Sometimes I fly like an eagle
But sometimes I’m deep in despair
Sometimes I fly like an eagle, like an eagle
I go flying flying.”

The trick a mathematician must learn is to avoid despair during the dry periods, and persevere to savor the moments of insight and enlightenment.

“Perhaps I can best describe my experience of doing mathematics in terms of a journey through a dark unexplored mansion. You enter the first room of the mansion and it’s completely dark. You stumble around bumping into the furniture, but gradually you learn where each piece of furniture is. Finally, after six months or so, you find the light switch, you turn it on, and suddenly it’s all illuminated. You can see exactly where you were. Then you move into the next room and spend another six months in the dark. So each of these breakthroughs, while sometimes they’re momentary, sometimes over a period of a day or two, they are the culmination of, and couldn’t exist without, the many months of stumbling around in the dark that precede them.”

Andrew Wiles

64Quoted in interview for the PBS TV Nova program, ‘The Proof’.
“Doing research in mathematics is frustrating and if being frustrated is something you cannot get used to, then mathematics may not be an ideal occupation for you. Most of the time one is stuck, and if this is not the case for you, then either you are exceptionally talented or you are tackling problems that you knew how to solve before you started. There is room for some work of the latter kind, and it can be of a high quality, but most of the big breakthroughs are earned the hard way, with many false steps and long periods of little progress, or even negative progress.”

*Peter Sarnak*

“Thought is only a flash between two long nights, but this flash is everything.”

*Henri Poincaré*

“Mathematical discoveries, small or great, are never born of spontaneous generation. They always presuppose a soil seeded with preliminary knowledge and well prepared by labour, both conscious and subconscious.”

*Henri Poincaré*

“Well, some mathematics problems look simple, and you try them for a year or so, and then you try them for a hundred years, and it turns out that they’re extremely hard to solve.”

*Andrew Wiles*

“Unfortunately, mathematics is often taught as a mere matter of learning instructions and following them. You may have the habit of not trying anything in mathematics until you already ‘know what to do,’ until you feel that you ‘understand’ the problem. If this is your habit, try to overcome it as quickly as possible, for it will be the main obstacle to your progress.”

*Kenneth O. May*

“How does one discover how to prove a theorem? ... You must proceed as any person does who is confronted with a problem for which there are no set rules. ... half the battle will be won if you accept the fact that you are not supposed to know in advance how to prove theorems. The problem is not to know, but to discover.”

*Kenneth O. May*

“In research, if you know what you are doing, then you shouldn’t be doing it.”

*R. Hamming*
I.5.7. Scholarship vs. Practice

For every mathematician, from student to leading research mathematician, there is a constant tradeoff between studying the work of others and working on one’s own problems. Both are necessary for growth and development as a mathematician, although the relative emphasis can vary widely: some mathematicians are primarily scholars of mathematics, with vast knowledge of the work done almost entirely by others, while some of the most brilliant mathematicians have surprisingly sparse knowledge of others’ work, preferring to solve most problems arising in their work themselves as they come (this is definitely the exception rather than the rule among top mathematicians, however). For most of us, study of the work of others provides us not only with inspiration, but also a vast supply of machinery we can use in our own work.

According to P. Sarnak [Vil16, p. 115-116], Paul Cohen did not believe mathematics progresses incrementally, but rather by sudden great leaps, and therefore he strongly discouraged using, or even reading, related previous work on one’s problems. This is roughly the “Moore method” carried to its logical extreme. Although much good can be said about the Moore method, and there are even some positives about Cohen’s attitude (assuming it is accurately portrayed), and although Cohen was unquestionably an outstanding mathematician, I think this attitude is almost completely wrong: some of the biggest advances in mathematics do indeed come out of the blue, but most do not, and it is generally a very bad idea for a research mathematician to be ignorant (willfully or otherwise) of other work in the area. For one famous example, how can it be explained that calculus was simultaneously developed by two people in the latter 17th century? It is not adequate to simply say that two of the greatest mathematical minds of all time coincidentally did this at the same time; this is arguably a true statement, but it is also true that the mathematical terrain and atmosphere at the time was ripe for the development. Calculus did not suddenly arise out of nowhere, and most of the ideas and techniques of calculus already existed in some form; the main contribution of Newton and Leibniz (which I do not at all minimize) can be accurately described as largely “putting the pieces together.” In fact, if Cohen was right, worthwhile collaborative research in mathematics would be impossible.

Attempting to do mathematical research as a “lone wolf” has at least two related drawbacks: (1) You often end up “reinventing the wheel” due to inadequate familiarity with other work, although sometimes the new solutions are better than the previous ones and make an important contribution to the subject; (2) Especially nowadays when so much mathematical research is being done in such varied areas, unless you are an unusually great mathematician there is a good chance that someone at least as good as you are has already thought extensively about the problem or a closely related one, and can impart at least some words of wisdom, if not useful techniques or partial results.

A (rather imperfect) analogy with medicine is perhaps useful. The primary goal of medicine is to treat patients. To do this properly, a practicing doctor must not only have a rigorous medical school training, but must regularly keep up with medical journals and other research reports. On the other hand, there is a place, even a necessity, for some doctors to spend most of their time doing laboratory research, or instruction at medical schools and hospitals; however, almost all research or teaching physicians “keep their hand in practice” by treating at least a few patients.

I.5.8. Is Mathematics Created or Discovered?

One of the most basic controversies in the philosophy of mathematics is the question of whether working mathematicians actually create new mathematics which did not exist before, or whether they simply discover mathematical truths which already existed abstractly, somewhere (or whether it even makes sense to ask these questions.) Belief in the a priori existence of mathematical “objects” is referred to as realism (the term
Platonism is also often used, but Platonism is technically only one form of realism).

One popular version of the question is: if there is an intelligent race of aliens on another planet, would they develop mathematics, and if so would it bear any resemblance to the mathematics developed so far by humans? If mathematics is indeed universal, then it should be essentially the same everywhere in the universe.

“Beethoven and Shakespeare did unique work, and we would not have Fidelio or King Lear if they had not lived. However, symmetric functions would have been discovered by others if Newton had not lived.”

Richard Askey

My own view leans more towards the realist philosophy. Mathematical results are not arbitrary; the (provable) truth of a mathematical statement does not depend on the opinions or desires of the mathematicians who study it. Two mathematicians studying the same problem, making the same assumptions, cannot arrive at contradictory solutions (provided that the assumptions they make are not self-contradictory).

The importance of a new (or newly discovered) piece of mathematics is a much more subjective matter, and there can very well be differences of opinion among mathematicians; however, as time goes on there almost always seems to develop a remarkable consensus of opinion about what is significant and what is the “right” approach to an area of mathematics. This seems to provide evidence that there is some pre-existing mathematics either outside or deep within the human intellect. However, it seems likely that the exact form of the mathematics considered in the human mind or communicated between humans is dependent on specific human characteristics as well as on human history and culture (this is obviously true at least on the superficial level of notation and terminology, but probably goes much deeper). The “continent of mathematics” analogy (I) thus seems appropriate.

Realism as a philosophy of mathematics has definitely been unfashionable among philosophers. However, among mathematicians it is probably the predominant view. (Philosophers tend to be dismissive of the opinions of mathematicians on this issue as unreliable, unsophisticated, and/or uninformed, not entirely without justification.) Mathematicians generally have a strong feeling that the abstract objects they work with are “real,” although this could of course be an illusion. This feeling is reflected in the language mathematicians use to describe advances in mathematics, almost invariably referring to “discovering” or “finding” new results or proofs. The term “invent” is rarely used, and when it is (e.g. “Newton and/or Leibniz invented calculus”) it usually refers to the development of a new subdiscipline or point of view in mathematics, which can be viewed as a way of facilitating analysis of the structure of part of the “continent of mathematics” rather than creation of new mathematics per se.

I.5.9. Analogies for the Structure of Mathematics

There are at least three analogies which have been used to describe the subject of mathematics. All are useful, if of course vast oversimplifications; the differences between them reflect different philosophies of the nature of mathematics (we will not attempt to discuss such philosophies here; see I.6.1.).

---

72 R. Askey, *How can mathematicians and mathematical historians help each other?* [AK88, p. 202]. This is just one version of a line often used with many variations.
The Edifice of Mathematics

This picture or analogy was popularized by Descartes (who introduced the term “edifice”), but it may well not have originated there. It is probably the most widely-used picture of mathematics, although it primarily reflects a formalist or logicist philosophy:

“The discovery that all mathematics follows inevitably from a small collection of fundamental laws is one which immeasurably enhances the intellectual beauty of the whole; to those who have been oppressed by the fragmentary and incomplete nature of most existing chains of deduction this discovery comes with all the overwhelming force of a revelation; like a palace emerging from the autumn mist as the traveller ascends an Italian hill-side, the stately storeys of the mathematical edifice appear in their due order and proportion, with a new perfection in every part.”

— Bertrand Russell

If this view of mathematics is accepted, even partially, one must eventually consider what the building stands on and whether it has a solid foundation. Until the nineteenth century, construction and examination of the edifice of mathematics took place almost entirely “above the surface,” building upward from such surface features as numbers, points, and lines. Mathematicians for the most part did not concern themselves with, or even recognize or acknowledge, the problem (from the “edifice” point of view) that the building might stand on shifting sand instead of solid rock.

In the latter part of the nineteenth century, continuing into the twentieth and to this day, mathematicians started exploring the part of the edifice lying below the surface. The development of set theory seemed to provide at least a basement, if not a foundation, for the structure. Logic itself seemed to lie either in a subbasement or an entire substructure of the building. But as investigations went further, it became less clear, rather than more, that there is a solid and well-formed foundation underlying it all.

The Tree of Mathematics

The analogy of mathematics as a tree instead of a building has also been popular for a long time in various forms. The tree is a living, growing organism instead of a structure built with blocks of stone. As it grows, more and more branches of the tree appear and develop. Sometimes parts of these branches become so intertwined that it is nearly impossible to trace where the different strands come from.

The tree of mathematics not only grows upwards above the surface of the ground, but a root system also develops and grows, giving the tree increased (but not total) stability. If the stability of the tree is threatened in a certain direction, there is an impetus to extend the root system in that direction to restabilize the tree.

One problem with this view of mathematics as a tree, of course, is that it is unclear what role human mathematicians have in the growth and development of the tree; the idea that the tree grows on its own, with only fertile soil, water, and sunlight needed, is rather contrary to the picture of mathematics as a human activity. On the other hand, mathematics could be regarded as having a life of its own:

“Upon superficial observation mathematics appears to be a fruit of many thousands of scarcely related individuals scattered through the continents, centuries and millennia. But the internal logic of its development looks much more like the work of a single intellect that is developing his thought continuously and systematically, using as a tool only the variety of human personalities.

As in an orchestra performing a symphony by some composer, a theme is passing from one
instrument to another, and when a performer has to finish his part, another one is continuing it as if playing from music.”

I. R. Shafarevich

The view of mathematics as a tree makes some of the foundational questions less compelling: what is usually called “foundations of mathematics” is simply the root structure of the tree. Indeed, it can be argued from this point of view that the whole idea of a “foundation” of mathematics is not necessary or appropriate, so long as we have confidence that the tree is growing in some kind of solid ground.

The Continent of Mathematics

An analogy I particularly like, which I first saw in IAN STEWART’S book, Nature’s Numbers (cf. also Bel87, p. 8), compares mathematics to the landscape of a mostly unexplored continent. To paraphrase and expand on STEWART, when man first arrived on this remote continent, he could see very little through the impenetrable jungle beyond the beach. The continent has many resources, but is covered by thick vegetation and crisscrossed by mountains and gorges which are difficult and dangerous to cross. In time, some areas of the continent are explored, and settlements and roads built, and gradually more and more of the continent becomes known and accessible. The towns and roads impose a certain social order on the explored region, and some places become established as important centers of the society (perhaps with universities having mathematics departments.)

Here and there are high peaks which are mostly obscured by fog. On clear days, however, expert climbers can reach the summit and get panoramic views of large areas of the continent. They may be able to see undiscovered nearby verdant valleys which could be inhabited, or passes or natural bridges across mountains or gorges previously thought impassable. They may also be able to see that some areas thought to be far apart and unconnected are only actually separated by a narrow ridge and can easily be connected by a short road. (We assume this society never developed air or space travel.)

“Creating a new theory is not like destroying an old barn and erecting a skyscraper in its place. It is rather like climbing a mountain, gaining new and wider views, discovering unexpected connections between our starting point and its rich environment. But the point from which we started out still exists and can be seen, although it appears smaller and forms a tiny part of our broad view gained by the mastery of the obstacles on our adventurous way up.”

Albert Einstein

Mathematicians are the architects of the creation of a society on the continent of mathematics (which is actually a “virtual continent”, not physically altered by the society and capable of supporting simultaneous independent settlement by other cultures). Some mathematicians explore new regions of the continent; others build roads and bridges for the public to use; others design and build the cities; others invent ways of using the resources. Some operate farms or mines in recently explored regions where the climate or topography allows new crops to be grown or new minerals found. [Farms are probably a better analogy than mines, since mathematical resources, once discovered, cannot be depleted; but mines are apt in the sense that digging below the surface in mathematics can sometimes yield new and unexpected treasures.] Some logicians write the laws governing the society, and others study the scientific principles underlying the formation of the

---

74On some tendencies of the development of mathematics; cf. [Bog07], v. 2, p. 439.
continent. The top mathematicians are the expert climbers who can go up the peaks to get the big picture and see undiscovered regions and connections, although these can also sometimes be discovered at ground level. Most of the mathematicians may not be able to reach the summits without cable cars and guided tours, but there is much worthwhile to be done at all levels of the society.

In this view, the topography of the continent of mathematics is pre-existing and is discovered, not created, by the mathematicians. However, the society created by the mathematicians is not preordained: choices are made about where to build the cities and roads, what kind of political and social order to establish, and which resources to use and how; these choices depend on the intellectual ability and cultural background of those building the society, as well as seemingly random events such as what parts of the continent happen to be discovered or explored at a given time, or whether a sufficiently skilled climber comes along during the right weather conditions to get to the top of a critically located peak to catch the view. It could well happen that a different group of settlers (such as aliens from another planet) would establish a quite different society on the same continent.

“The true mathematician is always a good deal of an artist, an architect, yes, of a poet. Beyond the real world, though perceptibly connected with it, mathematicians have intellectually created an ideal world, which they attempt to develop into the most perfect of all worlds, and which is being explored in every direction. None has the faintest conception of this world, except he who knows it.”

A. Pringsheim

But as E. T. Bell [Bel87, p. 8] observes, exploration of the continent of mathematics is an imperfect process:

“If we marvel at the patience and the courage of the pioneers, we must also marvel at their persistent blindness in missing the easier ways through the wilderness and over the mountains. What human perversity made them turn east and perish in the desert, when by going west they could have marched straight through to ease and plenty? This is our question today. If there is any continuity in the progress of mathematics, the men [sic] of a hundred years hence will be asking the same question about us.”

---

75 Jahresbericht der Deutschen Mathematiker Vereinigung, Bd. 32, p. 381; cf. R. Moritz, Memorabilia Mathematica, 1108.
I.5.10. Pure vs. Applied Mathematics

Everyone recognizes that mathematics has enormous and vital applications to the “real world.” **Eugene Wigner** describes this as “the unreasonable effectiveness of mathematics.” (In my view, this thinking is a little backwards: it is not self-evident to me that there should be physical laws at all, but if there are, and the apparent orderly behavior of the universe suggests there are, they must necessarily, like everything else, operate in accordance with mathematical principles.) But mathematicians and nonmathematicians tend to view the applicability of mathematics in rather different ways. Nonmathematicians often view mathematics as just a tool to be used, a discipline whose importance is primarily in support of scientific and technical subjects (and increasingly other academic areas too); while they recognize its importance, they also understand its limitations in this respect. The following statement by an engineer is fairly typical of this point of view:

> “When the difficulty of a problem lies only in finding out what follows from certain fixed premises, mathematical methods furnish invaluable wings for flying over intermediate obstructions; but whenever the chief difficulty of a problem lies in the multiplicity and dubiousness of the premises themselves, and in reconciling them with each other, there is no safe course but to remain continuously on the solid ground of concrete fact.”

**A. M. Wellington**

Mathematicians, on the other hand, generally regard mathematics as an intellectual pursuit with a life of its own independent of applications; mathematics is no more simply a support subject for science than physics is just a support subject for engineering or chemistry a support subject for medicine. Mathematics as done by mathematicians bears the same relation to mathematics as used by scientists as literature bears to business communications.

> “Consider mathematics as some kind of giant computer with a large number of terminals on its periphery, representing fields of application. A practising scientist is like the terminal user. He is primarily interested in the output and will know something about what the computer can do for him, but he is not involved in what goes on inside the heart of the computer. In the early days of computers, users and designers were frequently the same people, but with their rapid growth and sophistication this is now the exception rather than the rule. Similarly it is the increasing sophistication of mathematics which has led to the large gap between ‘users’ and ‘designers’.”

**M. Atiyah**

The interest of many mathematicians in applications is limited to being pleased that nonmathematicians find mathematics important enough that it is worth encouraging and supporting (e.g. via university mathematics departments and NSF grants), but being scornful of occasional attempts by nonmathematicians or administrators to direct resources to “useful” parts of mathematics. Indeed, most mathematicians would say that no one can predict what parts of mathematics will turn out to be most useful, and anyway utility outside mathematics should play only a minor role, if any at all, in the day-to-day work of a mathematician.

These attitudes are largely shared by both “pure” and “applied” mathematicians. There is really not much systematic difference in the way pure and applied mathematicians work or in their approach to mathematics,
although there is some difference in the areas of theoretical mathematics they work in most heavily. The main difference, which provides the best definition of “pure mathematics” and “applied mathematics”, is simply in the origin of the problems they work on: in pure mathematics the problems come from within mathematics, while in applied mathematics the problems come from outside mathematics. (The applied mathematician also sometimes has the additional task of relating the solution of the mathematical problem to the original nonmathematical setting.) Thus almost all mathematicians are “pure mathematicians” at times and “applied mathematicians” at other times, and it is usually rather artificial to label a mathematician as one or the other.

Here are some more expressions of the mathematicians’ views on applications:

“Practical application is found by not looking for it, and one can say that the whole progress of civilization rests on that principle.”

J. Hadamard

“Only impractical dreamers spent two thousand years wondering about proving Euclid’s parallel postulate, and if they hadn’t done so, there would be no spaceships exploring the galaxy today.”

M. Greenberg

“Mathematics has the unique character of being a scientific discipline with applications to all other kinds of sciences and to practical life. But mathematics is also an art, the beauty lying in the symmetries, patterns, and intricately deep relationships which enchant the beholder. Discoveries that require the invention of new methods and great ingenuity are indeed to be hailed as important – at least from one point of view. Will these be of any practical use someday? Is it a legitimate question? Indeed, numerous are the examples when theories seemed for centuries to be gratuitous speculations, like the study of prime numbers, but today a mainstay of crucial applications in communications. It is the intrinsic quality of a new result which confers its importance.”

Paulo Ribenboim

“The mathematician does not study pure mathematics because it is useful; he studies it because he delights in it and he delights in it because it is beautiful.”

Henri Poincaré

“Understanding is a lot like sex. It’s got a practical purpose, but that’s not why people do it normally.”

Frank Oppenheimer

Scientists, too, express similar thoughts on an excessive preoccupation with applications:

---

78 cf. [Gre93, p. xxix].
79 [Gre93, p. xxix].
“If in the range of human endeavor after sound knowledge there is one subject that needs to be practical it is Medicine. Yet in the field of Medicine it has been found that branches such as biology and pathology must be studied for themselves and be developed by themselves with the single aim of increasing knowledge; and it is then that they can be best applied to the conduct of living processes. So also in the pursuit of mathematics, the path of practical utility is too narrow and irregular, not always leading far. The witness of history shows that, in the field of natural philosophy, mathematics will furnish the more effective assistance if, in its systematic development, its course can freely pass beyond the ever-shifting domain of use and application.”

A. R. Forsyth

“He who seeks for immediate practical use in the pursuit of science, may be reasonably sure, that he will seek in vain. Complete knowledge and complete understanding of the action of forces of nature and of the mind, is the only thing that science can aim at. The individual investigator must find his reward in the joy of new discoveries, as new victories of thought over resisting matter, in the esthetic beauty which a well-ordered domain of knowledge affords, where all parts are intellectually related, where one thing evolves from another, and all show the marks of the mind’s supremacy; he must find his reward in the consciousness of having contributed to the growing capital of knowledge on which depends the supremacy of man over the forces hostile to the spirit.”

H. Helmholtz

“In Plato’s time mathematics was purely a play of the free intellect; the mathematic-mystical reveries of a Pythagoras foreshadowed a far-reaching significance, but such a significance (except in the case of music) was as yet entirely a matter of fancy; yet even in that time mathematics was the prerequisite to all other studies! But today, when mathematics furnishes the only language by means of which we may formulate the most comprehensive laws of nature, laws which the ancients scarcely dreamed of, when moreover mathematics is the only means by which these laws may be understood,– how few learn today anything of the real essence of our mathematics! . . . In the schools of today mathematics serves only as a disciplinary study, a mental gymnastic; that it includes the highest ideal value for the comprehension of the universe, one dares scarcely to think of in view of our present day instruction.”

F. Lindemann, 1904

“What is the usefulness of a new-born child?”

Benjamin Franklin

85 When the usefulness of a new invention was questioned. J. Parton, *Life and Times of Benjamin Franklin* (1864), Part IV, Chapter 17.
I.5.11. Is Mathematics an Art or a Science?

I.5.11.1. Nonmathematicians, and especially scientists, tend to think of mathematics as a science; although there are obvious differences in character between mathematics and experimental sciences, the normal demonstrative nature of visible mathematics has much in common with techniques in science. Because of this, and the many fruitful interactions between mathematics and the experimental sciences, mathematics is often organizationally grouped among the sciences in universities. Many mathematicians are not so sure. Mathematics is a unique discipline with some flavor of science but also a creative aspect which to many more resembles art. Mathematics is not simply a mechanical or purely logical process; imagination plays an essential role, and what distinguishes great mathematicians from ordinary ones is much more a difference in imagination than technical ability. (To be sure, top-quality science also has a strong creative thought component.) And mathematics possesses an intrinsic beauty and elegance which can overwhelm those who delve deeply enough into the subject to experience it.

I.5.11.2. Indeed, mathematics cannot be considered a science at all unless one believes in some form of realism, since science is by definition the systematic study and understanding of some aspect of nature. Thus a logicist, formalist, or intuitionist/constructivist cannot regard mathematics as a science. But even a realist need not entirely subscribe to the notion that mathematics is a science; the Continent of Mathematics picture, for example, portrays mathematicians as far more than just scientists.

“I like to look at mathematics almost more as an art than as a science; for the activity of a mathematician, constantly creating as he is, guided though not controlled by the external world of the senses, bears a resemblance, not fanciful I believe but real, to the activity of an artist, of a painter let us say. Rigorous deductive reasoning on the part of the mathematician may be likened here to technical skill in drawing on the part of the painter. Just as no one can become a good painter without a certain amount of skill, so no one can become a mathematician without the power to reason accurately up to a certain point. Yet these qualities, fundamental though they are, do not make a painter or mathematician worthy of the name, nor indeed are they the most important factors in the case. Other qualities of a far more subtle sort, chief among which in both cases is imagination, go to the making of a good artist or good mathematician.

Maxime Bôcher

“Mathematics, rightly viewed, possesses not only truth, but supreme beauty – a beauty cold and austere, like that of sculpture, without appeal to any part of our weaker nature, without the gorgeous trappings of painting or music, yet sublimely pure, and capable of a stern perfection such as only the greatest art can show.”

Bertrand Russell

---

87 The study of Mathematics: Philosophical Essays; cf. R. Moritz, Memorabilia Mathematica, 1104.
“Surely the claim of mathematics to take a place among the liberal arts must now be admitted as fully made good. Whether we look at the advances made in modern geometry, in modern integral calculus, or in modern algebra, in each of these three a free handling of the material employed is now possible, and an almost unlimited scope is left to the regulated play of fancy.”

J. J. Sylvester

“The true mathematician is always a good deal of an artist, an architect, yes, of a poet. Beyond the real world, though perceptibly connected with it, mathematicians have intellectually created an ideal world, which they attempt to develop into the most perfect of all worlds, and which is being explored in every direction. None has the faintest conception of this world, except he who knows it.”

A. Pringsheim

“Mathematics has beauties of its own – a symmetry and proportion in its results, a lack of superfluidity, an exact adaptation of means to ends, which is exceedingly remarkable and to be found elsewhere only in the works of the greatest beauty. . . . The beauties of mathematics – of simplicity, of symmetry, of completeness – can and should be exemplified even to young children. When this subject is properly and concretely presented, the mental emotion should be that of enjoyment of beauty, not that of repulsion from the ugly and the unpleasant.”

J. W. A. Young

“The beautiful has its place in mathematics as elsewhere. The prose of ordinary intercourse and of business correspondence might be held to be the most practical use to which language is put, but we should be poor indeed without the literature of imagination. Mathematics too has its triumphs of the creative imagination, its beautiful theorems, its proofs and processes whose perfection of form has made them classic. He must be a ‘practical’ man who can see no poetry in mathematics.”

W. F. White

“The mathematician is entirely free, within the limits of his imagination, to construct what worlds he pleases. What he is to imagine is a matter for his own caprice; he is not thereby discovering the fundamental principles of the universe nor becoming acquainted with the ideas of God. If he can find, in experience, sets of entities which obey the same logical scheme as his mathematical entities, then he has applied his mathematics to the external world; he has created a branch of science.”

J. W. N. Sullivan

---

89 Jahresbericht der Deutschen Mathematiker Vereinigung, Bd. 32, p. 381; cf. R. Moritz, Memorabilia Mathematica, 1108.
92 Aspects of Science, 1925.
“[I]t was not its worldly utility that led Euclid or Archimedes or Georg Cantor to devote so much of their energy and genius to mathematics. These individuals did not feel compelled to justify their work with utilitarian applications any more than Shakespeare had to apologize for writing love sonnets instead of cookbooks or Van Gogh had to apologize for painting canvases instead of billboards.”

William Dunham\textsuperscript{93}

“Mathematics is not the rigid and rigidity-producing schema that the layman thinks it is; rather, in it we find ourselves at that meeting point of constraint and freedom that is the very essence of human nature.”

Hermann Weyl

“Proof is the end product of a long interaction between creative imagination and critical reasoning. Without proof the program remains incomplete, but without the imaginative input it never gets started.”

M. Atiyah\textsuperscript{94}

“Mathematics is the most perfect union between exact knowledge and theoretical thought.”

E. Curtius\textsuperscript{95}

“It is a relatively good approximation to truth \ldots that mathematical ideas originate in empirics, although the genealogy is sometimes long and obscure. But, once they are conceived, the subject begins to live a peculiar life of its own and is better compared to a creative one, governed by almost entirely aesthetical motivations.”

J. von Neumann\textsuperscript{96}

“Historically, mathematics developed out of man’s concern with physical problems. And although mathematics is ultimately a construction of the mind alone and exists only as a magnificent collection of ideas, from the earliest times down to the present day it has been stimulated and inspired by contact with the external world. Its problems are often idealizations of problems first encountered by the physicist or the engineer, or, more recently, by the social scientist. Many of its concepts are abstractions from the common experience of all men. And many areas of mathematics stem originally from the needs of scholars for more powerful analytical tools with which to pursue their investigations of the world around them. Surely, without contact with the external world, mathematics, if it existed at all, would be vastly different from what it is today.

\textsuperscript{93}[Dun90, p. vi].
\textsuperscript{94}The Princeton Companion to Mathematics, p. 1002.
\textsuperscript{95}Berliner Monatsberichte, 1873, p. 517; cf. [Mor93, 1409].
But mathematics repays generously her indebtedness to the other sciences. At the mere suggestion of a new problem, mathematics sets to work developing procedures for its solution, generalizing it, relating it to work already done and to results already known, until finally it gives back to scholars in the original field a well-developed theory for their use.

Oftentimes mathematics outruns completely the demands of the physical problem which may have stimulated it, and careless critics scoff at its ‘pure’ or ‘abstract’ or ‘useless’ character. Such criticism is absurd on two quite different counts. In the first place, all mathematics worthy of the name is pure or abstract or even, in a certain sense, useless, just as poetry and music and painting and sculpture are useless except as they bring satisfaction to those who create and to those who enjoy. It is no more appropriate to criticize mathematics for possessing the attributes of one of the creative arts than it is to criticize the arts themselves, unless it be that perhaps the number of those who find enjoyment in mathematics, though considerable, is less than those who enjoy the more conventional arts. Then in the second place, by a remarkable coincidence which is almost completely responsible for the existence of all present-day science and technology and which has no counterpart in the arts, even the most abstract parts of mathematics have turned out again and again to be highly ‘practical,’ as science, becoming ever more sophisticated, finds that it needs mathematical tools of greater and greater refinement.”

C. R. Wylie, Jr.\textsuperscript{97}

“Without mathematics we cannot penetrate deeply into philosophy. Without philosophy we cannot penetrate deeply into mathematics. Without both we cannot penetrate deeply into anything.”

I.6. The Foundations of Mathematics

Despite more than a hundred years of intense investigation, the foundations of mathematics remain almost as shaky as ever.

Until the nineteenth century, construction and examination of the edifice of mathematics took place almost entirely “above the surface,” building upward from such surface features as numbers, points, and lines. Mathematicians for the most part did not concern themselves with, or even recognize or acknowledge, the problem that the building might stand on shifting sand instead of solid rock.

In the latter part of the nineteenth century, continuing into the twentieth and to this day, mathematicians started exploring the part of the edifice lying below the surface. The development of set theory seemed to provide at least a basement, if not a foundation, for the structure. Logic itself seemed to lie either in a subbasement or an entire substructure of the building. But as investigations went further, it became less clear, rather than more, that there is a solid and well-formed foundation underlying it all.

I.6.1. Philosophies of Mathematics

“There is no primal language, or world view, or real line, but there are many languages, world views, and real lines, each of which can be understood to a large extent in terms of another but can only be fully understood on its own terms.”

T. W. Körner

There are, at least among philosophers, four principal philosophies of mathematics, or, more accurately, of the foundations of mathematics: realism or Platonism, intuitionism or constructivism, logicism, and formalism. Each has several variations. While the arcane details are more of interest to philosophers than working mathematicians, it is important for mathematicians to have some understanding of the differences.

Most philosophers admit that none of the four philosophies is adequate by itself as an overall philosophy of mathematics (see, for example, [Goo86]; my extended review of this article can be found at ()). Some modern-day philosophers are also critical of the historical preoccupation of philosophy with the foundations of mathematics, at the expense of studying its actual practice – see, for example, [Tym86] and [Cor03]). Indeed, each of them in its crudest form can be rather easily demolished as an absurdity. Nonetheless, each has some appealing and apparently accurate aspects, and most mathematicians (insofar as they can articulate any coherent personal philosophy of mathematics at all) seem to believe some combination of the philosophies; philosophers too acknowledge that belief in one of the philosophies does not preclude partial acceptance of the others. Indeed, I would say the primary shortcoming of each of the philosophies, at least in their more nuanced versions, is the assertion of exclusivity.

We will only give a bare introduction to these philosophies, which will necessarily be quite superficial and will give short shrift to the complex history of the ideas. Readers are referred to books on the philosophy of mathematics for details. I will also express some personal opinions; I do this advisedly, despite the warning from [Pot04, p. v]:

“... mathematicians have often been tempted, especially in later life, to commit to print philosophical reflections which are either wholly vacuous or hopelessly incoherent.”

99[Kör04, p. 394].
Realism and Platonism

Realism as a philosophy of mathematics has definitely been unfashionable among philosophers, to the extent that many philosophers talk about “the three schools of the philosophy of mathematics,” meaning the other three! However, among mathematicians it is probably the predominant view, and one which I largely subscribe to myself. (Philosophers tend to be dismissive of the opinions of mathematicians on this issue as unreliable, unsophisticated, and/or uninformed, not entirely without justification. Mathematicians are often similarly dismissive of philosophers; cf. I.6.1.30.) Mathematicians generally have a strong feeling that the abstract objects they work with are “real,” although this could of course be an illusion. This feeling is reflected in the language mathematicians use to describe advances in mathematics, almost invariably referring to “discovering” or “finding” new results or proofs. The term “invent” is rarely used, and when it is (e.g. “Newton and/or Leibniz invented calculus”) it usually refers to the development of a new subdiscipline or point of view in mathematics, which can be viewed as a way of facilitating analysis of the structure of part of the “continent of mathematics” per se.

“Mathematical truth has some sort of necessity about it, which contrasts with the merely contingent beliefs we have about the world of sense experience. There is a harshness about mathematical truth which makes it not only ineluctably true, but profoundly true, because it is immune to the changes and chances of this fleeting world of transient phenomena, and tells us about not what just is, but what must be, the case.”

J. R. Lucas

“[W]hile the other sciences search for the rules that God has chosen for this universe, we mathematicians search for the rules that even God has to obey.”

Jean-Pierre Serre

“Platonism seems obvious when you are thinking about mathematical truth, but impossible when you are thinking about mathematical knowledge.”

W. D. Hart

Existence

I.6.1.3. Some critics of realism or Platonism construe “existence” too narrowly, limiting it to actual observable physical objects. By this restricted use of the term most, if not all, mathematical “objects” do not exist. But then other things we commonly talk about also cannot exist. What about gravity, or more generally “force” as used in physics? Gravity is not an object and cannot itself be observed (at least so far – we can only observe effects we attribute to gravity). What about “good” and “evil”? Are all these things just constructs of the human mind, or do they really “exist”?

“Of course it is happening inside your head, Harry, but why on earth should that mean that it is not real?”

Albus Dumbledore

100 [Luc00, p. 20].
102 cf. [Luc00, p. 13].
Actually, what does “existence” mean for an abstract concept? This is a tough question, with many logical pitfalls. For example, while “the set of all sets” is a logical impossibility due to Russell’s Paradox, if we say that the set of all sets does not exist, then how can we talk about it? What is the meaning of the sentence “The set of all sets does not exist”? How can a sentence refer to a nonexistent concept?

We even use nonexistent objects or concepts routinely in mathematics. For example, the ancient proof that $\sqrt{2}$ is irrational, as it is usually written today (I.5.5.), begins with: “Suppose $a$ and $b$ are natural numbers with $\frac{a}{b} = \sqrt{2}$.” The proof goes on to show by contradiction that such $a$ and $b$ cannot exist. So how can we suppose they exist when they do not? Can we make a distinction between a conceivable concept and a concept that exists? If a concept does not exist, how can it be conceivable?

We often do not know whether mathematical objects exist. For example, no one knows whether “the smallest even natural number larger than two which cannot be written as a sum of two primes” exists or not. If it does not exist, how can I talk about it, as I just did?

The question of “existence” of numbers like 1 and 2 seems to me essentially the same as the question of “existence” of hydrogen and helium. Note that the existence of “hydrogen” is a subtly different question than the existence of hydrogen atoms. It is indisputable that hydrogen atoms exist in great abundance, as do helium atoms. But one needs a concept of “hydrogen” to say that two distinct hydrogen atoms are both hydrogen, and that a helium atom is not hydrogen. If “hydrogen” exists only in the human mind, how can hydrogen and helium atoms act differently chemically, and by what mechanism do all hydrogen atoms act identically? Although the concept “hydrogen” may be a human construct, there is an aggregate of properties or characteristics possessed by some atoms and not others constituting “hydrogenness” independently of any involvement of the human intellect. So it is with “oneness.” See I.6.1.12. for more comments.

If “one” and “two” exist as transcendent concepts, then what about the rest of the natural numbers? Do they all exist, and if not, what is the first one which does not?

Some things, if they “exist” at all, are certainly pure constructs of the human mind, e.g. Mickey Mouse, unicorns. But the distinction is not always so clear-cut: did the Piltdown Man ever exist, and if so, in what sense?

We can, of course, open a whole different can of worms by asking whether the empty set exists. On the one hand, the existence of anything would seem not to make sense unless we could contrast it with the existence of nothing; and if there does not exist anything, then nothing exists. On the other hand, if “nothing” exists, what kind of a thing could it be? And is the empty set the same as “nothing”, and is “zero” the same as either? See [Gar01] for an essay on this subject.

Atiyah [?] argues that even the natural numbers are simply constructs of the human mind, and would not necessarily come into the consciousness of an intelligent creature of a different form:

“But let us imagine that intelligence had resided, not in mankind, but in some vast solitary and isolated jellyfish, deep in the depths of the Pacific. It would have no experience of individual objects, only with the surrounding water. Motion, temperature and pressure would provide its basic sensory data. In such a pure continuum the discrete would not arise and there would be nothing to count.”

69
(Such a creature is certainly conceivable, and may actually exist, perhaps on Europa?) But Atiyah confuses existence with familiarity. Just because natural numbers might not be within its sense experience and may be discovered late or not at all, it does not mean that they are any less “real.” Four-dimensional geometry is not within our sense experience and thus began to be accepted and studied only relatively recently, but from a mathematical standpoint it is just as “real” as three-dimensional geometry. And eventually such a creature would find things to count, the dimensions in which it could move if nothing else; if it is intelligent enough to develop some form of calculus, it would also encounter first derivatives, second derivatives, etc.

Atiyah goes on to raise a more troubling point:

“Even more fundamentally, in a purely static universe without the notion of time, causality would disappear and with it that of logical implication and of mathematical proof.”

We can hardly conceive of the absence of time and causality, and mathematics and logic as they exist for us certainly have causality at their root. But mathematics, broadly enough defined, might well have aspects not even dependent on causality.

Atiyah makes some good points and convincingly argues that mathematics as we know and understand it is a creation of the human mind with origins in human sense experience, but his arguments that mathematical objects and truths do not have some type of independent existence do not hold water.

I.6.1.10. A common but misguided way of dismissing realism which I find particularly obnoxious is to equate it to theology or belief in God. Apparently the rationale is that everything must be created by someone, and if mathematics is discovered and not created in the human mind, it must have been created by God. This is simply baloney. One direction of the argument has some validity: realism would evidently be attractive to a religious mathematician, and it is a historical fact that some mathematicians and philosophers (including Plato himself) have been drawn to realism by their religious beliefs. But belief in mathematical realism does not in any way entail belief in a Creator, any more than belief in the existence of physical laws does; a mathematical realist is no more compelled to be religious than an astronomer or biologist.

“[Platonic] ‘existence’ is really just the objectivity of mathematical truth.”

Roger Penrose

I.6.1.11. An interesting and rather different existence question is discussed in [Gow02]: Does the complex number \( i \) exist? This is not the same as asking whether the complex numbers exist: even if we accept that they do, there are two complex numbers whose square is \(-1\), and unlike the two square roots of \( 2 \) in \( \mathbb{R} \) where there is a reasonable way to pick one (the positive one) to call \( \sqrt{2} \), there is no logical way to pick one of the square roots of \(-1\) to be called \( i \). But this is really more a question of definition rather than existence: it is really the fact that there is no well-defined (e.g. continuous) square root function defined on \( \mathbb{C} \). It also relates to the logical problem of making the common definition of \( \mathbb{C} \) as the complex plane: in addition to the logical difficulties discussed in III.6.2.24., there are two equally reasonable ways to identify \( \mathbb{C} \) with \( \mathbb{R}^2 \).

\[104\][Pen05, p. 13].
Invention vs. Discovery vs. ???

I.6.1.12. Returning to the subject of chemical elements, some recent developments in chemistry/atomic physics raise interesting questions related to the existence question of mathematical objects, and whether mathematicians “discover” or “invent” new mathematics. It was reported that scientists had, with high probability, created a few atoms of the element with atomic number 118 (now called oganesson). Although these atoms lasted for only a minute fraction of a second, the existence of this element was transformed from a theoretical possibility to a physical fact.

I.6.1.13. It does not seem accurate to say that these scientists had either “discovered” or “invented” Element 118. Some news accounts referred to the achievement as a “discovery.” This assertion seems rather similar to the common statement in history books that Peary “discovered” the North Pole. While Peary, or a member of his team, was (possibly!) the first person to reach the North Pole, he did not discover it; in fact, the North Pole was actually discovered by the first person who realized that the earth is a round ball and rotates on an axis (the North Star has been known and used for navigation since ancient and possibly even prehistoric times, although it was a different star in ancient times due to precession; once one realizes that the North Star rises higher in the sky as one moves north, it is not much of a leap to expect that it will eventually be straight overhead if one goes far enough north, assuming the earth has no edge, although uniqueness of this point on the earth is not so obvious). After all, did Neil Armstrong discover the moon?

I.6.1.14. It also does not seem accurate to say that the scientists “invented” Element 118. While they were evidently the first humans to actually assemble such an atom, the potential existence of Element 118 has long been recognized in increasingly great detail, and even the likely methods of creation of a 118 atom were widely known to specialists. This is more of a semantic question than the “discovery” one: for example, is it accurate to say that the Wright brothers “invented” the airplane? Of course, they built the first one that actually flew, and one cannot minimize the importance of that achievement; but the concept of the airplane goes back to antiquity, and specific designs of airplanes which could have flown with sufficient technical refinements go back at least to Leonardo da Vinci (in fact, if the internal combustion engine had been available to da Vinci, he might very well have built the first flying airplane.)

I.6.1.15. Perhaps the best verb for this situation is produce: the scientists were the first to produce an element 118 atom. This might be an appropriate term to also describe some advances in mathematics, avoiding the “invent” vs. “discover” question.

I.6.1.16. Scientists have long speculated about even heavier elements. For example, many scientists believe that if the right isotope of an atom with atomic number 126 could be assembled, it would be fairly stable, and they can predict with a fair degree of confidence what its chemical and physical properties would be. So let us ask: does Element 126 exist?

I.6.1.17. Of the three possible answers, Yes, No, and Maybe, the only one which cannot be rationally justified is No. No one can know that there is not a single atom of this element anywhere in the universe. A more interesting question is whether existence of such an atom somewhere is even relevant to the discussion, since it seems there is no possible way for us to ever know whether Element 126 atoms currently exist or existed at one time, say, in the remnants of a star in a galaxy millions of light-years away (according to the theory of relativity, it does not even make sense to ask whether such an atom currently exists.)
I.6.1.18. To answer the existence question, one must really decide what “existence” means in this case. Does it mean having an actual atom, or does it just mean having a very specific and rather well-understood theoretically possible physical object? Without actual atoms at hand, Element 126 is only a theoretical concept, but it seems quite different in character than, say, the postulated extra dimensions of string theory. Even a high-school student who knows about the periodic table can easily speculate about the existence of Element 126 and understand exactly (at least in general terms) what kind of physical object it would be.

I.6.1.19. It would be easy to say that Element 126 thus clearly exists as an abstract concept. After all, otherwise how could scientists even talk about it, much less study its properties? But a note of caution must be given here. Mathematicians have often talked about “the set of all sets,” and sometimes still do, even though it is now well known that such a set is a logical impossibility. Someday someone may discover a scientific principle which makes assembly of an Element 126 atom impossible; how would such a discovery affect the existence of Element 126 as an abstract concept?

I.6.1.20. Furthermore, if Element 126 is an object whose existence can be reasonably contemplated, what about Element 1000 (an atom with atomic number 1000)? I don’t imagine most chemists or physicists think there is any theoretical possibility that atoms this large could ever be created. What is the largest atomic number which is conceivable as a potential physical object? If 1000 is not big enough, what about Element $10^{100}$, which is clearly physically impossible since there are (according to our present knowledge) far less than $10^{100}$ protons and electrons in the universe.

Logicism

Logicism has the most succinct nutshell description of any of the philosophies of the foundations of mathematics: in Bertrand Russell’s words, it is the belief that “Mathematics is logic.” Or, as he later said in a more detailed and perhaps more accurate statement:

“Mathematics and logic, historically speaking, have been entirely distinct studies. . . . But both have developed in modern times: logic has become more mathematical and mathematics has become more logical. The consequence is that it has now become wholly impossible to draw a line between the two; in fact the two are one. They differ as boy and man: logic is the youth of mathematics and mathematics is the manhood of logic.”

Bertrand Russell

Specifically, logicism holds that all mathematical objects and truths, beginning with the natural numbers, are just simple consequences of the laws of logic. All more advanced parts of mathematics are built up from basic logical principles by repeated applications of the same rules of logic.

Russell [?, p. 3] gives the following definition of (pure) mathematics:

“Pure mathematics is the class of all propositions of the form ‘$p$ implies $q,$’ where $p$ and $q$ are propositions containing one or more variables, the same in the two propositions, and neither $p$ nor $q$ contains any constants except logical constants. And logical constants are all notions definable in terms of the following: Implication, the relation of a term to a class of which it is a member, the notion of such that, the notion of relation, and such further relations as may be involved in

---

105 Introduction to Mathematical Philosophy, 1919.
the general notion of propositions of the above form. In addition to these, mathematics uses a notion which is not a constituent of the propositions which it considers, namely the notion of truth.”

Quite apart from the vagueness of parts of this definition, it would surely not be considered an adequate description of mathematics by most modern mathematicians. (It should be noted that this definition was written more than a hundred years ago, and the conception of mathematics and its breadth and depth have changed markedly over this time. Indeed, Russell himself expressed second thoughts about this definition in the preface to the second edition of [? in 1938.]

It is hard to see, for example, how the Axiom of Choice, or even the Axiom of Infinity or Peano’s (second-order) axiom P5 ( ), could be considered as derivable from basic logic. Indeed, Russell admits [?, p. viii]:

“Such existence-theorems, with certain exceptions, are, I should now say, examples of propositions which can be enunciated in logical terms, but can only be proved or disproved by empirical evidence.”

This assertion seems to seriously undermine the argument that mathematics is simply a part of logic.

**Intuitionism and Constructivism**

The terms *intuitionism* and *constructivism* are often used more or less interchangeably to mean a combination of two rather distinct notions. They are usually thought of together since the primary proponent, L. Brouwer, forcefully argued for the combination. However, although there are obvious reasons why constructivism would be attractive to an intuitionist, there does not appear to be any necessary implication between the two, in either direction.

The thesis of intuitionism is that mathematics consists of the study of “mental mathematical constructions.” To an intuitionist, mathematics, or a “mathematical construction”, need not be based on formal logic or even be formalizable in the accepted sense of the term. Acceptable modes of mathematical reasoning are not completely specified, but simply consist of all reasoning the human mind considers convincing. As with all other aspects of human thought, the conception and understanding of a piece of mathematics may vary slightly from person to person, and communication of mathematics (or writing it down) is at best an imperfect representation of the mental construction involved. Thus it cannot be said that any piece of mathematics is entirely rigorous. The question of whether mathematical objects have a transcendent or mind-independent existence is not relevant in intuitionism, and perhaps does not even make sense.

I have considerable (but not complete) sympathy with the philosophy of intuitionism when it is expressed in this way, so long as the term “mental mathematical construction” is given a sufficiently liberal interpretation. For example, I see no reason to think that humans cannot make a “mental construction” of an infinite set, or even the set of real numbers. Most intuitionists have a rather restricted view of what a “mental mathematical construction” can be, and thus reject existence of infinite sets as “completed” objects, although they accept “potentially infinite” mathematical objects such as the natural numbers or even the real numbers. Most intuitionists reject the Law of the Excluded Middle, and some even reject the whole idea of negation (cf. [Gri46]–[Gri51], [Hey66, 8.2]), while others embrace the notion of contradiction in a limited form. As with all philosophies of mathematics, there is considerable variation in the specifics of the theories of various proponents of intuitionism.

Mathematicians often make use of arguments which do not have any obvious formalization, and sometimes accept such arguments as proofs. A good example is given in [Lak76, ]. Formalizable but nonconstructive
Arguments are even more common in modern mathematics, although they were unusual as recently as the nineteenth century: when Hilbert first made a name for himself by giving a fairly simple but totally nonconstructive proof of a theorem on existence of finite systems of invariants, generalizing a result which had previously been proved laboriously by a constructive argument by P. Gordan. Gordan’s reaction was “Das ist nicht Mathematik, das ist Theologie!” Gordan later warmed up to Hilbert’s methods, and admitted, “I have convinced myself that theology also has its advantages.” [Kli72, p. 930].

Even a good formalization of a theory is generally an imperfect representation of the intuitive theory. For example, ZF (and even ZFC) set theory is inadequate to settle the Continuum Hypothesis. In fact, Gödel’s Incompleteness Theorem guarantees that essentially any formalization of a mathematical theory is inadequate in some respect.

Constructivism is a rather different, although not unrelated, idea: that mathematical objects only exist when they have been given an explicit finite construction. In the most common version, the natural numbers (individually, not as a completed totality) are regarded as “given” and all other mathematical objects must be explicitly constructed from them. This is the form of constructivism espoused by Brouwer, but its origins go back at least to Kronecker, to whom is attributed the famous statement

“God made the integers [natural numbers]: all else is the work of man.”

Intuitionists find this form of constructivism natural and/or attractive since they regard the natural numbers (or, more precisely, specific small natural numbers) as being mathematical objects whose mental construction is self-evident and needs no further explanation or justification. Thus constructivism can be regarded as a natural logical consequence, or a somewhat extreme special case, of intuitionism. However, one could embrace constructivism without accepting the overall philosophy of intuitionism, e.g. it would be easy to instead justify constructivism on the basis of some type of formalism. Indeed, most constructivists greatly restrict acceptable modes of reasoning, in a manner arguably more in line with formalism than intuitionism.

The specification of natural numbers, and not, say, real numbers, points and lines, or sets, as the fundamental objects of mathematics out of which everything else must be built, can seem a bit strange and arbitrary, but constructivists have extensive arguments purporting to justify it. See ().

Among mathematicians, the most forceful modern-day proponent of constructivism was Errett Bishop, who showed that a quite remarkable amount of classical analysis can be developed within constructivist mathematics; see [BB85]. (Much of this was developed before Bishop, notably by Brouwer; see, for example, [Hey66]. This development has continued since Bishop; see, for example, [BV06].) Bishop’s book also contains a lengthy exposition of his philosophy of mathematics, which, it must be noted, differed significantly from Brouwer’s. For a less dogmatic introduction to intuitionism and constructivism, see [Hey66] or [Dum00]. Heyting actually presents intuitionist logic in an intriguing way, as a generalization of ordinary logic where statements do not just have a truth value of 0 or 1, but a truth value in a more general Boolean algebra. (This is similar to, but not the same as, fuzzy logic, which despite the name is a mathematically sound theory where truth values can be numbers between 0 and 1; fuzzy logic has yet to become a part of mainstream mathematics.)

The development of the theory of imaginary and complex numbers is an interesting case study for the philosophies of intuitionism and constructivism, although the discussion is purely academic since historically the entire development of the complex numbers predated the formulation of intuitionism or any of the other

---

106 This was said at a meeting of the Berliner Naturforscher-Versammlung in 1886; cf. Jahresbericht der Deutschen Mathematiker-Vereinigung, Bd. 2, p. 19. Bell [Bel87, p. 33] says, “As he said this in an after-dinner speech, perhaps he should not be held to it too strictly.”
modern philosophies of mathematics. Imaginary numbers were contemplated at least as far back as the 16th
century, when CARDANO, and, subsequently and more clearly, BOMBELLI, discovered that even to represent
the real roots of a cubic polynomial with real coefficients by an algebraic formula, square roots of negative
numbers must sometimes be used. They, and most other mathematicians for centuries afterward, regarded
such square roots to be “nonexistent” as numbers and “meaningless” (many, including CARDANO, even felt
the same way about negative real numbers), but found that they could be used algebraically as though they
made sense in order to obtain real results, without apparent logical contradiction. (Not all mathematicians
of the era had this problem; in the seventeenth century, JOHN WALLIS accepted the legitimacy of complex
numbers and even came close to describing the complex plane; cf. [Kli72, p. 594-595].) It was only much
later that anything resembling an actual construction was done of imaginary and complex numbers, and
that they began to be accepted as actual mathematical objects. Modern mathematicians consider the terms
“real” and “imaginary” as historical artifacts which are still used merely for convenience; today, we would
say there is nothing inherently more (or less) “real” about \( \sqrt{2} \) than about \( i = \sqrt{-1} \), although \( \sqrt{2} \) may be
more familiar to many people (but see I.6.1.11.).

An intuitionist might well say (although I doubt most would) that CARDANO and BOMBELLI had made
a “mental construction” of square roots of negative numbers, despite their reservations about whether these
objects represented anything “real”, and that imaginary numbers were part of mathematics from that time
onward. (One must be careful here: as brilliant a mathematician as FREGE made a “mental construction”
of the set of all sets, and worked for ten years on a theory based on this notion before becoming aware
of Russell’s Paradox.) A constructivist, on the other hand, probably would say that complex numbers did
not become mathematical objects until the nineteenth century, and some would say that CARDANO and
BOMBELLI were not justified in using them at all; in fact, if strict constructivist methods had been insisted
on, several hundred years of mathematical progress probably would not have happened.

Constructivists disagree about whether Goldbach’s Conjecture (that every even number greater than 2 is
a sum of two primes) has a truth value at present. Most mathematicians would argue that this statement is
definitely either true or false, and not logically indeterminate, since if it is false there is a finitely constructible
even number for which it fails. The fact that it is not now known which it is, and may never be known, is
not really relevant for most mathematicians. (On the other hand, the same argument can be made about
the consistency of ZF set theory.)

For perhaps a clearer example, suppose \( x \) is a fixed number of 100,000 digits, say with no prime factors of
less than 10,000 digits (beyond our current ability to test primality in practice). It is hard to imagine even
an ardent constructivist saying that the statement “\( x \) is prime” has no definite truth value, since there is an
obvious process of fixed finite length which will definitively establish the truth or falsity of the statement,
even though the process is not one which we are currently able to carry out. What about the statement

\[
35933408596862231041960188598043661065388726959079837 \text{ is prime.}
\]

(which is now known to be true)? Was this statement already true 100 years ago, or did it only become true
when modern computers made it possible to determine the number’s primality? What will happen in the
future if some catastrophe leaves mankind without computers – will this statement still be true?

My view is that constructivist mathematics is good and interesting mathematics, and the techniques
and results are of both theoretical and practical importance. A constructivist proof of a theorem is usually
“better” (albeit sometimes less “elegant”), and says more, than a nonconstructive one. But constructivist
mathematics is by no means all of mathematics!

This is the fundamental point of disagreement I have with (some) constructivists, who believe that
constructivist mathematics is the only legitimate mathematics. For example, one finds the following grandiose
claim made as an apparently serious assertion:
“A presentation of today’s intuitionist mathematics sets out from meaningful mathematics and, following a clear, bright road of mathematical reasons, arrives at a firm vantage from which conventional mathematics is seen to be generally false and set theory, analysis, arithmetic, algebra – all the fields of modern mathematics – reappear, scoured clean of fallacy and error.”

D. C. McCarty\textsuperscript{107}

(I should not accuse all constructivists of this exclusivity attitude – for example, the philosophy of constructivism described in \cite{BV06} is a healthy one with which I almost entirely agree.)

This quote also illustrates a point made in \cite{Luc00}: intuitionists claim that legitimate mathematical arguments are simply ones that mathematicians find convincing; but most mathematicians find classical mathematics convincing, and (many) intuitionists think they are wrong to do so.

“Intuitionists can no more argue that classical mathematicians are wrong to argue as they do than a jazz pianist can argue that Bach is wrong to compose as he did.”

J. R. Lucas\textsuperscript{108}

Until I see that the Law of the Excluded Middle and other nonconstructive arguments lead to some contradiction or absurdity, I see no reason not to use them, although I think it is very worthwhile to see how much of mathematics can be developed and proved without them. In this respect my opinion about the Law of the Excluded Middle (called the “excluded muddle” in \cite{Bel87}) is not very different from my attitude about the Axiom of Choice.

It is sometimes asserted that intuitionists/constructivists have created a “new” or “different” mathematics. I disagree with this assertion; my conception of what mathematics is is broad enough to comfortably include intuitionist mathematics as well as “classical” mathematics, and also potentially more mathematics based on other logical and language schemes.

Frege, although he is considered a logicist, also seemed to leave open the possibility of multiple logics in a statement which also admirably summarized the axiomatic method:

“It cannot be demanded that everything be proved … but we can require that all propositions used without proof be expressly declared as such, so that we can see distinctly what the whole structure rests upon. After that we must try to diminish the number of these primitive laws as far as possible by proving everything that can be proved. Furthermore, I demand – and in this I go beyond Euclid – that all methods of inference employed be specified in advance . . . .”

\textit{Gottlob Frege}\textsuperscript{109}

\section*{Formalism}

The crudest expression of formalism is the assertion that mathematics is simply a “game” of symbol manipulation according to agreed rules. As such, there is no “meaning” or “truth” in mathematics, only formal derivation of new statements from agreed starting assumptions or previously derived consequences.

\textsuperscript{107}\cite[p. 357]{Sha05}
\textsuperscript{108}\cite[p. 171]{Luc00}
\textsuperscript{109}Grundgesetze der Arithmetik, v. 1, introduction, translated by M. Furth; cf. \cite[p. 231]{Gra00}.
“Mathematics, like dialectics, is an organ of the higher sense, in its execution it is an art like eloquence. To both nothing but the form is of value; neither cares anything for content. Whether mathematics considers pennies or guineas, whether rhetoric defends truth or error, is perfectly immaterial to either.”

Goethe

“The results of systematic symbolical reasoning must always express general truths, by their nature; and do not, for their justification, require each of the steps of the process to represent some definite operation upon quantity. The absolute universality of the interpretation of symbols is the fundamental principle of their use.”

William Whewell

“If the question of ‘truth’ of axioms isn’t the mathematician’s business to discuss whose is it?”

Hilary Putnam

There are considerably more complex and nuanced versions of formalism, however, which cannot be discredited nearly as easily as the crude version of the previous paragraph. Hilbert is regarded as the father of formalism, but Hilbert's formalism is almost unrecognizably different from the description above. Hilbert maintained that there are indeed real mathematical objects such as numbers and geometric objects like points and lines, with some sort of Platonic or intuitive existence, but that the right way to derive the properties of these real objects is to abstract them into theories applying to not only the real objects but also to additional “ideal” objects which really have no meaning or existence on their own, but about which formal statements can be derived, in particular giving valid statements about the real objects one began with. When phrased in this way, formalism more or less just appears to be a codification of the abstraction process commonly accepted and used throughout mathematics.

The set of real numbers is a good and relevant example of expanding a set of “meaningful” objects into an ideal theory which can be formalized and axiomatized. Only certain real numbers can be said to have intuitive meaning, arguably only finitely many; in fact, in principle, at most countably many real numbers can even have an explicit (finite) description or characterization. But uncountably many “ideal” numbers must be added to make a theory that can be axiomatized in the standard way we describe in this book. Hilbert actually regarded any infinite set, considered as a “completed” object, to be an idealization, but did not shy away from considering and working with them formally.

Hilbert went on to state that the only arguments which should be accepted as proofs are “finitary” arguments which can be completely and explicitly carried out according to the most basic logical principles. In this respect, the limitations he argued for might not be terribly different than what constructivists insist on, although Hilbert was a severe critic of Brouwer and the intuitionists/constructivists; indeed, Hilbert regarded any kind of potential mathematical objects not leading to a logical contradiction as being things whose existence could be legitimately assumed, or could at least be worked with as though they really existed. Hilbert did not reject the role of intuition and non-finitary arguments in developing and understanding mathematics, but regarded such arguments as no substitute for finitary proofs.

110 Sprüche in Prosa, Natur IV, 946; cf. R. Moritz, Memorabilia Mathematica, 1307.
111 The Philosophy of the Inductive Sciences (London, 1858), Part I, Bk. 2, chap. 12, sect. 2; cf. R. Moritz, Memorabilia Mathematica, 1212.
Hilbert’s goal was the formalization of all of mathematics, with finite mechanical processes to determine the truth or falsity of every mathematical statement. Although his ultimate hopes were dashed by Gödel’s Incompleteness Theorem, Hilbert’s program led to the subject of metamathematics, which could be regarded as the mathematical theory of mathematical theories (including mathematical logic), and which is an important and flourishing branch of mathematics today.

“[Gödel’s Incompleteness Theorem] means that man can never eliminate the necessity of using his own intelligence, no matter how cleverly he tries.”

*Paul Rosenbloom*¹¹³

For a working mathematician, there is little practical difference between logicism and formalism; both assert that the only valid mathematical arguments are completely formal ones, and that intuition and plausibility arguments have no place in mathematics proper (at least officially). There are, however, large philosophical differences between the two, which have led to vigorous criticism of each by proponents of the other. For example, logicists regard mathematics as part of logic, while formalists consider logic, at least “mathematical logic,” to be just a part of mathematics. Formalists, at least at the basic level described above, deny that there is any notion of mathematical “truth”; logicists maintain that there is, but that mathematical “truth” is really just logical “truth.” Formalists (basic ones, not Hilbert) say that mathematics is not really “about” anything, a point of view vehemently rejected by logicists, who view logic, and hence mathematics, as being “about” everything.

**The Practice of Mathematics**

“There is probably no other science which presents such different appearances to one who cultivates it and one who does not, as mathematics. To [the noncultivator] it is ancient, venerable, and complete; a body of dry, irrefutable, unambiguous reasoning. To the mathematician, on the other hand, his science is yet in the purple bloom of vigorous youth, everywhere stretching out after the “attainable but unattained,” and full of the excitement of nascent thoughts; its logic is beset with ambiguities, and its analytic processes, like Bunyan’s road, have a quagmire on one side and a deep ditch on the other, and branch off into innumerable by-paths that end in a wilderness.”

*C. H. Chapman, 1892*¹¹⁴

Mathematics, as practiced by human mathematicians, consists of two rather distinct and almost independent aspects:

1. Ascertaining what is true and significant in mathematics, including good formulation of mathematical ideas and statements.

2. Proving that the statements thought to be true are in fact true.

Both aspects are essential. They are not entirely independent; a third aspect which bridges the other two, of comparable importance, is:

¹¹⁴Bulletin of the New York Mathematical Society, 2, 1892, p. 61; cf. [Bel92, p. v].
1.5. Understanding why the statements which are true are true.

Some mathematicians would say that 1.5 and 2 are really the same thing, but they are not (at least not exactly). One can sometimes prove a statement without having much real understanding of why it is true, except in a formal sense. And one can often gain a pretty good “understanding” of how a mathematical subject works and of what must be true without being able to actually prove it. In fact, much of calculus had this status for about 200 years.

“The logician cuts up, so to speak, each demonstration into a very great number of elementary operations; when we have examined these operations one after the other and ascertained that each is correct, are we to think we have grasped the real meaning of the demonstration? Shall we have understood it even when, by an effort of memory, we have become able to reproduce all these elementary operations in just the order in which the inventor had arranged them? Evidently not; we shall not yet possess the entire reality; that I know not what, which makes the unity of the demonstration, will completely elude us . . .

If you are present at a game of chess, it will not suffice, for the understanding of the game, to know the rules of moving the chess pieces. That will only enable you to recognize that each move has been made conformably to these rules, and this knowledge will truly have very little value. Yet this is what the reader of a book on mathematics would do if he were a logician only. To understand the game is wholly another matter; it is to know why the player moves this piece rather than that other which he could have moved without breaking the rules of the game. It is to perceive the inward reason which makes of this series of moves a sort of organized whole. This faculty is still more necessary for the player himself, that is, for the inventor.”

Henri Poincaré

“We are not very pleased when we are forced to accept a mathematical truth by virtue of a complicated chain of formal conclusions and computations, which we traverse blindly, link by link, feeling our way by touch. We want first an overview of the aim and of the road; we want to understand the idea of the proof, the deeper context.”

Hermann Weyl

It can be argued that 1, and even 1.5, are not really part of mathematics at all. This is exactly what (basic) formalism does: it gives a good, precise, and rather accurate description of 2, but has nothing to say about 1 or 1.5, and in effect excludes them from mathematics proper, and also implies that the history of mathematics has no place in the study of present-day mathematics; indeed, full acceptance of formalism (or logicism) would imply that humans did virtually no actual mathematics before the late nineteenth century (Euclid perhaps excluded). In fact, in 1901 Russell only half-jokingly wrote:

“Pure mathematics was discovered by Boole, in a work which he called The Laws of Thought (1854). This work abounds in assererations that it is not mathematical, the fact being that Boole was too modest to suppose his book the first ever written on mathematics.”

However, 1 and 1.5 are certainly parts, and important parts, of human mathematics, and a philosophy of mathematics which does not recognize and embrace this is an inadequate and empty one. Russell [?, p. 280] acknowledges this point:

“It is a peculiar fact about the genesis and growth of new disciplines that too much rigour too early imposed stifles the imagination and stultifies invention. A certain freedom from the strictures of sustained formality tends to promote the development of a subject in its early stages, even if this means the risk of a certain amount of error.”

André Weil [Wei62] elaborated on and at the same time qualified this view:

“The mathematician who first explores a promising new field is privileged to take a good deal for granted that a critical investigator would feel bound to justify step by step; at times when vast territories are being opened up, nothing could be more harmful to the progress of mathematics than a literal observance of strict standards of rigor. Nor should one forget . . . that the so-called ‘intuition’ of earlier mathematicians, reckless as their use of it may sometimes appear to us, often rested on a most painstaking study of numerous special examples, from which they gained an insight not always found among modern exponents of the axiomatic creed. At the same time, it should always be remembered that it is the duty, as it is the business, of the mathematician to prove theorems, and that this duty can never be disregarded for long without fatal effects. The experience of many centuries has shown this to be a matter on which, whatever our tastes or tendencies, whether ‘creative’ or ‘critical,’ we mathematicians dare not disagree.”

Felix Klein [Kle04, p. 207-208] similarly expounded on the nature of mathematics and formalism:

“You can hear often from non mathematicians, especially from philosophers, that mathematics consists exclusively in drawing conclusions from clearly stated premises; and that, in this process, it makes no difference what these premises signify, whether they are true or false, provided only that they do not contradict one another. But a person who has done productive mathematical work will talk quite differently. In fact those persons are thinking only of the crystallized form into which finished mathematical theories are finally cast. The investigator, however, in mathematics, as in every other science, does not work in this rigorous deductive fashion. On the contrary, he makes essential use of his phantasy and proceeds inductively, aided by heuristic expedients. One can give numerous examples of mathematicians who have discovered theorems of the greatest importance, which they were unable to prove. Should one, then, refuse to recognize this as a great accomplishment and, in deference to the above definition, insist that this is not mathematics, and only the successors who supply polished proofs are doing real mathematics? After all, it is an arbitrary thing how the word is to be used, but no judgment of value can deny that the inductive work of the person who first announces the theorem is at least as valuable as the deductive work of the one who first proves it. For both are equally necessary, and the discovery is the presupposition of the later conclusion.”

M. Postnikov [ZD07, p. 166] described the stages of development of new mathematics:

“In general, mathematical work consists of three stages. The first stage is the most pleasant: thinking up the theorem and an idea for proving it. The second step – less pleasant, but still with an element of satisfaction – is to organize the proof, fill the gaps, check and simplify the
computations, derive the necessary technical lemmas. The distasteful third stage – which, alas!, takes up 90% of one’s time – consists in writing out the proof on paper in an understandable form. It is not surprising that many mathematicians shortchange this last stage, as a result of which their work becomes a mysterious puzzle, and one often finds it easier to think up a proof oneself than to figure out the author’s text.”

Many mathematicians would take issue with the distaste Postnikov expressed about the last step. I personally find considerable satisfaction and pleasure in producing a readable exposition of a mathematical result; admittedly it is much easier with the advent of word processing to do this today, and Postnikov’s last two steps are generally more or less done simultaneously now. I also find that on average the quality of exposition in current mathematics publications is significantly better than in the past. But the separation of the development of the ideas and the formal exposition is something about which I think mathematicians would widely agree.

“Mathematics is regarded as a demonstrative science. Yet this is only one of its aspects. Finished mathematics presented in a finished form appears as purely demonstrative, consisting of proofs only. Yet mathematics in the making resembles any other human knowledge in the making. You have to guess a mathematical theorem before you prove it; you have to guess the idea of the proof before you carry through the details. You have to combine observations and follow analogies; you have to try and try again. The result of the mathematician’s creative work is demonstrative reasoning, a proof; but the proof is discovered by plausible reasoning, by guessing. If the learning of mathematics reflects to any degree the invention of mathematics, it must have a place for guessing, for plausible inference.”

G. Polya

“[I]ntuition comes to us much earlier and with much less outside influence than formal arguments which we cannot really understand unless we have reached a relatively high level of logical experience and sophistication. . . . In the first place, the beginner must be convinced that proofs deserve to be studied, that they have a purpose, that they are interesting.”

G. Polya

“If we say that a theorem has no meaning except as a conclusion from axioms, then do we say that Gauss did not know the fundamental theorem of algebra, Cauchy did not know Cauchy’s integral formula, and Cantor did not know Cantor’s theorem?”

Reuben Hersh

“The object of mathematical rigor is to sanction and legitimize the conquests of intuition, and there was never any other object for it.”

J. Hadamard

“I believe the search for an explanation, for understanding, is what we should really be aiming for. Proof is simply part of that process, and sometimes its consequence.”

M. Atiyah\textsuperscript{121}

“Proofs really aren’t there to convince you that something is true – they’re there to show you why it is true.”

Andrew Gleason\textsuperscript{122}

On the other hand, it is quite remarkable that most, if not all, true mathematical statements can be proved simply through formal deductions from accepted axioms, and elegant formal, or at least quasi-formal, proofs are generally very satisfying if not always very illuminating. I personally find this aspect of mathematics rather mysterious, but enormously appealing, and it gives formalism, especially the Hilbert version, much credibility as a partial explanation of the nature of mathematics.

“Mathematical understanding develops by a mysterious interplay between intuitive insight and symbolic manipulation.”

Robert Goldblatt\textsuperscript{123}

It has been said (\textsuperscript{124}) that a typical mathematician is a Platonist during the week and a formalist on Sunday. He or she works all week formulating the problems and understanding the answer, all the time convinced that the problems and results concern real if abstract objects, and then at the end tries to write down a proof which is at least an outline of a formal argument, often leaving out or obscuring most of the ideas and intuition leading to the statement or proof in the first place. (It is fortunate that most mathematicians willingly, even eagerly, reveal such details in conversations and lectures, and sometimes in written surveys; published manuscripts are only part of the important communication which goes on in the mathematical community.)

This somewhat schizophrenic interplay of two disparate views of the nature of mathematics not only aids the progress of mathematics, but is psychologically useful too, and also convenient, as the next quote observes:

“On foundations we believe in the reality of mathematics, but of course when philosophers attack us with their paradoxes we rush behind formalism and say: ‘Mathematics is just a combination of meaningless symbols.’ \ldots Finally we are left in peace to go back to our mathematics and do it as we have always done, with the feeling that each mathematician has that he is working with something real.”

Jean Dieudonné\textsuperscript{124}

We conclude with an extensive quote which nicely summarizes the process of doing and communicating mathematics, and the healthy role formalism can play in the process:

\textsuperscript{121} The Princeton Companion to Mathematics, p. 1003.
\textsuperscript{123}[Ga98, p. v]
\textsuperscript{124}J. Dieudonné, The work of Nicholas Bourbaki, American Mathematical Monthly, 77 (1970), 134-145.
“... Let us imagine that we wish to convince someone of the correctness of a certain statement. We may try to convince him by citing some authority in which he believes (sometimes called ‘proof by intimidation’), by getting him to ‘see’ (‘proof by intuition’), by appealing to his emotions (‘proof by waving the red flag’), by confusing and tricking him with words and faulty logic (‘elastic inference’), or by other methods familiar to everyone. These methods have two serious disadvantages: (a) They can be used to establish false statements just as easily as to establish true ones, and (b) They do not lead to universal agreement.

If we wish to convince a person of the correctness of a statement in such a way that our success does not depend on his weaknesses or our cleverness and so that our argument would be equally convincing to others, we must adopt a method of proof that meets with general agreement. Whatever this method is, it must certainly involve making statements, since it is hard to conceive of convincing anyone of anything without communicating with him. So we must carry on proof by means of statements. But suppose that the listener objects to some of our statements? Then we must convince him of them before we can continue. Now we can only do this by making other statements. Again if the listener does not agree with these, we should have to try to justify them – of course by making still other statements. Evidently, we cannot convince anyone of anything unless we can get him to agree to something! Apparently, we cannot prove all statements any more than we could define all terms. We must begin by assuming some statements without proof.

If we wish to prove any theorems we must begin by assuming some axioms. But what if our listener does not agree that our axioms are truly laws? Is there no way out if we cannot obtain agreement on any axioms we propose? There is a way out. Namely we may ask our listener to agree merely that if our axioms are indeed laws, then our theorems are also laws. If we take this tack we eliminate argument about the truth of both the axioms and the theorems. The only question we ask our listener to agree on is whether the theorems really do follow from the axioms! Now this is precisely the procedure we follow in mathematics. Any formal mathematical theory begins with certain axioms and derives from them certain theorems. The mathematician claims only that the theorems follow from the axioms, and he has no objection if someone prefers to adopt different axioms.

But suppose that our listener objects to the manner in which we derive the theorems from the axioms? Then we will have to come to some agreement with him as to what procedures are legitimate. And if we cannot agree with him on method of proof? Then we take the same way out as before. We say to him, ‘Let us merely agree that if these axioms are accepted and if these methods of proof are used, then these theorems can be obtained.’ In constructing a formal mathematical theory we state in advance the acceptable methods of deriving theorems from axioms. Then all we claim is that the theory is derived from the axioms according to these rules. If the axioms and the rules are acceptable to anyone, then the theorems should be also. If the axioms are applicable to any particular situation (i.e. are true in a particular case), then the theorems can be applied to that situation.

When we construct a theory on the basis of explicitly stated axioms and rules of proof, we have not really eliminated all possibility of controversy. There may, for one thing, be differences of opinion as to whether we have correctly applied the rules of proof. But this is just a question of whether we have made a mistake. Mistakes may be hard to find, but such differences of opinion can be solved by sufficiently careful examination of the theory. Unsolvable disagreement is still possible, however, on whether the axioms and rules of proof should have been adopted at all, whether the theory that results from them is a good theory, and so on. Such questions are not answered by
the theory itself, but they are placed outside the theory when we agree to argue on the basis of the axioms and the methods of proof. Hence we may expect universal agreement within the theory, but no universal agreement about it. ... Evidently, we cannot eliminate disagreement or controversy, but we can construct a theory in such a way that disagreement is possible only about certain parts of it – namely the axioms and the methods of proof. This is a great advantage because it leads to universal agreement over a considerable area, avoids arguing about matters that can be agreed upon, and identifies the really controversial issues."

Kenneth O. May

Proof Beyond a Reasonable Doubt

I.6.1.21. There is an important trend in the standard of rigor in mathematics which is emerging (or, more accurately, reemerging) largely as a result of the advent of powerful computers which can perform extensive and sophisticated mathematical computations. This point of view is articulated rather persuasively, and sometimes entertainingly, in [BB08], [BBG04], and [BD09]. I am, however, not yet personally convinced that this approach to rigor will, or should, be the future of mathematics. See also [Kra11] for an interesting discussion.

I have adopted the legal term “proof beyond a reasonable doubt” for this approach, although mathematicians undoubtedly have a different idea of what this phrase means than the courts. The idea is that it can sometimes be established with very high probability that a result is true, even in the absence of what would be considered a rigorous proof, and sufficiently high probability of truth should be enough for mathematicians to accept the result, although the search for a rigorous proof should not be abandoned.

Such “proof beyond a reasonable doubt” normally consists of a combination of an intuitive, heuristic, and/or nonrigorous argument for the plausibility of the result, along with extensive experimental or calculation evidence supporting the result (similar to standards for accepting a scientific theory).

I.6.1.22. Such arguments are not new, and were quite common before the increased rigor of the nineteenth century. To illustrate, we consider a well-known example due to Euler. The problem was to compute

\[
\sum_{n=1}^{\infty} \frac{1}{n^2}.
\]

This series was already “known” to converge (although the notion of convergence of an infinite series in the modern sense was not yet well understood) and that the numerical value of the sum was approximately 1.645; but the problem was to find what we would call a closed form expression for the exact sum.

Euler combined together some ingenious arguments and “known” facts to convince himself that

\[
\sum_{n=1}^{\infty} \frac{1}{n^2} = \frac{\pi^2}{6}
\]

(an outline of his argument is given below). He recognized that his argument was not a rigorous proof (even by the standards of the time), but simply gave a strong candidate for the exact value of the sum. He then calculated both the sum and \(\frac{\pi^2}{6}\) to a number of decimal places (about 20), and found that the numbers agreed.

\[\text{Fundamental Mathematics, preliminary edition, 1955, p. 75-78.}\]
at least to the limits of his calculation. He took this agreement as definitive verification that the formula
is correct (as indeed it is; cf. I.6.1.29.). Whether he regarded the argument plus numerical calculation as
a “proof” of the formula is somewhat unclear; he subsequently made efforts to make parts of his argument
more rigorous (see [Pó99a, p. 17-21] for a further discussion). Indeed, he did say:

“The kind of knowledge which is supported only by observations and is not yet proved must
be carefully distinguished from the truth; it is gained by induction, as we usually say. Yet we
have seen cases in which mere induction led to error. Therefore, we should take great care not to
accept as true such properties of the numbers which we have discovered by observation and which
are supported by induction alone. Indeed, we should use such a discovery as an opportunity to
investigate more exactly the properties discovered and to prove or disprove them; in both cases
we may learn something useful.”

L. Euler

It should be noted that although the modern definition of convergence of a sequence or series was not
detailed until the nineteenth century, it would be unfair and inaccurate to suggest that Euler did not
understand the difference between convergent and divergent series; in fact, he was acutely aware of the
distinction. He said he had grave doubts as to the use of divergent series, but that he had never been led
into error by using his definition of “sum”. Of course, few other mathematicians of the time, or any other
time, have had Euler’s awesome intuition and insight.

I.6.1.23. I am sure few if any modern mathematicians would regard what Euler did as a rigorous proof
of the formula. After all, there are known examples of potential formulas which are supported by heuristic
arguments and which are accurate to more decimal places than Euler calculated, but turn out not to be
exact (some examples can be found in [?]; see also III.9.4.3. and V.14.4.4.).

However, suppose Euler had had access to a supercomputer and found that the sum agreed with \( \sum_{n=1}^{\infty} \frac{1}{n^2} \)
only to a million, or a billion, decimal places. Would we take this as compelling evidence of the truth of the formula? I
imagine most mathematicians would not. But is the chance that the result fails in light of such evidence
really greater than the chance that a standard proof of some standard theorem in mathematics contains
a subtle flaw so far unnoticed by mathematicians? One cannot say for certain that even the best-known
“rigorous” mathematical proofs cannot have some inadequacy or error.

I.6.1.24. An interesting example concerns the classification of finite simple groups, which was one of
the crowning achievements of mathematics in the late twentieth century. Even the statement of the result
is far too complicated to give here, and the full proof (at least at present) consists of many research papers
totaling about 15,000 printed pages. See [GLS94] for a survey of the project and result.

Group theorists take a curious combination of positions on this statement. They generally claim that the
result is proved, i.e. a theorem, while at the same time acknowledging that it is virtually certain that some
parts of the 15,000-page proof contain errors or at least gaps. *****UPDATE*****

The Role of Computers

“The computer is a precision tool. It should not be used as a bludgeon or a substitute for thought.”

Forman S. Acton

I.6.1.25. It is unquestionably true that computers have had a significant and growing influence on the practice of mathematics. It is a matter of some disagreement whether this influence has been entirely beneficial.

There is universal agreement that computers can be very useful in many parts of mathematics, especially applied mathematics. They have long been crucial for numerical calculations needed to turn theoretical results into practical solutions to many problems. They are also valuable in “experiments” testing the plausibility of conjectures, and in helping mathematicians analyze behavior of complex mathematical systems and develop new conjectures. They can even find and identify reasonable conjectures (and not just numerical ones) which would be difficult or impossible for a human mathematician to come up with, and, perhaps even more importantly, refute some apparently reasonable conjectures.

More controversial is the use of computers to actually carry out parts of arguments constituting actual proofs (or at least purported proofs) of mathematical results. The most famous case of this is the proof of the Four-Color Theorem; see () for extensive discussions of this example. This theorem is significant at least in part because it shows that there are theorems in mathematics whose statement is simple enough to be understood by almost anyone, but whose proof is necessarily so long and complicated as to be beyond the ability of any human mathematician to completely understand it or even completely verify its correctness.

Computers and computation have also had an influence on the mindset of mathematics (or at least of mathematicians). An algorithmic approach to much of mathematics has come more into vogue. There have even been predictions that the “age of infinity” in mathematics is drawing to a close! Such an assertion is preposterous, in my opinion: while the algorithmic and computational parts of mathematics will undoubtedly grow greatly in importance and sophistication, the mathematics of infinity, including most of analysis, is and will remain far too important and central to fade away. What will instead happen is that the interplay between these two complementary parts of mathematics will become ever greater and more essential.

Fraud in Mathematics

The nature of mathematics, at least in its present state, has one nice consequence: almost uniquely among academic subjects, there is almost no possibility of fraud in mathematics. (This may change with the spread of large-scale computation as an integral part of mathematics.) Just about the only type of fraud conceivable in mathematics today is plagiarism, and even this is very hard to get away with since the world of mathematics is generally so small and interconnected that experts in a subdiscipline usually have a pretty good idea of what all the other experts are doing. And nowadays most new mathematical results are quickly written up and posted on the arXiv in preprint form, unlike in sciences where confidentiality of a paper is often jealously guarded until actual publication; as a result priority for new results in mathematics can rarely be disputed. (Correctness and completeness of purported proofs of new results may be another matter!)
Euler’s Argument

We now outline Euler’s argument for the above formula.

I.6.1.26. He began with the already “known” formula

\[ \sin x = \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n+1}}{(2n+1)!} \]

which is just the Maclaurin (Taylor) series, and is valid for all \( x \in \mathbb{R} \) (the validity of this formula had not yet been proved to modern standards). Thus if we set

\[ f(x) = \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n}}{(2n+1)!} \]

we have that

\[ f(x) = \frac{\sin x}{x} \text{ for } x \neq 0. \]

I.6.1.27. Next, he observed that if \( p(x) \) is a polynomial of degree \( m \) with roots \( a_1, \ldots, a_m \), all nonzero (but not necessarily distinct), then

\[ p(x) = p(0) \prod_{n=1}^{m} \left( 1 - \frac{x}{a_n} \right) . \]

Thus, since the roots of \( f(x) \) are \( \{ \pm \pi, \pm 2\pi, \pm 3\pi, \ldots \} \), he concluded by analogy that

\[ \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n}}{(2n+1)!} = f(x) = f(0) \prod_{n=1}^{\infty} \left[ \left( 1 + \frac{x}{n\pi} \right) \left( 1 - \frac{x}{n\pi} \right) \right] = \prod_{n=1}^{\infty} \left( 1 - \frac{x^2}{n^2\pi^2} \right) \]

since \( f(0) = 1 \). (This formula turns out to be correct, but the proof of correctness needs a good bit more work than Euler did.)

I.6.1.28. Finally, he multiplied out the right side as though it was a finite product, and compared the coefficients of powers of \( x \) on both sides of the equation. In particular, the coefficient of \( x^2 \) on the right side is \( -\sum_{n=1}^{\infty} \frac{1}{n^2\pi^2} \), and on the left it is \( -\frac{1}{6} \), giving the desired formula. (Comparison of coefficients of other powers of \( x \) gave additional formulas for other infinite series.)

A Proof of Euler’s Formula

I.6.1.29. For completeness, we give a slick proof of the formula, from [LeV56] (where originality is not claimed). This proof and a couple of others, including one closer in spirit to Euler’s argument, can be found in [AZ10]. The argument uses some theorems from integration theory; the special cases used can easily be established directly.

Set

\[ f(x, y) = \frac{1}{1 - xy} . \]
Let $R$ be the unit square $[0, 1]^2$ in $\mathbb{R}^2$. We will calculate

$$I = \iint_R f \, dA$$

two ways. Note that this is an improper Riemann integral since $f$ has a singularity at $(1, 1)$; but the integrand is nonnegative on $R$, so the meaning of the integral is unambiguous.

The infinite series (geometric series)

$$\sum_{k=0}^{\infty} (xy)^k$$

with nonnegative terms converges pointwise to $f$ on $R \setminus \{(1, 1)\}$; thus by the Monotone Convergence Theorem () we have

$$I = \sum_{k=0}^{\infty} \left[ \iint_R (xy)^k \, dA \right].$$

By the continuous version of Fubini’s Theorem (XIV.3.4.7.), these integrals can be calculated as iterated integrals:

$$\iint_R (xy)^k \, dA = \int_0^1 \int_0^1 x^k y^k \, dy \, dx = \left[ \int_0^1 x^k \, dx \right] \left[ \int_0^1 y^k \, dy \right] = \frac{1}{(k+1)^2}$$

and thus

$$I = \sum_{k=0}^{\infty} \frac{1}{(k+1)^2} = \sum_{n=1}^{\infty} \frac{1}{n^2}.$$

On the other hand, $I$ can be calculated by a change of variable

$$x = u - v, \quad y = u + v$$

i.e. by the Change of Variables Theorem () with $\phi(u,v) = (u-v, u+v)$ we have

$$I = \iint_R f \, dA = \iint_D (f \circ \phi) |J_{\phi}| \, dA$$

where $D = \phi^{-1}(R)$ is the diamond with vertices $(0, 0)$, $(\frac{1}{2}, \frac{1}{2})$, $(\frac{1}{2}, -\frac{1}{2})$, $(1, 0)$. We have that

$$J_{\phi}(u,v) = det \begin{bmatrix} 1 & -1 \\ 1 & 1 \end{bmatrix} = 2$$

for all $(u,v)$ (the change of variables is linear, making things easy), so we have

$$I = 2 \iint_D (f \circ \phi) \, dA.$$

We have that

$$(f \circ \phi)(u,v) = \frac{1}{1 - u^2 + v^2}$$

and by Tonelli’s Theorem () the double integral over $D$ can be computed by an iterated integral:

$$I = 2 \left[ \int_0^{1/2} \left( \int_u^1 \frac{1}{1 - u^2 + v^2} \, dv \right) \, du + \int_1^{1/2} \left( \int_{1-u}^1 \frac{1}{1 - u^2 + v^2} \, dv \right) \, du \right].$$
(Note that the singularity of \( f \) at \((1, 1)\) “disappears” under this transformation.) We have

\[
\int \frac{1}{1 - u^2 + v^2} \, dv = \frac{1}{\sqrt{1 - u^2}} \arctan \left( \frac{v}{\sqrt{1 - u^2}} \right) + C
\]

for \( 0 \leq u < 1 \), so we have

\[
I = 4 \int_0^{1/2} \frac{1}{\sqrt{1 - u^2}} \arctan \left( \frac{u}{\sqrt{1 - u^2}} \right) \, du + 4 \int_{1/2}^{1} \frac{1}{\sqrt{1 - u^2}} \arctan \left( \frac{1 - u}{\sqrt{1 - u^2}} \right) \, du .
\]

The first integral can be evaluated by the substitution

\[
s = \arctan \left( \frac{u}{\sqrt{1 - u^2}} \right), \quad ds = \frac{1}{\sqrt{1 - u^2}} \, du
\]

to obtain

\[
\int_0^{1/2} \frac{1}{\sqrt{1 - u^2}} \arctan \left( \frac{u}{\sqrt{1 - u^2}} \right) \, du = \int_0^{\arctan(1/\sqrt{3})} s \, ds = \int_0^{\pi/6} s \, ds = \frac{1}{2} \left( \frac{\pi}{6} \right)^2 .
\]

Similarly, the second integral can be calculated by the substitution

\[
t = \arctan \left( \frac{1 - u}{\sqrt{1 - u^2}} \right) = \arctan \left( \frac{\sqrt{1 - u^2}}{1 + u} \right), \quad dt = -\frac{1}{2 \sqrt{1 - u^2}} \, du
\]

to obtain

\[
\int_{1/2}^{1} \frac{1}{\sqrt{1 - u^2}} \arctan \left( \frac{1 - u}{\sqrt{1 - u^2}} \right) \, du = 2 \int_0^{\pi/6} t \, dt = \left( \frac{\pi}{6} \right)^2 .
\]

Thus we have

\[
I = 4 \cdot \frac{1}{2} \left( \frac{\pi}{6} \right)^2 + 4 \left( \frac{\pi}{6} \right)^2 = 6 \left( \frac{\pi}{6} \right)^2 = \frac{\pi^2}{6} .
\]

Mathematicians on Philosophy

I.6.1.30. Mathematicians tend to look down on philosophy, sometimes excessively, as a subject unworthy of their time and intellect. The only aspect of philosophy which is of any widespread interest among mathematicians is the foundations of mathematics, and even this interest is pretty limited. Here are some of the opinions expressed about philosophy; I emphasize that I do not personally endorse them, but just present them in the interest of full disclosure:

“[P]hilosophy proper is a subject, on the one hand so hopelessly obscure, on the other so astonishingly elementary, that there knowledge hardly counts.”

G. H. Hardy\textsuperscript{129}

\textsuperscript{129}Mathematical Proof, in [7, p. 173].
“Philosophers may be unable to understand how we can know mathematical truths, but they have a bad track record at being able to understand anything.”

J. R. Lucas\textsuperscript{130}

“... People who study philosophy too long, and don’t treat it simply as part of their early education and then drop it, become, most of them, very odd birds, not to say thoroughly vicious; while even the best of them are reduced by this study ... to complete uselessness as members of society.”

Plato\textsuperscript{131}

**Should Mathematicians Care About Foundations?**

“Mathematics changes slowly. After ten years, some problems have been solved and some new problems have arisen, but the subject is recognisably the same. However, over a century it changes in ways which mathematicians at the beginning of that century could not conceive. ... Given this, it seems presumptuous to seek a permanent foundation for mathematics. It is a happy accident that almost all of mathematics, as we now know it, can be deduced from one set of axioms; but, just as history has taught us that there is not one geometry but many, so it is not unlikely that the future will present us with different mathematics deduced from radically different axiom schemes. The art of the mathematician will still consist in the rigorous proof of unexpected conclusions from simple premises, but those premises will change in ways that we cannot possibly imagine.”

T. W. Körner\textsuperscript{132}

I.6.1.31. The question of which, if any, of the philosophies of the foundations of mathematics is correct has rather little to do with the day-to-day work of most mathematicians. Mathematicians generally just take for granted that mathematics has some sort of logical, consistent foundation, whether it is understood yet or not. I think it is fair to say that the only foundational issue that does, or probably even should, concern every mathematician is the consistency of mathematics.

“God exists since mathematics is consistent, and the Devil exists since we cannot prove it.”

André Weil\textsuperscript{133}

Even if it were shown that, say, ZF set theory is inconsistent, most mathematicians would be at least moderately interested, but not particularly upset; this would just mean that ZF set theory was not the right theory to base mathematics on after all. They would then simply go on doing their mathematics as usual.

The only thing that would really upset mathematicians is if mathematics itself (e.g. real analysis as axiomatized in (), or geometry, algebra, etc.) were discovered to be inconsistent. Mathematicians mostly

\textsuperscript{130}Luc00, p. 19.

\textsuperscript{131}The Republic, VII.3; cf. ?.

\textsuperscript{132}Kör04, p. 356.

\textsuperscript{133}In H. Eves, Mathematical Circles Adieu, Boston: Prindle, Weber and Schmidt, 1977.
just take on faith that this is an impossibility; indeed, belief in some form of realism would preclude this possibility. After all, the very existence of mathematics as a subject is entirely based on the belief that if one starts with correct statements and applies valid, careful reasoning, correct conclusions will always be obtained. It seems inconceivable to us that an inconsistency could show up in mathematics, especially since the massive edifice already created has produced no hint of inconsistency. At the very core of every mathematician is a certain conviction of the consistency of mathematics, reinforced by all the mathematics they see and do throughout their careers.

“If mathematical thinking is defective, where are we to find truth and certitude?”

D. Hilbert

I.6.2. Mathematical Theories

I.6.3. Languages

Any theory must be expressed in some sort of language. Actually, it is generally accepted that there must be at the outset some sort of metalanguage which is simply understood, and in which certain phrases and terms have meaning. The metalanguage is not part of the theory, or really part of mathematics at all; it is just a vehicle for communication and specification of the theory. In [Kle02], KLEENE calls this the observer’s language (with the term “metalanguage” reserved for an observer’s language with certain technical restrictions), which seems apt terminology.

In addition, a mathematical theory must have a specified language in which it is expressed, called the object language in [Kle02]. At a minimum, the language of a theory must define some collection of “statements” which are considered “meaningful” for the theory (although no actual meaning in the usual sense of the term need be attached to them), and there needs to be a way to combine together statements or transform them into new statements according to specific rules.

There does not seem to be any necessity that the language consist of finite one-dimensional strings of discrete symbols (human spoken language is an obvious exception), but languages in mathematics, called formal languages, are normally taken to be of this sort: an alphabet of symbols is specified, and certain finite strings of these symbols are the “statements.” This restriction is necessary (at least at present) to make formulation and analysis of mathematical theories manageable. It can be argued that formal languages can satisfactorily encode anything which could be called a “language”, although it must be noted that even ordinary written language is at best an imperfect representation of human spoken language; in spoken language there is a lot of subtle information conveyed in timing, stress and intonation, facial expressions, gestures, and body language which is not captured in the written language (even transmission of spoken language over a telephone or radio causes significant losses of information).

In a good formal language we need to have the ability to make definitions. In effect, a definition is simply the establishment of an “abbreviation” for a (generally more complicated) phrase. In principle, the defined term can always be replaced by the phrase it abbreviates without loss of utility, and thus from a strictly logical point of view definitions are unnecessary. However, in practice it is very useful, often essential, to be able to make definitions: otherwise, statements involving even moderately complex mathematical ideas would become unmanageably or even incomprehensibly complicated.

134 On the Infinite, cf. [?].
I.6.4. Logic

“Logic is the systematic study of the conditions of valid inference.”

\textit{Abraham Wolf}\textsuperscript{135}

“Logic is the systematic study of the structure of propositions and of the general conditions of valid inference by a method which abstracts from the content or \textit{matter} of the propositions and deals only with their logical \textit{form}.”

\textit{Alonzo Church}\textsuperscript{136}

Logic is a discipline which is not merely descriptive, but normative as well, being concerned more with how we \textit{ought} to reason than with how we habitually do so. … We shall seek to construct an ideal theory of correct reasoning, based on a small number of general principles which we postulate as ‘laws of thought.’ ”

\textit{G. T. Kneebone}\textsuperscript{137}

“Few persons care to study logic, because everyone conceives himself to be proficient enough in the art of reasoning already.”

\textit{C. S. Peirce}\textsuperscript{138}

As with languages, a distinction must be made between what may be called \textit{metalogic} (this term is not commonly used in the literature), which is an underlying feature, and \textit{logic}, which is a part of the mathematics. Unlike with language, this distinction is often not carefully made and has led to much confusion and disagreement over the last century, with arguments about whether logic was part of mathematics or vice versa (or neither). The subject of \textit{mathematical logic} has since become established.

Metalogic can be thought of as the rules of inference which are assumed to underly not only mathematics but all rational discourse. An example of a principle of metalogic is transitivity of implication:

\begin{quote}
If $P$ implies $Q$ and $Q$ implies $R$, then $P$ implies $R$.
\end{quote}

(Here $P$, $Q$, and $R$ are statements.) Another example, called \textit{modus ponens}, is

\begin{quote}
If $P$ is true and $P$ implies $Q$, then $Q$ is true.
\end{quote}

To rephrase \textit{modus ponens} without using the loaded term “true”, we could say instead:

\begin{quote}
If we assume or conclude $P$ and we assume or conclude ($P$ implies $Q$), then we conclude $Q$.
\end{quote}

I.6.5. Mathematical Structures and Models

\textsuperscript{135}Encyclopaedia Britannica, fourteenth edition, 1929; cf. [?], p. 5.
\textsuperscript{137}[?], p. 8.
\textsuperscript{138}Collected Papers; cf. [?].
I.7. Printed or Online?

When this book project began, I envisioned the result as a traditional printed volume. But I fairly quickly became convinced that it should be an online book instead. An online book has at least four enormous advantages over a printed one:

(1) An online book is much more widely, easily, and freely available to potential readers. Production, reproduction, and distribution costs are almost nonexistent. The path from author to reader is direct without having to pass through a publisher.

(2) Unlike with a printed book, there is no practical limit to the length of an online book. Redundancy (within reason) does not have to be avoided.

(3) An online book does not have to be organized linearly.

(4) Revisions, corrections, and additions can be made immediately and painlessly.

Advantage (1) is obvious and needs no further comment. As to (2), an author of a printed book usually has to make difficult and delicate decisions about what to include and what to omit, and how much detail should be included. A printed book with too much material or detail not only becomes physically unwieldy and expensive to produce, but also creates psychological problems for the reader: it can be difficult for a reader to plow through a mass of detail to extract the essentials he/she needs, and an abundance of ancillary material can be intimidating to a reader not yet familiar with the subject and can make the theory appear to be more complex and difficult than necessary.

An online book, if properly organized, avoids most (but not all) of these problems. Extra details, technicalities, and side threads can be included in such a way that they are invisible to readers not specifically interested in looking at them. The book can consist of a large number of separate sections connected only by links organized by a complicated directed graph. Each section can have a set of links to the prerequisite sections and another set of links to potential successors. (However, one serious danger in a non-linear organization of a mathematics book is the possibility of circularity in definitions and arguments; great care must be exercised to avoid circularity.)

A reader of a book organized in this way will probably need some guidance through the material, a “road map.” Actually, several road maps will be required for readers of various backgrounds and interests, and I plan to provide some. If this book is used as a text or supplementary text for a course, the instructor will have to settle on a road map appropriate for the course, or provide his/her own. Every instructor has a slightly different idea about how the material of the subject should be organized and presented. This book by and large represents my idea, but I am trying to make the organization flexible enough that an instructor who wants a different flow through the material can develop a satisfactory road map for the desired journey.

One advantage related to (4) is that the book can be placed online before it is “finished,” so long as it is far enough along to be useful. (The currently posted version is already probably about the 1000th edition; it is likely that most of these editions have not been read by anyone but me!) In fact, my expectation is that I will never regard the book as finished. I have a dream that this book will eventually turn into an all-encompassing treatment of real analysis. Of course, I am far from having the personal expertise, or enough time and energy left in my lifetime, to accomplish this goal by myself. I hope eventually that others will contribute to the project by adding treatments of additional material and/or alternative treatments of material already covered. I hope also that experts interested in other parts of mathematics, especially parts of mathematics that are mature enough that a reasonably definitive exposition can be given, will undertake
similar projects in their specialties, and that eventually a massive and interconnected body of knowledge and understanding of a large part of mathematics will exist. Previous attempts have been made along this line, notably by Bourbaki, but I do not regard my efforts or goals to be at all comparable or duplicative of such work. The current and rapidly expanding treatment of mathematics in Wikipedia and other websites is laudable and very useful, but also not comparable in goals. (Wikipedia articles on some other subjects, especially ones with political or nationalistic overtones, are notoriously unreliable; however, I have found most Wikipedia articles on mathematics to be quite good, although they should not be taken as gospel. Articles on mathematicians and/or the history of mathematics are not always as good.)

It must be said that even in an online book of potentially infinite length, the necessity of making decisions about what to include and what to omit is not completely avoided unless one plans to cover all of mathematics. The decision is particularly critical in regard to material which is ancilliary to the main topic of the book, such as the intricacies of set theory or topology in my case. I have necessarily employed subjective standards based on my personal interests and limitations, and I have included more detail than necessary on some topics I like, and (at least so far) much too little detail on other topics. At least I can rationalize some of these decisions by saying I have not yet finished a complete treatment of the subject. Or I suppose I could just invoke the words of Descartes [?]:

“I hope that posterity will judge me kindly, not only as to the things of which I have explained, but also as to those which I have intentionally omitted so as to leave to others the pleasure of discovery.”

I expect that many, if not most, sections of this book will eventually have “short” (“appetizer”) and “long” (“main course”) versions. The short version will generally be more of a survey of the high points of the specific topic, with most proofs and technical details suppressed, and sometimes with definitions and/or statements of results stated somewhat informally. (Current versions of many sections probably fall somewhere between the ultimate short and long versions.) I will insist, though, that even the short treatments be mathematically “honest.”

There are two common kinds of mathematical “dishonesty” frequently encountered in lower-level (and sometimes higher-level) texts:

(1) Suggesting that a certain mathematical statement is true more generally than it actually is.

(2) Suggesting that a certain mathematical statement is “obvious” and does not require proof, when in fact it does.

A variation of (2), related to (1), is

(2') Suggesting that an informal definition of something (e.g. tangent line, area) is mathematically adequate.

A third kind of mathematical dishonesty, somewhat less common but still frequently seen, and arguably more serious than (1) and (2), is

(3) Giving a purported “proof” of something which is not complete or not rigorous, while suggesting it is.

“Few will deny that even in the first scientific instruction in mathematics the most rigorous method is to be given preference over all the others. Especially will every teacher prefer a consistent proof to one which is based on fallacies or proceeds in a vicious circle, indeed it will be morally impossible for the teacher to present a proof of the latter kind consciously and thus
in a sense deceive his pupils. Notwithstanding these objectionable so-called proofs, so far as the foundation and the development of the system is concerned, predominate in our textbooks to the present time. Perhaps it will be answered, that rigorous proof is found too difficult for the pupil’s power of comprehension. Should this be anywhere the case, – which would only indicate some defect in the plan or treatment of the whole, – the only remedy would be to merely state the theorem in a historic way, and forego a proof with the frank confession that no proof has been found which could be comprehended by the pupil; a remedy which is ever doubtful and should only be applied in the case of extreme necessity. But this remedy is to be preferred to a proof which is no proof, and is therefore wholly unintelligible to the pupil, or deceives him with an appearance of knowledge which opens the door to all superficiality and lack of scientific method."

H. Grassmann, 1904

In my opinion, as a general rule a written argument should not be called a “proof” unless it is complete and rigorous (although I must admit that I myself have not always adhered to this principle!)

I certainly do not mean to suggest that it is necessary, or even desirable, that all the technicalities, ramifications, or potential pathologies connected with a particular topic being discussed in an elementary text be treated or even mentioned. However, I believe that mathematical honesty is possible even in, say, a Business Calculus text, although maintaining mathematical honesty while at the same time keeping the discussion at a reasonable and appropriate level of detail and sophistication is a fine art and not easily accomplished.

I.7.1. How Much Generality?

Another constantly encountered problem in preparing an exposition of real analysis (or of many other parts of mathematics) is the question of whether to do things in the utmost generality, or stick to an important special case. There is no simple answer to this dilemma, and I found it impossible (as well as undesirable) to be entirely consistent.

There are several considerations, which are often in tension:

1. It is desirable to have results recorded in the greatest generality that can be reasonably stated, for future reference, even if the immediate applications one has in mind require only a special case.
2. It is often easier to understand and appreciate a proof if the statement of the result contains the exact hypotheses needed to make the proof work.

On the other hand:

3. The proof of the most general case of a result can often be considerably harder or more delicate than that of a crucial special case.
4. Even the statement of the most general result can be much harder to write or digest than a clean statement of a special case.
5. It may seem farfetched in some cases that increased generality would ever be useful, especially if it requires more work to state or prove than the result of obvious importance.

I have had to make many decisions of this type in the manuscript, and have each time had to settle on the best tradeoff between generality, difficulty, and usefulness. My decisions may not have always been the wisest, and will be subject to review and possible revision in the future.

139 cf. [Mor93, #538].
I.7.2. History vs. Logic

“Once a good building is completed its scaffolding should no longer be seen.”

*C. F. Gauss*140

“Whoever wants to get to know a science shouldn’t just grab the ripe fruit – he must also pay attention to how and where it grew.”

*J. C. Poggendorf*141

There are two competing schools of thought as to how mathematics, especially “finished” mathematics such as Real Analysis, should be presented:

(1) The ideas and results should be presented in the most efficient, elegant, and logical order, without regard to their origins or history.

(2) The historical development and context of all results and ideas should be carefully traced and presented.

The ultimate exponent of approach (1) is *Bourbaki*. There are numerous books on Analysis taking the second approach. Most textbooks basically take the first approach, with some lip service to the second.

New mathematics is usually not very elegant at first. The first proof of a result is rarely the most efficient one or done in the optimum generality, and historically it has often happened that the first “proof” of an important result is not even complete or correct. In fact, BESICOVITCH once said that a mathematician should be judged by how many bad proofs he has produced (he meant to imply a positive correlation). It usually takes time and effort, often quite a bit of it, before the “proper” approach or point of view for a part of mathematics is developed.

“The ways of discovery must necessarily be very different from the shortest way, indirect and circuitous, with many windings and retreats. It’s only at a later stage of knowledge, when a new domain has been sufficiently explored, that it becomes possible to reconstruct the whole theory on a logical basis, and show how it might have been discovered by an omniscient being, that is, if there had been no need for discovering it!”

*George Sarton*142

I have tried to steer somewhat of a middle ground between the two approaches, although the result is of necessity much closer to the first than the second since I am a mathematician, not a historian. But I have made considerable efforts to accurately put many things in historical context, not only because it is beneficial in understanding where the mathematics came from, but also because much of the history is fascinating. I have particularly tried to correctly trace the history of some things which I discovered have been commonly misportrayed in modern references. I am certainly not the first to try to do this: for example, in [Kle04, p. 234], *KLEIN* points out that what is (even today!) commonly called the “Maclaurin series” had been previously obtained by TAYLOR, explicitly stated as a special case of the Taylor series, and was acknowledged as such by MACLAURIN himself. *KLEIN* states:

---

140cf. [Rem98, p. viii].

141cf. [Rem98, p. vii].

“Errors of this sort are common. . . . It is difficult, if not impossible, to overcome such deeprooted absurdities. At best, one can only spread the truth in the small circle of those who have historical interests.”

I hope this is unduly pessimistic!

Despite my efforts along these lines, I am sure my amateur historical research is highly inadequate in many cases and probably inaccurate in some respects. I will endeavor to gradually improve it as I learn more.
Chapter II

The Formalities of Mathematics

In this chapter, we have collected together discussions of the basic language and tools of mathematics (not just analysis). These vary widely in sophistication, ranging from elementary (from the point of view of modern mathematics), e.g. formal statements, basic set theory, functions, and relations, to very advanced, e.g. the intricacies of the Axiom of Choice, ordinals, and large cardinals. The sections in this chapter can be regarded primarily as reference material for our treatment of analysis.
II.1. Formal Statements, Negations, and Mathematical Arguments

“Mathematics is often considered a difficult and mysterious science, because of the numerous symbols which it employs. Of course, nothing is more incomprehensible than a symbolism which we do not understand. Also a symbolism, which we only partially understand and are unaccustomed to use, is difficult to follow. In exactly the same way the technical terms of any profession or trade are incomprehensible to those who have never been trained to use them. But this is not because they are difficult in themselves. On the contrary they have invariably been introduced to make things easy. So in mathematics, granted that we are giving any serious attention to mathematical ideas, the symbolism is invariably an immense simplification.”

A. N. Whitehead

“The domain over which the language of analysis extends its sway, is, indeed, relatively limited, but within this domain it so infinitely excels ordinary language that its attempt to follow the former must be given up after a few steps. The mathematician, who knows how to think in this marvelously condensed language, is as different from the mechanical computer as heaven from earth.”

A. Pringsheim

“The prominent reason a mathematician can be judged by none but mathematicians, is that he uses a peculiar language. The language of mathesis is special and untranslatable. In its simplest form it can be translated, as, for instance, we say a right angle to mean a square corner. But you go a little higher in the science of mathematics, and it is impossible to dispense with a peculiar language. It would defy all the power of Mercury himself to explain to a person ignorant of the science what is meant by the single phrase ‘functional exponent.’ . . . But to one who has learned this language, it is the most precise and clear of all modes of expression. It discloses the thought exactly as conceived by the writer, with more or less beauty of form, but never with obscurity.”

Thomas Hill

Mathematical statements are typically given in a hybrid of symbolic language and standard English. For example:

“For every real number \( x \) there is a unique integer \( n \) such that \( n \leq x < n+1 \).”

(Of course, comparable statements can be made equally well using other languages than English.) It is fairly easy to understand what a statement like this means, but many mathematical statements, particularly in analysis, are considerably more complicated, such as:

“For every real number \( a \) and every \( \epsilon > 0 \) there is a \( \delta > 0 \) such that, for every real number \( x \) with \( |x - a| < \delta \), \( |f(x) - f(a)| < \epsilon \).”

---

1. Introduction to Mathematics, 1911, p. 59-60; cf. [Mor93, 1218].
(Some statements are much more complicated than this!) We need to have a systematic way to analyze the meaning of a statement like this. In particular, it is often important to be able to write (and understand) the negation of such a statement. A very useful tool for these problems is to rewrite mathematical statements in a language-independent formal way. This section describes how to do this.

The presentation in this section is intended for students preparing to be working mathematicians, and we will not strictly adhere to the (sometimes rather arcane) conventions of the subject of mathematical logic. Thus our notation and terminology will not necessarily agree with that found in texts on logic.

II.1.1. Formal Statements

II.1.1.1. A formal statement equivalent to the second one above is

\[(\forall a \in \mathbb{R})(\forall \epsilon > 0)(\exists \delta > 0)(\forall x \in \mathbb{R})[|x - a| < \delta \Rightarrow (|f(x) - f(a)| < \epsilon)].\]

We will explain what this formal statement means and how to get it.

II.1.1.2. A formal statement (or proposition) will be a string of symbols; however, not every string of symbols will be regarded as a formal statement. The allowable symbols will be of three types: constants, variables, and logical symbols. A formal statement will then be, roughly speaking, a string of allowable symbols which is in a form to which a truth value (true or false) can potentially be attached, perhaps depending on the values assigned to the variables in the statement. We will in due course be more precise.

Constants

II.1.1.3. Constants are symbols standing for previously defined specific objects. The objects may be elements, sets, ordered pairs, functions, relations, binary operations, or any other type of object specifically defined in the theory being discussed (all the types of objects listed are officially sets, so one could just say that the objects are all sets to be precise). Additional constants can be defined in the course of the discussion. Note that some standard objects in mathematics have names consisting of compound symbols, such as \(\sin\), \(\frac{d}{dx}\), or \(\int \cdot \, dx\), which are regarded as single constants. Note also that a function which is a constant in this sense (i.e. simply a specified function) is generally not a “constant function” in the function sense of taking the same value at any input.

Variables

II.1.1.4. Variables are similar to constants, but are symbols which have not been previously defined to represent specific objects, and thus can potentially represent many different objects. The type of object that a particular variable represents can be specified, and can be any of the types of objects that can be constants.

The distinction between variables and constants can be a subtle one. For example, in the statement in II.1.1.1., the \(f\) might be either a constant or a variable depending whether it had previously been defined to be a specific function. Even more subtle is the specification of variable names which are treated essentially like constants although they remain variables; this is discussed in II.1.7.7.

Logical Symbols

II.1.1.5. There are only a few logical symbols we will use. These fall into the categories of relations, set operations, connectives, and quantifiers, and one additional symbol for negation.
Relations:

\[ = \text{ (“equals”) } \]
\[ \in \text{ (“is a member of” or “belongs to”) } \]
\[ \subseteq \text{ (“is a subset of”) } \]

Set Operations:

\[ \cup \text{ (“union”) } \]
\[ \cap \text{ (“intersection”) } \]
\[ \setminus \text{ (“relative complement”) } \]

Connectives:

\[ \land \text{ (“and”) } \]
\[ \lor \text{ (“or”) } \]
\[ \implies \text{ (“implies”) } \]

Quantifiers:

\[ \exists \text{ (“there exists”) } \]
\[ \forall \text{ (“for all”) } \]

Negation:

\[ \neg \text{ (“not”) } \]

The symbols \( \land, \implies, \) and \( \neg \) are sometimes written \&, \( \rightarrow \), and \( \sim \) respectively. The set operation \( \setminus \) is also sometimes written \( \sim \) or \( - \).

II.1.1.6. The set-theoretic operations are not strictly speaking logical symbols, but constant operations (functions) defined in set theory. However, they are so universal that we can regard them as logical symbols. Other set-theoretic operations such as symmetric difference can also be defined and given symbols. The relations \( \in \) and \( \subseteq \) are also technically constant relations defined in set theory.

II.1.1.7. The symbols we have given here are somewhat redundant; not all are needed, since some can be defined in terms of others, as described below. But it is useful to have all of them since equivalent statements written without them can be considerably more complicated. A few other useful logical symbols such as \( \iff \) and \( ! \) will be defined later in terms of the standard ones.
Parentheses

II.1.1.8. Parentheses are technically not symbols of the formal language, and are used merely to make the formal statements more comprehensible. They can be avoided entirely if certain conventions of interpretation are strictly adhered to. But they are very desirable to have in practice, and we will make use of them freely. For clarity, nested parentheses can be written as (), [], or rarely even {}, which all have the same meaning (or lack thereof).

Terms

II.1.1.9. Definition. A simple term of a certain type is a constant or variable of the specified type. A compound term of level 2 of a certain type is a function whose value is of the specified type, whose arguments are simple terms of the appropriate types. A compound term of level $n \geq 2$ of a certain type is a function whose value is of the specified type, whose arguments are simple terms or compound terms of level $< n$ of the appropriate type.

A simple term or a compound term of any (finite) level is called a term.

The level of a compound term is of little if any significance; even the distinction between simple and compound terms is unimportant. The important thing is that terms are objects of a specified type built up from constants and variables through a finite number of steps.

II.1.1.10. Examples. Examples of simple terms of type “real number” are $0$, $\sqrt{2}$, $\pi$, $x$ where $x$ is a variable of type “real number.” If $f$ is a variable which is of type “real-valued function of three real arguments”, and we recall that $+$ is a constant of type “function from pairs of real numbers to real numbers”, then such expressions as $f(x, y, 5)$ and $x + z$ (where $x, y, z$ are variables of type “real number”) are compound terms of level 2 of type “real number”, and $f(x + y, x + 2, f(x, x, y))$ is a compound term of level 3 of type “real number.”

Atomic Statements

II.1.1.11. Definition. An atomic statement, or simple statement, is an expression of the form $R(x_1, \ldots, x_n)$, where $R$ is an $n$-ary constant or logical relation ($n \geq 2$) and $x_1, \ldots, x_n$ are terms (simple or compound) of the appropriate types.

The words sentence and proposition are often used interchangeably with statement.

II.1.1.12. Examples. Expressions of the form $x = y$, $(x + 5) \in A$, $f(x, y, \sin(z)) > 0$, etc., are atomic statements, where $x, y, z$ are variables of type “real number” and $A$ is a constant or variable of type “set of real numbers.”

General Formal Statements

II.1.1.13. Definition. A formal statement is an expression built up from atomic statements by a finite number of connectives, quantifications, and negations. Specifically:

Every atomic statement is a formal statement.

If $P$ and $Q$ are formal statements, then the following are also formal statements:
\( P \land Q \).
\( P \lor Q \).
\( P \Rightarrow Q \).
\( \neg P \).

\((\forall x)(P)\), where \( x \) is a variable not already quantified in \( P \).

\((\exists x)(P)\), where \( x \) is a variable not already quantified in \( P \).

(Quantification is discussed in detail in the next subsection.)

The level of a formal statement can be defined as in II.1.1.9.: atomic statements have level 1, and every connective, quantification, or negation adds one to the level. Every formal statement has level \( n \) for some finite \( n \).

**First-Order vs. Higher-Order Statements**

II.1.1.14. There is an important point, which, however, need not concern us very much at this level. In most contexts, there is a natural set of objects being discussed, usually called the *domain of discourse*. In most of this book, the domain of discourse would be the real numbers.

II.1.1.15. While constants can be not only objects in the domain of discourse, but also subsets of this domain, functions and relations on this domain, etc., logicians often (in fact, usually) restrict variables to represent only actual elements of the domain of discourse. Statements containing only variables taking values in the domain of discourse are called *first-order statements*, and statements with variables ranging over larger sets are *higher-order statements*. Levels of higher-order statements can be defined similarly to II.1.1.9.; for example, a statement containing one or more variables ranging over subsets of the domain of discourse or functions from the domain of discourse to itself is a *second-order statement*. Thus, for example, the statements of II.1.1.1. and II.1.3.11. are first-order statements, but the statement in II.1.3.12. is second-order.

II.1.1.16. The distinction between first-order and higher-order statements can be eliminated by expanding the domain of discourse. However, in practice the domain of discourse is usually established by a set of axioms assumed in the discussion, so cannot be easily expanded. (Also, even expanding the domain of discourse does not convert second-order theories to first-order theories.)

II.1.1.17. A *first-order theory* is a theory in which all statements are first-order. “First-order logic” can be used in first-order theories. “Higher-order logic” is needed for higher-order theories; higher-order logic is not as well behaved, or as well understood, as first-order logic, and indeed “logic” means “first-order logic” to many logicians.

One common criticism of second-order logic, made particularly in [?], is that second-order logic is essentially first-order set theory, and hence is “mathematical” and not “logic”; in [?] second-order logic is called “set theory in sheep’s clothing.” See [?] for an attempt to refute this criticism.

While restriction to first-order logic may make sense to logicians, it does not work well for mathematics in general; second-order logic is really needed to properly describe real analysis and even ordinary arithmetic.
the way mathematicians do it. See e.g. [Luc00] or [Sha05, Chapter 25] for details. As J. Barwise [?, p. 5] puts it:

As logicians, we do our subject a disservice by convincing others that logic is first-order and then convincing them that almost none of the concepts of modern mathematics can really be captured in first-order logic."

II.1.1.18. We will feel free to use higher-order statements (i.e. quantify as we see fit) in our development of analysis, and just assume enough higher-order logic exists to justify this policy (this assumption is in fact justifiable despite the incompleteness of higher-order logic).

II.1.2. Meaning of Statements

II.1.2.1. The “meaning” of a formal statement is not something that can really be defined. We will limit our discussion to the interpretation of truth values for formal statements.

II.1.2.2. The truth value of an atomic formal statement cannot be determined (in most cases) unless values for the variables are specified. Once they are, the statement is true if and only if the resulting n-tuple is one which satisfies the defining relation (technically, the relation is a set of n-tuples, and the relation is “satisfied” by a particular n-tuple if it is in the relation). A statement is false if it is not true.

II.1.2.3. Truth values for compound statements depend on the truth values of the constituent parts in a precise way which we will now describe. The first three are simple and fairly obvious:

\[(P \land Q)\] is true if and only if both \(P\) and \(Q\) are true.

\[(P \lor Q)\] is true if and only if \(P\) is true or \(Q\) is true or both. (Thus \(\lor\) is sometimes called “inclusive or”, as opposed to the “exclusive or” used primarily in computer science.)

\[\neg P\] is true if and only if \(P\) is false.

Implication

II.1.2.4. The meaning of \(\Rightarrow\) is less obvious. \((P \Rightarrow Q)\) is read “\(P\) implies \(Q\),” “If \(P\) then \(Q\),” or “\(P\) only if \(Q\).” Mathematicians have found through experience that the proper meaning of \((P \Rightarrow Q)\) is

\[\neg P \lor Q\] .

The idea is that if \(P\) is true, then \(Q\) must necessarily be true, but if \(P\) is false, no conclusion about the truth of \(Q\) may be drawn. So the implication is only violated if \(P\) is true but \(Q\) is false; the implication is satisfied (not violated) in all other cases. If \(P\) is false, the implication is not violated irrespective of whether \(Q\) is true or false, and if \(Q\) is true, the implication is not violated irrespective of whether \(P\) is true or false.

This interpretation leads to some jarring conclusions in cases where there appears to be no logical relationship between \(P\) and \(Q\). Thus mathematicians would regard the implication

“\(1 = 2\), then the sky is green.”

as being “true.” But there is no other reasonable interpretation in terms of truth values for \((P \Rightarrow Q)\) than \[\neg P \lor Q\].
II.1.2.5. The connective $\Rightarrow$ can thus be defined in terms of $\neg$ and $\lor$, and so is strictly speaking redundant. But we will use it freely since it is natural and many statements are simpler and more comprehensible if it is used.

Converse, Inverse, and Contrapositive

II.1.2.6. Definition. Let $P$ and $Q$ be statements.

(i) The converse of the statement $P \Rightarrow Q$ is $Q \Rightarrow P$.

(ii) The inverse of the statement $P \Rightarrow Q$ is $(-P) \Rightarrow (-Q)$.

(iii) The contrapositive of the statement $P \Rightarrow Q$ is $(-Q) \Rightarrow (-P)$.

II.1.2.7. It is important and basic that the converse of a statement does not have the same meaning; there is no implication either way between a statement and its converse, as almost any example shows. It is a common mistake to confuse a statement and its converse, which requires practice to learn to avoid. However:

II.1.2.8. Proposition. A statement and its contrapositive are logically equivalent (if ordinary logic is used).

Proof: The statement $P \Rightarrow Q$ means $(-P) \lor Q$, and its contrapositive $(-Q) \Rightarrow (-P)$ means $[\neg(-Q)] \lor (-P)$, and $\neg(-Q)$ is equivalent to $Q$ in ordinary logic.

II.1.2.9. Note that similarly, the converse and inverse of a statement are logically equivalent; indeed, the inverse is the contrapositive of the converse.

II.1.2.10. So to prove a statement, it is just as good to prove the contrapositive, and this is frequently easier or more natural. In fact, we will often just prove the contrapositive of a statement without comment.

If and Only If

II.1.2.11. We can define one other convenient logical connective, which can be regarded as merely an abbreviation if desired. If $P$ and $Q$ are statements, we write $P \iff Q$, read “$P$ if and only if $Q$”, to mean

$$[(P \Rightarrow Q) \land (Q \Rightarrow P)] .$$

Rewriting this without the symbol $\Rightarrow$, we obtain

$$[((-P) \lor Q) \land [P \lor (-Q)]] .$$

The statement $P \iff Q$ is also logically equivalent to

$$[(P \land Q) \lor [(-P) \land (-Q)]] .$$
II.1.2.12. The following table summarizes the behavior of truth values under connectives and negation:

<table>
<thead>
<tr>
<th>$P$</th>
<th>$Q$</th>
<th>$\neg P$</th>
<th>$(P \land Q)$</th>
<th>$(P \lor Q)$</th>
<th>$(P \Rightarrow Q)$</th>
<th>$(P \Leftrightarrow Q)$</th>

II.1.3. Quantification and Closed Statements

II.1.3.1. The quantifiers $\exists$ and $\forall$ are called the existential quantifier and the universal quantifier respectively. They are used to modify a statement $P$ by specifying the sense in which a certain variable is used in $P$. A variable appearing in $P$ which has not been quantified is called free; free variables give a degree of incompleteness in a statement. For example, if we just state “$x > 3$”, we cannot pass judgment on the truth of the statement without knowing what the $x$ is supposed to stand for. But if we write $(\forall x)(x > 3)$ (“For all $x$, $x > 3$”) or $(\exists x)(x > 3)$ (“There exists an $x$ such that $x > 3$”), we have a self-contained statement and we know what we are talking about, and it makes sense to say the statements are false and true respectively (in the real numbers).

Note, however, that if the statement $x > 3$ appears in the course of a discussion, and $x$ has been previously defined in the discussion to be a specific number (e.g. suppose there has been a previous line “Let $x = \sqrt{10}$.”), then the $x$ in the statement $x > 3$ is a constant, not a variable, and a truth value can be unambiguously assigned (true in this case).

Quantified variables can be regarded as “dummy variables” whose names are really just placeholders in an expression. The $x$ in $(\forall x)(x > 3)$ plays the same role as the $x$ in $f(x) = x^2 + 1$ or $\int_0^1 x^2 \, dx$, or the $n$ in $\sum_{n=1}^t(2n - 1)$. The symbol used is unimportant; it can be replaced by any other variable name which does not already appear in the expression without changing the meaning.

II.1.3.2. A variable in a statement $P$ which has been quantified is called a bound variable. A bound variable cannot be quantified again.

Logicians use the term “bound” to refer only to a variable quantified by an existential quantifier. In fact, universal quantifiers are normally not used at all in mathematical logic; they are often just understood, or if needed can be defined in terms of existential quantifiers and negations ($\neg$). But universal quantifiers are very useful in practice in mathematics, and it is good form to use them explicitly rather than to let them just be understood or implicit; statements with explicit universal quantifiers (where needed) are generally much clearer and more comprehensible.

Restricted Quantification

II.1.3.3. When quantifying variables, we often (even usually) want to place explicit restrictions on the values the variables are allowed to take. Thus we often want to write expressions like $(\forall n \in \mathbb{N})$ or $(\exists \delta > 0)$. With proper interpretation, such restricted quantification is allowable and causes no problems; a restricted quantification of a statement will just be an ordinary quantification of a related but more complicated statement.
II.1.3.4. In the usual case where we have a specified domain of discourse, e.g. the real numbers $\mathbb{R}$, the expressions $(\forall x \in \mathbb{R})$ or $(\exists x \in \mathbb{R})$ mean exactly the same thing as the simple expressions $(\forall x)$ and $(\exists x)$ respectively, and writing $(\forall x \in \mathbb{R})$ or $(\exists x \in \mathbb{R})$ simply adds to the clarity of the statement by specifying what type of variable $x$ is.

II.1.3.5. In the case where $A$ is a constant (previously specified) subset of the domain of discourse, we take $(\forall x \in A)(P)$ to mean
\[(\forall x)[(x \in A) \Rightarrow P]\]
and we take $(\exists x \in A)(P)$ to mean
\[(\exists x)[(x \in A) \land P].\]

II.1.3.6. Similarly, if $R$ is a relation on the domain of discourse, and we write $R(x)$ to denote $R$ with $x$ used as one of the arguments, along with other terms, then by $(\forall x R(x))(P)$ we mean
\[(\forall x)[R(x) \Rightarrow P]\]
and by $(\exists x R(x))$ we mean
\[(\exists x)[R(x) \land P].\]

For example, if the domain of discourse is $\mathbb{R}$, the expression $(\exists \delta > 0)(P)$ means
\[(\exists \delta)[(\delta > 0) \land P].\]

Order of Quantifiers

II.1.3.7. In a statement with more than one quantifier, the order of quantifiers is crucial; interchanging the order of a universal quantifier and an existential quantifier can drastically alter the meaning of a statement. For example, consider the following statement:

“For every natural number $n$ there is a real number $x$ with $x > n$.”

The corresponding formal statement is
\[(\forall n \in \mathbb{N})(\exists x \in \mathbb{R})(x > n).\]

This statement is true (e.g. can take $x = n + 1$).

But suppose the order of the quantifiers is reversed, i.e. we take the formal statement
\[(\exists x \in \mathbb{R})(\forall n \in \mathbb{N})(x > n)\]

which in English says

“There is a real number $x$ such that for every natural number $n$, $x > n$.”

This statement is false (). The point is that in the first statement, only the existence of an $x$ satisfying $x > n$ for one particular, though unspecified, $n$ is asserted (the $x$ can depend on the $n$), whereas in the second it is asserted that there exists one $x$ which satisfies the inequality simultaneously for all $n.$
II.1.3.8. There is an implication one way, however: for any statement $P$, and for any free variables $x$ and $y$ in $P$, we have

$$[(\exists x)(\forall y)(P)] \Rightarrow [(\forall y)(\exists x)(P)].$$

II.1.3.9. The order of two consecutive universal quantifiers, or two consecutive existential quantifiers, can be reversed without changing the meaning of the statement. If two consecutive quantifiers of the same type have identical restrictions, they can be combined into one abbreviated quantification expression. For example, the expressions $(\forall x \in \mathbb{R})(\forall y \in \mathbb{R})$ and $(\forall y \in \mathbb{R})(\forall x \in \mathbb{R})$ have an identical meaning, and can be abbreviated as $(\forall x, y \in \mathbb{R})$. We can similarly write $(\exists x, y \in \mathbb{R})$ to mean $(\exists x \in \mathbb{R})(\exists y \in \mathbb{R})$ or $(\exists y \in \mathbb{R})(\exists x \in \mathbb{R})$.

Closed Statements

II.1.3.10. DEFINITION. A closed statement is a formal statement $P$ in which every variable is quantified (i.e. every variable in $P$ is bound, or $P$ contains no free variables).

Closed statements are the ones which are “self-contained” and to which a well-defined truth value can (potentially) be attached. Restricted quantification is allowable in closed statements; such a statement can be rewritten as a more complicated closed statement with only ordinary quantification.

II.1.3.11. In principle, the statement of any theorem is a closed statement, and it is good mathematical form to write the statement of every result in the form of, or in a form easily translatable into, a closed statement. In practice it may sometimes be overly pedantic to do this, and we sometimes abbreviate when no confusion is likely. We also sometimes for stylistic reasons write theorem statements in a form not exactly of a closed statement. For example, many theorems are phrased in the form of the next statement, or slight variations of it:

**Theorem.** Let $x$ and $y$ be real numbers. If $x < y$, then there is a rational number $r$ with $x < r < y$.

The corresponding closed formal statement is

$$(\forall x \in \mathbb{R})(\forall y \in \mathbb{R})[((x < y) \Rightarrow ((\exists r \in \mathbb{Q})[(x < r) \land (r < y)]))]$$

which is a little awkward to express directly in English.

II.1.3.12. Sometimes the formal statement is even more different from the English one. For example:

**Theorem.** Every nonempty subset of $\mathbb{N}$ has a smallest element.

A corresponding formal statement would be:

$$(\forall S \subseteq \mathbb{N})[(\exists n)(n \in S) \Rightarrow ((\exists m)[(m \in S) \land (\forall n \in S)(m \leq n)])].$$

This statement explicitly incorporates the meaning of “nonempty” and “smallest element.” It also illustrates that variable objects which can remain unnamed in the English statement must often be given names in the formal statement.
II.1.3.13. One mistake often made by beginners (and sometimes by non-beginners too!) is to write a statement where the same letter is used to mean two or more different things in the expression, i.e. to stand for two or more different variables or constants. The statement in II.1.3.12. does not have this mistake since the two uses of \( n \) occur within disjoint quantifications (convince yourself of this!), but it would have been safer, and perhaps clearer, to use another letter in place of one of the uses of \( n \). It is always safest to use a separate letter or symbol for every different object in a statement. See II.1.7.7. for further discussion of a related point.

II.1.3.14. There is a related (mostly nonmathematical) issue concerning style. In a mathematical statement or argument, it is a good idea to use easily distinguishable symbols for unrelated objects; using the same letter in upper and lower case, or in different typefaces, can be confusing to a reader. It is often good practice to use related symbols for related objects: for example, it is usually good practice to use a lower-case letter to denote an element of a set whose name is the same upper-case letter (e.g. \( x \in X, n \in \mathbb{N} \)). Some extension of this is often also good practice, e.g.

"Let \( x_n \in X \) for all \( n \geq N \)."

(Here \( N \) is a previously specified number.) But this can be taken to ridiculous lengths. For example, I have seen the following statement in a book (which shall remain anonymous):

"Let \( A_a \in \mathfrak{A}_a \) for all \( a \in A \)."

Here \( A \) was an index set, \( a \) an index, and \( \mathfrak{A}_a \) a set for each \( a \). Although there is nothing mathematically wrong with such a statement, DON'T DO THIS! (I admit we have been forced by standard conventions to do something like this in Section XIII.4.3., but it is still to be avoided whenever possible.)

II.1.3.15. There is a wide choice of possible symbols available for use in mathematical statements. In principle any sort of symbol can be used, although in practice one should use symbols which can be easily recognized, distinguished, and remembered (and pronounced!) Besides standard mathematical symbols, one should generally stick to Latin or Greek letters, although other symbols are sometimes used. German \textit{fraktur} is common (more common in older references). Hebrew letters, notably \( \aleph \), are standard in certain contexts. I admit to occasionally using Cyrillic letters. And in a paper with a Danish coauthor, we used the Danish letter \( æ \) in a context where it was appropriate, although we refrained from also using the Danish letter \( ø \), as in

"Let \( \emptyset \) be a set, and \( \emptyset \in \emptyset \)."

I recommend exercising restraint in using uncommon letters or symbols.

II.1.3.16. A closed statement need not have any variables at all. Ones which do not tend to be simple formulas like elementary statements about arithmetic (e.g. \( 2 + 2 = 4 \)), but they are not necessarily so simple. One example is the following result, which caused a minor stir when it was discovered by F. Cole in 1903 since it provided a counterexample to an old conjecture of Mersenne in number theory (cf. [Bel87, p. 228]):

\textbf{Theorem.} \( 2^{67} - 1 = 193707721 \times 761838257287 \).
II.1.4. Negations

II.1.4.1. It is particularly important to be able to write the negation of a mathematical statement. In one sense, it is a triviality to do this: just insert the word “not” (and perhaps adjust the statement slightly to make it grammatically acceptable), i.e. the negation of the statement \( P \) is \( \neg P \). But this begs the question: in order to have a useful phrasing of the negation of a statement (e.g. in order to disprove the original statement, or to prove it by contradiction), we need a way of writing the negation affirmatively without the words “no” or “not”. (In fact, it is most useful to write every mathematical statement affirmatively without such words when possible, and correspondingly to write formal statements without using the symbol \( \neg \), and it turns out it is almost always possible to do this.)

It is often quite difficult to do this for statements written in English (try it for the two statements in the introduction of this section!) But there is a systematic way to affirmatively write the negation of a formal statement (although it involves what could be regarded as a bit of a subterfuge for atomic statements). So a procedure for finding the negation of a mathematical statement expressed in English would be:

1. Rewrite the statement as a formal statement.
2. Find the negation of the formal statement.
3. If desired, convert the negated formal statement into an English statement.

II.1.4.2. We should emphasize that this discussion of negations uses ordinary (or “classical”) logic. Negations behave rather differently if intuitionistic logic is used (cf. (1)).

Negations of Atomic Statements

II.1.4.3. It is quite simple to affirmatively write the negation of an atomic statement: just replace the relation in the statement with its complementary relation. (A relation is a subset of a Cartesian product, and the complementary relation is just the set-theoretic complement in the Cartesian product.) Sometimes there is a simple formula for the complementary relation: for example, if the domain of discourse is \( \mathbb{R} \), the negation of the statement \( (x > 3) \) is \( (x \leq 3) \). But it is not always so simple: for example, in a general domain of discourse there is no simple way to write the negation of the sentence \( (x = y) \) except as \( (x \neq y) \). (If the domain of discourse is \( \mathbb{R} \), the negation can be written \([ (x < y) \lor (x > y) ] \), but this is rather special to \( \mathbb{R} \).)

Negations of Compound Statements

II.1.4.4. The negation of \( \neg P \) is \( P \), i.e. \( P \) is logically equivalent to \( \neg \neg P \) for any statement \( P \).

II.1.4.5. The negation of \( P \lor Q \) is

\[
[(\neg P) \land (\neg Q)].
\]

To see this, note that \( P \lor Q \) is true if and only if \( P \) is true or \( Q \) is true or both. Thus \( P \lor Q \) is false if and only if both \( P \) and \( Q \) are false.

An almost identical argument (or an application of II.1.4.4.) shows that the negation of \( P \land Q \) is

\[
[(\neg P) \lor (\neg Q)].
\]

So if \( P \) and \( Q \) are sentences whose negations can be written without use of \( \neg \) (e.g. if \( P \) and \( Q \) are atomic sentences), then the negations of \( P \lor Q \) and \( P \land Q \) can be written also without use of \( \neg \).
II.1.4.6. Example. The negation of \([(x > 3) \lor (x \leq 1)]\) is \([x \leq 3] \land (x > 1)\], which can be abbreviated \((1 < x \leq 3)\).

II.1.4.7. Since \((P \Rightarrow Q)\) is logically equivalent to \(\neg[(\neg P) \lor Q]\), the negation of \((P \Rightarrow Q)\) is

\[
[P \land (\neg Q)]
\]

So if \(P\) and \(Q\) are sentences whose negations can be written without use of \(\neg\) (e.g. if \(P\) and \(Q\) are atomic sentences), then the negation of \(P \Rightarrow Q\) can be written also without use of \(\neg\).

II.1.4.8. Since we have \(\neg(P \lor Q)\) logically equivalent to \([\neg P] \land (\neg Q)]\), we have that \((P \lor Q)\) is logically equivalent to \(\neg[(\neg P) \land (\neg Q)]\). Thus \((P \lor Q)\) can be defined to mean \((\neg P) \land (\neg Q)\), i.e. \(\lor\) can be defined in terms of \(\neg\) and \(\land\). Similarly, we have that \((P \land Q)\) is logically equivalent to \(\neg[(\neg P) \lor (\neg Q)]\), i.e. \(\land\) can be defined in terms of \(\neg\) and \(\lor\). We will not want to do this, for two reasons: (1) both \(\lor\) and \(\land\) are natural and useful in writing comprehensible formal statements, and (2) we actually want to avoid using \(\neg\) as much as possible.

II.1.4.9. The negation of \((P \iff Q)\) can be found by writing it as \([P \lor (\neg Q)] \land [Q \lor (\neg P)]\), whose negation is \([(\neg P) \land Q] \lor [(\neg Q) \land P]\). \((P \iff Q)\) can also be rewritten as \([P \land Q] \lor [(\neg P) \land (\neg Q)]\), whose negation is \([P \lor Q] \land [(\neg P) \lor (\neg Q)]\).

Negations of Quantified Statements

II.1.4.10. The negation of \((\exists x)(P)\) is

\[
(\forall x)(\neg P)
\]

To see this, note that \((\exists x)(P)\) is true if and only if there is at least one \(x\) making \(P\) true. The negation is that every \(x\) makes \(\neg P\) false, i.e. every \(x\) makes \(\neg P\) true.

Similarly (or by an application of II.1.4.4.), the negation of \((\forall x)(P)\) is

\[
(\exists x)(\neg P)
\]

Thus to take the negation of a statement with a quantifier, just take the negation of the inside statement and change the quantifier from existential to universal or vice versa.

II.1.4.11. If a statement has two or more consecutive quantifiers, change each but leave the order of the quantifiers unchanged. Thus the negation of the statement \((\forall x)(\exists y)(P)\) is

\[
(\exists x)(\forall y)(\neg P)
\]

Negations of Statements with Restricted Quantifiers

It can be confusing to try to reason out the negation of a statement with restricted quantifiers. It is easy to make the mistake of changing too much!
II.1.4.12. Proposition. The negation of the statement \((\forall x \in A)(P)\) is
\[(\exists x \in A)(\neg P)\].

The negation of the statement \((\exists x \in A)(P)\) is
\[(\forall x \in A)(\neg P)\].

Proof: These can be reasoned out just as ordinary quantifiers, but we can also argue formally on the basis of the meaning of the restricted quantifiers. Since \((\forall x \in A)(P)\) means
\[(\forall x)[(x \in A) \land P]\]
we have that the negation is
\[(\exists x)[\neg(x \in A) \lor (\neg P)]\]
which by definition is the same as
\[(\exists x)[(x \in A) \Rightarrow (\neg P)]\]
and this is the meaning of \((\exists x \in A)(\neg P)\). The second half is the same argument run backwards, with \(P\) and \(\neg P\) interchanged.

By an almost identical argument, we obtain:

II.1.4.13. Proposition. If \(R\) is a relation, then the negation of \((\forall x R(x))(P)\) is
\[(\exists x R(x))(\neg P)\]
and the negation of \((\exists x R(x))(P)\) is
\[(\forall x R(x))(\neg P)\].

II.1.4.14. Thus, in taking the negation of a statement with restricted quantifiers, the inside statement is negated, universal and existential quantifiers are switched, but the restrictions on each quantifier stay the same. If there is more than one quantifier, the order of the quantifiers stays the same.

II.1.4.15. Example. Consider the statement
\[(\forall a \in \mathbb{R})(\forall \epsilon > 0)(\exists \delta > 0)(\forall x \in \mathbb{R})[|x - a| < \delta \Rightarrow (|f(x) - f(a)| < \epsilon)]\]
of II.1.1.1. Its negation is
\[(\exists a \in \mathbb{R})(\exists \epsilon > 0)(\forall \delta > 0)(\exists x \in \mathbb{R})[|x - a| < \delta \land (|f(x) - f(a)| \geq \epsilon)]\]
(using an application of II.1.4.7. on the statement inside the quantifiers).
II.1.4.16. By repeated applications of the techniques of this section, the negation of any formal statement \( P \) can be written. If \( P \) can be written without use of \( \neg \), so can its negation.

II.1.5. Uniqueness Statements

II.1.6. Tautologies

II.1.6.1. A tautology is a statement form which is always true no matter what truth values are assigned to the constituents. Some standard tautologies (for ordinary logic) are:

\[
\neg[P \land (\neg P)] \quad (\text{Consistency}) \\
P \lor (\neg P) \quad (\text{Law of the Excluded Middle}) \\
[P \Rightarrow Q] \iff [(\neg P) \lor Q] \quad (\text{Definition of } \Rightarrow)
\]

Some tautologies discussed in the section on negation are:

\[
P \iff \neg(\neg P) \quad (\text{Law of Double Negation}) \\
[\neg(P \lor Q)] \iff [(\neg P) \land (\neg Q)] \\
[\neg(P \land Q)] \iff [(\neg P) \lor (\neg Q)] \\
[\neg(P \Rightarrow Q)] \iff [P \land (\neg Q)] \\
[\neg[(\forall x)(P)]] \iff [(\exists x)(\neg P)] \\
[\neg[(\exists x)(P)]] \iff [(\forall x)(\neg P)]
\]

Some other tautologies which can be verified by using truth tables:

\[
[(P \lor Q) \lor S] \iff [P \lor (Q \lor S)] \quad (\text{Associativity of } \lor) \\
[(P \land Q) \land S] \iff [P \land (Q \land S)] \quad (\text{Associativity of } \land) \\
(P \lor Q) \iff (Q \lor P) \quad (\text{Commutativity of } \lor) \\
(P \land Q) \iff (Q \land P) \quad (\text{Commutativity of } \land) \\
[(P \lor Q) \land S] \iff [(P \land S) \lor (Q \land S)] \quad (\text{Distributivity of } \land) \\
[(P \land Q) \lor S] \iff [(P \lor S) \land (Q \lor S)] \quad (\text{Distributivity of } \lor) \\
[(P \Rightarrow Q) \land (Q \Rightarrow S)] \Rightarrow [P \Rightarrow S] \quad (\text{Transitivity of } \Rightarrow \text{ or Syllogism Law}) \\
[P \Rightarrow Q] \iff [(\neg Q) \Rightarrow (\neg P)] \quad (\text{Law of Contrapositive}) \\
[P \Rightarrow (Q \Rightarrow S)] \iff [(P \land Q) \Rightarrow S] \\
P \iff (P \land [Q \lor (\neg Q)]) \\
P \iff (P \lor [Q \land (\neg Q)])
\]
\[ P \leftrightarrow ([P \land Q] \lor [P \land (\neg Q)]) \]

\[ P \leftrightarrow ([P \lor Q] \land [P \lor (\neg Q)]) \]

\[ P \leftrightarrow ([Q \Rightarrow P] \land [(\neg Q) \Rightarrow P]) \text{ (Case Testing)} \]

\[ [(\exists x)(\forall y)(P)] \Rightarrow [(\forall y)(\exists x)(P)] \]

\[ P \Rightarrow P \text{ (note that this is by definition equivalent to the Law of the Excluded Middle, and thus is not a tautology in intuitionist logic!)} \]

\[ P \Rightarrow (P \lor Q) \]

\[ (P \land Q) \Rightarrow P \]

\[ (\neg P) \Rightarrow (P \Rightarrow Q) \]

\[ Q \Rightarrow (P \Rightarrow Q) \]

\[ [P \land (P \Rightarrow Q)] \Rightarrow Q \text{ (Modus Ponens)} \]

II.1.6.2. A tautology of the form \( A \iff B \), where \( A \) and \( B \) are statement forms involving \( P \)'s, \( Q \)'s, etc., is called a tautological equivalence. A tautological equivalence is a logical equivalence, i.e. any occurrence of a statement of form \( A \) can be replaced by the corresponding statement of form \( B \), or vice versa, without changing the logical meaning of the statement. (A logical equivalence need not be a tautological equivalence, however.) Such substitutions allow for simplification or modification of statements in arguments.

II.1.6.3. A tautology of form \( A \Rightarrow B \) can be used similarly, allowing replacement of a statement of form \( A \) by the corresponding one of form \( B \) (but not conversely). The converted statement is not (necessarily) logically equivalent to the original, but is a logical consequence. This type of substitution can also be used in arguments; however, such an argument is then not reversible.

Use of modus ponens is a particularly important example: if one shows that \( P \) is true and that \( (P \Rightarrow Q) \) is true, it can be concluded that \( Q \) is true. This logical argument is used constantly.

II.1.6.4. If intuitionist logic is used, not all of these tautologies hold. For example, intuitionists do not accept the Law of the Excluded Middle (and hence not \( P \Rightarrow P \) either!) They (mostly) accept \( P \Rightarrow [\neg(\neg P)] \), but not the converse. Several of the other tautologies listed above are not valid in intuitionist logic; we leave it to the reader to identify which ones.

II.1.7. Definitions

II.1.7.1. Definitions in mathematics are of two rather different sorts:

(1) A precise specification of the meaning of a word or phrase.

(2) A specification that a certain symbol (or compound symbol) is to stand for a particular mathematical object (i.e. the specification of a constant in the sense of II.1.3.).
II.1.7.2. **Examples.** (i) Examples of definitions of the first kind are the definitions of *partial order* (), *field* (), *metric space* (), *measure* (), *Riemann integral* (), · · · .

(ii) Examples of definitions of the second type are expressions of the form

(a) “Let $f(x) = x^2 + 1.$”

(b) “Let $x = \lim_{k \to \infty} x_k.$”

(c) “Let $B$ be the set of all upper bounds of the set $A$ [where $A$ has been previously defined].”

II.1.7.3. A definition of the first kind is simply the establishment of an “abbreviation” for a (generally more complicated) phrase. In principle, the defined term can always be replaced by the phrase it abbreviates without loss of utility, and thus from a strictly logical point of view such definitions are unnecessary. However, in practice it is very useful, often essential, to be able to make these definitions: otherwise, statements involving even moderately complex mathematical ideas would become unmanageably or even incomprehensibly complicated.

Definitions of the first kind are often of words which are standard terms used widely by mathematicians, and are frequently even the basic subject matter of whole parts of mathematics. But definitions of this kind can also be conveniently used to create a name for a concept of no obvious interest beyond the specific discussion at hand but which must be referred to multiple times, such as a concept which will shortly be shown to be equivalent to some other well-known concept.

II.1.7.4. Definitions of the second kind are another story. In principle, they too can be avoided, but in practice it is often hard to see how arguments can be reasonably phrased without their use.

II.1.7.5. Definitions of the second kind are normally made as part of a mathematical argument, and are operative only for the duration of the argument. Definitions of the first kind can be made in the same way as part of an argument, but are more commonly stand-alone statements.

Note that a definition is not a formal mathematical statement as described in this section, although it may resemble a formal statement in form.

II.1.7.6. Sometimes a definition of the second kind is dependent on other results for it to make sense. For example, in II.1.7.2 (iib), it must be previously (or subsequently) shown that $\lim_{k \to \infty} x_k$ exists, and that limits are unique.

A common instance where a definition must be justified is a situation where the object defined apparently or potentially depends on some choices. It must be shown that the definition always gives the same result no matter how the choices are made. In this situation, we say the resulting object is *well defined*. For example, we might make a definition (cf. (i))

“Let $f(x) = \lim_{k \to \infty} f(x_k)$, where $(x_k)$ is any sequence in $E$ converging to $x$.”

To show that $f(x)$ is well defined, it must be shown not only that $\lim_{k \to \infty} f(x_k)$ always exists for every such choice of $(x_k)$, but also that the same limit is always obtained no matter how the $x_k$ are chosen (so long as they are in $E$ and converge to $x$).

Although from a logical standpoint justifications should be put before the definition, the justification for the legitimacy of a definition is stylistically often put after the definition itself.
Ambiguity of Terminology

Ideally, every term used in mathematics should have a unique, unambiguous precise definition. But in practice there are many instances where the same name is used in mathematics to refer to quite different concepts in different contexts (this is probably inevitable since there is only a limited supply of suitable words in English to describe mathematical concepts, and is not even entirely undesirable since there is often some similarity between distinct concepts). Some common examples are closed, complete, free, independent, regular, normal, and separable. In different instances there may be a greater or lesser philosophical resemblance between the usages; but there is still a tendency for the mathematically uninitiated to make too much of the coincidence of terminology by taking the names too literally.

In most if not all languages where mathematical terms have been named, there are similar instances where the same name is used in different contexts. But the ambiguities are not always the same. For example, French mathematicians use the word fermé to refer to closed sets in topology, but algebriquement clos for algebraically closed fields. On the other hand, the French word noeud is used to mean both node and knot (and I have seen it translated incorrectly in English translations of French mathematics books!) Thus a French-speaking neophyte in mathematics may confuse different mathematics concepts than an English-speaking one.

Separated Quantification

II.1.7.7. There is a variant of type two definitions which is frequently employed, which is technically not a true definition at all. In mathematical arguments, we often write phrases such as

“Let $x$ be an element of $A$.”

(Here, $A$ is a previously defined set; in order to legitimately make such a statement, it must be known, or already shown, that $A$ is nonempty.) This is not really a definition, since it does not specify exactly what $x$ is. The $x$ remains a variable, but from that point on it is treated essentially like a constant in that it must always refer to the same (variable) object (this is related to the discussion in II.1.3.13.). If we then show that a statement $P(x)$ containing the variable $x$ is true, without further specifying what $x$ is or making assumptions about it beyond that it is an element of $A$, what we have shown is that the statement $(\forall x \in A)[P(x)]$ is true.

II.1.7.8. What is technically being done here is that quantification of a variable is stylistically moved to the beginning of a section of a discussion in which it is used repeatedly, which we call separated quantification. Separated quantification can be eliminated, but the price of elimination in many cases is a horribly complex compound quantified statement which is difficult to understand. So separated quantification is very important to use to make mathematical discussions readable and understandable.

II.1.7.9. Sometimes “definitions” of this sort are made implicitly. For example, if $(x_k)$ is known to be a bounded sequence, one can legitimately say:

“Since $(x_k)$ is bounded, there is an $M$ such that $x_k \leq M$ for all $k$.”

This implicitly defines $M$ to be a (variable) number satisfying the inequality for all $k$.

It is good mathematical form to phrase things in this way. A bad form mistake beginners often make is to write something like
“Since \((x_k)\) is bounded, \(x_k \leq M\) for all \(k\).”

where the \(M\) is a variable which has not yet been specified, i.e. the variable name \(M\) has not yet appeared in the discussion. (It is a more serious mistake if the name \(M\) has already been used to mean something else.) A reader seeing a statement like this must assume that the \(M\) refers to something which has already been defined, and wonders “What is \(M\)?” Some time and effort then must be wasted trying to find or figure out what the \(M\) refers to, and if it is concluded that the statement is intended to be an implicit “definition” of \(M\), the conclusion is only an educated guess, so there is a lack of precision and rigor.

II.1.7.10. There are subtle and potentially confusing instances where it is unclear whether an implicit separated definition is being made, for example in the common calculus statement

\[
\int x \, dx = \frac{x^2}{2} + C.
\]

Is the \(C\) now a quantified variable? We often write

\[
\int x \, dx = \frac{x^2}{2} + C, \quad \int x^2 \, dx = \frac{x^3}{3} + C.
\]

Are the \(C\)'s supposed to be the same? If we have these two statements, what about

\[
\int (x + x^2) \, dx?
\]

Is this \(\frac{x^2}{2} + \frac{x^3}{3} + C\), or \(\frac{x^2}{2} + \frac{x^3}{3} + 2C\)? It is standard to write the first, since by convention the \(C\) in each statement is not a specific constant, but simply denotes that any constant can be added. This convention, although universal, is a little unfortunate. Another instance of violation of usual ambiguity rules of mathematical language is in the big-\(O\) and little-\(o\) notation ().

II.1.8. Languages and Relational Systems

We should really have begun the entire discussion of formal statements by first specifying a language and a domain of discourse. We did not do this at first because we didn’t want to make the discussion too abstract. But there is merit in considering systems of formal statements based on various languages, or, from a different point of view, systems where the language and statements are restricted to be of a certain form.

II.1.8.1. Definition. A relational system is a triple \(S = (\Omega, \mathcal{R}, \mathcal{F})\), where \(\Omega\) is a set, \(\mathcal{R}\) is a set of relations on \(\Omega\), and \(\mathcal{F}\) a set of functions on \(\Omega\) (with codomain \(\Omega\)). The relations and functions may be \(n\)-ary for any \(n \geq 1\), which may vary from relation to relation, and may have domains which are proper subsets. The set \(\Omega\) is called the domain of discourse of the relational system.

Every function is just a special kind of relation, so it seems unnecessary to explicitly also include a set of functions in the definition; but the relations and functions are used in very different ways, so it is necessary to specify both \(\mathcal{R}\) and \(\mathcal{F}\) as part of the definition. Note that \(\mathcal{R}\) and/or \(\mathcal{F}\) need not contain all relations or functions on \(\Omega\).

The discussion of the previous part of this section concerned the relational system where \(\Omega\) was some universal set containing all objects under discussion (in many cases \(\Omega\) could be taken to be the real numbers \(\mathbb{R}\)), and \(\mathcal{R}\) and \(\mathcal{F}\) the sets of all relations and all functions on \(\Omega\).
II.1.8.2. Definition. Let $\mathcal{S}$ be a relational system. A language for the relational system $\mathcal{S} = (\Omega, \mathcal{R}, \mathcal{F})$ is:

(i) A set of symbols

(ii) A set of terms

(iii) A set of formulas

where the set of symbols includes at least one constant symbol for each element of $\Omega$ and each relation in $\mathcal{R}$ and function in $\mathcal{F}$, called its name (an element of $\Omega$ can have more than one name); a set of variables; a set of logical symbols including $\land$, $\lor$, and $\forall$; and parentheses. The terms satisfy

1. Each constant or variable symbol is a term.

2. If $f \in \mathcal{F}$ is a function of $n$ arguments, and $t_1, \ldots, t_n$ are terms, then $f(t_1, \ldots, t_n)$ is a term.

A variable $x$ occurs in the term $f(t_1, \ldots, t_n)$ if it equals or occurs in one of the $t_k$.

The formulas are certain finite strings of symbols including all strings of the form

(a) $R(t_1, \ldots, t_n)$, where $R$ is an $n$-ary relation in $\mathcal{R}$ and each $t_k$ is a term involving only constants which are names of elements of $\Omega$ and variables.

(b) $\forall x(P)$, where $P$ is a formula and $x$ is a variable not quantified in $P$. The variable $x$ is then quantified in $\forall x(P)$.

(c) $P_1 \land \cdots \land P_n$, where $P_1, \ldots, P_n$ are formulas, and if $x$ is a variable which is quantified in some $P_k$, then $x$ does not appear unquantified in any other $P_j$.

(d) $P_1 \Rightarrow P_2$, where $P_1$ and $P_2$ are formulas, and if $x$ is a variable which is quantified in one $P_k$, then $x$ does not appear unquantified in the other $P_j$.

A statement, or closed statement for emphasis, is a formula in which all variables are quantified, i.e. in which there are no free variables (variables which occur and are not quantified).

If every term in the language is obtained by a finite number of applications of (1) and (2), and every formula built up from a finite number of applications of (a), (b), (c), and (d), the language is a simple language for $\mathcal{S}$. Each term and each formula then has a well-defined level, and is built up from terms or formulas of strictly lower level.

In some references the word “sentence” is used in place of “formula” and in some other references “sentence” is used in place of “statement.” Because of the nonuniformity of usage, we have avoided the word “sentence” entirely. In the earlier part of this section, the word “statement” was used a little informally; in many of the places it was used we should have instead said “formula.”

II.1.8.3. A language can be a language for more than one relational system. But it is very hard for a language to be a simple language for more than one relational system, although it can be if the names of elements and relations are chosen in a different way. Conversely, a relational system can have many associated languages, but a simple language for a relational system is essentially uniquely determined by the relational system.
II.1.8.4. Suppose $L$ is a language for a relational system $S = (\Omega, \mathcal{R}, \mathcal{F})$, which we will take to be a simple language. It makes sense to say whether or not closed statements in $L$ (and only closed statements!) are “true” in $S$:

II.1.8.5. **Definition.** Suppose $L$ is a simple language for a relational system $S = (\Omega, \mathcal{R}, \mathcal{F})$. If $t$ is a term in $L$, then

(i) If $t$ is a constant $c$ which is the name of an element $\omega \in \Omega$, then $t$ is **interpretable in** $S$ as $\omega$.

(ii) If $t = f(t_1, \ldots, t_n)$ and $t_1, \ldots, t_n$ are interpretable in $S$ as $\omega_1, \ldots, \omega_n$ respectively, and $(\omega_1, \ldots, \omega_n)$ is in the domain of $f$, then $t$ is **interpretable in** $S$ as $f(\omega_1, \ldots, \omega_n)$.

If $t$ is interpretable in $S$ via a finite string of applications of (i) and (ii), then $t$ is interpretable in $S$; otherwise $t$ is not interpretable in $S$.

II.1.8.6. **Definition.** Suppose $L$ is a simple language for a relational system $S = (\Omega, \mathcal{R}, \mathcal{F})$. Then

(i) If $P$ is the statement $R(t_1, \ldots, t_n)$ involving no variables, and $t_1, \ldots, t_n$ are interpretable in $S$ as $\omega_1, \ldots, \omega_n$ respectively, and $(\omega_1, \ldots, \omega_n) \in R$ (i.e. $R(\omega_1, \ldots, \omega_n)$ holds in $\Omega$), then $P$ holds (or is true) in $S$.

(ii) If $P$ is the formula $R(t_1, \ldots, t_n)$, with all variables occurring in $t_1, \ldots, t_n$ included among $x_1, \ldots, x_m$, $c_1, \ldots, c_m$ are names of elements of $\Omega$, and $P$ holds when, for each $k$, $c_k$ is substituted for each instance of $x_k$ in $P$, then $P$ holds (or is true) for $(c_1, \ldots, c_m)$ in $S$.

(iii) If $P$ is a formula containing only unquantified variables among $x_1, \ldots, x_m, x_{m+1}, \ldots, x_p$ and quantified variables among $x_{p+1}, \ldots, x_r$, $c_1, \ldots, c_m$ are names of elements of $\Omega$, and for every set of constants $c_{m+1}, \ldots, c_r$ in $L$ which are names of elements of $\Omega$, $P$ holds for $(c_1, \ldots, c_m)$, then

\[
\forall x_{m+1} \cdots \forall x_p(P)
\]

holds (or is true) for $(c_1, \ldots, c_m)$ in $S$. If $m = 0$, then the statement

\[
\forall x_1 \cdots \forall x_p(P)
\]

holds (or is true) in $S$.

(iv) If $P_1, \ldots, P_n$ are formulas containing only unquantified variables among $x_1, \ldots, x_m$, with no variable quantified in some $P_k$ and free in another $P_j$, $c_1, \ldots, c_m$ are names of elements of $\Omega$, and each sentence $P_j$ holds for $(c_1, \ldots, c_m)$, then

\[
P_1 \land \cdots \land P_n
\]

holds (or is true) for $(c_1, \ldots, c_m)$ in $S$. If $m = 0$, i.e. if $P_1, \ldots, P_n$ are statements, then the statement

\[
P_1 \land \cdots \land P_n
\]

holds (or is true) in $S$. 

119
(v) If $P_1$ and $P_2$ are formulas containing only the free variables $x_1, \ldots, x_m$, none of which are quantified in one and free in the other, $c_1, \ldots, c_m$ are names of elements of $\Omega$ for which $P_2$ holds in $S$ or $P_1$ does not hold in $S$, then

$$P_1 \Rightarrow P_2$$

holds (or is true) for $(c_1, \ldots, c_m)$ in $S$. If $m = 0$, i.e. if $P_1$ and $P_2$ are statements, then the statement

$$P_1 \Rightarrow P_2$$

holds (or is true) in $S$.

If $P$ is a statement in $L$, and $P$ is built up from a finite chain of formulas which hold in $S$, then $P$ holds in $S$; otherwise $P$ does not hold (or is false) in $S$.

II.1.8.7. There are two quite distinct ways a statement can fail to hold:

(1) At some point, a term is not interpretable.

(2) All terms are always interpretable, but a relation does not hold.

II.1.8.8. Unless the set $R$ of relations is empty (in which case $L$ has no formulas) there are statements which hold in $S$: if $P$ is any formula, and $x_1, \ldots, x_m$ are the unquantified variables in $P$, then the statement

$$\forall x_1 \cdots \forall x_m (P \Rightarrow P)$$

holds in $S$. It can happen that every statement in $L$ holds in $S$, but only if $R = \emptyset$, or if $R$ consists only of the full relation and, for every $n$, every $n$-ary function in $F$ has full domain $\Omega^n$. Such a relational system is called degenerate. In a nondegenerate relational system there is a statement $\Phi = R(t_1, \ldots, t_n)$ containing no variables which is false (and there are also statements which are true, e.g. $\Phi \Rightarrow \Phi$).

II.1.8.9. If we fix such a $\Phi$, then for any formula $P$ containing free variables among $x_1, \ldots, x_m$, and every set $c_1, \ldots, c_m$ of names of elements of $\Omega$, the formula $P \Rightarrow \Phi$ holds for $(c_1, \ldots, c_m)$ in $S$ if and only if $P$ does not hold for $(c_1, \ldots, c_m)$ in $S$. We can thus interpret this formula as $\neg P$, i.e. we can extend $L$ by adding the symbol $\neg$, and formulas $\neg (P)$, where the formula $\neg (P)$ in the extended language is translated to mean $P \Rightarrow \Phi$ in the simple language.

II.1.8.10. We can then further extend $L$ by adding the symbols $\forall$ and $\exists$, where

$$P_1 \lor \cdots \lor P_n$$

is translated to mean

$$\neg (\neg (P_1) \land \cdots \land \neg (P_n))$$

(this will be a formula of the extended language if no variable is quantified in one of the $P_k$ and unquantified in another $P_j$), and

$$\exists x_1 \cdots \exists x_m (P)$$

is translated to mean

$$\neg (\forall x_1 \cdots \forall x_m (\neg (P)))$$

(this will be a formula of the extended language if no $x_k$ is quantified in $P$). More complicated formulas of the extended language can be built up from repeated applications of these translations.
II.1.8.11. We may thus extend a simple language $\mathcal{L}$ for a nondegenerate relational structure $\mathcal{S}$ to an extended simple language $\mathcal{L}'$, which includes all the standard logical symbols with their usual meanings, for which every formula has a well-defined translation into a formula of $\mathcal{L}$, and it makes sense to say whether statements in $\mathcal{L}'$ are true or false in $\mathcal{S}$.

II.1.8.12. In the extended simple language, the usual rules for taking negations hold. We can define an additional logical symbol $\iff$ by translating $P \iff Q$ as $(P \implies Q) \land (Q \implies P)$, and we say $P$ and $Q$ are equivalent in $\mathcal{S}$ if $P \iff Q$ holds in $\mathcal{S}$. Then

$$\neg(\neg(P)) \iff P$$

for every statement $P$. A statement form like this which holds in $\mathcal{S}$ for every statement $P$ is called a tautology in $\mathcal{S}$. The other tautologies in II.1.6.1. are also tautologies in $\mathcal{S}$.

II.1.9. Mathematical Arguments and Formal Proofs

II.1.9.1. Informally, a mathematical argument consists of a derivation of a mathematical statement (conclusion) from a set of initial assumptions, using acceptable mathematical reasoning. The argument, if logically sound, constitutes a proof of the conclusion.

II.1.9.2. The initial assumptions can be divided into two kinds: general assumptions underlying an entire mathematical theory, called axioms, and assumptions particular to the individual statement being proved, called hypotheses. There is not always a clear dividing line between axioms and hypotheses, and anyway the distinction between them is unimportant for the purpose of making and understanding mathematical arguments.

II.1.9.3. In practice, mathematical arguments are usually written out in a combination of English (or another language) and formal symbolism.

A formal mathematical argument

II.1.10. Exercises

II.1.10.1. Let $P(x)$ and $Q(x)$ be statements with a free variable $x$.
(a) Show that the statement $\forall x(P(x) \land Q(x))$ is logically equivalent to $[\forall x(P(x))] \land [\forall x(Q(x))]$.
(b) Show that the statement $\forall x(P(x) \lor Q(x))$ is not logically equivalent to $[\forall x(P(x))] \lor [\forall x(Q(x))]$.
(c) Show that the statement $\exists x(P(x) \lor Q(x))$ is logically equivalent to $[\exists x(P(x))] \lor [\exists x(Q(x))]$.
(d) Show that the statement $\exists x(P(x) \land Q(x))$ is not logically equivalent to $[\exists x(P(x))] \land [\exists x(Q(x))]$.
(e) Which implications are valid in (b) and (d)?

II.1.10.2. (a) Show that $P \implies P$ and $P \implies (Q \implies Q)$ are tautologies.
(b) Are $(P \implies P) \implies Q$ and $P \implies (P \implies Q)$ tautologies?
(c) Is $\implies$ “associative,” i.e. is

$$[(P \implies Q) \implies R] \iff [P \implies (Q \implies R)]$$

a tautology?
II.1.10.3. If $S$ is nondegenerate, a statement $\Phi$ is false if and only if $\Phi \Rightarrow P$ holds for every statement $P$. Show that any two false statements are equivalent.

II.1.10.4. Give a careful justification for all the assertions in II.1.8.11. and II.1.8.12.

II.1.10.5. [Bar00] Is

$$(P \Rightarrow Q) \lor (Q \Rightarrow P)$$

a tautology? Does this mean that for any statements $P$ and $Q$, either $P$ implies $Q$ or $Q$ implies $P$? In particular, does it mean “If a number is prime, then it is odd, or if a number is odd, then it is prime”?
Theorems, Corollaries, Propositions, Lemmas

The terms *Theorem*, *Corollary*, *Proposition*, and *Lemma* all mean essentially the same thing, with nuances of difference. All refer to mathematical statements which must be, and are, proved.

The terms are largely interchangeable, and the same statements can be found in various books called by any of the names. But there are conventions which are generally followed, although they are subjective and subject to interpretation. So the following descriptions should be taken with a grain of salt, and are intended only as a guide:

II.1.10.6. A *Theorem* is a result which (i) is of major significance and/or (ii) is difficult to prove. Many have widely-used official names, e.g. “The Fundamental Theorem of Calculus.” It is good practice to use the term “Theorem” sparingly, to really call attention to the big results.

II.1.10.7. A *Corollary* is a result which follows immediately or easily from another result. Sometimes a Corollary of a Theorem is simply a crucial special case of the theorem. A result which is a combination of two or more Theorems can also be called a Corollary.

II.1.10.8. A *Proposition* is a statement which (i) is less significant than a Theorem and/or (ii) has an easy or obvious proof. Propositions are not necessarily insignificant: fundamental immediate consequences of definitions and other observations are often called Propositions, with the proof often omitted if it is thought obvious.

II.1.10.9. A *Lemma* is a statement which is not of particular interest in and of itself, but which is of use in proving something else of greater interest. Statements of lemmas are often rather technical, and proofs can be complicated (although neither is a necessary attribute). Lemmas are roughly used in two ways. It is sometimes convenient to break a long proof involving many steps into a sequence of Lemmas to make the overall argument easier to follow and understand. And sometimes a subsidiary result which must be used repeatedly in the main argument can be conveniently isolated as a Lemma.

The best description of a Lemma I have heard came when I was a student in a course on Automata Theory. It was a mathematics course, with theorems and proofs, but many of the students were graduate students in Computer Science, with a different outlook than mathematicians. One day the instructor wrote a Lemma on the board, and one of the students asked, “What’s a Lemma?” Another CS student immediately replied, “It’s a subroutine.”

There are statements commonly called Lemmas which are significant Theorems, e.g. “Urysohn’s Lemma” () (which is probably called a “Lemma” simply to distinguish it from “Urysohn’s Metrization Theorem”, although it is a crucial tool in the proof of the Metrization Theorem).

II.1.10.10. The terms are occasionally used in a somewhat different sense. For example, the name “Fermat’s Last Theorem” has been used for nearly two hundred years, even though it only became a theorem (or, perhaps more accurately, became known to be a theorem, i.e. was proved) quite recently. And “Zorn’s Lemma” () is not really a Lemma, but a useful equivalent restatement of the Axiom of Choice ()

II.1.10.11. Certain theorem-level results have common names using other terms, such as the “Product Rule,” “l’Hôpital’s Rule,” the “Sequential Criterion for Continuity,” the “Ratio Test,” the “Cauchy Integral Formula,” the “Principle of the Argument,” etc.
II.2. Set Theory

II.2.1. New Sets from Old

The Power Set of a Set

Ordered Pairs and Cartesian Products

The Union of a Set

The Constituent Set of a Set

II.2.1.1. Definition. Let $X$ be a set. Inductively set

$$C_1(X) = \bigcup X = \{y : \exists x \in X \text{ with } y \in x\}$$

$$C_{n+1}(X) = C_1(C_n(X))$$

$$C(X) = \bigcup_{n=1}^{\infty} C_n(X).$$

The set $C(X)$ is called the constituent set of $X$.

Intuitively, $X \cup C(X)$ is the collection of all things $X$ is “made up of.” The constituents of $X$, i.e. the elements of $C(X)$, are the things that the elements of $X$ are made of. (It is a matter of convention not to assume that $X \subseteq C(X)$, i.e. to define $C(X)$ as we have instead of as $X \cup (\bigcup_{n=1}^{\infty} C_n(X))$, but our definition turns out to be more notationally useful.)

II.2.1.2. $C(X)$ is a set by the Axiom of Union and the Axiom of Infinity. However, the cardinality of $C(X)$ is quite independent of $\text{card}(X)$, as the following examples show (but see II.2.1.6.).

II.2.1.3. Examples. (i) $C_1(\emptyset) = C(\emptyset) = \emptyset$. $C_1(\{\emptyset\}) = C(\emptyset) = \emptyset$. $C_1(\{\{\emptyset\}\}) = C(\emptyset) = \emptyset$. $C_1(\emptyset) = C(\emptyset) = \emptyset$. $C_1(\{\emptyset\}) = C(\emptyset) = \emptyset$. $C_1(\emptyset) = C(\emptyset) = \emptyset$.

(ii) If $\sigma$ is a successor ordinal (II.8.2.8.), then $C_1(\sigma) = C(\sigma) = \sigma - 1$. If $\sigma$ is a limit ordinal, then $C_1(\sigma) = C(\sigma) = \sigma$.

(iii) If $x$ is a set of cardinality $\kappa$, and $X = \{x\}$, then $\text{card}(X) = 1$ but $\text{card}(C_1(X)) = \kappa$ since $C_1(X) = x$. The cardinality of $C(X)$ may be even larger.

(iv) If the elements of $X$ are not sets (i.e. are urelements ($\emptyset$)), then $C(X) = \emptyset$ no matter how large $\text{card}(X)$ is.

II.2.1.4. If $x \in X$, then $C_n(x) \subseteq C_{n+1}(X)$ for each $n$, and thus $C(x) \subseteq C(X)$. More generally, if $x \in C(X)$, then $C(x) \subseteq C(X)$. If $Y \subseteq X$, then $C_n(Y) \subseteq C_n(X)$ for every $n$, so $C(Y) \subseteq C(X)$. Similarly, if $Y \subseteq C(X)$, then $C(Y) \subseteq C(X)$. In particular, we have $C(C(X)) \subseteq C(X)$, but they need not be equal (II.2.1.3.(i)).

II.2.1.5. Let $X$ be a set. Since $C_1(\mathcal{P}(X)) = X$, $C(\mathcal{P}(X)) = X \cup C(X)$.

II.2.1.6. If $X$ contains no urelements, then $X \subseteq \mathcal{P}(C_1(X))$, and hence

$$\text{card}(X) \leq 2^{\text{card}(C_1(X))} \leq 2^{\text{card}(C(X))}$$

so $\text{card}(C(X))$ cannot be “too much smaller” than $\text{card}(X)$.
II.3. Relations and Functions

The idea of a relation is a crucial one, both within and outside of mathematics. Mathematicians have formalized the intuitive idea of a relation, and special kinds of relations abound throughout mathematics. The three most important kinds of relations in mathematics are functions, equivalence relations, and partial orderings. The first two will be discussed in this section, and partial orderings described in the next section.

II.3.1. General Relations

To formalize the notion of a relation between elements of a set $X$ and a (possibly different) set $Y$, we can think of the relation as consisting of certain ordered pairs $(x; y)$. Thus the formal definition is:

II.3.1.1. Definition. A relation from a set $X$ to a set $Y$ is a subset $R$ of $X \times Y$. If $(x; y) \in X \times Y$, write $x R y$ if $(x; y) \in R$. If $X = Y$, $R$ is called a relation on $X$.

The set $\{x \in X : x R y \text{ for some } y \in Y\}$ is called the domain of $R$, denoted $\text{Dom}(R)$; and the set $\{y \in Y : x R y \text{ for some } x \in X\}$ is called the range of $R$, denoted $\text{Range}(R)$.

II.3.1.2. Examples.

(i) The relation $\leq$ can be regarded as a relation on $\mathbb{R}$: it is technically the set $\{(x, y) \in \mathbb{R}^2 : x \leq y\} \subseteq \mathbb{R}^2 = \mathbb{R} \times \mathbb{R}$.

(ii) Let $S$ be the set of students at Ivory State University, and $C$ the set of classes offered this semester. Define a relation $E$ from $S$ to $C$ by letting $s E c$ if student $s$ is enrolled in class $c$. (There are obviously an enormous variety of variations on this example.) The domain is probably not quite all of $S$, since there may be students not taking any classes this semester; the range may or may not be all of $C$, depending on whether classes with zero enrollment are counted.

(iii) Let $X$ and $Y$ be any sets. Then $\emptyset$ and $X \times Y$ are relations from $X$ to $Y$, called the empty relation and full relation respectively.

(iv) If $X$ is a set, the identity relation on $X$ is the relation $I$ (often written $I_X$) defined by $x I y$ if and only if $x = y$. The domain and range of $I$ are all of $X$.

II.3.1.3. Definition. Let $R$ and $S$ be relations from $X$ to $Y$. $S$ is an extension of $R$ if $R \subseteq S$, i.e. $x R y$ implies $x S y$.

If $A \subseteq X$, the restriction of $R$ to $A$ is

$$R|_A = R \cap (A \times Y) = \{(x, y) : x \in A, \ y \in Y, \ x R y\}.$$

Note that $R$ is an extension of $R|_A$. However, not every extension comes from a restriction in this way.
II.3.1.4. **Definition.** Let $R$ be a relation from $X$ to $Y$. The *inverse relation* $R^{-1}$ is the relation from $Y$ to $X$ defined by

\[ R^{-1} = \{(y, x) : (x, y) \in R\} \]

(in other words, $yR^{-1}x$ if and only if $xRy$.) The domain of $R^{-1}$ is the range of $R$, and vice versa; and $(R^{-1})^{-1} = R$.

As a relation, $R^{-1}$ appears to be only superficially or notationally different from $R$; however, it can have rather different properties, as we will see later.

**Composition**

Relations can be composed:

II.3.1.5. **Definition.** Let $R$ be a relation from a set $X$ to a set $Y$, and $S$ a relation from $Y$ to a set $Z$. The *composition* of $S$ and $R$, written $S \circ R$, is the relation from $X$ to $Z$ defined by

\[ S \circ R = \{(x, z) \in X \times Z : xRy \text{ and } ySz \text{ for some } y \in Y\} \]

(Note the order in which $R$ and $S$ are written.)

II.3.1.6. **Examples.**

(i) Let $E$ be the relation from $S$ to $C$ defined in II.3.1.2.(ii), and let $L$ be the relation from $C$ to the set $B$ of buildings at Ivory State with $cLb$ if class $c$ meets at least once a week in building $b$. Then $L \circ E$ is the relation $R$ from $S$ to $B$ with $sRb$ if and only if student $s$ has at least one class a week in building $b$.

(ii) If $I$ is the identity relation on a set $X$, and $R$ is any relation from $X$ to $Y$, then $R \circ I = R$.

(iii) If $F$ is the full relation from $X$ to $Y$, and $G$ the full relation from $Y$ to $Z$, then $G \circ F$ is the full relation from $X$ to $Z$ (provided $Y \neq \emptyset$).

(iv) If $<$ is the usual strict inequality relation on $\mathbb{R}$, then $(< \circ <) = <$. However, the relation $< \circ <$ on $\mathbb{N}$ is not the same as $<$ on $\mathbb{N}$: $m(< \circ <)n$ if and only if $n - m \geq 2$. Thus the sets on which a relation is defined are very important to specify carefully.

(v) The composition of $<$ and $>$ on $\mathbb{R}$ is the full relation on $\mathbb{R}$.

(vi) Let $P$ be the set of all people. Define relations $B$ and $S$ on $P$ by saying $xBy$ if $x$ is the brother of $y$, and $xSy$ if $x$ is the sister of $y$. Then (disregarding modern surgical procedures) $B \circ (S^{-1})$ is the empty relation on $P$.

II.3.1.7. The domain of $S \circ R$ is a subset of the domain of $R$, and the range is a subset of the range of $S$. Either or both containments can be proper. See II.3.4.1.
Images and Preimages

II.3.1.8. Definition. Let $R$ be a relation from $X$ to $Y$, and let $A \subseteq X$. Then the image of $A$ under $R$ is

$$R(A) = \{ y \in Y : xRy \text{ for some } x \in A \} .$$

If $B \subseteq Y$, the preimage (or inverse image) of $B$ under $R$ is

$$R^{-1}(B) = \{ x \in X : xRy \text{ for some } y \in B \} .$$

II.3.1.9. The notation is consistent: $R^{-1}(B)$ is the image of $B$ under the relation $R^{-1}$. Thus images and preimages can be considered on the same basis. We prefer the term “preimage” to “inverse image,” especially in the case of functions, where “inverse image” can mistakenly seem to imply the existence of an inverse function.

Images (and hence also preimages) behave nicely with respect to unions, but not quite so nicely under intersections:

II.3.1.10. Proposition. Let $R$ be a relation from $X$ to $Y$, and $\{A_i : i \in I\}$ an indexed collection of subsets of $X$. Then

(i) $R(\bigsqcup_i A_i) = \bigsqcup_i R(A_i)$.

(ii) $R(\bigcap_i A_i) \subseteq \bigcap_i R(A_i)$.

The proof is left as an exercise (Exercise {}).

II.3.1.11. Simple examples show that equality does not hold in (ii) in general. For example, if $F$ is the full relation from $X$ to $Y$, and $A$ is any nonempty subset of $X$, then $F(A) = Y$. If $A_1$ and $A_2$ are nonempty but $A_1 \cap A_2 = \emptyset$, then

$$\emptyset = F(\emptyset) = F(A_1 \cap A_2) \neq F(A_1) \cap F(A_2) = Y .$$

II.3.2. Functions

Functions are officially relations of a special kind, although they are not usually thought of in this way.

II.3.2.1. Definition. Let $X$ and $Y$ be sets. A function from $X$ to $Y$ is a relation $f$ in which no two ordered pairs have the same first coordinate, i.e., if $x \in X$ and $xfy_1$ and $xfy_2$ for some $y_1, y_2 \in Y$, then $y_1 = y_2$.

Thus, if $f$ is a function, then for every $x \in \text{Dom}(f)$ there is a unique $y \in Y$ with $xfy$. We normally write $f(x) = y$ instead of $xfy$, and call $y$ the value of $f$ at $x$ or the image of $x$ under $f$.

The vast majority of functions considered in analysis are ones taking numerical values, but there is no reason to restrict attention only to numerical functions.
II.3.2.2. Examples.

(i) If $X$ and $Y$ are sets, the empty relation from $X$ to $Y$ and the identity relation on $X$ are functions. The identity relation on $X$, when regarded as a function, is written $\iota_X$. The full relation from $X$ to $Y$ is not a function unless $Y$ is a singleton (or $\emptyset$).

(ii) Let $X$ and $Y$ be sets, and $y_0$ a fixed element of $Y$. Set $f(x) = y_0$ for all $x \in X$. Then $f$ is a function, called the constant function $y_0$. By slight abuse of notation, we will often use the symbol $y_0$ as the name of this constant function, especially if $Y$ is a set of numbers. Thus, for example, we will often use a phrase like “the constant function 5”, meaning the function with $f(x) = 5$ for all $x$.

(iii) The relations $E$ of II.3.1.2. (ii) and $B$ and $S$ of II.3.1.6. (vi) are not functions since a student cannot take more than one class and a person can have more than one brother or sister. The relation $L$ of II.3.1.6. (i) is also probably not a function, since a class can meet in different buildings on different days (for example, it could have a lab or discussion session in another building.)

(iv) The set $\{(x, y) \in \mathbb{R}^2 : y = x^2\}$ is a typical function from $\mathbb{R}$ to $\mathbb{R}$ defined by a formula.

II.3.2.3. Terminology: It is especially important with functions to carefully specify the domain; thus we should always specify something like “$f$ is a function from $X$ to $Y$ with domain $A$.” Without further qualification, the phrase “$f$ is a function from $X$ to $Y$” will be taken to mean that $\text{Dom}(f)$ is all of $X$. In this case, we often write $f : X \to Y$. When $f$ is defined by a formula or rule, without explicit specification to the contrary the domain will always be taken to be all elements of $X$ for which the formula or rule makes sense. Thus, when we write $f : X \to Y$, the domain $X$ is determined by $f$. The set $Y$ is called the codomain of $f$ when written in this way. It is a subtle matter whether the $Y$ should be regarded as determined by $f$, since it is not the range of $f$ in general. See II.3.2.12.

Mappings

Functions are usually thought of as mappings:

II.3.2.4. Definition. A mapping $f$ from a set $X$ to a set $Y$ is an assignment to each $x \in X$ of a unique element $f(x)$ of $Y$. A mapping $f$ is often represented pictorially:

II.3.2.5. This definition of a mapping is not quite precise enough mathematically, hence the formal definition of function given above. But there is a natural correspondence: a function can obviously be pictured as a mapping, and a mapping $f$ from $X$ to $Y$ gives a function

$$\{(x, y) \in X \times Y : f(x) = y\}.$$  

This set is often called the graph of the mapping $f$; formally, a function is its own graph. Thinking of functions and graphs as the same thing can be confusing, but is technically useful.
II.3.2.6. We are in the habit of defining functions, especially numerical functions, by algebraic formulas; we typically write something like “let \( f(x) = \frac{\cos x}{x-2} \)” to define a function, where we really mean

\[
f = \left\{ (x, y) \in \mathbb{R}^2 : y = \frac{\cos x}{x-2} \right\}.
\]

By our convention, the domain of this function would be \( \{x \in \mathbb{R} : x \neq 2\} \).

Images and Preimages

Since functions are relations, the definitions of image and preimage (II.3.1.8.) make sense. We rephrase them in function notation:

II.3.2.7. Definition. Let \( f : X \to Y \) be a function.

(i) If \( A \subseteq X \), the image of \( A \) under \( f \) is

\[
f(A) = \{ f(x) : x \in A \} \subseteq Y.
\]

(ii) If \( B \subseteq Y \), the preimage (or inverse image) of \( B \) under \( f \) is

\[
f^{-1}(B) = \{ x \in X : f(x) \in B \} \subseteq X.
\]

II.3.2.8. We prefer the term “preimage” to “inverse image,” since there is not necessarily an inverse function \( f^{-1} : Y \to X \) (there is an inverse relation, which is not a function in general). The notation \( f^{-1}(B) \) can also be confusing, but is standard; note that this notation does not mean there is an inverse function! Preimages are defined for arbitrary functions and arbitrary subsets of the codomain. In the special case that there is an inverse function, the preimage of a set is indeed just the image under the inverse function, so the notation is consistent.

II.3.2.9. If \( f : X \to Y \) and \( a \in X \), there is a subtle difference between \( f(a) \) and \( f(\{a\}) \): \( f(a) \) is an element of \( Y \), while \( f(\{a\}) \) is a subset of \( Y \). In fact, \( f(\{a\}) = \{f(a)\} \). The distinction is more pronounced for preimages: if \( b \in Y \), then \( f^{-1}(\{b\}) \) is a subset of \( X \) which can be a singleton, but can also be empty (if \( b \) is not in the range of \( f \)) or it can have many elements. The notation \( f^{-1}(b) \) does not make sense unless \( f \) has an inverse function \( f^{-1} \).

II.3.2.10. If \( f : X \to Y \) is a function, then \( f(\emptyset) = \emptyset \), and if \( A \subseteq X \) and \( f(A) = \emptyset \), then \( A = \emptyset \). Preimages are more complicated: \( f^{-1}(\emptyset) = \emptyset \), but if \( B \subseteq Y \), then \( f^{-1}(B) = \emptyset \) does not imply that \( B = \emptyset \) – it only means the intersection of \( B \) with the range of \( f \) is empty.

We have \( f^{-1}(Y) = X \), but not necessarily \( f(X) = Y \): \( f(X) \) is the range of \( f \). If \( A \subseteq X \) and \( B \subseteq Y \), we have \( A \subseteq f^{-1}(f(A)) \) and \( f(f^{-1}(B)) \subseteq B \), but we do not have equality in general.

Preimages respect unions, intersections, and complements, but images only respect unions in general (cf. II.3.4.3.):
II.3.2.11.  **Proposition.** Let $f : X \to Y$ be a function.

(i) If $\{A_i : i \in I\}$ is a collection of subsets of $X$, then $f(\bigcup_{i \in I} A_i) = \bigcup_{i \in I} f(A_i)$ and $f(\bigcap_{i \in I} A_i) \subseteq \bigcap_{i \in I} f(A_i)$.

(ii) If $\{B_i : i \in I\}$ is a collection of subsets of $Y$, then $f^{-1}(\bigcup_{i \in I} B_i) = \bigcup_{i \in I} f^{-1}(B_i)$ and $f^{-1}(\bigcap_{i \in I} B_i) = \bigcap_{i \in I} f^{-1}(B_i)$.

(iii) If $B \subseteq Y$, then $f^{-1}(B^c) = [f^{-1}(B)]^c$ (i.e. $f^{-1}(Y \setminus B) = X \setminus f^{-1}(B)$).

**Proof:** We prove as a sample the second statement of (ii). The other proofs are very similar and are left as an exercise. Note that in all cases except the second statement of (i), two containments must be shown.

Let $x \in f^{-1}(\bigcap_{i \in I} B_i)$. Then $f(x) \in \bigcap_{i \in I} B_i$, so for each $i \in I$, $f(x) \in B_i$ and so $x \in f^{-1}(B_i)$. Thus $x \in \bigcap_{i \in I} f^{-1}(B_i)$.

For the reverse containment, let $x \in \bigcap_{i \in I} f^{-1}(B_i)$. Then, for each $i \in I$, $x \in f^{-1}(B_i)$, so $f(x) \in B_i$. Thus $f(x) \in \bigcap_{i \in I} B_i$, so $x \in f^{-1}(\bigcap_{i \in I} B_i)$.

---

**Injective and Surjective Functions**

**Is the Codomain Uniquely Determined?**

II.3.2.12.  There is a subtle problem with codomains of functions which is overlooked in many texts, which sometimes even make contradictory statements as a result. If we have a function $f : X \to Y$, by our convention (II.3.2.3.) $X$ is the domain of $f$ and is thus uniquely determined by $f$. The $Y$ is called the codomain of $f$, but it is only a set containing the range of $f$ in general. Should we regard the codomain as being intrinsic to $f$, i.e. uniquely specified by $f$? This is a trickier question than would first appear: no matter which convention we take, it will be impossible to cleanly answer both of the following questions:

(i) When are two functions equal?

(ii) When is a function surjective?

II.3.2.13.  It is stated in many books that two functions $f : X \to Y$ and $g : Z \to W$ are equal if and only if $X = Z$, $Y = W$, and $f(x) = g(x)$ for all $x \in X = Z$. But suppose $f : \mathbb{R} \to \mathbb{R}$ is defined by $f(x) = x^2$, and $g : \mathbb{R} \to [0, +\infty)$ is defined by $g(x) = x^2$. Are $f$ and $g$ equal functions, or are they different functions? (And does “equal functions” mean “the same function”?)

On the other hand, if $f$ and $g$ are the same function, does it really make sense to say that $g$ is surjective and $f$ is not surjective? How can a function be both surjective and not surjective?

II.3.2.14.  If a function is defined to be a set of ordered pairs, as is the usual definition in set theory, then two functions with the same domain taking the same values at all points of the domain, such as the $f$ and $g$, consist of exactly the same ordered pairs, and then must be equal as sets by the Extension Axiom of set theory, whether or not the specified codomains are the same.

One can proceed differently: in Category Theory, every function (morphism) has a specified domain and codomain which are part of the definition of a morphism. Thus from a category theory point of view the above $f$ and $g$ are different. This point of view gives a clean meaning to surjectivity (technically called an *epimorphism*, although the abstract category definition must be done differently, cf. ())).
II.3.2.15. Since we have used the ordered pair definition of function, we ought to, and will, adopt the
convention that the codomain of a function is not intrinsic to the function, and thus two functions are equal
if they have the same domain and take the same values at all points of the domain; thus we will regard the
above \( f \) and \( g \) to be the same function. This is the most common convention in Analysis, and is a useful
one: the codomain can be taken to just be any convenient target set containing the range. For example,
the most common types of functions considered in basic analysis are real-valued functions, and it is most
convenient to simply take the codomain to be \( \mathbb{R} \) in all cases. The reader should be warned, however, that
surjectivity of a function depends crucially on what codomain is specified.

II.3.2.16. The same logical question arises with more general relations: if \( \mathcal{R} \) is a relation from \( X \) to \( Y \),
are the \( X \) and \( Y \) intrinsic to \( \mathcal{R} \)? In this case we do not conventionally assume even that \( X \) is the domain of
the relation, so using the ordered pair definition we should not consider either \( X \) or \( Y \) to be intrinsic to \( \mathcal{R} \).
However, this problem will rarely if ever arise in this book.

Composition of Functions

Sequences

Indexed Collections of Sets

General Cartesian Products

II.3.3. Equivalence Relations

The second important class of relations are equivalence relations. There are three standard points of view
for these relations which can, and will, be used interchangeably.

II.3.3.1. Definition. A relation on a set is an \textit{equivalence relation} if it is reflexive, symmetric, and
transitive.

It is common to use the symbol \( \sim \) for an equivalence relation, although other similar symbols are sometimes
used. Thus a relation \( \sim \) on a set \( X \) is an equivalence relation if it has the following properties:

(i) \( x \sim x \) for all \( x \in X \).

(ii) If \( x, y \in X \) and \( x \sim y \), then \( y \sim x \).

(iii) If \( x, y, z \in X \), \( x \sim y \), and \( y \sim z \), then \( x \sim z \).

Note that by (i), the domain and range of an equivalence relation on \( X \) are all of \( X \).

II.3.3.2. Examples. (i) If \( X \) is any set, the identity relation (II.3.1.2.(iv)) is a (not very interesting)
equivalence relation on \( X \). The full relation (II.3.1.2.(iii)) on \( X \) is another equivalence relation (also not very
interesting). The identity relation and the full relation are the “smallest” and “largest” equivalence relations
on \( X \).

(ii) On \( \mathbb{R}^2 \), set \( (x_1, y_1) \sim (x_2, y_2) \) if and only if \( x_1 = x_2 \). Then \( \sim \) is an equivalence relation on \( \mathbb{R}^2 \).

(iii) Fix \( n \in \mathbb{N} \). On \( \mathbb{Z} \), set \( x \sim y \) if and only if \( x - y \) is divisible by \( n \). Then \( \sim \) is an equivalence relation on
\( \mathbb{Z} \), called \textit{congruence modulo} \( n \). We usually write \( x \equiv y \mod n \) if \( x \sim y \) for this relation.

131
(iv) For a generic example including (i) and (ii) (and, in slight disguise, (iii)), let $X$ and $Y$ be sets, and $f : X \to Y$ a function. If $x_1, x_2 \in X$, set $x_1 \sim_f x_2$ if and only if $f(x_1) = f(x_2)$. Then $\sim_f$ is an equivalence relation on $X$. We will see that every equivalence relation on $X$ is of this form for some $Y$ and $f$. By replacing $Y$ by the range of $f$, there is no loss of generality in assuming that $f$ is surjective, in which case the $Y$ and $f$ are uniquely determined (up to bijective equivalence) by the relation $\sim_f$ (II.3.3.9.).

Equivalence Classes

The crucial notion connecting equivalence relations with the other points of view is equivalence classes:

II.3.3.3. **Definition.** Let $\sim$ be an equivalence relation on a set $X$, and $x \in X$. Then the equivalence class (or $\sim$-equivalence class) of $x$ is

$$[x] = \{ y \in X : x \sim y \} \subseteq X.$$  

Note that $x \in [x]$ since $\sim$ is reflexive.

II.3.3.4. **Proposition.** If $\sim$ is an equivalence relation on a set $X$, and $x, y \in X$, then either $[x] = [y]$ or $[x]$ and $[y]$ are disjoint. We have $[x] = [y]$ if and only if $x \sim y$.

**Proof:** Suppose $x \sim y$. If $z \in [y]$, i.e. $y \sim z$, then $x \sim z$ by transitivity, so $z \in [x]$ and $[y] \subseteq [x]$. Since also $y \sim x$ by symmetry, by interchanging $x$ and $y$ in the argument we obtain $[x] = [y]$. Now suppose $[x]$ and $[y]$ are not disjoint, and let $z \in [x] \cap [y]$. Then $x \sim z$ and $z \sim y$, so $x \sim y$ and $[x] = [y]$.

II.3.3.5. Thus the set $X$ partitions into a disjoint union of equivalence classes. The equivalence classes completely determine the equivalence relation: two elements of $X$ are equivalent if and only if they are in the same equivalence class.

II.3.3.6. **Examples.** (i) If $\sim$ is the identity relation on $X$, then each equivalence class is a singleton (and conversely), i.e. $[x] = \{ x \}$ for each $x \in X$. If $\sim$ is the full relation on $X$, there is only one equivalence class: $[x] = X$ for every $x \in X$.

(ii) In the equivalence relation of II.3.3.2.(ii), we have

$$[\langle x_1, y_1 \rangle] = \{ \langle x_1, y \rangle : y \in \mathbb{R} \}$$

so the equivalence classes are the vertical lines in $\mathbb{R}^2$.

(iii) In the equivalence relation of II.3.3.2.(iii), we have

$$[x] = \{ x + kn : k \in \mathbb{Z} \}.$$ 

If $n = 2$, the equivalence class of any even integer is the set of all even integers, and the equivalence class of any odd integer is the set of all odd integers. For general $n$, there are exactly $n$ equivalence classes: $[0], [1], \ldots, [n-1]$.
(iv) In the equivalence relation of II.3.3.2 (iv), we have \([x] = f^{-1}(f(x))\) for any \(x \in X\), i.e. the equivalence classes are just the (nonempty) preimages of elements of \(Y\) (more correctly, singleton subsets of \(Y\)). Thus if \(f\) is surjective, there is a natural parametrization of the equivalence classes by elements of \(Y\).

II.3.3.7. Conversely, suppose \(\{X_i : i \in I\}\) is a partition of a set \(X\), i.e. the \(X_i\) are disjoint and nonempty and \(\bigcup_{i \in I} X_i = X\). Define a relation \(\sim\) on \(X\) by setting \(x \sim y\) if and only if \(x\) and \(y\) are in \(X_i\) for the same \(i\). Then \(\sim\) is an equivalence relation on \(X\) whose equivalence classes are precisely the \(X_i\). Thus there is a natural one-one correspondence between equivalence relations on \(X\) and partitions of \(X\). Viewing equivalence relations as partitions is the second standard point of view.

II.3.3.8. Suppose \(\{X_i : i \in I\}\) is a partition of a set \(X\). Define a function \(f : X \to I\) by setting \(f(x) = i\) if \(x \in X_i\). Then \(f\) is a well-defined function from \(X\) to \(I\), which is surjective since all the \(X_i\) are nonempty, and the equivalence relation defined by the partition is exactly \(\sim_f\) as defined in II.3.3.2 (iv). Conversely, if \(g\) is a function from \(X\) onto a set \(Y\), the equivalence classes of the relation \(\sim_g\) are indexed by the elements of \(Y\) as in II.3.3.6 (iv). Thus the third point of view of equivalence relations on a set \(X\) is via surjective functions from \(X\) to other sets. The target set corresponding to an equivalence relation can be identified with the set of equivalence classes of the relation.

We summarize the three points of view:

II.3.3.9. Theorem. Let \(X\) be a set. There is a natural one-one correspondence between

(i) Equivalence relations on \(X\).

(ii) Partitions of \(X\).

(iii) Surjective functions from \(X\) to other sets (up to bijective equivalence).

In (iii), “up to bijective equivalence” means: if \(f : X \to Y\) and \(g : X \to Z\) are surjective functions, then \(f\) and \(g\) are bijectively equivalent if there is a bijection \(\phi : Y \to Z\) with \(g = \phi \circ f\) (so \(f = \phi^{-1} \circ g\)), i.e. the functions are the “same” up to renaming the elements of the target set.

II.3.4. Exercises

II.3.4.1. Let \(R\) be a relation from \(X\) to \(Y\), and \(S\) a relation from \(Y\) to \(Z\). Show that \(\text{Dom}(S \circ R) = R^{-1}(\text{Range}(R) \cap \text{Dom}(S))\) and \(\text{Range}(S \circ R) = S(\text{Range}(R) \cap \text{Dom}(S))\).

II.3.4.2. Here is a common but fallacious argument that a relation which is symmetric and transitive must also be reflexive, hence an equivalence relation. “Let \(R\) be a relation on a set \(X\) which is symmetric and transitive, and let \(x \in X\). Let \(y\) be any element of \(X\) with \(xRy\). Then \(yRx\) by symmetry, and hence \(xRx\) by transitivity. Thus \(R\) is reflexive.”

(a) What is wrong with this argument?
(b) Give an example of a relation on a set which is symmetric and transitive, but not reflexive.
II.3.4.3. (a) What is wrong with the following argument that the image of an intersection under a function is the intersection of the images?

Let \( f : X \rightarrow Y \) be a function, and \( \{ A_i : i \in I \} \) an indexed collection of subsets of \( X \). Let \( y \in \bigcap_{i \in I} f(A_i) \). Then, for each \( i \in I \), \( y \in f(A_i) \), so there is an \( x \in A_i \) with \( f(x) = y \). Then \( x \in \bigcap_{i \in I} A_i \), so \( y \in f(\bigcap_{i \in I} A_i) \).

(b) Give an example of an \( f \) and two subsets \( A_1, A_2 \) of \( X \) and a \( y \in f(A_1) \cap f(A_2) \) for which \( y \notin f(A_1 \cap A_2) \). [Consider a constant function.]

(c) Use your example in (b) to show that \( f(A^c) \neq [f(A)]^c \) in general.

(d) Under what conditions on \( f \) can we assert that the image under \( f \) of an intersection is always the intersection of the images? Under what conditions is the image of a complement always the complement of the image?
II.4. Ordered Sets and Induction

II.4.1. Partially Ordered Sets

Partially ordered sets arise throughout mathematics. A particularly important use in analysis and topology is to use partially ordered index sets to describe convergence.

II.4.1.1. DEFINITION. A transitive, antisymmetric relation on a set \( X \) is called a partial order on \( X \). A partially ordered set is a set with a specified partial order. Elements \( x \) and \( y \) (\( x \neq y \)) in a partially ordered set \( (X \preceq) \) are comparable if \( x \preceq y \) or \( y \preceq x \); otherwise they are incomparable. A partial order \( \preceq \) on a set \( X \) is a total order if any two elements of \( X \) are comparable, i.e. if, for every \( x, y \in X \), at least one of \( x \preceq y \), \( x = y \), or \( y \preceq x \) holds.

The symbols \( \preceq, <, \preceq, \preceq, \ll, \) and their reversals (\( \geq, \), etc.) are typically used for partial orders, although other similar symbols can be used.

II.4.1.2. A partial order need not be reflexive; in fact, it can happen that \( x \not\preceq x \) for any \( x \), for example with \( < \) on \( \mathbb{R} \). Such a partial order is called a strict partial order. If \( \preceq \) is a partial order on a set \( X \), there is an associated reflexive partial order \( \preceq \) defined by \( x \preceq y \) if and only if \( x \preceq y \) and \( x \neq y \), and similarly there is an associated reflexive partial order \( \preceq \) defined by \( x \leq y \) if and only if \( x \preceq y \) or \( x = y \). We will usually consider reflexive partial orders for definiteness; there is no essential loss of generality in doing so. We will sometimes (slightly carelessly) not distinguish between partial orders whose associated reflexive partial orders coincide (and hence whose associated strict partial orders also coincide); such partial orders will be called equivalent.

II.4.1.3. If \( Y \) is a subset of \( X \), then the restriction to \( Y \) of any partial order on \( X \) is a partial order on \( Y \), called the induced ordering.

II.4.1.4. Examples.

(i) \( <, \leq, >, \geq \) are total orders on \( \mathbb{R} \), or any subset of \( \mathbb{R} \).

(ii) For any set \( X \), \( \subseteq \) and \( \supseteq \) are reflexive partial orders on \( \mathcal{P}(X) \). These are not total orders if \( X \) has more than one element: if \( x \neq y \), then \( \{x\} \) and \( \{y\} \) are incomparable.

(iii) On \( \mathbb{R}^2 \) (or any subset), define \( (x_1, y_1) \preceq (x_2, y_2) \) if and only if \( x_1 \leq x_2 \) and \( y_1 \leq y_2 \). This is a reflexive partial order which is not a total order [(1,0) and (0,1) are incomparable], called the ordinary ordering on \( \mathbb{R}^2 \).

(iv) On \( \mathbb{R}^2 \) (or any subset), define \( (x_1, y_1) \preceq (x_2, y_2) \) if and only if \( (x_1, y_1) = (x_2, y_2) \), or \( x_1 < x_2 \) and \( y_1 < y_2 \). This is a different reflexive partial order which is also not a total order [(1,0) and (1,1) are incomparable], called the strict ordering on \( \mathbb{R}^2 \) (the name is well established but somewhat unfortunate, since this is not a strict partial order.)

(v) On \( \mathbb{R}^2 \) (or any subset), define \( (x_1, y_1) \preceq (x_2, y_2) \) if and only if \( x_1 < x_2 \), or \( x_1 = x_2 \) and \( y_1 \leq y_2 \). This is a reflexive total order, called the lexicographic ordering on \( \mathbb{R}^2 \).
Examples (iii)-(v) can be generalized to arbitrary Cartesian products of partially ordered sets (for (v), the index set must be ordered; see Exercise ()). The term “lexicographic ordering” is used because this ordering is an analog of the alphabetical ordering of words, regarding the alphabet as a totally ordered set. An important generalization of (iii) is:

(vi) Let $X$ be a set, and $\mathbb{R}^X$ the set of all functions from $X$ to $\mathbb{R}$. If $f, g \in \mathbb{R}^X$, set $f \leq g$ if $f(x) \leq g(x)$ for all $x \in X$. This is the ordinary ordering on $\mathbb{R}^X$. It is not a total order if $X$ has more than one element.

A more complicated example, which is typical of a class of examples arising in analysis, is:

(vii) Let $X$ and $Y$ be sets, and $\mathcal{F}(X,Y)$ the set of functions from subsets of $X$ to $Y$. Write $f \preceq g$ if $g$ extends $f$, i.e. the domain of $g$ contains the domain of $f$ and $g = f$ on the domain of $f$. Then $\preceq$ is a partial order on $\mathcal{F}(X,Y)$ which is not a total order if $Y$ has more than one element. In fact, in general, “almost all” pairs of functions are incomparable.

There is a lot of terminology in the theory of partially ordered sets which we need to introduce, mostly related to upper and lower bounds of subsets.

II.4.1.5. Definition. Let $(X, \preceq)$ be a partially ordered set, and $A \subseteq X$. An element $x \in X$ is an upper bound for $A$ if $a \preceq x$ for every $a \in A$. The element $x$ is the supremum, or least upper bound, of $A$, written $x = \sup(A)$, if $x$ is an upper bound for $A$ and $x \preceq y$ for every upper bound $y$ of $A$. Lower bounds and greatest lower bounds are defined similarly; the greatest lower bound of $A$ is also called the infimum of $A$, written $\inf(A)$. $A$ is bounded above if it has an upper bound, and bounded below if it has a lower bound; $A$ is bounded if it is both bounded above and bounded below.

II.4.1.6. It is obvious from antisymmetry that the supremum or infimum of a set, if it exists, is unique. Note that an upper or lower bound for a subset $A$ is not a member of $A$ in general. For example, if $X = \mathbb{R}$ and $A = (0, 1)$, then any $x \geq 1$ is an upper bound for $A$, and $\sup(A) = 1$; similarly, any negative number is a lower bound for $A$ and $\inf(A) = 0$.

In a general partially ordered set, a subset which is bounded above need not have a supremum; examples are given in the exercises.

II.4.1.7. Definition. Let $(X, \preceq)$ be a partially ordered set. Then $(X, \preceq)$ is complete if every bounded subset of $X$ has a supremum and infimum.

II.4.1.8. One of the most important properties of $\mathbb{R}$ is the Completeness Axiom:

Completeness Axiom. $(\mathbb{R}, \leq)$ is complete.

There are many other properties of $\mathbb{R}$ which are equivalent to the completeness axiom, e.g. (), (), (), . . . . The completeness axiom is the main feature which distinguishes $\mathbb{R}$ from other number systems such as $\mathbb{Q}$. See Exercise ()

136
II.4.1.9. There are other important complete partial orders. Among the examples of II.4.1.4., (i), (ii), (iii), (vi), and (vii) are complete (in (ii), the supremum of a collection of subsets is their union; see Exercise () for (vii)), while (iv) and (v) are not complete (Exercises ().)

II.4.1.10. There are two finite versions of completeness which are important. A partially ordered set \((X;\preceq)\) is directed (technically, upward directed) if every pair of elements has an upper bound, and is a lattice if every pair of elements has a supremum and an infimum. The supremum and infimum of \(x\) and \(y\) are usually denoted \(x \lor y\) and \(x \land y\) respectively. Every totally ordered set is a lattice, and a lattice-ordered set is directed. Of the examples, (i), (ii), (iii), (iv), and (vi) are lattices, (iv) is directed but not a lattice, and (vii) is not directed (see Exercises ().) In a directed set \([\text{lattice}]\), every finite subset has an upper bound [supremum and infimum] (Exercise ()).

II.4.1.11. Definition. Let \((X;\preceq)\) be a partially ordered set. An element \(x \in X\) is a maximal element if \(y \in X\), \(x \preceq y\) implies \(y = x\). The element \(x \in X\) is the largest element if \(y \preceq x\) for all \(y \in X\). Minimal elements and smallest elements are defined similarly.

II.4.1.12. A largest element, if it exists, is obviously unique, and is a maximal element. In a totally ordered set, the two things are the same; but in a general partially ordered set a maximal element need not be a largest element, and there can be more than one maximal element. For example, in \(\mathcal{F}(X,Y)\) (II.4.1.4.(vii)), a function is a maximal element if and only if its domain is all of \(X\), and there is no largest element (if \(Y\) has more than one element.) The situation is the same for smallest or minimal elements.

There is also a notion of morphism for partially ordered sets:

II.4.1.13. Definition. Let \((X;\preceq)\) and \((Y;\leq)\) be partially ordered sets. A function \(f : X \to Y\) is order-preserving if \(x_1 \preceq x_2\) implies \(f(x_1) \leq f(x_2)\). The function \(f\) is an order-isomorphism if it is a bijection and both \(f\) and \(f^{-1}\) are order-preserving, i.e. \(x_1 \preceq x_2\) if and only if \(f(x_1) \leq f(x_2)\).

II.4.1.14. Caution: an order-isomorphism is more than an order-preserving bijection: for example, the identity map from \(\mathbb{R}^2\) with the strict ordering () to \(\mathbb{R}^2\) with the ordinary ordering () is an order-preserving bijection, but not an order-isomorphism.

II.4.1.15. A composition of order-preserving functions is order-preserving, so the collection of partially ordered sets and order-preserving functions forms a category.

II.4.1.16. We also slightly carelessly say that \((X;\preceq)\) and \((Y;\leq)\) are order-isomorphic if there is a bijection from \(X\) to \(Y\) which is an order-isomorphism between \(\preceq\) and a partial order on \(Y\) equivalent to \(\leq\). Thus, for example, we say that \((\mathbb{R},\leq)\) and \((\mathbb{R},<)\) are order-isomorphic.

II.4.2. Well-Ordered Sets and Transfinite Induction

There is a very special type of ordered set which is important in some applications:
II.4.2.1. Definition. A partially ordered set \((I, \preceq)\) is well-ordered if every nonempty subset has a smallest element.

We will generally use \(I\) and \(J\) as names of well-ordered sets since well-ordered sets are primarily used in analysis as index sets.

A well-ordered set \(I\) is totally ordered (if \(i, j \in I\), then \(\{i, j\}\) has a smallest element), and \(I\) itself has a smallest element. Every subset of a well-ordered set is well-ordered in the induced ordering.

The ordering on a well-ordered set is called a well ordering. While the term “well-ordered” is grammatically correct English, the term “well ordering” is an abuse of language (the word “well” used as an adjective is the opposite of “sick”), but the term is unfortunately “well established.”

II.4.2.2. Examples.

(i) Any finite totally ordered set is well-ordered.

(ii) \(\mathbb{N}\) is well-ordered.

(iii) \(\mathbb{N}^2\) with lexicographic ordering is well-ordered.

(iv) \(\mathbb{Z}, \mathbb{Q}, \mathbb{R}\) are not well-ordered since they have no smallest element. \([0, \infty)\) is not well-ordered either: it has a smallest element, but the subset \((0, \infty)\) does not.

II.4.2.3. Actually, well-ordered sets are quite unusual. While there are many of them, they all look somewhat the same except for length: if \(I\) and \(J\) are well-ordered, then one of them is order-isomorphic to an initial segment of the other, in a unique way (II.4.2.19.). Well-ordered sets are described in more detail in ()

II.4.2.4. Every element of a well-ordered set, except the largest element if there is one, has an immediate successor: for any \(i\), the set \(\{j : i \prec j\}\), if nonempty, has a smallest element. An element need not have an immediate predecessor, however; for example, in \(\mathbb{N}^2\) with lexicographic order, \((2, 1)\) has no immediate predecessor. An element with no immediate predecessor is called a limit element.

II.4.2.5. A well ordering is a complete ordering: if \((I, \preceq)\) is well-ordered, and \(A \subseteq I\) is nonempty, then \(A\) has a smallest element which is \(\inf(A)\); and the set of upper bounds for \(A\), if nonempty, has a smallest element which is \(\sup(A)\).

Transfinite Induction

A proof procedure generalizing ordinary induction can be based on any well-ordered set.

II.4.2.6. Theorem. [Principle of Transfinite Induction] Let \((I, \preceq)\) be a well-ordered set, and suppose \(P(i)\) is a statement for each \(i \in I\). Suppose, for each \(i \in I\), the following inductive implication holds:

“If \(P(j)\) is true for all \(j < i\), then \(P(i)\) is true.”
Then $P(i)$ is true for all $i \in I$.

We have not been precise about the meaning of the term “statement”, since to be so would require an extensive excursion into set theory and mathematical logic. Many books on mathematical logic such as [?] contain a careful discussion of this point. But any type of mathematical statements likely to be made by a working mathematician come within the scope of the principle.

II.4.2.7. We outline the proof (although we cannot be completely precise because of the imprecision in the term “statement.”) Let $J$ be the set of $j \in I$ such that $P(j)$ is true. If $J \neq I$, since $I$ is well-ordered there is a smallest element $i \in I \setminus J$. But then $P(j)$ is true for all $j < i$, and therefore $P(i)$ is true by the inductive implication; this is a contradiction, so $I = J$.

II.4.2.8. The term “transfinite induction” is usually used in the case where $I$ properly contains an initial segment order-isomorphic to $\mathbb{N}$, and especially in the case where $I$ is uncountable.

One of the most frequently used consequences of the principle of transfinite induction is:

II.4.2.9. Corollary. Let $(I, \leq)$ be a well-ordered set, and $J \subseteq I$. If $J$ has the property that, for every $i \in I$, $\{j \in J \text{ for all } j < i\}$ implies $i \in J$, then $J = I$.

Proof: Let $P(i)$ be the statement “$i \in J$”, and apply II.4.2.6.

II.4.2.10. Transfinite induction in the special case $I = \mathbb{N}$ is usually called complete induction. Complete induction is not quite the same as ordinary induction, where statements $P(n)$ indexed by $\mathbb{N}$ are proved for all $n$ by proving $P(1)$ and $[P(n) \Rightarrow P(n+1)]$ for all $n$. Instead, in complete induction, we assume $P(k)$ is true for all $k \in \mathbb{N}, k < n$, and deduce $P(n)$. Ordinary induction is a special case of complete induction; on the other hand, complete induction can be easily deduced from ordinary induction (Exercise ()).

Complete induction is useful where there is no simple relationship between $P(n)$ and $P(n+1)$, but there is a relationship between $P(n)$ and $P(k)$ for certain $k$’s less than $n$. The next simple example is a good illustration.

II.4.2.11. Proposition. Every natural number can be written as a finite product of prime numbers. [We define the product of an empty set of primes to be 1, and a product of one prime $p$ to be $p$.]

Proof: For each $n \in \mathbb{N}$, let $P(n)$ be the statement “The integer $n$ can be written as a finite product of prime numbers.” Fix $n \in \mathbb{N}$, and assume $P(k)$ is true for all $k < n$; we must prove that $P(n)$ is true. There are three cases:

1. $n = 1$. Then $n$ is an empty product of prime numbers.
2. $n > 1$ is prime. Then $n$ is a product of one prime number.
3. $n > 1$ is not prime. Then $n = n_1n_2$ for some $n_1, n_2 \in \mathbb{N}, n_1, n_2 > 1$. Then $n_1, n_2 < n$, so by assumption $n_1$ and $n_2$ can each be written as a finite product of prime numbers. Hence so can $n_1n_2 = n$. 

139
II.4.2.12. Note that in complete induction, it is not necessary in general to separately prove \( P(1) \), since it is included in the general case. In the case \( n = 1 \), the assumption that \( P(k) \) is true for all \( k < n \) is automatically satisfied since there are no such \( k \)'s (in this case, the hypothesis is said to be vacuous.) Of course, it is allowed to prove \( P(1) \) as a special case, as was done in the proof of II.4.2.11.

Definitions by Transfinite Induction or Recursion

Transfinite induction (or, technically, transfinite recursion) can also be used to define functions whose domain is a well-ordered set. We will again not be completely precise in defining terms; see, for example, [? p. 249-250] for a careful treatment.

II.4.2.13. Let \( (I, \leq) \) be a well-ordered set, and \( X \) any set. Suppose, for each \( i \in I \), we have a definite procedure or rule \( R_i \) for choosing an \( f(i) = x_i \in X \), which may depend on the choice of the \( f(j) \) for \( j < i \). Then

II.4.2.14. Theorem. There is a unique \( f : I \to X \) such that, for each \( i \in I \), \( f(i) \) is determined by the specified procedure \( R_i \) applied to \( \{f(j) : j < i\} \).

Roughly speaking, if \( f \) can be defined “one step at a time” by the rules \( R_i \), then \( f \) can be defined “all at once.”

II.4.2.15. We outline an argument “proving” the theorem, overlooking the imprecision in the term “procedure”. We first prove uniqueness of \( f \) by transfinite induction: if \( f \) and \( g \) have \( f(i) \) determined for each \( i \) by applying \( R_i \) to \( \{f(j) : j < i\} \), and \( g(i) \) determined by applying \( R_i \) to \( \{g(j) : j < i\} \), let \( J \) be the set of \( i \) for which \( f(i) = g(i) \). If \( i \in I \) and \( j \in J \) (i.e. \( f(j) = g(j) \)) for all \( j < i \), then applying \( R_i \) we obtain \( f(i) = g(i) \), so \( i \in J \). Thus \( J = I \) by II.4.2.9.

For existence, let \( J \) be the set of all \( i \) such that there is a function \( f_i \) on \( \{k : k \leq i\} \) with \( f_i(k) \) determined by \( R_k \) applied to \( \{f_i(j) : j < k\} \) for each \( k \leq i \). If \( i_1, i_2 \in J \) and \( k \leq i = \min(i_1, i_2) \), then \( f_{i_1}(k) = f_{i_2}(k) \) by the uniqueness of the first part of the proof, applied to \( \{k : k \leq i\} \). Thus, if \( i \in I \) and \( j \in J \) for all \( j < i \), there is a (unique) function \( f \) on \( \{j : j < i\} \) with \( f(j) \) determined by \( R_j \) applied to \( \{f(k) : k < j\} \) for all \( j < i \). Apply \( R_i \) to \( \{f(j) : j < i\} \) to define \( f(i) \) and extend \( f \) to \( \{j : j \leq i\} \). Thus \( i \in J \). By II.4.2.9, \( J = I \).

This “proof” is actually fallacious; see Exercise (). The actual proof (cf. []) is an adaptation of the proof of the following special case, which is the most important one for applications.

II.4.2.16. Theorem. Let \( X \) be a set, and for each \( n \in \mathbb{N} \) let \( f_n \) be a function from \( X^n \) to \( X \). If \( x_1 \) is any element of \( X \), then there is a unique sequence \( (x_n) \) in \( X \) with \( x_{n+1} = f_n(x_1, \ldots, x_n) \) for all \( n \in \mathbb{N} \).

Proof: Let \( S \) be the smallest subset of \( \mathbb{N} \times X \) containing \( (1, x_1) \), with the property that if, for any \( n \in \mathbb{N} \), whenever \( \{(k, y_k) : k \in \mathbb{N}, k \leq n\} \subseteq S \) for \( (y_1, \ldots, y_n) \in X^n \), then \( (n+1, f_n(y_1, \ldots, y_n)) \in S \). \( S \) is the intersection of all subsets of \( \mathbb{N} \times X \) with these two properties; there is at least one such subset, \( \mathbb{N} \times X \) itself.) Then let

\[ A = \{n \in \mathbb{N} : (k, x_k) \in S \text{ for exactly one } x_k \in X \text{ for all } k \in \mathbb{N}, k \leq n\} \, . \]

First we show \( 1 \in A \). Set

\[ S' = \{(1, x_1)\} \cup \{(n, x) \in S : n > 1\} \]

140
and note that \( S' \subseteq S' \), \((1, x_1) \in S'\), and \( \{(k, y_k) : k \in \mathbb{N}, k \leq n\} \subseteq S'\) implies \((n + 1, f_n(y_1, \ldots, y_n)) \in S'\); hence \( S' = S \) and \( 1 \in A \). Now suppose \( n \in A \), i.e. there is a unique \( x_k \in X \) with \((k, x_k) \in S\) for all \( k \in \mathbb{N} \), \( k \leq n \). Set

\[
S'' = \{(k, x_k) : k \in \mathbb{N}, k \leq n\} \cup \{(n + 1, f_n(x_1, \ldots, x_n))\} \cup \{(m, x) \in S : m > n + 1\}
\]

and note that \( S'' \subseteq S', (1, x_1) \in S'' \), and \( \{(k, y_k) : k \in \mathbb{N}, k \leq m\} \subseteq S'' \) implies \((m + 1, f_m(y_1, \ldots, y_m)) \in S''\). Thus \( S'' = S \) and \( n + 1 \in A \). So \( A = \mathbb{N} \).

For each \( n \in \mathbb{N} \), let \( x_n \) be the unique element of \( X \) for which \((n, x_n) \in S \). Let \( B = \{ n \in \mathbb{N} : x_{n+1} = f_n(x_1, \ldots, x_n) \}\). We have \( 1 \in B \) since \((2, f_1(x_1)) \in S\); and if \( n \in B \), then \((n + 2, f_{n+1}(x_1, \ldots, x_{n+1})) \in S\), so \( n + 1 \in B \). Thus \( B = \mathbb{N} \).

Note that no form of the Axiom of Choice is needed in this proof; in fact, the AC is not needed even for the transfinite result II.4.2.14.

II.4.2.17. In other words, if a definite rule is specified for each \( n \) for determining the \((n + 1)\)'st term of the sequence from the first \( n \) terms, there is a unique sequence generated beginning with any first term. The rule \( f_n \) can vary with \( n \), but all the \( f_n \) must be specified in advance. The sequence is said to be defined by induction (or, more correctly, defined by recursion) from \( x_1 \) by the functions \((f_n)\).

II.4.2.18. Caution: In definitions by transfinite induction, the rule \( R_i \) can be quite general, but it must be a definite rule giving a specific element as a function of \( \{f(j) : j < i\} \). Thus, for example, a “rule” like “Let \( f(i) \) be any element of \( X \setminus \{f(j) : j < i\} \)” is not permissible, even if it is proved that this set is always nonempty (say, by a cardinality argument.) But if \( X \) is well-ordered, it is permissible to let \( R_i \) be the rule “Let \( f(i) \) be the first element of \( X \setminus \{f(j) : j < i\} \)” (provided this set is always nonempty.) In fact, this rule can be used to give a proof of the “uniqueness up to length” of well orderings:

II.4.2.19. Theorem. Let \((I, \leq)\) and \((J, \leq)\) be well-ordered sets. Then there is a unique order-isomorphism from one of \( I \), \( J \) onto an initial segment of the other.

Proof: The idea is that we pair up the first element of \( I \) with the first element of \( J \), and each succeeding element of \( I \) with the next remaining element of \( J \), until we “run out of elements” in either \( I \) or \( J \). This is clearly the only possible way to obtain an order-isomorphism of the desired type, giving uniqueness.

More precisely, we try to define \( f : I \rightarrow J \) as follows. For each \( i \in I \) let \( f(i) \) be the first element of \( J \setminus \{f(k) : k \prec i\} \). This inductively defines \( f \) on the set \( A = \{i \in I : Y \setminus \{f(k) : k \prec i\} \neq \emptyset\} \). This set \( A \) is either all of \( I \) or is of the form \( \{k \in I : k \prec i\} \) for some \( i \in I \), which is a proper initial segment of \( I \); and \( f \) is an order-isomorphism from \( A \) onto \( f(A) \). In the case \( A \neq I \), \( f \) maps \( A \) bijectively to \( J \). If \( A = I \), then either \( f \) maps \( I \) onto \( J \), or there is a smallest element \( j \) of \( J \setminus f(I) \), in which case \( f(I) = \{k \in J : k < j\} \), which is an initial segment of \( J \), since we can never have \( j \leq f(i) \) for any \( i \in I \) by the way \( f \) is defined.

An alternate proof not using transfinite induction is outlined in Exercises ()

141
II.4.3. Exercises

II.4.3.1. Consider the partially ordered set \((\mathbb{R}^2, \preceq)\) of II.4.1.4.(iv) (strict ordering).
(a) Show that \((1,0), (0,1), \text{ and } (1,1)\) are mutually incomparable.
(b) Show that \(\{(1,0),(0,1)\}\) has no supremum or infimum.
(c) Show that \(\{(x,y) : i \in I\}\) is bounded in \((\mathbb{R}^2, \preceq)\) if and only if \(\{x_i\}\) and \(\{y_i\}\) are bounded in \(\mathbb{R}\). Conclude that \((\mathbb{R}^2, \preceq)\) is directed.
(d) Define an analog of the strict ordering on \(\mathbb{R}^X\) for a nonempty set \(X\), and prove that \((\mathbb{R}^X, \preceq)\) is directed but not a lattice (unless \(X\) is a singleton.)

II.4.3.2. Consider the partially ordered set \((\mathbb{R}^2, \preceq)\) of II.4.1.4.(v) (lexicographic ordering).
(a) Show that a subset \(\{(x_i,y_i) : i \in I\}\) is bounded in \((\mathbb{R}^2, \preceq)\) if and only if \(\{x_i\}\) is bounded in \(\mathbb{R}\).
(b) Show that \(\{(x,y) : 0 < x < 1\}\) and \(\{(x,y) : 0 \leq x \leq 1\}\) are bounded but have no supremum or infimum.

II.4.3.3. Consider the partially ordered set \(F(X,Y)\) of II.4.1.4.(vii).
(a) Show that if \(f\) and \(g\) have a common domain point at which they disagree, then \(\{f,g\}\) has no upper bound. Hence \(F(X,Y)\) is not (upward) directed.
(b) If \(A = \{f_i : i \in I\}\) is a nonempty subset of \(F(X,Y)\) which is bounded above by a function \(g\), let \(h\) be the restriction of \(g\) to the union of the domains of the \(f_i\). Then \(h = \sup(A)\).
(c) Every subset of \(F(X,Y)\) is bounded below; in fact, \(F(X,Y)\) has a smallest element, the function whose domain is \(\emptyset\).
(d) If \(A = \{f_i : i \in I\}\) is a nonempty subset of \(F(X,Y)\), set
\[
Z = \{x \in X : x \in \text{Dom}(f_i) \text{ for all } i \in I, \ f_i(x) = f_j(x) \text{ for all } i,j \in I\}
\]
and let \(g\) be the restriction of any \(f_i\) to \(Z\). Then \(g = \inf(A)\). Thus \(F(X,Y)\) is complete.

II.4.3.4. Suppose \(\{X_i : i \in I\}\) is an indexed collection of partially ordered sets, and \(I\) also has a well ordering. We will put a lexicographic ordering on \(\prod_{i \in I} X_i\). Use the symbol \(\preceq\) for all the partial orders on \(I\) and the \(X_i\)'s, and write \(x < y\) if \(x \preceq y\) and \(x \neq y\).
(a) If \(x = (x_i)\) and \(y = (y_i)\) are elements of \(\prod X_i\), and \(x \neq y\), then \(\{i \in I : x_i \neq y_i\}\) is nonempty, hence has a smallest element \(i_0\). Let \(x \preceq y\) if \(x_{i_0} \preceq y_{i_0}\). Show that \(\preceq\) is a partial order on \(\prod X_i\).
(b) \(\prod X_i\) is totally ordered if and only if each \(X_i\) is totally ordered.
(c) If each \(X_i\) is well-ordered, is \(\prod X_i\) well-ordered?
(d) Discuss the difficulties in trying to define a lexicographic ordering if \(I\) is not well-ordered.

II.4.3.5. Explain why ordinary induction is a special case of complete induction.

The next three problems give an alternate proof of Theorem II.4.2.19 not using transfinite induction.

II.4.3.6. Let \((I, \preceq)\) be a well-ordered set, and \(f : I \to I\) an injective order-preserving function. Prove directly from the definition of a well-ordered set that \(f(i) \geq i\) for all \(i \in I\). [If not, let \(i_0\) be the smallest \(i\) for which \(f(i) < i\), and set \(j = f(i_0)\). Show that \(f(j) < j\).]

142
II.4.3.7. (a) Let \((I, \leq)\) be a well-ordered set. Then the only order-isomorphism from \(I\) onto an initial segment of \(I\) is the identity map on \(I\). [If \(f\) is such an order-isomorphism, then \(f(i) \geq i\) for all \(i\) by II.8.4.2.]

Let \(i_0\) be the smallest \(i\) with \(f(i) > i\), and let \(j \in I\) with \(f(j) = i_0\). Show \(j < i_0\) and \(f(j) > j\].

(b) Let \((I, \preceq)\) and \((J, \leq)\) be well-ordered sets. Then there is at most one order-isomorphism from \(I\) to \(J\).

II.4.3.8. Let \((I, \preceq)\) and \((J, \leq)\) be well-ordered sets. If \(u \in I\), write \(I_u = \{i \in I : i < u\}\). Also, if \(X\) and \(Y\) are partially ordered sets, write \(X \sim Y\) if \(X\) and \(Y\) are order-isomorphic. Define

\[
\Gamma = \{(u, v) \in I \times J : I_u \sim J_v\}.
\]

Show that \(\Gamma\) (or \(\Gamma^{-1}\)) is the graph of an order-isomorphism from an initial segment of \(I\) onto \(J\) (or an order-isomorphism from an initial segment of \(J\) onto \(I\)), as follows:

(a) Let \(I_0 = \{u \in I : \exists v \in J : (u, v) \in \Gamma\}\), \(J_0 = \{v \in J : \exists u \in I : (u, v) \in \Gamma\}\)

(i.e. \(I_0\) and \(J_0\) are the domain and range of the relation \(\Gamma\)) Show that \(I_0\) and \(J_0\) are initial segments of \(I\) and \(J\) respectively. [If \((u_0, v_0) \in \Gamma\) and \(f : I_{u_0} \to J_{v_0}\) is an order-isomorphism, and \(u \leq u_0\), \(v \leq v_0\), restrict \(f\) and \(f^{-1}\) to \(I_u\) and \(J_v\).]

(b) Show that \(\Gamma\) is the graph of a one-to-one function \(\phi\) from \(I_0\) to \(J_0\). [Suppose \(u \in I\), \(v_1, v_2 \in J\), \(v_1 \leq v_2\), and \((u, v_1), (u, v_2) \in \Gamma\). Let \(f : I_u \to J_{v_1}\) and \(g : I_u \to J_{v_2}\) be order-isomorphisms. Then \(f \circ g^{-1}\) is an order-isomorphism from the well-ordered set \(J_{v_2}\) onto its initial segment \(J_{v_1}\), so \(v_1 = v_2\) (and \(f = g\) by II.4.3.7..]

(c) Show that \(\phi\) is an order-isomorphism from \(I_0\) onto \(J_0\). [Suppose \((u_1, v_1)\) and \((u_2, v_2)\) are in \(\Gamma\) and \(u_1 < u_2\), and \(f : I_{u_1} \to J_{v_1}\) and \(g : I_{u_2} \to J_{v_2}\) are order-isomorphisms. If \(v_1 > v_2\), then \(h = g \circ f^{-1}\) is an injective order-preserving function from \(J_{v_1}\) to \(J_{v_2}\) \(\subseteq J_{v_1}\) with \(h(v_2) < v_2\), contradicting II.8.4.2..]

(d) Show that either \(I_0 = I\) or \(J_0 = J\). [If not, let \(u_0\) be the smallest element of \(I \setminus I_0\) and \(v_0\) the smallest element of \(J \setminus J_0\). Then \(I_0 = I_{u_0}\), \(J_0 = J_{v_0}\), and \(\phi\) gives an order-isomorphism from \(I_{u_0}\) to \(J_{v_0}\), so \((u_0, v_0) \in \Gamma\).]

(e) The function \(\phi\) gives the unique order-isomorphism from \(I_0\) to \(J_0\) by II.4.3.7..
II.4.4. Directed Sets

There is another kind of “ordered” set which is important, especially in topology. In many instances, one only needs to have a notion of “sufficiently large” elements of an “ordered” set. This notion is made precise in a useful way in directed sets.

II.4.4.1. Definition. Let \( X \) be a nonempty set. A direction on \( X \) is a transitive relation (preorder) \( \leq \) with the property that any two elements of \( X \) have an upper bound, i.e. for any \( a, b \in X \) there is a \( c \in X \) with \( a \leq c \) and \( b \leq c \). A directed set is a pair \((X, \leq)\) where \( X \) is a nonempty set and \( \leq \) is a direction on \( X \). A direction \( \leq \) on a set \( X \) is proper if for every \( a \in X \) there is a \( c \in X \) with \( a \leq c \) and \( c \not\leq a \).

II.4.4.2. Note that a direction on a set does not have to be a partial order, i.e. a direction does not have to be antisymmetric; however, many important directions are partial orders, and there is no essential loss of generality in requiring that the preorder be a partial order (II.4.4.1.), although there is a loss of utility in applications.

A direction is also often required to be reflexive, but this is unnecessary (and can be easily arranged anyway; see Exercise II.4.5.1.). In the definition, \( a \) and \( b \) do not have to be distinct, i.e. in a directed set \( X \), for any \( a \in X \) there is a \( c \in X \) with \( a \leq c \). A directed set in the sense of II.4.4.1. is sometimes called upward directed. Downward directed sets can also be defined, but we will not work with them in this book.

II.4.4.3. Examples. (i) Any totally ordered set is a directed set (provided the “largest” element \( a \), if there is one, satisfies \( a \leq a \)). The ordering is a proper direction if and only if there is no largest element. In particular, \( \mathbb{N} \) is properly directed in the usual order.

(ii) More generally, any lattice is a directed set. In particular, the power set of any set \( X \) is directed by inclusion, as is the collection of finite subsets of \( X \); the latter is a properly directed set if \( X \) is infinite.

(iii) Any partially ordered set with a largest element is directed but not properly directed. These sets are not very interesting as directed sets; the interesting directed sets are ones with no maximal elements, since the most important feature of a directed set is its “tails.” A partially ordered and directed set is properly directed if and only if it has no maximal elements.

(iv) A set with the full relation (\( x \leq y \) for all \( x \) and \( y \)) is a directed set which is not partially ordered.

(v) The equality relation on a set with more than one element is a partial order which is not a direction.

(vi) The partially ordered set of (\( \emptyset \)) is not directed.

(vii) Here is a very important example from topology. Let \( X \) be a topological space and \( p \in X \). Let \( \mathcal{N}_p \) be the set of all neighborhoods of \( p \). If \( U, V \in \mathcal{N}_p \), let \( V \subseteq U \) if \( U \subseteq V \). Then \( \mathcal{N}_p \) is a directed set with this ordering. \( \mathcal{N}_p \) can be replaced here by the set of open neighborhoods of \( p \), or by any local base for the topology at \( p \). There are other variations, such as setting \( V \leq U \) if the closure of \( U \) is contained in \( V \) (if \( X \) is a regular space).

(viii) As a variation of (vii), let \( X \) be a set and \( \mathcal{F} \) be a filter (\( \emptyset \)) of subsets of \( X \). If \( A, B \in \mathcal{F} \), set \( A \leq B \) if \( B \subseteq A \). Then \((\mathcal{F}, \leq)\) is a directed set.

(ix) If \((X, \leq)\) is a directed set, a subset \( Y \) of \( X \) is cofinal in \( X \) if for every \( x \in X \) there is a \( y \in Y \) with \( x \leq y \). A cofinal subset of a directed set is directed in the induced preorder.
II.4.4.4. **Proposition.** Let \((X, \leq)\) be a directed set. Then any finite subset of \(X\) has an upper bound, i.e. for any finite subset \(\{a_1, \ldots, a_n\}\) of \(X\), there is a \(c \in X\) with \(a_k \leq c\) for all \(1 \leq k \leq n\).

**Proof:** The \(c\) (or, more accurately, a \(c\) that works – the \(c\) will not be unique in general) can be found iteratively: let \(c_2\) be an upper bound for \(a_1\) and \(a_2\), \(c_3\) an upper bound for \(c_2\) and \(a_3\), \ldots, \(c\) an upper bound for \(c_{n-1}\) and \(a_n\). (This argument should really be done more carefully by induction.)

II.4.4.5. **Proposition.** Let \(\leq\) be a direction on a set \(X\). Then \(\leq\) is proper if and only if there is no largest element (an element \(a\) is a largest element if \(x \leq a\) for all \(x \in X\)).

**Proof:** If there is a largest element, then \(\leq\) is obviously not proper. Suppose there is no largest element. If \(a \in X\), then there is a \(b \in X\) such that \(b \not\leq a\). Let \(c\) be an upper bound for \(\{a, b\}\). Then \(a \leq c\). If \(c \leq a\), then since \(b \leq c\) we get \(b \leq a\) by transitivity, a contradiction. Thus \(c \not\leq a\) and \(\leq\) is proper.

We also need the notion of a direction-preserving function between directed sets:

II.4.4.6. **Definition.** Let \((X, \leq)\) and \((Y, \preceq)\) be directed sets. A function \(f : X \to Y\) is directed if, for every \(b \in Y\), there is an \(a \in X\) such that \(b \preceq f(a)\) for all \(a \in X\) with \(a \leq x\).

The condition in the definition is sometimes called the cofinal condition.

II.4.4.7. **Note** that for \(f\) to be directed, it is neither necessary nor sufficient that \(f\) be order-preserving. For example, the function from \(\mathbb{N}\) to \(\mathbb{N}\) which interchanges \(2n - 1\) and \(2n\) for each \(n\) is directed but not order-preserving. In fact, any bijection from \(\mathbb{N}\) to \(\mathbb{N}\) is directed (II.4.5.2.). But a constant function from \(\mathbb{N}\) to \(\mathbb{N}\) is not directed, even though it is order-preserving. There are even injective order-preserving functions which are not directed: the inclusion of \(\mathbb{N}\) into \(\mathbb{N} \cup \{+\infty\}\) is an example. Directed functions are “almost order-preserving” (Exercise II.4.5.3.).

Directed functions preserve “tails” or “cofinality” and thus are the appropriate maps between directed sets. In particular, the inclusion of a subset \(Y\) of \(X\) into \(X\) is a directed function if and only if \(Y\) is cofinal (II.4.3.(ix)) in \(X\).

The next result is easily verified:

II.4.4.8. **Proposition.** A composition of directed functions is directed.

II.4.4.9. **Definition.** Let \((X, \leq)\) and \((Y, \preceq)\) be directed sets. A function \(f : X \to Y\) is a directed equivalence if \(f\) is a bijection and \(f\) and \(f^{-1}\) are directed. \((X, \leq)\) and \((Y, \preceq)\) are directed equivalent if there is a directed equivalence from \(X\) to \(Y\). Two directions \(\leq\) and \(\preceq\) on a set \(X\) are equivalent if the identity map from \((X, \leq)\) to \((X, \preceq)\) is a directed equivalence.
II.4.4.10. The directed sets and directed functions form a category (\(\mathcal{D}\)), and the directed equivalences are just the isomorphisms in this category.

A largest element in a partially ordered set, if there is one, is unique; but a largest element in a directed set is not necessarily unique (if \(X\) has the full relation, then every element of \(X\) is a largest element.) The directions equivalent to partially ordered directions are precisely the ones for which this does not happen:

II.4.4.11. Theorem. Let \(\leq\) be a direction on a set \(X\). Then there is an equivalent direction \(\preceq\) on \(X\) which is a reflexive partial order if and only if there is at most one largest element for \(\preceq\). In particular, if \(\leq\) is proper, there is an equivalent proper direction which is a reflexive partial order.

Proof: Suppose \(b\) and \(c\) are largest elements of \(X\), and suppose there is a direction \(\leq\) equivalent to \(\preceq\) which is a partial order. Let \(a\in X\) such that \(a\leq x\) implies \(b\leq x\). Applying this with \(x=c\), we obtain \(b\leq c\). A similar argument shows that \(c\leq b\), so \(b=c\) since \(\leq\) is a partial order. Thus \((X,\leq)\) cannot have more than one largest element.

Suppose \(\leq\) has exactly one largest element \(c\). Define \(\preceq\) by \(x\preceq y\) if \(x=y\) or \(y=c\). Then \(\preceq\) is a direction on \(X\) which is a reflexive partial order. To show that \(\preceq\) is equivalent to \(\leq\), we need that for every \(b\in X\) there is an \(a\in X\) such that \(a\leq x\) implies \(b\leq x\), and for any \(a\in X\) there is a \(b\in X\) such that \(b\leq x\) implies \(a\leq x\). Just take \(a=c\) in the first case and \(b=c\) in the second.

Now suppose \(\leq\) is proper, i.e. there are no largest elements. Define \(\preceq\) by setting \(x\preceq y\) if \(x=y\) or if \(x\neq y\), \(x\leq\), and \(y\neq x\). It is obvious that \(\preceq\) is reflexive and antisymmetric. To see that \(\preceq\) is transitive, suppose \(x\leq y\) and \(y\leq z\). If \(x=z\), then \(x\leq z\). Suppose \(x\neq z\). If \(x=y\) or \(y=z\), it is trivial that \(x\leq z\), so we may assume \(x, y, z\) are all distinct. Then \(x\leq y\) and \(y\leq z\), so \(x\leq z\). If \(z\leq x\), then \(z\leq y\) by transitivity; but \(y\neq z\) and \(y\leq z\), so \(z\neq y\), a contradiction. Thus \(z\neq x\) and \(x\leq z\).

To show that \(\preceq\) is equivalent to \(\leq\), let \(a, b\in X\). Take \(c\in X\) with \(a\leq c\) and \(b\leq c\), and take \(d\in X\) with \(c\leq d\) and \(d\not\leq c\). We have \(d\neq a\) and \(d\neq b\), and \(a\leq d\) and \(b\leq d\) by transitivity. If \(d\leq a\), we would have \(d\leq c\) by transitivity, a contradiction; thus \(d\not\leq a\), i.e. \(a\leq d\). Similarly \(b\leq d\).

Finally, to show that \(\preceq\) is equivalent to \(\leq\), let \(b\in X\). We must find \(a\in X\) such that \(a\leq x\) implies \(b\leq x\). Let \(a\in X\) with \(b\leq a\) and \(a\not\leq b\). If \(a\leq x\), then either \(a=x\) or \(a\leq x\); in either case \(b\leq x\). Conversely, let \(a\in X\). We must find \(b\in X\) such that \(b\leq x\) implies \(a\leq x\). Take \(b\in X\) with \(a\leq b\) and \(b\not\leq a\). If \(x\in X\) and \(b\leq x\), then \(x\neq a\) and \(a\leq x\) by transitivity. If \(x\leq a\), then \(b\leq a\) by transitivity, a contradiction, so \(x\not\leq a\) and \(a\leq x\).

Note that no form of Choice is needed for this result (rephrase the last two paragraphs as proofs by contradiction; a contradiction can be obtained by making only finitely many choices).

II.4.5. Exercises

II.4.5.1. Let \(\preceq\) be a direction on a set \(X\). Define \(\preceq\) on \(X\) by \(a\preceq b\) if \(a\preceq b\) or \(a=b\). Show that \(\preceq\) is a reflexive direction on \(X\) which is equivalent to \(\preceq\).

II.4.5.2. (a) Show that a function \(f: \mathbb{N} \to \mathbb{N}\) is directed (for the usual order) if and only if \(f^{-1}\{\{n\}\}\) is finite for every \(n\in \mathbb{N}\).

(b) Show that every bijection from \(\mathbb{N}\) to \(\mathbb{N}\) is a directed equivalence.
II.4.5.3. Let \((X, \leq)\) and \((Y, \preceq)\) be directed sets, and \(f : X \to Y\) a directed function. Show that there is a direction \(\leq\) on \(X\) which is equivalent to \(\leq\), for which \(f\) is order-preserving. [Set \(a \leq b\) if \(a \leq b\) and \(f(a) \preceq f(b)\).]

II.4.5.4. Let \((X, \leq)\) and \((Y, \preceq)\) be directed sets. On \(X \times Y\), define \((x_1, y_1) \leq (x_2, y_2)\) if \(x_1 \leq x_2\) and \(y_1 \preceq y_2\). Show that \(\leq\) is a direction on \(X \times Y\), and that the coordinate projections are directed functions. Generalize to arbitrary Cartesian products of directed sets (the Axiom of Choice is needed in the general case).

II.4.5.5. There are interesting countable directed sets other than \(\mathbb{N}\) with the usual ordering. Define a relation \(\lessdot\) on \(\mathbb{N}\) by setting \(n \lessdot m\) if \(n|m\).

(a) Show that \(\lessdot\) is a partial order and a proper direction on \(\mathbb{N}\).
(b) Show that \((n!)\) is a subsequence of \((\mathbb{N}, \lessdot)\), i.e. is cofinal.
(c) Show that the sequence of prime numbers is not a subsequence of \((\mathbb{N}, \lessdot)\).
(d) Show that \(\lessdot\) is not equivalent to the ordinary order \(\leq\) on \(\mathbb{N}\).
(e) Can \((\mathbb{N}, \lessdot)\) be written as an infinite product (cf. II.4.5.4.) of copies of \((\mathbb{N}, \leq)\)?
II.5. Cardinality of Sets

“The infinite! No other question has ever moved so profoundly the spirit of man; no other idea has so fruitfully stimulated his intellect; yet no other concept stands in greater need of clarification than that of the infinite.”

David Hilbert

“The rather colorless idea of a collection of elements that had lurked in the background of mathematical thought since prehistory might have remained there to this day if Cantor had not had the audacity to assume that they could be infinite. This was the bold and revolutionary hypothesis that launched modern mathematics; it should be seen as nothing less.”

Penelope Maddy

One of the great mathematical advances of the late nineteenth century was Cantor’s discovery, as part of his pioneering systematic study of infinite sets, that there are different “sizes” of infinite sets. Cantor’s ideas were only gradually accepted by mathematicians, but eventually became one of the foundational cornerstones of modern analysis.

II.5.1. Cardinality

The term cardinality is used to denote the “size” of sets. This notion is most interesting and important for infinite sets; for finite sets it reduces to the “number of elements” in the set. While it is not essential for an analyst to have a detailed knowledge of the theory of cardinality, it is crucial to understand the most basic aspects of the theory: the distinction between finite and infinite sets, and between countable and uncountable sets. In this section, we will develop only enough of the general theory to establish what we need in analysis; a more complete treatment of the theory is in ( ).

The underlying idea is quite straightforward: two sets are the “same size” if there is a one-to-one correspondence (bijective function) between them.

II.5.1.1. Definition. Let $X$ and $Y$ be sets. $X$ and $Y$ have the same cardinality, or are equipotent (or equipollent), written $\text{card}(X) = \text{card}(Y)$ or $|X| = |Y|$, if there is a bijective function from $X$ to $Y$. We say $\text{card}(X) \leq \text{card}(Y)$ if $X$ is equipotent with a subset of $Y$, i.e. if there is an injective function from $X$ to $Y$. Write $\text{card}(X) < \text{card}(Y)$ if $\text{card}(X) \leq \text{card}(Y)$ and $\text{card}(X) \neq \text{card}(Y)$.

Note that we do not actually say what $\text{card}(X)$ is; we only use the term in comparing two sets. A definition of a cardinality (cardinal number) is given in ( ). Later in this section we will use particular symbols to denote the cardinality of certain standard sets, but even then no intrinsic meaning need be assigned to the cardinalities involved.

“Mathematicians are not interested in the nature of their objects ... or in their metaphysical character. What matters are the relations and operations applying to the objects ... just as chess players are not interested in what a bishop 'is' but in how it performs.”

A. Fraenkel
II.5.2. Finite and Infinite Sets

“The notion of infinity is our greatest friend; it is also the greatest enemy of our peace of mind.”

James Pierpont

“The infinite in mathematics is always unruly unless it is properly treated.”

Edward Kasner and James Newman

Infinite sets have some unusual properties which could be considered paradoxical, but with sufficient familiarity one can work with them comfortably; an analyst must develop a comfort level with them. One important feature of infinite sets is that they contain proper subsets which are as “large” as the whole set. For example, \( \mathbb{N} \) can be written as the disjoint union of the even and odd natural numbers. Each of these sets is intuitively only “half” of \( \mathbb{N} \), but on the other hand they are both actually equipotent with \( \mathbb{N} \): the functions \( f(n) = 2n \) and \( g(n) = 2n - 1 \) give bijections from \( \mathbb{N} \) onto the even and odd numbers, respectively. (The oldest surviving printed record of this observation is due to Galileo, although it would be a little surprising if it was not known in ancient Greece.)

This phenomenon cannot occur in a finite set. Intuitively, a finite set is one which can be “counted.” There are thus two standard ways of defining finite sets:

II.5.2.1. Definition. Let \( X \) be a set.

(i) \( X \) is finite if \( X = \emptyset \) or \( \text{card}(X) = \text{card}(\{m \in \mathbb{N} : 1 \leq m \leq n\}) \) for some \( n \in \mathbb{N} \). In the latter case, we say \( \text{card}(X) = n \); and \( \text{card}(\emptyset) = 0 \).

(ii) \( X \) is Dedekind-finite if it is not equipotent with any proper subset of itself.

II.5.2.2. We can show (II.5.2.3.) that the two conditions are equivalent (technically, we must assume some version of the Axiom of Choice; the Countable AC suffices). A set which is not finite (in sense (i)) is called infinite. A set which is equipotent with a finite [infinite] set is finite [infinite]. It is intuitively obvious that any subset of a finite set is finite (see Exercise () for a proof); and hence any set which has an infinite subset is infinite.

We now carefully state the equivalence between the two definitions of a finite set. It is convenient to phrase the equivalence for infinite sets rather than for finite sets; the statement can be easily converted into the equivalence for finite sets.

II.5.2.3. Proposition. Let \( X \) be a set. Then the following are equivalent:

(i) \( X \) is infinite.

(ii) There is an injective function from \( X \) to \( X \) which is not surjective (i.e. \( X \) is not Dedekind-finite).

(iii) There is a surjective function from \( X \) to \( X \) which is not injective.

The proof, which uses II.5.2.5. below, is left to the exercises. The implication (ii) \( \Rightarrow \) (i) is Exercise ()(c), (iii) \( \Rightarrow \) (i) is Exercise ()(e), and (i) \( \Rightarrow \) (ii) and (i) \( \Rightarrow \) (iii) are Exercise ()

149
II.5.2.4. The most obvious and important example of an infinite set is \( \mathbb{N} \). (It is a fundamental property of \( \mathbb{N} \) that it is not equipotent with \( \{1, \ldots, n\} \) for any \( n \). Although this seems obvious, it must in fact be proved; see Exercise (.) \( \mathbb{N} \) is the “smallest” infinite set in the following sense:

II.5.2.5. **Proposition.** Let \( X \) be a set. Then \( X \) is infinite if and only if \( X \) has a subset equipotent with \( \mathbb{N} \), i.e. if and only if there is an injective function from \( \mathbb{N} \) to \( X \) (or, in other words, a sequence of distinct elements in \( X \)).

**Proof:** If there is an injective function from \( \mathbb{N} \) to \( X \), then \( X \) is infinite. Conversely, suppose \( X \) is infinite. We will use an inductive procedure to define an injective function \( f : \mathbb{N} \to X \). Let \( f(1) \) be any element of \( X \) (\( X \neq \emptyset \) since \( X \) is infinite.) Suppose \( f(1), \ldots, f(n) \) have been defined to all be distinct. \( X \setminus \{f(1), \ldots, f(n)\} \neq \emptyset \), since otherwise \( X \) would be equipotent with \( \{1, \ldots, n\} \) and thus finite. So choose \( f(n+1) \) to be any element of \( X \setminus \{f(1), \ldots, f(n)\} \) (the Axiom of Choice, or at least the Axiom of Dependent Choice, is needed to do this properly; in fact, the result depends on the Countable AC – see Exercises II.5.6.14. and II.6.4.9.) \( \Box \)

Another Approach

We describe an alternate approach to finite sets which does not presuppose the availability of \( \mathbb{N} \). This approach is perhaps less satisfying since it does not really specify what finite sets are, but it avoids certain circularities in definitions. It can be shown (II.5.6.16.) that the sets which are finite according to this definition are precisely the sets which are finite according to Definition II.5.2.1. This approach was first taken by Sierpiński [].

The following definition is quite reminiscent of Peano’s axiom P5 (III.2.2.1.).

II.5.2.6. **Definition.** If \( X \) is a set, the **finite subsets** of \( X \) are the elements of the smallest subset \( \mathcal{F}(X) \) of \( \mathcal{P}(X) \) satisfying:

(i) \( \emptyset \in \mathcal{F}(X) \).

(ii) \( \{x\} \in \mathcal{F}(X) \) for all \( x \in X \).

(iii) If \( A, B \in \mathcal{F}(X) \), then \( A \cup B \in \mathcal{F}(X) \).

\( X \) is a **finite set** if \( X \in \mathcal{F}(X) \).

For any \( X \), there is such a smallest subset \( \mathcal{F}(X) \) of \( \mathcal{P}(X) \), the intersection of all subsets of \( \mathcal{P}(X) \) satisfying (i)–(iii) (this is well defined within ZF set theory).

II.5.2.7. **Proposition.** Let \( Y \subseteq X \). Then \( \mathcal{F}(Y) = \{A \cap Y : A \in \mathcal{F}(X)\} \).

**Proof:** Let \( \mathcal{S} = \{A \cap Y : A \in \mathcal{F}(X)\} \subseteq \mathcal{P}(Y) \). Then it is easily checked that \( \mathcal{S} \) satisfies (i)–(iii) (with \( X \) replaced by \( Y \)), and hence \( \mathcal{F}(Y) \subseteq \mathcal{S} \). On the other hand, set

\[
\mathcal{T} = \{A \cup B : A \in \mathcal{F}(Y), B \in \mathcal{F}(X \setminus Y)\} \subseteq \mathcal{P}(X) .
\]

It is again easily checked that \( \mathcal{T} \) satisfies (i)–(iii), and hence \( \mathcal{F}(X) \subseteq \mathcal{T} \). If \( C \in \mathcal{P}(X) \), then \( C \) can be uniquely written as \( A \cup B \) with \( A \in \mathcal{P}(Y) \) and \( B \in \mathcal{P}(X \setminus Y) \), namely \( A = C \cap Y \) and \( B = C \cap (X \setminus Y) \); if \( C \in \mathcal{F}(X) \), then \( C \in \mathcal{T} \), and hence \( A = C \cap Y \in \mathcal{F}(Y) \). Thus \( \mathcal{S} \subseteq \mathcal{F}(Y) \). \( \Box \)
II.5.2.8. Proposition. If $A \in \mathcal{F}(X)$ and $B \subseteq A$, then $B \in \mathcal{F}(X)$. In particular, every subset of a finite set is finite.

Proof: Let $\mathcal{S} = \{A \in \mathcal{P}(X) : B \in \mathcal{F}(X) \text{ for all } B \subseteq A\}$. Then $\mathcal{S} \subseteq \mathcal{F}(X)$. It is easily checked that $\mathcal{S}$ satisfies (i)–(iii), so $\mathcal{F}(X) \subseteq \mathcal{S}$. 

II.5.2.9. Corollary. If $Y \subseteq X$, then $\mathcal{F}(Y) \subseteq \mathcal{F}(X)$, i.e. every subset of $Y$ which is a finite subset of $Y$ is a finite subset of $X$.

Proof: Let $B \in \mathcal{F}(Y)$. Then $B = Y \cap A$ for some $A \in \mathcal{F}(X)$. Thus $B \subseteq A$, so $B \in \mathcal{F}(X)$. 

II.5.2.10. Corollary. If $Y \subseteq X$, then $\mathcal{F}(X) = \{A \cup B : A \in \mathcal{F}(Y), B \in \mathcal{F}(X \setminus Y)\}$.

Proof: Set $\mathcal{T} = \{A \cup B : A \in \mathcal{F}(Y), B \in \mathcal{F}(X \setminus Y)\}$. The proof of II.5.2.7. shows that $\mathcal{F}(X) \subseteq \mathcal{T}$. Conversely, $\mathcal{F}(Y)$ and $\mathcal{F}(X \setminus Y)$ are contained in $\mathcal{F}(X)$ by II.5.2.9., and hence $\mathcal{T} \subseteq \mathcal{F}(X)$ by property (iii).

II.5.2.11. Proposition. Let $X$ and $Y$ be sets and $f : X \to Y$ a function. If $A \in \mathcal{F}(X)$, then $f(A) \in \mathcal{F}(Y)$, i.e. the image of a finite set is finite.

Proof: Let $\mathcal{S} = \{B \subseteq X : f(B) \in \mathcal{F}(Y)\}$. Then it is easily checked that $\mathcal{S}$ satisfies (i)–(iii); hence $\mathcal{F}(X) \subseteq \mathcal{S}$. 

II.5.2.12. Proposition. Let $X$ be a totally ordered set. Then every nonempty finite subset of $X$ has a largest element and a smallest element.

Proof: Let $\mathcal{S}$ be the collection of subsets of $X$ consisting of $\emptyset$ and all nonempty subsets of $X$ which have a largest element and a smallest element. It is easily checked that $\mathcal{S}$ satisfies (i)–(iii). Thus $\mathcal{F}(X) \subseteq \mathcal{S}$. 

II.5.3. Countable and Uncountable Sets

Until the work of Cantor, it was commonly believed by mathematicians that all infinite sets (if such sets exist at all; some mathematicians, both before and after Cantor, rejected infinite sets entirely) were essentially the same (although even in ancient Greece a distinction was made between the “infinite” and the “infinitesimal”). But in fact there are sets which are not only infinite, but “very infinite” in the sense of having cardinality greater than $\text{card}(\mathbb{N})$. We explain this surprising fact in this section.
II.5.3.1. **Definition.** A set $X$ is *countable* if $\text{card}(X) \leq \text{card}(\mathbb{N})$. $X$ is *countably infinite* if $\text{card}(X) = \text{card}(\mathbb{N})$. A (necessarily infinite) set $X$ is *uncountable* if $\text{card}(X) > \text{card}(\mathbb{N})$.

A set $X$ is uncountable if there are “too many” elements in $X$ to list in a sequence, or in other words if any sequence in $X$ necessarily leaves out some elements of $X$. Any subset of a countable set is countable; thus if a set $X$ has an uncountable subset, then $X$ itself is uncountable.

II.5.3.2. The symbol $\aleph_0$, pronounced “aleph zero”, “aleph naught”, or “aleph null”, is commonly used to denote the cardinality of $\mathbb{N}$. ($\aleph$, “aleph”, is the first letter of the Hebrew alphabet.) Thus $X$ is countable if $X$ is finite or $\text{card}(X) = \aleph_0$.

It is not obvious that uncountable sets exist, but the following famous theorem of **Cantor** shows that they do exist in abundance:

II.5.3.3. **Theorem.** Let $X$ be any set. Then $\text{card}(\mathcal{P}(X)) > \text{card}(X)$.

**Proof:** It is easy to see that $\text{card}(X) \leq \text{card}(\mathcal{P}(X))$, since there is an obvious one-one correspondence between $X$ and the set of singleton subsets of $X$. So we need to show that $X$ and $\mathcal{P}(X)$ are not equipotent. Suppose $f$ is a function from $X$ to $\mathcal{P}(X)$; we will show that $f$ cannot be surjective, which will prove the theorem. If $x \in X$, then $f(x)$ is a subset of $X$, so it makes sense to ask whether $x \in f(x)$. Define

$$Y = \{x \in X : x \notin f(x)\} \subseteq X.$$ 

We claim there can be no $y \in X$ with $Y = f(y)$. Suppose there is; is $y \in Y$? If $y \in Y$, then $y \in f(y)$ since $Y = f(y)$ by assumption; but then $y \notin Y$ by definition of $Y$, a contradiction. Similarly, if $y \notin Y$, then $y \in f(y)$, so $y \in Y$, another contradiction. Thus the assumption that $Y = f(y)$ for some $y \in X$ necessarily leads to a contradiction, so there is no such $y$.

II.5.3.4. This proof was adapted by **Bertrand Russell** to establish his Paradox (II.5.6.13.) (Zermelo actually discovered this paradox before Russell, using a similar argument). A simple version of this paradox based on II.5.3.3. is the following: if there is a set $X$ of all sets, then every subset of $X$ is a set, hence a member of $X$; so $\mathcal{P}(X) \subseteq X$. But it is then easy to construct a surjective function from $X$ to $\mathcal{P}(X)$ (cf. II.5.4.1.), contradicting II.5.3.3.

A similar, but more sophisticated, type of “self-referential” argument was used by **Kurt Gödel** in his famous *Incompleteness Theorem* (see [?]) or [Ruc82] for mathematically accurate popular accounts of this theorem; for the full story see [Smm92].

II.5.3.5. **Corollary.** $\mathcal{P}(\mathbb{N})$ is an uncountable set.

Since $\text{card}(\mathcal{P}(\mathbb{N})) = \text{card}([0,1]^{\mathbb{N}})$, we obtain that there are uncountably many sequences of 0’s and 1’s. Because of this, the symbol $2^{\mathbb{N}}$ is often used for the cardinality of $\mathcal{P}(\mathbb{N})$ (the notation is explained in ). From this we can obtain a proof (see Exercise ) of the following theorem, which is one of the most important facts in analysis. We instead give a somewhat different proof, using a “diagonalization argument” of Cantor (the proof is not really different; see II.5.6.9. For another version of the same proof, see II.5.6.10.)
II.5.3.6. Theorem. \( \mathbb{R} \) is uncountable. In fact, every nonempty open interval in \( \mathbb{R} \) is uncountable.

Proof: It suffices to show that \([0,1)\) is uncountable, since every open interval contains a half-open subinterval, which is equipotent with \([0,1)\) via a linear function. Every number in \([0,1)\) has a unique decimal expansion

\[ a_1a_2a_3 \cdots \]

where \(0 \leq a_n \leq 9\) for each \(n\), which does not end in an infinite string of 9's.

Suppose we consider a sequence \((x_n)\) in \([0,1)\). We will construct an \(x \in [0,1)\) which is not equal to any \(x_n\); this will prove that \([0,1)\) is uncountable since no sequence can exhaust the set. Write \(x_n\) in its decimal expansion

\[ x_n = a_{n1}a_{n2}a_{n3} \cdots \]

not ending in a string of 9's, where \(a_{nm}\) is the \(m\)'th decimal digit of \(x_n\). Now for each \(n\) let \(b_n\) be a digit which is not 9 and which is different from \(a_{nn}\) (to be precise, we can let \(b_n = 0\) if \(a_{nn} \neq 0\) and \(b_n = 1\) if \(a_{nn} = 0\)), and set \(x = .b_1b_2b_3 \cdots\). Then, for any \(n\), \(x \neq x_n\) since it differs from \(x_n\) in at least the \(n\)'th decimal place.

II.5.3.7. The cardinality of \(\mathbb{R}\) is often called the cardinality of the continuum, denoted \(\mathfrak{c}\). In fact, \(\text{card}(\mathbb{R}) = \text{card}(\mathcal{P}(\mathbb{N}))\) (for \(\mathbb{N}\) being the set of natural numbers), so \(\mathfrak{c} = 2^{\aleph_0}\). Every nontrivial interval in \(\mathbb{R}\) also has cardinality \(\mathfrak{c}\) by Exercise ().

II.5.3.8. From Theorem II.5.3.3., it follows that not only are there uncountable sets, but there are uncountable sets of different sizes: for example, \(\text{card}(\mathcal{P}(\mathbb{R})) = \text{card}(\mathcal{P}(\mathcal{P}(\mathbb{N}))) > \text{card}(\mathcal{P}(\mathbb{N})) = 2^{\aleph_0}\) (i.e. \(\mathcal{P}(\mathbb{R})\) is "very uncountable.") The symbol \(2^\mathfrak{c}\) or \(2^{\aleph_0}\) is used for \(\text{card}(\mathcal{P}(\mathbb{R}))\). In fact, there is a never-ending hierarchy of infinite cardinalities:

\[ \text{card}(\mathbb{N}) < \text{card}(\mathbb{R}) < \text{card}(\mathcal{P}(\mathbb{R})) < \text{card}(\mathcal{P}(\mathcal{P}(\mathbb{R}))) < \text{card}(\mathcal{P}(\mathcal{P}(\mathcal{P}(\mathbb{R})))) < \cdots \]

and there is no "largest cardinality." (There are even cardinalities much larger than all the ones on this list!)

II.5.3.9. Note that II.5.3.3. is valid also in the case where \(X\) is a finite set. In this case, it amounts to the statement that \(2^n > n\) for every \(n \geq 0\).

II.5.4. Properties of Countable Sets

We will now analyze countable sets in more detail. We first establish a useful criterion for countability:

II.5.4.1. Proposition. Let \(X\) be a nonempty set. Then \(X\) is countable if and only if there is a surjective function from \(\mathbb{N}\) to \(X\).

Proof: First assume that \(X\) is countable. By definition, there is an injective function \(f : X \to \mathbb{N}\). Fix an \(x_0 \in X\), and let \(S = f(X) \subseteq \mathbb{N}\). Define a function \(g : \mathbb{N} \to X\) by \(g(n) = x\) if \(n \in S\) and \(f(x) = n\) (this is well defined since \(f\) is injective), and set \(g(n) = x_0\) if \(n \notin S\). Then \(g\) is a surjective function from \(\mathbb{N}\) to \(X\).

Conversely, suppose \(g : \mathbb{N} \to X\) is a surjective function. For each \(x \in X\), let \(f(x)\) be the smallest number in \(g^{-1}(\{x\})\). Then \(f\) is an injective function from \(X\) to \(\mathbb{N}\), so \(\text{card}(X) \leq \text{card}(\mathbb{N})\).
II.5.4.2. Corollary. If $X$ and $Y$ are sets and there is a surjective function $f : X \to Y$, and $X$ is countable, then $Y$ is countable.

It seems obvious that if $X$ is countable, then either $X$ is finite or $\text{card}(X) = \text{card}(\mathbb{N})$, and hence the term “countably infinite” means precisely “countable and infinite”; however, this takes a little proof:

II.5.4.3. Proposition. Let $X$ be a countable set. Then either $X$ is finite, or $\text{card}(X) = \text{card}(\mathbb{N})$.

This would seem to follow from II.5.2.5., which says that $\text{card}(\mathbb{N}) \leq \text{card}(X)$ if $X$ is infinite, and $\text{card}(X) \leq \text{card}(\mathbb{N})$ by definition if $X$ is countable. However, it is not obvious that these two inequalities together imply that $\text{card}(X) = \text{card}(\mathbb{N})$ (that is, that the “ordering” on cardinalities is antisymmetric.) This antisymmetry is true in general by the Schröder-Bernstein Theorem, but we can and will take a simpler approach in the countable case.

Proof: If $X = \emptyset$, the conclusion is true since $\emptyset$ is finite by definition. Assume $X$ is nonempty. By II.5.4.1., there is a surjective function $g : \mathbb{N} \to X$. Inductively define a function $f : X \to \mathbb{N}$ as follows. Let $x_1 = g(1)$, and set $f(x_1) = 1$. If $x_1, \ldots, x_n$ have been defined with $f(x_k) = k$ for $1 \leq k \leq n$, then either $X = \{x_1, \ldots, x_n\}$, in which case $X$ is finite, or $Y_n = X \setminus \{x_1, \ldots, x_n\} \neq \emptyset$. In the latter case, let $k$ be the smallest element of $\mathbb{N}$ with $g(k) \in Y_n$ (there is such a $k$ since $g$ is surjective.) Set $x_{n+1} = g(k)$ and $f(x_{n+1}) = k$. If this process terminates, then $X$ is finite; and if it never terminates, then $f$ is an injective function from $X$ onto $\mathbb{N}$. ✖️

Another useful fact is that $\mathbb{N}^2 = \mathbb{N} \times \mathbb{N}$ is equipotent with $\mathbb{N}$. This seems a little surprising, but is easily proved:

II.5.4.4. Proposition. $\mathbb{N}^2$ is equipotent with $\mathbb{N}$, and hence is countable (countably infinite.)

Proof: The function $(n, m) \mapsto 2^{n-1}(2m - 1)$ is a bijection from $\mathbb{N}^2$ to $\mathbb{N}$, as is easily checked using the unique factorization in $\mathbb{N}$. ✖️

II.5.4.5. Corollary. A Cartesian product of a finite number of countable sets is countable.

II.5.4.6. It is not true that a Cartesian product of a countable number of countable sets is countable; for example, $\{0, 1\}^\mathbb{N}$ is uncountable .

There are some other very important consequences of II.5.4.4.:

II.5.4.7. Corollary. $\mathbb{Z}$ and $\mathbb{Q}$ are countable.

Proof: To show that $\mathbb{Z}$ is countable, define a function $f : \mathbb{N}^2 \to \mathbb{Z}$ by $f(n, m) = (-1)^n(m - 1)$; then $f$ is surjective, so $\mathbb{Z}$ is countable by II.5.4.4. and II.5.4.2.. Thus $\mathbb{Z} \times \mathbb{N}$ is countable. Define $g : \mathbb{Z} \times \mathbb{N} \to \mathbb{Q}$ by $g(n, m) = n/m$, and apply II.5.4.2. again to conclude that $\mathbb{Q}$ is countable. ✖️
II.5.4.8. **Corollary.** A countable union of countable sets is countable. More precisely, let \( \{ X_i : i \in I \} \)
be an indexed collection of sets. If each \( X_i \) is countable and \( I \) is countable, then \( \bigcup_{i \in I} X_i \) is countable.

**Proof:** We may assume each \( X_i \) is nonempty by deleting the empty ones. For each \( i \) let \( f_i \) be a surjective function from \( \mathbb{N} \) onto \( X_i \). Then \( (i, n) \mapsto f_i(n) \) is a surjective function from \( I \times \mathbb{N} \) to \( \bigcup_{i \in I} X_i \). Apply II.5.4.5. and II.5.4.2. (This argument requires the Countable Axiom of Choice.)

There is also a version of these facts for the continuum:

II.5.4.9. **Proposition.**

(i) If \( X \) and \( Y \) have cardinality \( \leq 2^{\aleph_0} \), then \( \text{card}(X \times Y) \leq 2^{\aleph_0} \).

(ii) Let \( \{ X_i : i \in I \} \) be an indexed collection of sets. If \( \text{card}(X_i) \leq 2^{\aleph_0} \) for all \( i \) and \( \text{card}(I) \leq 2^{\aleph_0} \), then \( \text{card}(\bigcup_{i \in I} X_i) \leq 2^{\aleph_0} \).

**Proof:** It suffices to prove (i), since then (ii) follows as in the proof of II.5.4.8. (the full Axiom of Choice is needed). To prove (i), we need only show that \( \text{card}(\mathcal{P}(\mathbb{N}) \times \mathcal{P}(\mathbb{N})) = 2^{\aleph_0} \). But there is a bijective function from \( \mathcal{P}(\mathbb{N}) \times \mathcal{P}(\mathbb{N}) \) to \( \mathcal{P}(\mathbb{N}) \) given by \( (A, B) \mapsto f(A) \cup g(B) \), where \( f(n) = 2n \) and \( g(n) = 2n - 1 \) are bijections from \( \mathbb{N} \) onto the even and odd numbers.

This result is actually true for any infinite cardinal (\( \) (but depends on the Axiom of Choice).

**Countable Ordered Sets**

II.5.4.10. The ordered set \( \mathbb{Q} \) can be characterized by a few simple properties. \( \mathbb{Q} \) satisfies:

(i) \( \mathbb{Q} \) is countable.

(ii) \( \mathbb{Q} \) is totally ordered.

(iii) \( \mathbb{Q} \) has no largest or smallest element.

(iv) \( \mathbb{Q} \) has no consecutive elements: if \( a, b \in \mathbb{Q} \), \( a < b \), then there is a \( c \in \mathbb{Q} \) with \( a < c < b \).

Property (iv) is sometimes phrased by saying that the ordering on \( \mathbb{Q} \) is dense. This condition implies, by repeated application, that between any two elements of \( \mathbb{Q} \) there are actually infinitely many other elements.

It turns out that these conditions completely characterize \( \mathbb{Q} \) as an ordered set:
II.5.4.11. Theorem. Let \((X, \preceq)\) be a countable totally ordered set with no consecutive elements and no first or last element. Then \((X, \preceq)\) is order-isomorphic to \(Q\).

Proof: Let \((x_n : n \in N)\) be an enumeration of \(X\), and \((y_n : n \in N)\) an enumeration of \(Q\). We will inductively construct an order-isomorphism \(f\) of \(X\) onto \(Q\). Begin by defining \(f(x_1) = y_1\). Now suppose \(f\) has been defined on \(x_1, \ldots, x_n\) and possibly finitely many other \(x_i\), and \(y_1, \ldots, y_n\) are in the range of the part of \(f\) already defined. We will define \(f\) on \(x_{n+1}\) and possibly on another \(x_i\), so that \(y_{n+1}\) is in the range. Let \(X_n\) be the set of \(x_i\) for which \(f\) has already been defined, and \(Y_n = f(X_n)\).

First define \(f\) on \(x_{n+1}\). If \(x_{n+1} \in X_n\), \(f(x_{n+1})\) is already defined and we skip this step. Otherwise, note that either \(x_{n+1} \prec x_i\) for all \(x_i \in X_n\), or there is a largest \(x_i \in X_n\) with \(x_i \prec x_{n+1}\); let \(a\) be this \(x_i\). Similarly, either \(x_j \prec x_{n+1}\) for all \(x_j \in X_n\), or there is a smallest \(x_j\) with \(x_{n+1} \prec x_j\); let \(b\) be this \(x_j\). Let \(k\) be the smallest index for which \(y_k\) satisfies \(f(a) < y_k < f(b)\) (or \(y_k < f(b)\) if \(a\) is undefined, \(f(a) < y_k\) if \(b\) is undefined.) We automatically have \(y_k \notin Y_n\). Set \(f(x_{n+1}) = y_k\).

Then work backwards in a similar way for the other part of the inductive step. If \(y_{n+1}\) is already in the range of \(f\), skip this step. Otherwise, let \(c\) and \(d\) be the largest and smallest elements of the range of \(f\) (as defined so far) with \(c < y_{n+1} < d\) (either \(c\) or \(d\) may be undefined.) Then \(c = f(x_i)\) and \(d = f(x_j)\) for some \(i, j\). Let \(k\) be the smallest index for which \(x_i \prec x_k \prec x_j\); then \(f(x_k)\) is undefined and so we can define \(f(x_k) = y_{n+1}\).

It is easy to check that the \(f\) thus defined is a bijection and an order-isomorphism.

II.5.4.12. A similar argument shows that if \((X, \preceq)\) is a countable totally ordered set with no consecutive elements, but with a first or last element, then \((X, \preceq)\) is order-isomorphic to \(Q \cap [0, 1)\), \(Q \cap (0, 1]\), or \(Q \cap [0, 1]\).

II.5.4.13. Corollary. Every countable totally ordered set is order-isomorphic to a closed subset of \(Q\).

Proof: Let \((X, \preceq)\) be a countable totally ordered set. If \(x \in X\), define \(Y_x \subseteq Q\) by

- \(Y_x = \{0\}\) if \(x\) has no immediate predecessor or successor.
- \(Y_x = Q \cap (-\infty, 0]\) if \(x\) has an immediate predecessor but no immediate successor.
- \(Y_x = Q \cap [0, \infty)\) if \(x\) has an immediate successor but no immediate predecessor.
- \(Y_x = Q\) if \(x\) has an immediate predecessor and an immediate successor.

Let \(Z = \{(x, y) : y \in Y_x\} \subseteq X \times Q\). Give \(X \times Q\) the lexicographic ordering, and give \(Z\) the relative ordering. It is easily checked that \(Z\) with this ordering is countable, totally ordered, and has no consecutive elements or largest or smallest element. Thus \(Z\) is order-isomorphic to \(Q\). \((X, \preceq)\) is order-isomorphic to the subset \(X \times \{0\}\) of \(Z\). It is easy to check that if \((x_n)\) is an increasing sequence in \(X\) with supremum \(x\), then \((x, 0)\) is the supremum of \(((x_n, 0))\) in \(Z\) and conversely, and similarly for decreasing sequences, so \(X \times \{0\}\) is closed in \(Z \cong Q\) by (A).

Note that we could have simplified the argument to just consider \((X, \preceq) \cong X \times \{0\}\) as a subset of \(X \times Q\) with lexicographic ordering if we did not want to require that the image of \(X\) in \(Q\) is closed.
II.5.5. Additional Facts about Cardinality

There are three rather natural questions about cardinality which turn out to have interesting answers:

II.5.5.1. Questions.

(1) If $X$ and $Y$ are sets with $\text{card}(X) \leq \text{card}(Y)$ and $\text{card}(Y) \leq \text{card}(X)$, is $\text{card}(X) = \text{card}(Y)$, i.e. if each of $X$ and $Y$ can be put in bijective correspondence with a subset of the other, are $X$ and $Y$ equipotent? (Is the “ordering” on cardinalities a true partial order, i.e. antisymmetric?)

(2) If $X$ and $Y$ are sets, is it always true that $\text{card}(X) \leq \text{card}(Y)$ or $\text{card}(Y) \leq \text{card}(X)$, i.e. are any two sets comparable in size? (Is the partial ordering on cardinalities a total ordering?)

(3) Is $\mathfrak{c} = 2^{\aleph_0}$ the smallest cardinality larger than $\aleph_0$, i.e. if $X \subseteq \mathbb{R}$, is it true that either $X$ is countable or $\text{card}(X) = \text{card}(\mathbb{R})$? (The i.e. statement is only equivalent to the first statement if the answer to question (2) is yes for subsets of $\mathbb{R}$.)

It turns out that only question 1 has a definitive answer, given by the Schröder-Bernstein Theorem:

II.5.5.2. Theorem. Let $X$ and $Y$ be sets. If $\text{card}(X) \leq \text{card}(Y)$ and $\text{card}(Y) \leq \text{card}(X)$, then $\text{card}(X) = \text{card}(Y)$.

A proof is outlined in Exercise II.5.6.11. Actually, the commonly-used name “Schröder-Bernstein Theorem” is not really accurate, since the proof published by SCHRÖDER in 1898 was incorrect; the proof published by F. BERNE Stein the same year (he was 19 years old when he did it) was the first and only correct proof at that time and is the one still commonly used. The theorem is sometimes called the “Cantor-Bernstein Theorem” since CANTOR stated it in his book without proof; apparently CANTOR tried rather hard to prove it, without success. There are indications that DEDEKIND found a proof in the 1880’s, but never published it.

II.5.5.3. Question 2 turns out to be dependent on the Axiom of Choice, which is independent of the other (ZF) axioms of set theory. If the Axiom of Choice is assumed, as is usual in analysis, then a positive answer to question 2 can be obtained; see II.9.7.1.

II.5.5.4. The conclusion of Question 3, that $\mathfrak{c}$ is the smallest uncountable cardinality, is called the Continuum Hypothesis. This is also known to be independent of the other axioms of set theory, including the Axiom of Choice (ZFC), through work of KURT GÖDEL and PAUL COHEN. There is also a Generalized Continuum Hypothesis which is independent of ZFC.

II.5.6. Exercises

II.5.6.1. Let $f$ be an injective function from $\{1, \ldots, n\}$ to $\{1, \ldots, n\}$. Inductively define a function $g$ from an initial segment of $\mathbb{N}$ to $\{1, \ldots, n\}$ as follows. Let $k_1$ be the smallest element of $S = f(\{1, \ldots, n\})$, and set $g(1) = f^{-1}(k_1)$. Inductively let $k_{r+1}$ be the smallest element of $S \setminus \{k_1, \ldots, k_r\}$ if this set is nonempty, and $g(r+1) = f^{-1}(k_{r+1})$. 157
(a) Show that \( g \) is defined precisely on \( \{1, \ldots, n\} \), and that \( g \) maps \( \{1, \ldots, n\} \) bijectively to itself.
(b) Let \( h = f \circ g \). Show that \( h \) is an injective function from \( \{1, \ldots, n\} \) onto \( S \), and prove inductively that \( h \)
is increasing and \( h(k) \geq k \) for every \( k \in \{1, \ldots, n\} \).
(c) On the other hand, \( h(n) \leq n \) since \( S \subseteq \{1, \ldots, n\} \). Conclude that \( h(k) = k \) for every \( k \), and thus that \( h \)
is surjective, i.e. that \( f \) is surjective. [Show inductively that if \( h(k_0) > k_0 \) for some \( k_0 \), then \( h(k) > k \) for all \( k \).
(d) Use this to show that an injective function from a finite set to itself is surjective.
(c) A real or complex number is algebraic if it is a root of a nonzero polynomial with rational coefficients (which can be assumed to be integers by clearing denominators.) Show that the set of algebraic numbers is countable.

II.5.6.5. Let \( S \) be a subset of \( \{1, \ldots, n\} \). Define a function \( f \) from \( S \) to \( \mathbb{N} \) inductively by letting \( k_1 \) be the smallest element of \( S \) and setting \( f(k_1) = 1 \), and inductively letting \( k_{r+1} \) being the smallest element of \( S \setminus \{k_1, \ldots, k_r\} \) if this set is nonempty, and \( f(k_{r+1}) = r + 1 \).

(a) Prove by induction that \( f(k) \leq k \) for every \( k \in S \).
(b) Conclude that \( f(S) = \{1, \ldots, m\} \) for some \( m \leq n \), and hence that \( S \) is finite.
(c) Show that a subset of a finite set is finite.
(d) Show that if \( X \) and \( Y \) are finite sets with \( card(X) = n \) and \( card(Y) = m \) for some \( n, m \in \mathbb{N} \cup \{0\} \), then \( card(Y) \leq card(X) \) if and only if \( m \leq n \), so the “ordering” on cardinalities of finite sets is consistent with the ordering on \( \mathbb{N} \cup \{0\} \). In particular, if \( Y = X \), then \( m = n \), i.e. the cardinality of a finite set is a well-defined nonnegative integer.

II.5.6.6. Let \( X \) be an infinite set, and \( Y \) a countable set. Prove that \( card(X \cup Y) = card(X) \). [Use II.5.6.5.]

II.5.6.7. Show that the set of sequences in \( \mathbb{Q} \) with only finitely many nonzero terms is countable. [Use II.5.4.5. and II.5.4.8.]

II.5.6.8. (a) Prove that the set of polynomials with rational coefficients is countable. [Use Exercise II.5.6.5.]
(b) A real or complex number is algebraic if it is a root of a nonzero polynomial with rational coefficients (which can be assumed to be integers by clearing denominators.) Show that the set of algebraic numbers is countable.
(c) A real or complex number is transcendental if it is not algebraic. Prove that there exists a transcendental real number (and, in fact, the cardinality of the set of transcendental real numbers is \( \aleph_0 \) by Exercise II.5.6.4.)
II.5.6.7.  (a) Prove that any two bounded open intervals \((a,b)\) and \((c,d)\) in \(\mathbb{R}\) are equipotent by finding a bijection [consider linear functions.]
(b) Use the tangent function to show that \((-\frac{\pi}{2}, \frac{\pi}{2})\) is equipotent with \(\mathbb{R}\).
(c) Give two proofs that \(\text{card}([0,1]) = \text{card}([0,1]) = \text{card}([0,1])\), one using the Schröder-Bernstein Theorem and the other by directly finding bijections [use II.5.2.5.]
(d) Show that all intervals in \(\mathbb{R}\) have the same cardinality.

II.5.6.8.  (a) Define a function \(f : \{0,1\}^\mathbb{N} \to [0,1]\) by \(f(a_1,a_2,a_3,\ldots) = .a_1a_2a_3\ldots\), where the last expression is the decimal expansion of a number in \([0,1]\). Show that \(f\) is injective, and hence \(\text{card}([0,1]) \geq \text{card}(\{0,1\}^\mathbb{N}) = 2^{\aleph_0}\), so \([0,1]\) is uncountable.
(b) Define a function \(g : \mathbb{R} \to \{0,1\}^\mathbb{N}\) by \(g(x) = (a_1,a_2,\ldots)\), where \(x = .a_1a_2\ldots\) is the binary expansion of \(x\) not ending in a string of 1’s. Show that \(g\) is injective, and hence \(\text{card}([0,1]) \leq \text{card}([0,1]^\mathbb{N}) = 2^{\aleph_0}\).
(c) Apply the Schröder-Bernstein Theorem to conclude that \(\text{card}([0,1]) = 2^{\aleph_0}\).
(d) As an alternative to (c), \([0,1]^\mathbb{N}\setminus g([0,1])\) consists precisely of all sequences which are eventually 1. Show that this set is countable (see Exercise II.5.6.5.), and hence \(\text{card}([0,1]^\mathbb{N}) = \text{card}(g([0,1]) = \text{card}([0,1]) = \text{card}(\mathbb{R})\) by Exercises II.5.6.4. and II.5.6.7.

II.5.6.9.  Show that the proof of II.5.3.3. is really a diagonalization argument along the lines of the proof of II.5.3.6., as follows.
(a) Let \(X\) be a set, and \(f\) a function from \(X\) to \(\mathcal{P}(X)\). Define a subset \(Y\) of \(X\) as follows: for \(x \in X\), let \(x \in Y\) if and only if \(x \notin f(x)\).
(b) Show that \(Y\) is not in the range of \(f\), i.e. \(Y\) is not in the “list” \(\{f(x) : x \in X\}\) of subsets of \(X\) defined by \(f\), since for each \(x \in X\) the set \(Y\) differs from \(f(x)\) at least with regard to membership of \(x\) (i.e. for each \(x \in X\), \(x\) belongs to the symmetric difference \(Y \triangle f(x)\)).

II.5.6.10.  This exercise outlines a different proof that \(\mathbb{R}\) is uncountable, based on the Nested Intervals Theorem (). This was essentially CANTOR’s original proof. We show that \([0,1]\) is uncountable.
(a) Let \((x_n)\) be a sequence in \([0,1]\). We will show that there is an \(x \in [0,1]\) with \(x \neq x_n\) for all \(n\).
(b) Let \(I_0 = [0,1]\). Inductively define \(I_n\) as follows. Suppose \(I_n\) has been defined. Subdivide \(I_n\) into three closed subintervals \(I_{n,1}, I_{n,2}, I_{n,3}\) from left to right, of equal length \(3^{-(n-1)}\), meeting only at endpoints. Then there is at least one \(k\) with \(x_{n+1} \notin J_{n,k}\); let \(I_{n+1}\) be the leftmost such \(J_{n,k}\).
(c) Set \(S = \cap_{n=1}^{\infty} I_n\). Then \(S \neq \emptyset\) by the Nested Intervals Theorem. If \(x \in S\), then \(x \neq x_n\) for all \(n\). (Actually \(S = \{x\}\).)

II.5.6.11.  This exercise outlines a proof of the Schröder-Bernstein Theorem. Suppose \(X\) and \(Y\) are sets, and there are injective functions \(f : X \to Y\) and \(g : Y \to X\). We will construct a bijection \(h\) from \(X\) to \(Y\).
Let \(X_1 = X \setminus g(Y)\) and \(Y_1 = Y \setminus f(X)\), and inductively define \(X_{n+1} = g(Y_n)\) and \(Y_{n+1} = f(X_n)\).
(a) Prove by induction on \(n\) that the \(X_n\) are disjoint subsets of \(X\) and the \(Y_n\) are disjoint subsets of \(Y\).
(b) Let \(X_\infty = X \setminus (\cup_{n=1}^{\infty} X_n)\) and \(Y_\infty = Y \setminus (\cup_{n=1}^{\infty} Y_n)\). Show that \(f\) maps \(X_\infty\) onto \(Y_\infty\).
(c) Define \(h : X \to Y\) as follows. If \(x \in X_n\), \(n\) odd, or if \(x \in X_\infty\), let \(h(x) = f(x)\). If \(x \in X_n\), \(n\) even, let \(h(x) = g^{-1}(x)\). Show that \(h\) is a bijection from \(X\) to \(Y\).
II.5.6.12. Let $X$ be a set of cardinality $\kappa$. Assume that $\kappa^2 = \kappa \geq \aleph_0$ and that $X$ can be totally ordered. Fix a total order on $X$ and a one-one correspondence $\phi : X \to X^2$, and a one-to-one map $\psi : \mathbb{N} \to X$.

(a) Show that for $n > 2$, iteration of $\phi$ defines a one-one correspondence $\phi_n$ from $X$ to $X^n$. Let $\phi_2 = \phi$ and $\phi_1 : X \to X$ be the identity.
(b) Show that the $\phi_n$ define a one-one correspondence between $\mathbb{N} \times X$ and the disjoint union of the $X^n$.
(c) Use the fixed ordering on $X$ to identify the set of $n$-element subsets of $X$ with a subset of $X^n$. From (b) and (c) obtain a one-one correspondence between the set of finite subsets of $X$ and a subset of $\mathbb{N} \times X$. The function $\psi$ then gives a one-one correspondence between $\phi$ and a subset of $X^2$. Conclude that $|\Phi| \leq |X^2| = |X|$, so that $|\Phi| = |X|$ by the Schröder-Bernstein Theorem.

II.5.6.13. (Russell’s Paradox) This argument shows that there can be no such thing as the “set of all sets.”

(a) Say that a set $A$ is ordinary if $A$ is not a member of $A$. (Almost every set normally encountered in mathematics is an ordinary set by this definition.)
(b) Suppose $X$ is the set of all sets. Let $Y$ be the collection of all ordinary sets. Then $Y$ is a subset of $X$, hence a set. Is $Y$ an ordinary set?

II.5.6.14. Show without using any form of the Axiom of Choice that a set is Dedekind-finite if and only if it does not have any countably infinite subset. [One direction follows from II.5.2.3. Conversely, if there is an $f : X \to X$ which is injective but not surjective, fix $x \in X$ not in the range of $f$, and consider $x, f(x), f(f(x)), \ldots$. See Exercise II.6.4.9.]

II.5.6.15. (a) Show (without any form of AC) that if $X$ is any set, then there is a set $z$ with $z \notin X$.
[Use II.5.3.3. to show that $X \cap \mathcal{P}(X)$ is a proper subset of $\mathcal{P}(X)$.]
(b) Use (a) to give an alternate proof that there is no “set of all sets.”
(c) Show (without any form of AC) that if $X$ and $Y$ are sets, then there is a set $Y'$ which is equipotent with $Y$ and disjoint from $X$. [Let $z$ be a set which is not in $\mathcal{C}(X)$, and let $Y' = \{(z, y) : y \in Y\} = \{\{z\}, \{z, y\} : y \in Y\}$. If $x \in Y'$, then $z \in \mathcal{C}(x)$, but then $x \notin X$ by II.2.1.4.]

II.5.6.16. Show that a nonempty set $X$ is finite in the sense of II.5.2.6. if and only if $X$ is equipotent to $\{1, \ldots, n\}$ for some $n \in \mathbb{N}$. [Show that the set $\mathcal{S}$ of $\emptyset$ and all sets equipotent to $\{1, \ldots, n\}$ for some $n$ satisfies (i)–(iii). For the converse, see III.2.6.10.]
II.6. The Axiom of Choice and Zorn’s Lemma

If \( \{X_i : i \in I\} \) is an indexed collection of nonempty sets, it would seem obvious that we could pick an element out of each set; after all, isn’t this what is meant by saying that each \( X_i \) is nonempty? However, with more thought, although we can “obviously” choose an element out of any individual \( X_i \) (but see II.6.1.6.), it becomes less obvious that we could simultaneously choose an element out of each \( X_i \). In fact, it can be neither proved nor disproved in ordinary (ZF) set theory that this can always be done! Since it is very useful in analysis (and elsewhere in mathematics) to be able to make such selections, an additional axiom is usually added to set theory, called the Axiom of Choice; the expanded theory is called ZFC set theory.

II.6.1. The Axiom of Choice

II.6.1.1. Definition. Let \( \{X_i : i \in I\} \) be an indexed collection of (nonempty) sets. A choice function for \( \{X_i : i \in I\} \) is a function \( c : I \to \bigcup_{i \in I} X_i \) such that \( c(i) \in X_i \) for each \( i \).

If there is a choice function for \( \{X_i : i \in I\} \), then each \( X_i \) is obviously nonempty. The Axiom of Choice asserts the converse:

II.6.1.2. Axiom of Choice: (Indexed Form) If \( \{X_i : i \in I\} \) is an indexed collection (set) of nonempty sets, then there is a choice function for \( \{X_i : i \in I\} \).

The Axiom of Choice is often stated in a slightly different but equivalent form:

II.6.1.3. Axiom of Choice: (Power Set Form) If \( X \) is a nonempty set, there is a function (choice function) \( c : \mathcal{P}(X) \setminus \{\emptyset\} \to X \) with \( c(A) \in A \) for every nonempty \( A \subseteq X \).

II.6.1.4. To obtain the Power Set Form from the Indexed Form, set \( I = \mathcal{P}(X) \setminus \{\emptyset\} \), and set \( X_A = A \). Conversely, to obtain the Indexed Form from the Power Set Form, let \( \{X_i : i \in I\} \) be an indexed collection of nonempty sets, and set \( X = \bigcup_{i \in I} X_i \). Let \( c : \mathcal{P}(X) \setminus \{\emptyset\} \to X \) be a choice function for \( X \), and let \( h : I \to \mathcal{P}(X) \setminus \{\emptyset\} \) be defined by \( h(i) = X_i \). Then \( c \circ h \) is a choice function for \( \{X_i : i \in I\} \).

II.6.1.5. The Axiom of Choice (abbreviated AC) is often slightly misunderstood, and it is important to understand what it does not say. The AC is frequently stated somewhat informally as:

“If \( \{X_i\} \) is a collection of nonempty sets, you can choose (or simultaneously choose) an element out of each of the sets.”

This statement of the AC is not incorrect if properly interpreted, but it can be misleading. What the AC actually asserts is simply the existence of a choice function; it does not give any procedure for finding or describing one, or even assert that there is an explicit description of one (in fact, the AC is typically invoked precisely in situations where an explicit description of a choice function is not possible.)

---

8This statement is only true if ZF set theory is assumed to be consistent; consistency of ZF set theory remains unproved and is perhaps unprovable (it is unprovable within ZF.)
The distinction comes into sharpest focus when just one nonempty set $X$ is considered. One can ask two very different questions about $X$:

1. Does there exist an element (equivalently, a singleton subset) of $X$?

2. Can one find or identify an explicit element of $X$?

The answer to Question 1 is trivially yes: this is the very definition of the word “nonempty.” The Axiom of Choice in this setting simply asserts a positive answer to Question 1; thus the AC is trivially true for a collection consisting of one nonempty set. (It is also true, only slightly less trivially, for a collection of a finite number of nonempty sets.) But Question 2 is definitely nontrivial, and is more of a philosophical than a mathematical question. For example, suppose one proves that $\mathbb{R}$ is uncountable (II.5.3.6.) and that the set of algebraic numbers is countable (II.5.6.6.). These results together prove that the set of transcendental numbers is nonempty (and, in fact, uncountable). However, just knowing these results one would be very hard pressed to exhibit a transcendental number. (Actually, in this instance, the standard proofs of the assertions could in principle be used to give an extremely cumbersome construction of an explicit transcendental number. There are, of course, much better ways of identifying explicit transcendental numbers, e.g. III.8.2.35., III.9.3.1., III.9.3.2.)

As pointed out by J. Hadamard [Moo82, ], the situation is very similar to the question of whether we allow consideration of functions from $\mathbb{R}$ to $\mathbb{R}$ for which we have no formula or effective way of calculating the values. Indeed, until Riemann in the mid-19th century, the term “function” was restricted to functions with a closed-form formula, or at least a power-series representation (i.e. analytic functions). The modern definition of function as simply a set of ordered pairs without necessarily a specified rule or method for calculation of its values would have been much too broad to be acceptable 200 years ago.

The Axiom of Choice is a pure existence assertion, not a constructive one.

Equivalent Formulations

The Axiom of Choice has many other equivalent reformulations, some of which seem intuitively plausible and others intuitively implausible. This situation reflects the unexpectedly subtle nature of the Axiom of Choice; it must be kept in mind that it is meaningless (within ZF) to ask whether any of these versions of the Axiom are “true”.

An obvious reformulation which seems plausible concerns Cartesian products. A choice function for $\{X_i : i \in I\}$ is just an element of $\prod_{i \in I} X_i$. Thus the Axiom of Choice is equivalent to:

**Multiplicative Axiom:** If $\{X_i : i \in I\}$ is an indexed collection of nonempty sets, then $\prod_{i \in I} X_i$ is not empty.

Bertrand Russell, who first formulated the Multiplicative Axiom version (he phrased it somewhat differently since infinite Cartesian products were not defined at the time), regularly called the Axiom of Choice by this name.

One potential way of generating a choice function is by transfinite induction. Thus the Axiom of Choice appears to be related to well ordering. In fact, the Axiom of Choice is equivalent to the Well-Ordering Principle:

**Well-Ordering Principle:** Every set can be well ordered.
II.6.2.3. To see that the Well-Ordering Principle implies the Axiom of Choice, suppose \( \{X_i : i \in I\} \) is an indexed collection of nonempty sets, and fix a well ordering \( \preceq \) on \( I \) and a well ordering \( \preceq_i \) on \( X = \cup_{i \in I} X_i \). For \( i \in I \), let \( R_i \) be the rule “Let \( c(i) \) be the first element of \( (X, \preceq_i) \) which is in \( X_i \)” Then a choice function \( c \) is defined by transfinite induction (\( \cdot \)).

The proof that the Axiom of Choice implies the Well-Ordering Principle uses the notion of ordinals, and will be discussed in (\( \cdot \)). In fact, the Axiom of Choice was first formulated by E. Zermelo specifically to prove the Well-Ordering Principle.

**Zorn’s Lemma and the Hausdorff Maximal Principle**

There are two similar statements about partially ordered sets which are also equivalent to the Axiom of Choice. To describe them simply, we need a definition:

II.6.2.4. **Definition.** Let \( (X, \preceq) \) be a partially ordered set. A **chain** in \( (X, \preceq) \) is a subset of \( X \) which is totally ordered in the induced ordering. A **maximal chain** is a chain which is not properly contained in any larger chain.

II.6.2.5. **Hausdorff Maximal Principle:** Let \( (X, \preceq) \) be a partially ordered set. Then \( (X, \preceq) \) contains a maximal chain.

II.6.2.6. **Zorn’s Lemma:** Let \( (X, \preceq) \) be a partially ordered set. If each chain in \( (X, \preceq) \) has an upper bound in \( X \), then \( X \) contains a maximal element.

Zorn’s Lemma is called a “Lemma” for historical reasons, but it is in fact equivalent to the Axiom of Choice. A name like **Zorn’s Principle** might be more suitable from a logical standpoint. The Hausdorff Maximal Principle is also sometimes called **Kuratowski’s Lemma** (HAUSDORFF and KURATOWSKI independently studied essentially this condition, with nuances of differences; the Hausdorff Maximal Principle was originally stated only for sets ordered by inclusion.)

II.6.2.7. It is fairly easy to see that the Hausdorff Maximal Principle and Zorn’s Lemma are equivalent. To see that the Hausdorff Maximal Principle implies Zorn’s Lemma, let \( (X, \preceq) \) be a partially ordered set in which every chain has an upper bound. Assume the Hausdorff Maximal Principle and let \( C \) be a maximal chain in \( X \). Then \( C \) has an upper bound \( x \), and we must have \( x \in C \) since otherwise \( C \cup \{x\} \) would be a chain properly containing \( C \). Thus \( x \) is the largest element of \( C \). Then \( x \) must be a maximal element of \( X \), since if there were a \( y \in X \) with \( x \prec y \), then \( C \cup \{y\} \) would be a chain properly containing \( C \).

II.6.2.8. The proof that Zorn’s Lemma implies the Hausdorff Maximal Principle is a good example of how Zorn’s Lemma is used in practice. Let \( (X, \preceq) \) be a partially ordered set. Let \( C \) be the set of all chains in \( (X, \preceq) \); then \( C \) is partially ordered by inclusion. If \( \{C_i : i \in I\} \) is a chain in \( (C, \subseteq) \), i.e. each \( C_i \) is a chain in \( (X, \preceq) \) and for any \( i, j \in I \), one of \( C_i \) and \( C_j \) is contained in the other, then it is easy to verify that \( \cup_{i \in I} C_i \) is a chain in \( X \): if \( x, y \in \cup_{i \in I} C_i \), then \( x \in C_i, y \in C_j \) for some \( i, j \in I \); but either \( C_i \subseteq C_j \) or vice versa, so both \( x \) and \( y \) are in either \( C_i \) or \( C_j \), so they are comparable since both \( C_i \) and \( C_j \) are chains. Also, \( \cup_{i \in I} C_i \) contains each of the \( C_i \); so \( \cup_{i \in I} C_i \) is an upper bound for \( \{C_i : i \in I\} \) in \( (C, \subseteq) \). Thus by Zorn’s Lemma \( (C, \subseteq) \) has a maximal element \( C \), which is a maximal chain in \( (X, \preceq) \).
II.6.2.9. In applications of Zorn’s Lemma, as here, the Lemma is frequently applied to a judiciously constructed new partially ordered set. Another relevant example is the proof that Zorn’s Lemma implies the Well-Ordering Principle, which is left as an Exercise (Exercise (.) See Exercises (,), () for other applications of Zorn’s Lemma.

II.6.2.10. The proof that the Axiom of Choice, the Well-Ordering Principle, the Hausdorff Maximal Principle, and Zorn’s Lemma are equivalent is completed by showing that the Axiom of Choice implies Zorn’s Lemma. This argument uses ordinals, and will be discussed in ()

**Tukey’s Lemma**

Another variation of AC similar to Zorn’s Lemma and the Hausdorff Maximal Principle is Tukey’s Lemma, often (and properly) called the *Teichmüller-Tukey Lemma* since it was independently formulated by O. Teichmüller; but I don’t feel guilty slighting Teichmüller in the name since he was a Nazi.

II.6.2.11. **Definition.** A collection \( F \) of sets is of finite character if a set \( X \) is in \( F \) if and only if every finite subset of \( X \) is in \( F \).

A good example of a collection of finite character is the collection of all linearly independent subsets of a vector space \( V \), since a set of vectors in \( V \) is linearly independent if and only if every finite subset is linearly independent (since a linear combination involves only finitely many vectors).

II.6.2.12. **Tukey’s Lemma:** If \( F \) is a collection of sets of finite character, then \( F \) has a maximal element under inclusion, i.e. there is an \( X \in F \) not properly contained in any other set in \( F \).

II.6.2.13. Tukey’s Lemma is an easy consequence of Zorn’s Lemma, since if \( F \) is a collection of sets of finite character, regarded as a partially ordered set under inclusion, and \( C = \{C_i : i \in I\} \) is a chain in \( F \), then \( C = \cup_{i \in I} C_i \) is in \( F \) since every finite subset of \( C \) is contained in some \( C_i \), and \( C \) is an upper bound for \( C \).

II.6.2.14. It is also not difficult to show that Tukey’s Lemma implies the Axiom of Choice (Exercise II.6.4.11.).

II.6.2.15. The Axiom of Choice is also equivalent to Tikhonov’s Theorem: an arbitrary product of compact topological spaces is compact in the product topology. This theorem will be discussed in ().

II.6.2.16. It must be pointed out that the Axiom of Choice is not universally accepted by mathematicians, even by analysts. This was particularly true in the early 20th century when the foundations of mathematics were being axiomatized; see [Sie65] and [Moo82] for interesting discussions of the points of view of leading mathematicians of the time. Today most analysts are more comfortable with the Axiom of Choice. But there is a branch of analysis called *Constructive Analysis*, where the full Axiom of Choice is not and cannot be assumed. There are results of both theoretical and practical importance in Constructive Analysis, but this theory is a separate subject from the one treated in this book. See e.g. [BB85] and [BV06]. There is also an axiom called the *Axiom of Determinacy* which is sometimes considered, which is inconsistent with the Axiom of Choice. A weaker version of this axiom, called the *Axiom of Projective Determinacy*, not inconsistent with the Axiom of Choice, plays a role in Descriptive Set Theory ()

164
II.6.3. Weaker Forms of Choice

II.6.3.1. Weaker versions of the Axiom of Choice, which are somewhat more palatable to some mathematicians (see [Pot04, p. 164-165, 240] for some relevant philosophical discussion), are sometimes assumed. One is the Countable Axiom of Choice (or Axiom of Countable Choice), written Countable AC or sometimes ACω, which is also not provable or disprovable in ZF:

Countable Axiom of Choice: (Indexed Form) If \( \{ X_n : n \in \mathbb{N} \} \) is a sequence of nonempty sets, then there is a choice function for \( \{ X_n : n \in \mathbb{N} \} \).

Note that it is the index set, not the \( X_n \), which is required to be countable. It is a quite different matter to weaken the AC by requiring the \( X_i \) to be countable, or finite, with no restriction on the index set; see II.6.3.13. There is no implication either way between the Countable AC and these forms of AC.

II.6.3.2. Analysis in its usual form is impossible without at least the Countable AC. The following statements, which can be readily proved using Countable AC, cannot be proved in ZF [Jec73]:

(i) A countable union of countable sets is countable (Exercise II.6.4.8.).

(ii) \( \mathbb{R} \) is not a countable union of countable sets.

(iii) Every infinite set contains a countably infinite subset (Exercise II.6.4.9.).

(iv) In \( \mathbb{R} \), or in metric spaces, the sequential criterion for limits and continuity is equivalent to the \( \epsilon - \delta \) definition ( ).

(v) In \( \mathbb{R} \), or in metric spaces, a point \( p \) is in the closure of a subset \( A \) if and only if there is a sequence of points of \( A \) converging to \( p \) ( ).

(vi) Every second countable topological space is separable ( ).

II.6.3.3. It turns out that a slightly stronger axiom called the Axiom of Dependent Choice is often more useful:

Axiom of Dependent Choice: Let \( R \) be a relation on a set \( X \). If, for every \( x \in X \), there is a \( y \in X \) with \( xRy \), then there is a sequence \( (x_n) \) in \( X \) with \( x_nRx_{n+1} \) for all \( n \).

Roughly speaking, the Axiom of Dependent Choice (abbreviated DC) asserts that a sequence of choices can be made, each depending on the previous choice(s).

II.6.3.4. The Axiom of Choice implies the Axiom of Dependent Choice, which implies the Countable Axiom of Choice (Exercise ( )); neither of the implications can be reversed. See [?] for a discussion of the Axiom of Dependent Choice. In some of the applications of the Axiom of Choice in this book, one can get away with the Axiom of Dependent Choice or even the Countable AC; we will try to identify most of these (see Exercise ( ) for one example.)

II.6.3.5. Note that the Axiom of Dependent Choice is not needed (in fact no form of Choice is needed) to prove the existence of sequences defined by recursion (III.1.5.15.).

165
The Boolean Prime Ideal Theorem

Another AC-type statement which has several important and useful formulations is the Boolean Prime Ideal Theorem, abbreviated BPI. We give several equivalent formulations of this statement, without, however, explaining all the terms involved (see, for example, [Jec73]). For part of the proof, see XI.11.9.19.

II.6.3.6. Boolean Prime Ideal Theorem (BPI): Every ideal in a Boolean algebra is contained in a prime ideal.

II.6.3.7. Compactness Theorem of Model Theory: Let $\Sigma$ be a set of sentences in a first-order language. If every finite subset of $\Sigma$ has a model, then $\Sigma$ has a model.

II.6.3.8. Ultrafilter Property: Every filter on a set is contained in an ultrafilter (XII.1.6.15.).

II.6.3.9. Tikhonov’s Theorem for Hausdorff Spaces: An arbitrary product of compact Hausdorff spaces is compact in the product topology (XI.11.6.6.).

II.6.3.10. Stone-Čech Compactification Theorem: Every completely regular topological space has a Stone-Čech compactification (XI.11.9.13.).

II.6.3.11. Theorem. The following are equivalent in ZF set theory:

(i) The Boolean Prime Ideal Theorem.
(ii) The Compactness Theorem of Model Theory.
(iii) The Ultrafilter Property.
(iv) Tikhonov’s Theorem for Hausdorff spaces.

II.6.3.12. It is easy to deduce the Ultrafilter Property from Zorn’s Lemma (it is also not difficult to obtain the BPI directly from Zorn’s Lemma, and it is trivial to obtain the Hausdorff Tikhonov Theorem from the general one), and hence the AC implies the BPI. The converse is false, i.e. the BPI is a strictly weaker assumption than AC. In fact:

II.6.3.13. Theorem. The following statements are successively strictly logically weaker in ZF set theory, i.e. each can be proved from the previous one in ZF, and none follows in ZF from the succeeding ones (and even (v) is not a theorem of ZF for $n \geq 2$):

(i) The Axiom of Choice.
(ii) The Boolean Prime Ideal Theorem.
(iii) The Ordering Principle: Every set can be totally ordered.
(iv) The Axiom of Choice for Finite Sets: Every collection of nonempty finite sets has a choice function.

(v) For each fixed \( n \in \mathbb{N} \), the Axiom of Choice for \( n \)-element sets.

See Exercise II.6.4.10. for (iii) \( \Rightarrow \) (iv), and [Jec73] for a complete discussion including the failure of the converse implications, and other variations of AC. Here are some selected additional facts, discussed in [Jec73]:

**II.6.3.14.** DC does not imply (v), hence neither DC nor Countable AC implies any of the stronger statements. There is no implication the other way between any of (ii)–(v) and either the Countable AC or DC. (This last question is not discussed in [Jec73], but see [HR98].)

**II.6.3.15.** The statement that there exists a free ultrafilter on every infinite set is strictly weaker than the Ultrafilter Property. The existence of a free ultrafilter on \( \mathbb{N} \) (an assumption underlying nonstandard analysis) is weaker still.

**II.6.3.16.** There is another pair of equivalent statements which are important in analysis, which are strictly weaker than the BPI: the Hahn-Banach Theorem () and the Boolean Measure Theorem (). These statements are independent of Countable AC and DC and of II.6.3.13.(iv)–(v), and apparently independent of II.6.3.13.(iii).

See [RR85] for a compilation of many other statements equivalent to the AC or other versions of Choice, and [HR98] for an enormous variety of Choice statements of mostly strictly varying logical strength. The fact that there are so many models of set theory in which some of these statements are true and others false tends to seriously undercut the credibility of set theory in its present form as a satisfactory foundation for all of mathematics.

The Axiom of Choice has been controversial, and remains somewhat so; however, most modern mathematicians, especially analysts, have no serious qualms about accepting and using it, often without comment. The attitude of R. Boas [Boa96, p. xi] is widespread:

“[A]fter Gödel's results, the assumption of the axiom of choice can do no mathematical harm that has not already been done.”

In this book we will feel free to use the AC, but we will try to be careful to point out what version of Choice is used and really needed whenever it is employed. Analysis as we will develop it would not be the same, or even very similar, without it.

“Rarely have the practitioners of mathematics, a discipline known for the certainty of its conclusions, differed so vehemently over one of its central premises as they have done over the Axiom of Choice. Yet without the Axiom, mathematics today would be quite different. The very nature of modern mathematics would be altered and, if the Axiom's most severe constructivist critics prevailed, mathematics would be reduced to a collection of algorithms. Indeed, the Axiom epitomizes the fundamental changes – mathematical, philosophical, and psychological – that took place when mathematicians seriously began to study infinite collections of sets.”

*Gregory H. Moore*\(^9\)

\(^9\)[Moo82, p. 1]

II.6.4. Exercises

II.6.4.1. Show that a totally ordered set is well ordered if and only if it contains no strictly decreasing sequences. (The Axiom of Dependent Choice is needed for one direction.)

II.6.4.2. Let $X$ be a set. Let $W$ be the set of all pairs $(A, \leq)$, where $A \subseteq X$ and $\leq$ is a well ordering on $A$. Define a partial order $\preceq$ on $W$ by setting $(A, \leq_A) \preceq (B, \leq_B)$ if $A \subseteq B$, $A$ is an initial segment of $B$ under $\leq_B$, and the restriction of $\leq_B$ to $A$ is $\leq_A$. (Note that $W \neq \emptyset$ if $X \neq \emptyset$ since every singleton subset of $X$ has an obvious well ordering.)

(a) Show that if $\{(A_i, \leq_i) : i \in I\}$ is a chain in $W$, then $(A, \leq)$ is an upper bound, where $A = \bigcup_i A_i$ and $\leq = \leq_i$ on $A_i$. [It must be shown that $\leq$ is well defined on $A$ and is a well ordering, and that each $A_i$ is an initial segment.]

(b) If $(A, \leq)$ is any element of $W$, and $x \in X \setminus A$, extend $\leq$ to $A \cup \{x\}$ by setting $a \leq x$ for all $a \in A$. Show that $(A \cup \{x\}, \leq) \in W$.

(c) If $(A, \leq)$ is a maximal element of $W$, then $A = X$.

(d) Conclude that Zorn’s Lemma implies the Well-Ordering Principle.

II.6.4.3. (a) Prove that the Axiom of Choice implies the Axiom of Dependent Choice. [If $R$ is a relation on $X$, let $c : P(X) \setminus \{\emptyset\} \to X$ be a choice function, and set $x_{n+1} = c(\{y \in X : x_n R y\})$.] (b) Prove that the Axiom of Dependent Choice implies the Countable Axiom of Choice. [If $\{X_n : n \in \mathbb{N}\}$ is an indexed collection of nonempty sets, let $Z$ be the set of all ordered pairs $(n, x)$, where $n \in \mathbb{N}$ and $x \in X_n$. Let $(n, x) R (m, y)$ if and only if $m = n + 1$.]

II.6.4.4. Using the Axiom of Dependent Choice, prove that every infinite set $X$ contains a sequence $(x_n)$ of distinct elements (), i.e. there is an injective function from $\mathbb{N}$ to $X$. [Let $Z$ be the set of ordered pairs $(n, A)$, where $n \in \mathbb{N}$ and $A$ is an infinite subset of $X$. Define $(n, A) R (m, B)$ if and only if $m = n + 1$, $B \subseteq A$, and $A \setminus B$ contains exactly one element.]

II.6.4.5. The proof of Tikhonov’s theorem () uses the Axiom of Choice. Conversely, the Axiom of Choice can be proved from Tikhonov’s Theorem for $T_1$ spaces, showing that the two are equivalent.

(a) Let $X$ be a set. Define the $T_1$-compactification of $\mathbb{N}$ by $X$ to be the disjoint union $\mathbb{N} \cup X$, topologized by taking as the open sets any subset with finite complement, and any subset of $\mathbb{N}$. Show that $\mathbb{N} \cup X$ is compact if $X$ is nonempty, always $T_1$, but not Hausdorff if $X$ has more than one element.

(b) Let $\{X_i : i \in I\}$ be an indexed collection of nonempty sets, and let $X = \prod_{i \in I} X_i$. Show using Tikhonov’s Theorem that $X$ is nonempty, as follows. For each $i$, let $T_i$ be the $T_1$ compactification of $\mathbb{N}$ by $X_i$, and let $Y = \prod_{i \in I} Y_i$. Then $X \subseteq Y$, and $Y$ is compact by Tikhonov’s Theorem.

(c) $Y \neq \emptyset$: for each $n \in \mathbb{N}$ let $y_n \in Y$ be the point with i’th coordinate $n$ for all $i$. By compactness, the sequence $(y_n)$ has a cluster point $p$ in $Y$. Show that for each $i$, the $i$’th coordinate $p_i$ of $p$ is in $X_i$, so $p \in X$. It is known that Tikhonov’s Theorem for Hausdorff spaces is strictly weaker than the Axiom of Choice (it is equivalent to the BPI). Tikhonov’s Theorem for Hausdorff spaces is equivalent to the statement that any product of copies of $[0, 1]$ is compact. See II.6.3.11. for a discussion of this and related matters.
II.6.4.6. Identify how the proof of II.5.4.8. uses the Countable Axiom of Choice. [In fact, II.5.4.8. is not a theorem of ZF [], i.e. some type of Choice Axiom is necessary.]

II.6.4.7. ([Bla77]; cf. [Oxt71, p. 95]) Show that the Axiom of Dependent Choice is equivalent to the statement that if \((X_n)\) is a sequence of nonempty sets, then \(\prod_n X_n\) is a Baire space, where each \(X_n\) is given the discrete topology, as follows.

(a) Show that the product topology on \(\prod_n X_n\) is given by a complete metric (cf. ()).
(b) Let \(R\) be a relation on a nonempty set \(X\), such that for every \(x \in X\) there is a \(y \in X\) with \(x R y\). For each \(n\) let

\[
U_n = \{ f \in X^N : f(n) R f(m) \text{ for some } m > n \} .
\]

Show that \(U_n\) is a dense open subset of \(X^N\). [Write

\[
U_n = \bigcup_{m > n} \bigcup_{(a,b) \in R} \{ f \in X^N : f(n) = a, f(m) = b \} .
\]

(c) Let \(g \in \cap_{n=1}^\infty U_n\). Let \(k_1 = 1, x_1 = g(1)\), and inductively let \(k_{n+1}\) be the smallest \(m > k_n\) for which \(g(k_n) R g(m)\), and \(x_{n+1} = g(k_{n+1})\).

(d) Conclude that the Baire Category Theorem (BC) implies the Axiom of Dependent Choice (DC). Since the proof of (BC) uses only (DC) (along with ZF), ZF+(BC) is logically equivalent to ZF+(DC).

(e) Show that under the hypotheses of DC, the sequence \((x_n)\) can be chosen with \(x_1\) arbitrary. [\(\cap_{n=1}^\infty A_n\) is dense in \(X^N\) by (BC).]

(f) Show that the Countable Axiom of Choice is equivalent to the statement that \(\prod_n X_n\) is nonempty for any sequence \((X_n)\) of nonempty sets.

II.6.4.8. Show how the countable AC is used in the proof of ().

II.6.4.9. Using Countable AC, show that every infinite set contains a countably infinite subset. [A set \(X\) is infinite if and only if, for each \(n \in \mathbb{N}\), the collection \(\mathcal{P}_n(X)\) of \(n\)-element subsets of \(X\) is nonempty. Choose such a set for each \(n\) and consider their union.]

II.6.4.10. Show that the Ordering Principle implies the Axiom of Choice for Finite Sets. [If \(X\) is totally ordered, every finite subset of \(X\) has a smallest element.]

II.6.4.11. Let \(\{X_i : i \in I\}\) be an indexed collection of nonempty sets, and \(\mathcal{F}\) the set of all choice functions for subcollections of the form \(\{X_i : i \in J\}\) for \(J \subseteq I\). Each element of \(\mathcal{F}\) is a set of ordered pairs of the form \((i, x)\), where \(i \in I\) and \(x \in X_i\). Regard \(\mathcal{F}\) as a partially ordered collection of sets under inclusion.

(a) Show that \(\mathcal{F}\) is nonempty. [Consider choice functions on finite subsets of \(I\).]

(b) Show that \(\mathcal{F}\) is a collection of sets of finite character.

(c) Show that if \(f\) is a maximal element of \(\mathcal{F}\), then the domain of \(f\) is all of \(I\). [Show that a choice function defined on a proper subset of \(I\) can be extended to one more index.]

(d) If Tukey’s Lemma is assumed, conclude that \(\{X_i : i \in I\}\) has a choice function, i.e. that AC holds.
II.6.4.12. (cf. III.3.7.4.) Let $R$ be a unital ring (III.3.6.3.). A nonempty subset $I$ of $R$ is a \textit{(two-sided)} ideal if $I$ is closed under addition and $x \in I$, $y \in R$ imply $xy, yx \in I$. An ideal is \textit{proper} if it is a proper subset of $R$. A \textit{maximal ideal} is a proper ideal which is not contained in any strictly larger proper ideal.

(a) Show that $\{0\}$ is a (proper) ideal in $R$. More generally, if $S \subseteq R$, then the set of finite sums of elements of $R$ of the form $xzy$, where $z \in S$ and $x, y \in R$, is an ideal of $R$ (not necessarily proper), and is the smallest ideal of $R$ containing $S$, called the \textit{ideal generated by $S$}, usually denoted $(S)$.

(b) Show that if $I$ is an ideal in $R$, then $0 \in I$, and $x \in I$ implies $-x \in I$. [Use $-1 \in R$.]

(c) Show that an ideal $I$ in $R$ is proper if and only if $1 \notin I$.

(d) Show that any intersection of ideals in $R$ is an ideal in $R$.

(e) Show that a union of ideals is not an ideal in general. But the union of a \textit{chain} of ideals (under inclusion) is an ideal. If $I$ and $J$ are ideals, the ideal generated by $I \cup J$ is

$$I + J = \{x + y : x \in I, y \in J\}.$$ 

(f) Use Zorn’s Lemma to prove that every proper ideal in a unital ring $R$ is contained in a maximal ideal.

(g) Show that if $I$ and $J$ are ideals in $R$, then the set $IJ$ of finite sums of elements of the form $xy$, where $x \in I$ and $y \in J$, is an ideal of $R$ contained in $I \cap J$.

(h) A proper ideal $P$ of $R$ is \textit{prime} if, whenever $I$ and $J$ are ideals of $R$ with $IJ \subseteq P$, then $I \subseteq P$ or $J \subseteq P$. Show that every maximal ideal is a prime ideal. [If $M$ is a maximal ideal and $I$ and $J$ are ideals with $IJ \subseteq M$ and $I \not\subseteq M$, then $I + M = R$, so $1 \in I + M$.]

Ideals can be defined also in nonunital rings (although (b) is not automatic and must be included as part of the definition of ideal; cf. III.3.7.4.). However, a nonunital ring need not contain any maximal ideals, e.g. there can be an increasing sequence of proper ideals whose union is the whole ring.

The term “ideal” arose since ideals were first considered in rings of algebraic numbers (). Every element $x$ in a ring $R$ generates an ideal $(x) = \{x\}$; such ideals are called \textit{principal ideals}. In many rings such as $\mathbb{Z}$ or a polynomial ring in one variable over a field, every ideal is principal, so there is no real distinction between ideals and elements (or equivalence classes of elements obtained by multiplication by units, e.g. $(n) = (-n)$ in $\mathbb{Z}$). But in some rings of algebraic integers, not every ideal is principal, and in these rings arithmetic is more complicated. \textsc{Kummer} had the idea to add “ideal numbers” (i.e. nonprincipal ideals), and to consider the arithmetic of ideals, which turns out to be considerably simpler than arithmetic of numbers, e.g. every ideal in a ring of algebraic integers factors uniquely as a product of prime ideals. See books on Abstract Algebra or Algebraic Number Theory for details.
II.7. Axiomatic Set Theory

The first set of axioms for modern set theory was proposed by Ernst Zermelo in 1908, although closely related work had been done previously by Cantor, Russell, and several others. The axioms were refined by Abraham Fraenkel (in part using ideas of Thoralf Skolem), and are today known as the Zermelo-Fraenkel Axioms and the theory is called ZF set theory. An additional axiom proposed by John von Neumann (the Axiom of Regularity) is usually included. Most of Zermelo’s axioms were not controversial, but one of them was: the Axiom of Choice, discussed in (); the Axiom of Choice is customarily not included among the ZF axioms, and the theory with the Axiom of Choice included is called ZFC set theory. Other axiom systems, most notably the ones developed by Kurt Gödel and Paul Bernays, and Nicolas Bourbaki, have been proposed, but the principal ones turn out to be equivalent to ZF theory in the sense that exactly the same theorems about sets can be proved. The Gödel-Bernays axioms are generally similar to the ZF axioms except that classes which are not sets appear explicitly.

The framework of set theory is two undefined concepts: set and membership. All objects of set theory are sets (or sometimes classes which are too large to be sets); the elements of a set (or class) are also sets. Thus, to encode the rest of mathematics into set theory, other mathematical objects must be defined as sets of some kind. For example, an ordered pair \((x, y)\) is defined to be \(\{\{x\}, \{x, y\}\}\); thus relations and functions can be defined as sets of ordered pairs, i.e. sets of sets, and therefore as sets. In the appendix, we describe how to define the natural numbers as sets, and then \(\mathbb{Z}\) and \(\mathbb{Q}\) can be described as equivalence classes of ordered pairs of natural numbers. A description of real numbers as sets of rational numbers is given in ()

The basic axioms of set theory assert that the usual operations give sets. The Axiom of Infinity asserts that the natural numbers are sets and that the collection of all natural numbers is a set. The axioms of Union and Power Set assert that the union of the elements of a set \(x\) is a set, written \(\cup x\) (remember that the elements of a set are themselves sets, so this union makes sense), and that \(\mathcal{P}(x)\) is a set. Other axioms assert that any subset of a set is a set, and that the range of a function is a set. The axioms are all phrased in formal logical language: for example, the Axiom of Union is written

\[ \forall x \exists y \forall a \left( a \in y \iff (\exists z \left[ a \in z \& z \in x \right]\right) \]

We will not try to carefully state the other axioms, which can be found in most books on mathematical logic or set theory. The axioms are inspired by the following somewhat imprecise principle, first espoused by Cantor:

**Basic Principle of Set Theory:** Every collection of objects [sets] is regarded as a set unless there is some logical contradiction in allowing it.

Thus, for example, Russell’s Paradox disqualifies allowing “the set of all sets.”

Von Neumann’s Axiom of Regularity had its origin in Russell’s Paradox, where one of the main problems was the existence of sets which are not ordinary (i.e. a set \(x\) with \(x \in x\)) A similar problem arises if there is a finite loop \(x_1, \ldots, x_n\) of sets with \(x_{k+1} \in x_k\) for \(1 \leq k < n\) and \(x_1 \in x_n\), so this possibility should also be eliminated. Zermelo’s axioms allowed such situations, although they (apparently) do not create a paradox in his system. But it is undesirable to allow such sets, and Von Neumann’s solution was to add the following axiom, which is also sometimes called the “Axiom of Foundation”:

10The Nicolas Bourbaki of mathematics was not an actual person, but the *nom de plume* of a gradually changing consortium of leading French mathematicians whose goal has been to systematize all of mathematics. See [7], [8], or [9] for a history of this interesting project.
Axiom of Regularity: For every nonempty set $x$ there is a $y \in x$ with $y \cap x = \emptyset$.

Such a $y$ is called a minimal element of $x$ (the terminology is explained in ()). The Axiom of Regularity prevents the existence of loops of the type described above; in fact, it is equivalent to the following statement:

Descending Chain Condition: There is no infinite sequence $(x_n)$ of sets with $x_{n+1} \subset x_n$ for all $n$.

[The Axiom of Choice is needed to prove one direction of the equivalence.]

The Axiom of Regularity seems reasonable if one thinks of sets as being constructed in “stages”, for then the elements of a set constructed at one stage must have been constructed at a previous stage; an element constructed at the earliest possible stage would be a minimal element. This can be made precise, and it turns out that the Axiom of Regularity limits the universe just to the sets which can be constructed out of $\emptyset$ by repeated union, power set, and subset (see Exercise ()); thus it seems to be in conflict with the Basic Principle above. The fact that it is a restrictive axiom is the source of the discomfort some mathematicians have with it. On the other hand, set theory with the Axiom of Regularity is large enough to encode all of standard mathematics in the usual way, and there are no important results which seem to be provable with a weakened version of the Axiom but not with the full version, so there is (at present) no practical reason to weaken it.

The situation with the Axiom of Choice is the opposite: it is an expansive axiom, allowing a certain infinite operation. Some mathematicians are uncomfortable with it because it seems to allow too much freedom in manipulating sets (although it could be argued that it is more in line with the Basic Principle than the Axiom of Regularity is.) There continue to be parts of mathematics where the Axiom of Choice is not assumed, and sometimes a contradictory axiom is substituted. One of the root causes of the controversy over the Axiom of Choice was identified by B. Rotman and G. T. Kneebone:

“[T]he axiom of choice has a curious ambivalence, since it can be regarded with equal justification as a mathematical axiom, which guarantees the existence of a set in certain stated circumstances, and as a logical principle, needed for the authentication of a pattern of inference that is indispensable in many branches of mathematics.”

In his very interesting book, *The Banach-Tarski Paradox*, STAN WAGON describes the role of the Axiom of Choice in connection with the Paradox, and in mathematics in general:

“Despite the Banach-Tarski Paradox and other objections to the Axiom of Choice, often focusing on its nonconstructive nature, the great majority of contemporary mathematicians fully accept the use of AC. It is generally understood that nonmeasurable sets (either of the Vitali type or of the sort that arise in the Banach-Tarski Paradox) lead to curious situations that contradict physical reality, but the mathematics that is brought to bear on physical problems is almost always mathematics that takes place entirely in the domain of measurable sets. And even in this restricted domain of sets, the Axiom of Choice is useful, and ZF + AC provides a more coherent foundation than does ZF alone. . . .

Despite the general acceptance of AC, it is recognized that this axiom has a different character than the others. Because of the nonconstructivity it introduces, AC is avoided when possible, and proofs in ZF are considered more basic (and are often more informative) than proofs using AC. A purist might argue that once accepted as an axiom, AC should be accorded the same

---

status as the other axioms: a statement that is proved in ZF + AC is just as mathematically true as one proved in ZF. But there are sometimes beneficial side effects of a discriminating attitude towards the use of AC. For instance, consider the Schröder-Bernstein Theorem for cardinality [()], which is much easier to prove in ZFC than in ZF. . . But the ZF-proof . . . is much more valuable because it generalizes in a way that the ZFC-proof does not. . .

The interplay between ZF and ZF + AC works the other way as well. For example, the ZF-proof that a square is not paradoxical . . . was found by closely analyzing the original ZFC-proof. If a more restrictive attitude toward AC had prevailed, the original ZFC-proof might not have been discovered so soon, and the proof (in ZF) that squares are not paradoxical might have been delayed."

II.8. Ordinals

Ordinals can be thought of as standard models for well ordered sets.

II.8.1. Basic Definitions

The formal theory of ordinals takes place in ZF set theory, where every element of a set is itself a set and there is no reason to make notational distinctions between sets and their elements (so we will frequently use lower-case letters to denote both sets and elements.) Thus the following strange-looking definition makes sense:

II.8.1.1. Definition. A set \( x \) is transitive if every element of \( x \) is a subset of \( x \). A set \( x \) is an ordinal if \( x \) is transitive and every element of \( x \) is transitive. Denote the class of all ordinals by \( \Omega \).

The term “transitive” is appropriate, since \( y \subseteq x \) and \( z \in y \) imply \( z \subseteq x \).

We will normally use the Greek letters \( \sigma, \tau, \rho \) to denote general ordinals, and other lower-case Greek letters to denote specific ordinals.

There is one ordinal to begin with, \( \emptyset \) (so \( \Omega \neq \emptyset \)). There are many other ordinals which can be manufactured from \( \emptyset \) by “transfinite induction,” using the next two constructions.

II.8.1.2. Definition. Let \( \sigma \) be an ordinal. Then \( S(\sigma) = \sigma \cup \{\sigma\} \) is also an ordinal, called the successor of \( \sigma \).

Note that \( \sigma \notin \sigma \) by the Regularity Axiom (), so \( S(\sigma) \neq \sigma \). The term “successor” makes sense in reference to a natural ordering on ordinals, described below.

Similarly, the next result is immediate from the definition:

II.8.1.3. Proposition. Let \( \{\sigma_i : i \in I\} \) be a set of ordinals. Then \( \bigcup_{i \in I} \sigma_i \) and \( \bigcap_{i \in I} \sigma_i \) are ordinals.

Together, these operations give a very large supply of ordinals. In fact:

II.8.1.4. Proposition. If \( X = \{\sigma_i : i \in I\} \) is any set of ordinals, there is an ordinal \( \sigma \) which is not in \( X \).

Proof: Set \( \sigma = S(\bigcup_{i \in I} \sigma_i) \).

173
II.8.1.5. COROLLARY. The class $\Omega$ of all ordinals is not a set.

This is the Burani-Forti Paradox, which like Russell’s Paradox implies that there is no “set of all sets.”

We will describe specific examples arising from these constructions in the next section.

II.8.2. Ordering on Ordinals

We now discuss the natural ordering on ordinals. First comes a simple observation:

II.8.2.1. PROPOSITION. If $\sigma$ is an ordinal, then every element of $\sigma$ is also an ordinal.

Indeed, if $\tau \in \sigma$, then $\tau$ is transitive; and since $\tau \subseteq \sigma$, every element of $\tau$ is an element of $\sigma$, hence transitive.

II.8.2.2. DEFINITION. If $\sigma$ and $\tau$ are ordinals, then $\tau < \sigma$ if $\tau \in \sigma$.

Thus, if $\sigma$ is an ordinal, then

$$\sigma = \{ \tau \in \Omega : \tau < \sigma \}.$$  

So $<$ defines an “ordering” on the set $\sigma$.

II.8.2.3. PROPOSITION. The relation $<$ is a strict “partial order” on $\Omega$.

[The “relation” $<$ is technically not a relation in the usual sense, since $\Omega$ is not a set. However, the meaning of the term “partial order” is still clear. In particular, $<$ is a true partial order on any set of ordinals, and in particular on any ordinal itself.]

PROOF: If $\tau < \sigma$ and $\sigma < \rho$, then $\tau \in \sigma$ and $\sigma \subseteq \rho$, so $\tau \in \rho$, i.e. $\tau < \rho$, so $<$ is transitive. Antisymmetry and strictness of the partial order follow from the Regularity Axiom, which implies that $\sigma \not\in \sigma$ for any $\sigma$. \(\Diamond\)

Some version of the Regularity Axiom is necessary here; otherwise there could be strange sets $x$ with the property that $x = \{x\}$ and any such set would be an ordinal.

The Regularity Axiom also implies:

II.8.2.4. PROPOSITION. Every nonempty set of ordinals contains a minimal element (with respect to $<$.)

In fact, if $X$ is a nonempty set of ordinals, then any minimal element of $X$ in the sense of () is also minimal with respect to $<$, as is easily verified (this is the origin and explanation of the term minimal in the Regularity Axiom.)

The existence of minimal elements also applies to classes of ordinals which are not sets: if $V$ is a nonempty class of ordinals, let $\sigma \in V$, and let $X = \{ \tau \in V : \tau \leq \sigma \}$. Then $X$ is a nonempty set of ordinals, and any minimal element of $X$ is a minimal element of $V$.

This fact and the next one are probably the most important facts about the ordering on $\Omega$. 174
II.8.2.5. **Proposition.** The ordering on $\Omega$ is a total ordering, i.e. any two ordinals are comparable.

**Proof:** Suppose there are ordinals which are not comparable. Let $\sigma$ be a minimal ordinal for which there is an ordinal not comparable to $\sigma$, and let $\tau$ be a minimal ordinal which is not comparable to $\sigma$. If $\rho \in \sigma$, then $\rho < \sigma$ so $\rho$ is comparable to any ordinal, and hence to $\tau$. We cannot have $\tau \leq \rho$ since then $\tau < \sigma$, so $\rho < \tau$, i.e. $\rho \in \tau$, so $\sigma \subseteq \tau$. Similarly, if $\rho < \tau$, then $\rho$ is comparable to $\sigma$ and $\sigma \not\subseteq \rho$, so $\rho < \sigma$ and $\tau \subseteq \sigma$, i.e. $\tau = \sigma$, a contradiction. So there are no such $\sigma$ and $\tau$.

Putting together the last two results, we obtain:

II.8.2.6. **Theorem.** Every nonempty class of ordinals has a smallest element, i.e. $\Omega$ is well ordered (more correctly, every set of ordinals is well ordered in the induced ordering.)

In particular, since every ordinal is itself a set of ordinals, each ordinal is well ordered in its natural ordering. If $\sigma$ is an ordinal, then $S(\sigma)$ is indeed the smallest ordinal larger than $\sigma$, justifying the term “successor”.

II.8.2.7. **Corollary.** Let $\sigma$ and $\tau$ be ordinals. If $\tau \subseteq \sigma$, then $\tau \leq \sigma$ (i.e. $\tau = \sigma$ or $\tau \in \sigma$.)

Thus, on $\Omega$, the relation $\leq$ is the same as $\subseteq$.

It follows easily that if $x = \{ \sigma_i : i \in I \}$ is a nonempty set of ordinals, then $\bigcap_{i \in I} \sigma_i$ is the smallest element of $x$. It is also easily seen that $\bigcup_{i \in I} \sigma_i$ is the smallest ordinal $\sigma$ such that $\sigma_i \leq \sigma$ for all $i \in I$; this element is often called $\text{lim}(x)$ [$x$ is well ordered in the induced ordering and can be regarded as a net, and this net converges to $\text{lim}(x)$ in the order topology (])]. Note that $\text{lim}(x)$ is also the supremum of $x$ in $\Omega$, although the notation $\text{sup}(x)$ is often used in ordinal theory to denote $S(\text{lim}(x))$, in conflict with the usual notation for ordered sets.

II.8.2.8. **Definition.** An ordinal $\sigma$ is a **successor ordinal** if there is a $\tau$ with $\sigma = S(\tau)$. Otherwise $\sigma$ is a **limit ordinal**.

An ordinal $\sigma$ is a successor ordinal if and only if it contains a maximal element $\tau$, in which case $\sigma = S(\tau)$; it follows that the $\tau$ for which $\sigma = S(\tau)$ is unique.

By this definition, $\emptyset$ is a limit ordinal; but this ordinal is special (it is the smallest or first ordinal) and it is often treated separately from all others.

II.8.3. **Transfinite Induction**

The Principle of Transfinite Induction applies to the class $\Omega$:

II.8.3.1. **Theorem.** [PRINCIPLE OF TRANSFINITE INDUCTION] Suppose $P(\sigma)$ is a statement for each $\sigma \in \Omega$. Suppose, for each $\sigma$, the following **inductive implication** holds:

“If $P(\tau)$ is true for all $\tau < \sigma$, then $P(\sigma)$ is true.”

Then $P(\sigma)$ is true for all $\sigma \in \Omega$.

The argument is identical to the one in II.4.2.6.; the fact that $\Omega$ is not a set causes no difficulty. Definitions by Transfinite Induction also work for $\Omega$.

175
II.8.3.2. Theorem. Let $X$ be a set. Suppose, for each $\sigma \in \Omega$, we have a definite procedure or rule $R_\sigma$ for choosing an $f(\sigma) = x_\sigma \in X$, which may depend on the choice of the $f(\tau)$ for $\tau < \sigma$. Then there is a unique $f : \Omega \to X$ such that, for each $\sigma \in \Omega$, $f(\sigma)$ is determined by the specified procedure $R_\sigma$ applied to $\{f(\tau) : \tau < \sigma\}$.

[We are still being vague about the precise meaning of “statement”, “rule”, and “procedure”. There is also a technical difficulty in saying what is meant by a “function” whose domain is not a set; but the meaning in this context can be easily clarified in an intuitively acceptable way.]

II.8.3.3. Proposition. If $X$ is a set and $f : \Omega \to X$ is a function defined inductively as in II.8.3.2., then there are ordinals $\sigma$ and $\tau$ with $\sigma \neq \tau$ and $f(\sigma) = f(\tau)$.

This is because there cannot be a one-one correspondence between a set and a class which is not a set. (This follows from the Replacement Axiom of ZF set theory.)

II.8.4. Ordinals as Universal Models

We can now show that ordinals are universal models for well ordered sets. Recall that each ordinal is well ordered in its natural ordering.

II.8.4.1. Proposition. No two distinct ordinals are order-isomorphic.

Proof: It suffices to show that if $\tau < \sigma$, then there is no order-isomorphism from $\sigma$ onto $\tau$. Suppose $f$ is such an order-isomorphism. The set $\{\rho \in \sigma : f(\rho) < \rho\}$ is nonempty, since $\tau \in \sigma$ and $f(\tau) < \tau$. Let $\rho$ be the smallest element of $x$. Then, for every $\pi < \rho$, $\pi \leq f(\pi) < f(\rho)$ since $f$ is an order-isomorphism. But $\rho$ is the smallest ordinal larger than all $\pi < \rho$, so $\rho \leq f(\rho)$, a contradiction.

II.8.4.2. Theorem. Let $(I, \preceq)$ be a well ordered set. Then there is a unique ordinal $\sigma$ such that $(I, \preceq)$ is order-isomorphic to $(\sigma, \leq)$.

Proof: First fix an $x \notin I$ (for example, $x = I$.) Now define a function $f : \Omega \to I \cup \{x\}$ by transfinite induction, by letting $f(\sigma)$ be the first element of $I \setminus \{f(\tau) : \tau < \sigma\}$ if this set is nonempty, and $f(\sigma) = x$ otherwise. Then $f$ is not injective by II.8.3.3.; but $f(\sigma) = f(\tau)$ for $\sigma \neq \tau$ can only happen if $f(\sigma) = f(\tau) = x$ by the way $f$ is defined. Thus there is a smallest $\sigma$ such that $f(\sigma) = x$, and $f$ is a bijection from $\sigma = \{\tau \in \Omega : \tau < \sigma\}$ onto $I$. It is easily checked that $f$ is an order-isomorphism. Uniqueness follows from II.8.4.1.

The device in this argument of adding a new element $x$ and applying II.8.3.3. is commonly used, for example in the proof in II.8.5.2. and in Exercise (). It can also be used to carefully justify arguments such as the proof of (), where a function is defined by transfinite induction until the definition no longer “works”.

II.8.5. The Axiom of Choice and Zorn’s Lemma

Using ordinals and an argument like the proof of II.8.4.2., we can finally prove that the Axiom of Choice implies Zorn’s Lemma. We begin with a lemma:
II.8.5.1. **Lemma.** Let \((X, \preceq)\) be a partially ordered set in which every chain has an upper bound. If \(X\) has no maximal elements, then every chain \(C\) in \(X\) has an upper bound in \(X\) which is not in \(C\).

**Proof:** Suppose \(C\) is a chain. We must show there is an upper bound for \(C\) which is not in \(C\). By assumption, \(C\) has an upper bound \(x\). If \(x \notin C\), we are done. If \(x \in C\), then \(x\) is the largest element of \(C\). By assumption, \(x\) is not a maximal element of \(X\), so there is a \(y \in X\) with \(x < y\). Then \(y\) is an upper bound for \(C\) which is not in \(C\).

II.8.5.2. Now assume the Axiom of Choice, and let \((X, \preceq)\) be a partially ordered set in which every chain has an upper bound. Let \(d : \mathcal{P}(X) \setminus \{\emptyset\} \to X\) be a choice function for \(X\). Suppose that \(X\) has no maximal elements. Then by the lemma, for any chain \(C\), the set \(U_C\) of upper bounds for \(C\) which are not in \(C\) is nonempty. Fix \(y \notin X\) (say \(y = X\)) and define \(f : \Omega \to X \cup \{y\}\) by transfinite induction as follows. Let \(f(\sigma) = d(U_{C_\sigma})\) if \(C_\sigma = \{f(\tau) : \tau < \sigma\}\) is a chain, and \(f(\sigma) = y\) otherwise. It is then easily proved by transfinite induction that \(C_\sigma\) is a chain for every \(\sigma\), so \(f(\sigma) = d(U_{C_\sigma})\) for all \(\sigma\); hence \(f : \Omega \to X\) is injective, contradicting **II.8.3.3.** This contradicts the assumption that \(X\) has no maximal element.

II.8.5.3. Of course, since Zorn’s Lemma implies the Well-Ordering Principle, which implies the Axiom of Choice, the three are thus equivalent. A direct proof along the same lines as **II.8.5.2.** (but somewhat simpler) can be given that the Axiom of Choice implies the Well-Ordering Principle (Exercise ()).

II.8.6. **Ordinal Arithmetic and Examples**

In this section, we explicitly describe some of the standard ordinals, and also define arithmetic operations on the ordinals.

**Finite Ordinals**

II.8.6.1. The finite ordinals are essentially the natural numbers (along with 0.) In fact, in ZF set theory the natural numbers are defined to be the (nonzero) finite ordinals.

The finite ordinals are just constructed from \(\emptyset\) by repeated application of the successor operation:

- The first ordinal, \(\emptyset\), is usually denoted 0.
- The next ordinal, usually denoted 1, is \(S(0) = \{0\} = \emptyset\) (note that \(\emptyset \neq \emptyset\))
- The next ordinal, usually denoted 2, is \(S(1) = 1 \cup \{1\} = \{0, 1\} = \emptyset, \{\emptyset\}\).

The next ordinal, usually denoted 3, is \(S(2) = 2 \cup \{2\} = \{0, 1, 2\} = \emptyset, \{\emptyset\}, \emptyset, \{\emptyset\}\).

This process continues to give \(n = \{0, 1, 2, \ldots, n - 1\}\) for each \(n \in \mathbb{N}\).
Infinite Ordinals

II.8.6.2. The Axiom of Infinity in ZF set theory says that the class of all finite ordinals is a set, which is obviously an ordinal. This class, which is familiar as \( \mathbb{N} \cup \{0\} \), is usually denoted \( \omega \) when regarded as an ordinal (\( \omega_0 \) might be better notation.) The ordinal \( \omega \) is the first infinite ordinal, and is the first limit ordinal (other than 0.) The ordinals larger than \( \omega \) are also called infinite ordinals.

One can continue generating infinite ordinals via the successor operation, such as \( S(\omega) \), \( S(S(\omega)) \), etc. These can be much more efficiently described using ordinal arithmetic, so we will defer further discussion of them.

II.8.6.3. The Well-Ordering Principle implies that there is an uncountable well ordered set, and hence an uncountable ordinal by II.8.4.2.. It is perhaps surprising that the existence of an uncountable ordinal can be proved without resorting to the Axiom of Choice \( (\) \). The first uncountable ordinal is usually denoted \( \omega_1 \) (some authors use \( \Omega \), which we reserve for the class of all ordinals.) The ordinal \( \omega_1 \) is the set of all countable ordinals.

Similarly, the Well-Ordering Principle implies that there are ordinals of arbitrary cardinality. We will discuss this point more completely in the next section.

Ordinal Arithmetic

We can define addition, multiplication, exponentiation, and other algebraic operations on the set of ordinals. We begin with addition.

II.8.6.4. If \( \rho \) and \( \sigma \) are ordinals, we informally define \( \rho + \sigma \) to be the ordinal of the well-ordered set obtained by putting a copy of the well-ordered set \( \sigma \) at the end of the well-ordered set \( \rho \). More precisely, if \( \rho \) is a fixed ordinal, we define \( \rho + \sigma \) to be \( f(\sigma) \), where \( f \) is defined by transfinite induction according to the following rule:

\[
\begin{align*}
\quad f(0) & = \rho. \\
\quad \text{If } \sigma = S(\tau) & \text{, then } f(\sigma) = S(f(\tau)). \\
\quad \text{If } \sigma \text{ is a nonzero limit ordinal, then } f(\sigma) & = \lim \{f(\tau) : \tau < \sigma\}
\end{align*}
\]

We have that \( \rho + 1 = S(\rho) \) for every \( \rho \). In particular, \( \{\omega + 1, \omega + 2, \ldots\} \) is the strictly increasing sequence of immediate successors of \( \omega \). The limit of this set is \( \omega + \omega \).

II.8.6.5. Addition of finite ordinals coincides with usual addition of numbers, and has the usual familiar algebraic properties. However, most of the properties break down for general ordinals. For example, \( \omega + 1 = S(\omega) \neq \omega \), but it is easily checked that \( 1 + \omega = \omega \); thus addition of general ordinals is not commutative, and the right cancellation law also fails (\( \rho + \tau = \sigma + \tau \) does not imply \( \rho = \sigma \).) It can be proved by transfinite induction that the associative law does hold in general: \( (\rho + \sigma) + \tau = \rho + (\sigma + \tau) \) for any \( \rho, \sigma, \tau \) (Exercise 6.)

II.8.6.6. Subtraction of ordinals can be defined. If \( \tau < \sigma \), then there is a unique \( \rho \) such that \( \sigma = \tau + \rho \); \( \rho \) has the order type of \( \{\pi : \tau \leq \pi < \sigma\} \).
II.8.6.7. We can then define multiplication of ordinals in terms of addition. Informally, the well ordered set $\rho \cdot \sigma$ is obtained by taking the well ordered set $\sigma$ and replacing each element by a copy of $\rho$. One can describe this to be the set $\sigma \times \rho$ (note the order!) with lexicographic ordering. There is also an inductive definition. If $\rho$ is a fixed ordinal, we define $\rho \cdot \sigma$ to be $f(\sigma)$, where $f$ is defined by transfinite induction according to the following rule:

\[
f(0) = 0.
\]

If $\sigma = S(\tau)$, then $f(\sigma) = f(\tau) + \rho$.

If $\sigma$ is a nonzero limit ordinal, then $f(\sigma) = \lim\{f(\tau) : \tau < \sigma\}$

Then, for any $\rho$, $\rho \cdot 1 = \rho$, $\rho \cdot 2 = \rho + \rho$, etc.

II.8.6.8. As with addition, multiplication of finite ordinals coincides with ordinary multiplication of numbers, with the usual rules. But the commutative and right cancellation laws fail in general: $\omega \cdot 2 = \omega + \omega$, but it is easily checked that $2 \cdot \omega = \omega$. Ordinal multiplication is associative (Exercise).)

II.8.6.9. The next step is exponentiation. If $\rho$ is a fixed nonzero ordinal, we define $\rho^\sigma$ to be $f(\sigma)$, where $f$ is defined by transfinite induction according to the following rule:

\[
f(0) = 1.
\]

If $\sigma = S(\tau)$, then $f(\sigma) = f(\tau) \cdot \rho$.

If $\sigma$ is a nonzero limit ordinal, then $f(\sigma) = \lim\{f(\tau) : \tau < \sigma\}$

We define $0^\sigma = 0$ for all $\sigma \neq 0$ ($0^0$ is not defined.)

As usual, ordinal exponentiation coincides with usual exponentiation on the finite ordinals. In fact, for any $\rho$, we have $\rho^2 = \rho \cdot \rho$, etc.

This hierarchy can be continued, as will be indicated in the next subsection.

Countable Ordinals

We now give a more complete description of at least some of the countable ordinals.

First of all, note that the set of countable ordinals is closed under operations of finite or countable character:

II.8.6.10. Proposition.

(i) If $\sigma$ is a countable ordinal, so is $S(\sigma) = \sigma + 1$.

(ii) If $x = \{\sigma_i : i \in I\}$ is a countable set of countable ordinals, then $\lim(x)$ is countable.

(iii) If $\rho$ and $\sigma$ are countable ordinals, then $\rho + \sigma$, $\rho \cdot \sigma$, and $\rho^\sigma$ are countable.

Proof: Parts (i) and (ii) follow immediately from (i) (the Countable AC is needed for (ii)), and (iii) is easily proved by transfinite induction using (i) and (ii).

Countable ordinals can be pictured as subsets of $\mathbb{R}$ (in fact, of $\mathbb{Q}$ or $\mathbb{Q} \cap [0,1]$):

179
II.8.6.11. **Proposition.** Any subset of $\mathbb{R}$ which contains no strictly decreasing sequences is order-isomorphic (with respect to the induced ordering) to a countable ordinal. Every countable ordinal is order-isomorphic to such a set.

**Proof:** Any such set $X$ is well ordered in the induced ordering, hence is order-isomorphic to an ordinal $\sigma$. To see that $X$ is countable, let $g: \sigma \rightarrow X$ be an order-isomorphism, and for each $\tau < \sigma$, let $f(\tau)$ be a rational number between $g(\tau)$ and $g(\tau + 1)$ (to make this precise and avoid using the Axiom of Choice, let $f(\tau)$ be the first element of $G \cap (g(\tau), g(\tau + 1))$ according to some fixed enumeration of $G$.) Then $f$ is an injective function from $\sigma$ to $G$. The last statement follows from II.5.4.13.

Note, however, that there is no *natural or standard* way of picturing a countable ordinal as a subset of $\mathbb{R}$.

II.8.6.12. Some of the countable ordinals described earlier can be pictured in $[0, \infty)$ as follows:

- $\omega$ as $\{1 - \frac{1}{n} : n \in \mathbb{N}\}$ (or as $\mathbb{N} \cup \{0\}$)
- $\omega + 1$ as $\{1 - \frac{1}{n} : n \in \mathbb{N}\} \cup \{1\}$
- $\omega + 2$ as $\{1 - \frac{1}{n} : n \in \mathbb{N}\} \cup \{1, 2\}$
- $\omega + n$ as $\{1 - \frac{1}{n} : n \in \mathbb{N}\} \cup \{1, \ldots, n\}$

$\omega \cdot 2 = \omega + \omega$ as $\{1 - \frac{1}{n}, 2 - \frac{1}{n} : n \in \mathbb{N}\}$ (or as $\{1 - \frac{1}{n} : n \in \mathbb{N}\} \cup \mathbb{N}$)

$\omega \cdot 2 + 1$ as $\{1 - \frac{1}{n}, 2 - \frac{1}{n} : n \in \mathbb{N}\} \cup \{2\}$

$\omega^2 = \omega \cdot \omega$ as $\{1 - \frac{1}{n}, 1 - \frac{1}{n} - \frac{1}{n^2} : m, n \in \mathbb{N}\}$

$\omega^2 + \omega$ as $\{1 - \frac{1}{n}, 2 - \frac{1}{n}, 1 - \frac{1}{n} - \frac{1}{n^2} : m, n \in \mathbb{N}\}$

$\omega^2 \cdot 2 = \omega^2 + \omega^2$ as $\{1 - \frac{1}{n}, 2 - \frac{1}{n}, 1 - \frac{1}{n} - \frac{1}{n^2}, 2 - \frac{1}{n} - \frac{1}{n^2} : m, n \in \mathbb{N}\}$

$\omega^3 = \omega^2 \cdot \omega$ as $\{1 - \frac{1}{n}, 1 - \frac{1}{n} - \frac{1}{n^2}, 1 - \frac{1}{n} - \frac{1}{n^2} - \frac{1}{n^3} : m, n, k \in \mathbb{N}\}$

The intermediate and succeeding ordinals can be drawn in a similar manner. Note that the blocks between the ordinals shown grow successively longer: between $\omega^2$ and $\omega^3$ are all the ordinals of the form $\omega^2 \cdot n + \omega \cdot m + k$, for any $m, n, k, n \in \mathbb{N} \cup \{0\}$, $n > 0$.

II.8.6.13. We can make much larger countable ordinals. For example, $\omega^\omega = \lim \{\omega^n : n \in \mathbb{N}\}$. The elements of $\omega^\omega$ (i.e. the set of ordinals less than $\omega^\omega$) can be pictured as a subset of $\mathbb{R}$ (try it!) There is another way to describe this as an ordered set: they can be identified with the set of all polynomials with coefficients in $\mathbb{N} \cup \{0\}$, thought of as functions from $\mathbb{N}$ to $\mathbb{N}$, with $f < g$ if $f(n) < g(n)$ for all sufficiently large $n$. (This ordering is called the Fréchet ordering.)
II.8.6.14. We can go much farther. We can form \( \omega^{\omega^\omega}, \omega^{\omega^{\omega^\omega}}, \) etc. [As usual, these are grouped from the top down, e.g. \( \omega^{\omega^\omega} = \omega^{(\omega^\omega)}. \)] There is a limit to this sequence, i.e. a smallest ordinal larger than all these, which is countable and usually called \( \epsilon_0. \) See II.8.7.2. for a continuation.

II.8.6.15. The vertical arrow notation of Donald Knuth [Knu76] is useful here: if we define \( \uparrow \uparrow \sigma = \rho^\sigma \) for any \( \rho \) and \( \sigma, \) we can define

\[
\rho \uparrow \uparrow n = \rho \uparrow (\rho \uparrow \cdots (\rho \uparrow \rho) \cdots)) = \rho^{\rho^{\cdots}}
\]

(\( n \) levels), and \( \rho \uparrow \uparrow \omega = \lim \{\rho \uparrow \uparrow n : n \in \mathbb{N}\}. \) More generally, \( \rho \uparrow \uparrow \sigma \) for any \( \rho, \sigma \) can be defined inductively by setting \( \rho \uparrow \uparrow S(\sigma) = \rho \uparrow (\rho \uparrow \uparrow \sigma) = \rho^{\rho^{\cdots \rho}} \) and \( \rho \uparrow \uparrow (\lim(\sigma_i)) = \lim(\rho \uparrow \uparrow \sigma_i). \) (This operation is called tetration, and \( \rho \uparrow \uparrow \sigma \) is sometimes written \( \^\sigma \rho. \)) With this notation, \( \epsilon_0 = \omega \uparrow \uparrow \omega. \)

II.8.6.16. We can go on and define \( \uparrow \uparrow \uparrow \sigma \) starting by

\[
\rho \uparrow \uparrow \uparrow n = \rho \uparrow \uparrow (\rho \uparrow \uparrow \cdots (\rho \uparrow \rho) \cdots))
\]

(\( n \) levels), and then \( \rho \uparrow \uparrow \uparrow \sigma \) inductively for all \( \sigma. \) Similarly, for any \( n \) we can define \( \rho \uparrow \uparrow \uparrow \downarrow \sigma, \) \( \rho \uparrow \uparrow \downarrow \sigma = \rho \uparrow \cdots \uparrow \sigma, \) etc. The sequence

\[
\{\omega \uparrow \omega, \omega \uparrow \uparrow \omega, \omega \uparrow \uparrow \uparrow \omega, \omega \uparrow \uparrow \cdots \omega, \ldots \}
\]

has a limit which is again a countable ordinal.

II.8.6.17. We can still go on. We can define \( \uparrow \uparrow \sigma \) for any \( \rho, \sigma, \tau \) (Exercise ()), and then \( \rho \uparrow \sigma = \rho \uparrow ^\sigma \rho, \)

\[
\rho \uparrow \uparrow n = \rho \uparrow (\rho \uparrow \cdots (\rho \uparrow \rho) \cdots))
\]

(\( n \) levels), \( \rho \uparrow \uparrow \sigma, \rho \uparrow \uparrow \uparrow \sigma \) etc., etc., \ldots (see also II.8.7.4.) And if we run out of operations, we can always take a (countable) limit, take the successor of it, and start over again!

Even at that we have barely scratched the surface of the set of all countable ordinals. An internet search of “countable ordinals” will turn up numerous articles, from popular to technical, on naming or describing countable ordinals, some of which go far beyond what we have done in depth and sophistication (but even so fall far short of exhausting the countable ordinals). As Rudy Rucker puts it in his book, *Infinity and the Mind* [Ruc82],

“\[\text{In trying to think of bigger and bigger ordinals, one sinks into a kind of endless morass. Any procedure you come up with for naming larger ordinals eventually peters out, and the ordinals keep on coming. Finally, your mind snaps, and maybe you get a momentary glimpse of what the Absolute infinite is about. Then you try to formalize your glimpse, and you end up with a new system for naming ordinals \ldots which eventually peters out \ldots}\]

And this comment was just made in reference to the countable ordinals!
II.8.6.18. The first uncountable ordinal $\omega_1$ cannot be pictured as a subset of $\mathbb{R}$. However, it is order-isomorphic to a set of functions from $\mathbb{N} \cup \{0\}$ to $\mathbb{N} \cup \{0\}$ with Fréchet ordering, although there is no natural way to do it. An order-embedding $f : \sigma \mapsto f_\sigma$ can be defined by transfinite induction as follows. Let $f_0$ be the constant function 0. If $\sigma = \tau + 1$, let $f_\sigma(n) = f_\tau(n) + 1$ for all $n$. Now suppose $\sigma$ is a limit ordinal. It follows easily from II.8.6.11. that there is a strictly increasing sequence $(\sigma_n)$ of ordinals with $\sigma = \text{lim}(\sigma_n)$. Choose such a sequence (some version of the Axiom of Choice is needed to do this rigorously). Set $k_1 = 1$, and for $n > 1$ fix $k_n \in \mathbb{N}$ with $f_{\sigma_n}(m) > f_{\sigma_{n-1}}(m)$ for all $m \geq k_n$. Then set $f_\sigma(m) = f_{\sigma_n}(m)$ if $k_n \leq m < k_{n+1}$.

It is easily checked that this $f$ is an order-embedding. The function $f$ can be chosen to use the polynomial embedding for $\omega^\omega$, and can be extended in a standard way to the ordinals previously considered using the functions $x \uparrow n$, $x \uparrow^* x$, $x \uparrow^* n$, etc. [These formulas all give functions from $\mathbb{N}$ to $\mathbb{N}$, although they grow unimaginably fast: for example, even $4 \uparrow \uparrow 4 = 4^{4^{32}}$ is a number of more than $10^{154}$ digits, much larger than a googolplex, and $3 \uparrow \uparrow \uparrow 3 = 3 \uparrow (3 \uparrow 3) = 3 \uparrow \uparrow 3^{27} = \omega^{33 \cdot 3}$ (327 levels) is far too large to write using conventional notation.]

II.8.7. Exercises

II.8.7.1. Give a direct proof along the lines of (8) that the Axiom of Choice implies the Well-Ordering Principle. [Hint: If $X$ is a set, fix $y \notin X$ and a choice function $c : \mathcal{P}(X) \setminus \{\emptyset\} \to X$; set $f(\sigma) = c(X \setminus \{f(\tau) : \tau < \sigma\})$ if this set is nonempty, and $f(\sigma) = y$ otherwise.]

II.8.7.2. An $\epsilon$-number (defined by CANTOR) is an ordinal $\epsilon$ such that $\omega^\epsilon = \epsilon$.
(a) Show that $\epsilon_0$ (II.8.6.14.) is the smallest $\epsilon$-number.
(b) Show that the next $\epsilon$-number is
$$\epsilon_1 = \epsilon_0 \uparrow \omega = \text{lim}(\epsilon_0, \epsilon_0^\omega, \ldots) = \text{lim}(\omega^{\epsilon_0+1}, \omega^{\epsilon_0+1}, \ldots).$$
(c) Show that the $\epsilon$-numbers, in increasing order, are indexed by ordinals, and that $\epsilon_\alpha$ is countable if (and only if) $\alpha$ is countable.
(d) The ordinal $\Gamma_0 = \text{lim}(\epsilon_0, \epsilon_{\epsilon_0}, \epsilon_{\epsilon_{\epsilon_0}}, \ldots)$ is the smallest ordinal $\alpha$ such that $\epsilon_\alpha = \alpha$. $\Gamma_0$ is countable.

II.8.7.3. (a) Give a careful inductive definition of $\rho \uparrow \uparrow \sigma$ as outlined in II.8.6.15.
(b) Give a careful inductive definition of $\rho \uparrow \uparrow \uparrow \sigma$ and $\rho \uparrow \uparrow n \sigma$ for each $n$.
(c) Use transfinite induction on $\sigma$ to define $\uparrow^n \sigma$ for all $\sigma$ in terms of $\uparrow^\pi \sigma$ for all $\pi < \sigma$, i.e. suppose $\rho \uparrow^\pi \sigma$ has been defined for all $\pi < \sigma$ and all $\rho, \tau$. In defining $\rho \uparrow^\sigma \tau$, one may also assume that $\rho \uparrow^\sigma \pi$ has been defined for all $\pi < \tau$ (this assumption must be justified; consider lexicographic ordering.)
(d) Give a careful inductive definition of $\rho \uparrow \uparrow \sigma$, $\rho \uparrow \uparrow \uparrow \sigma$, $\rho \uparrow^\sigma \tau$, etc. Continue the hierarchy as far as possible.
II.8.7.4. Define Conway’s “chained arrow notation” as follows. All Latin letters denote natural numbers.

(i) \( a \rightarrow b \) denotes \( a^b \).

(ii) \( a \cdots x \rightarrow y \rightarrow 1 \) denotes \( a \cdots x \rightarrow y \).

(iii) \( a \cdots x \rightarrow y \rightarrow (z + 1) \) denotes

\[
\begin{align*}
& a \cdots x \text{ if } y = 1 \\
& a \cdots x \rightarrow (a \cdots x) \rightarrow z \text{ if } y = 2 \\
& a \cdots x \rightarrow (a \cdots x \rightarrow (a \cdots x) \rightarrow z) \rightarrow z \text{ if } y = 3 \\
& \quad \text{ etc.}
\end{align*}
\]

(a) Show that \( a \rightarrow b \rightarrow c = a \uparrow^c b \) for any \( a, b, c \).

(b) Show how to define \( \alpha \rightarrow \beta \rightarrow \cdots \rightarrow \sigma \) for any ordinals \( \alpha, \beta, \ldots, \sigma \). Show that these are again countable ordinals if \( \alpha, \beta, \ldots, \sigma \) are countable.

(c) Define \( a \Rightarrow b \) to be \( a \rightarrow a \rightarrow \cdots \rightarrow a (b \text{ terms}) \). Define \( a \Rightarrow b \Rightarrow \cdots \Rightarrow x \) inductively as for \( a \rightarrow b \rightarrow \cdots \rightarrow x \). Extend this to show how to define \( \alpha \Rightarrow \beta \Rightarrow \cdots \Rightarrow \sigma \) for any ordinals \( \alpha, \beta, \ldots, \sigma \). Show that these are again countable ordinals if \( \alpha, \beta, \ldots, \sigma \) are countable.

II.8.7.5. Transitive Sets. (a) Show that every nonempty transitive set contains \( \emptyset \) as an element. [If \( x \) is transitive, consider a minimal element of \( x \).]

(b) If \( x \) is any set, show there is a smallest transitive set containing \( x \). [Let \( x_1 = x \) and \( x_{n+1} = \cup x_n = \cup \{ y : y \in x_n \} \); then \( \cup \{ x_n : n \in \mathbb{N} \} \) is transitive.]

II.8.7.6. The ZF Universe. Define sets \( V_\sigma, \sigma \in \Omega \), inductively by letting \( V_0 = \emptyset, V_{\sigma+1} = \mathcal{P}(V_\sigma) \), and \( V_\sigma = \cup \{ V_\tau : \tau < \sigma \} \) if \( \sigma \) is a limit ordinal. Let \( V = \cup_\sigma V_\sigma \). Then \( V \) is a class which is not a set.

(a) Show by induction that each \( V_\sigma \) is transitive, and \( V_\tau \subseteq V_\sigma \) and \( V_\tau \in V_\sigma \) if \( \tau < \sigma \).

(b) Show that if \( x \) is a set and \( x \subseteq V \), then \( x \in V \). [For each \( y \in x \), let \( \sigma_y \) be the smallest \( \tau \) such that \( y \in V_\tau \), and set \( \sigma = \lim \{ \sigma_y : y \in x \} \).]

(c) Show that \( V \) is the entire universe \( \mathcal{U} \). [Suppose \( x \) is a transitive set which is not in \( V \). Then \( x \not\subseteq V \) by (b), so \( y = \{ z \in x : z \notin V \} \neq \emptyset \). Let \( z \) be a minimal element of \( y \). Then \( z \notin V \), so \( z \notin V \) by (b). If \( w \in z \subseteq x, w \notin V \), then \( w \in y \), a contradiction. Apply Exercise ()(b).]

(d) Give an explicit description of the sets in \( V_\omega \). (Note that all these sets are finite, and \( \text{card}(V_\omega) = \aleph_0 \).]

Thus every set is constructed from \( \emptyset \) by (transfinitely) repeated operations of subset, union, and power set. The sets in \( V_\sigma \) are called the sets constructed by the \( \sigma \)-th stage, or the sets constructible in \( \sigma \) steps.

The class \( V \) is called the von Neumann universe. There is an apparently smaller universe \( L \), called the Gödel constructible universe, where only “constructible” subsets are added at each stage. The hypothesis \( V = L \) is called the Axiom of Constructibility.

II.8.7.7. An ordinal \( \tau \) is called even if it is a limit ordinal or of the form \( \rho + \sigma 2n \) for a limit ordinal \( \rho \); otherwise \( \tau \) is odd. If \( \sigma \) is an ordinal, let \( \sigma_{ev} \) and \( \sigma_{odd} \) be the set of even and odd ordinals less than \( \sigma \), respectively. Then \( \sigma_{ev} \) and \( \sigma_{odd} \) are disjoint, and \( \sigma_{ev} \cup \sigma_{odd} = \sigma \). Show that if \( \sigma \) is a limit ordinal, then the maps \( f(\rho + \sigma 2n) = \rho + n \) and \( f(\rho + \sigma 2n + 1) = \rho + n, \) as \( \rho \) runs over all limit ordinals less than \( \sigma \), give bijections from \( \sigma_{ev} \) and \( \sigma_{odd} \) onto \( \sigma \).
II.9. Cardinals

We now want to make precise the notion of the cardinality of a set. In the course of this section, we will define \( \text{card}(X) \) for any set \( X \). To avoid confusion, we will use \(|X|\) to denote the informal notion of cardinality developed in (:); so the statements \(|X| = |Y|\), \(|X| \leq |Y|\), \(|X| < |Y|\) make sense for sets \( X, Y \), although we avoid attaching any meaning to \( |X| \) itself.

The idea is that we want to have a standard “model set” \( \text{card}(X) \) for any set \( X \), with the properties that 

\[ |\text{card}(X)| = |X| \]

for any \( X \) and, for any \( X, Y \), \( \text{card}(X) = \text{card}(Y) \) if and only if \(|X| = |Y|\). This process only really works well in the presence of the Axiom of Choice. Indeed, what we want to do is a form of Choice, identifying one model set from each equipotence equivalence class. We will, however, not make a blanket assumption of the Axiom of Choice, since the delineation of what can and cannot be proved without it gives good insight into the nature and role of the Axiom of Choice. Results which are dependent on the Axiom of Choice will be denoted by \((\text{AC})\); some of these can be obtained using weakened Choice axioms such as Dependent Choice (:).

II.9.1. Cardinals as Ordinals

Cardinals are ordinals of a special type:

II.9.1.1. Definition. An ordinal \( \sigma \) is a cardinal, or cardinal number, if \( |\tau| < |\sigma| \) for every \( \tau < \sigma \). A cardinal is finite [infinite] if it is finite [infinite] as an ordinal.

The letters \( \kappa, \lambda, \chi \) are frequently used to denote general cardinals, and \( \aleph \) is also used to denote a general infinite cardinal (if the Axiom of Choice is not assumed, the symbol \( \aleph \) is reserved for only certain infinite cardinals: see (:).) The class of cardinals has a natural ordering induced from \( \Omega \), under which it is well ordered (in particular, totally ordered.)

II.9.1.2. Examples.

(i) Any finite ordinal is a cardinal.

(ii) \( \omega \) is a cardinal. No other countable infinite ordinal is a cardinal.

(iii) \( \omega_1 \) is a cardinal.

When regarded as cardinals, \( \omega \) and \( \omega_1 \) are usually denoted \( \aleph_0 \) and \( \aleph_1 \) respectively. \( \aleph_0 \) is the smallest infinite cardinal, and \( \aleph_1 \) is the smallest uncountable cardinal and is the smallest cardinal greater than \( \aleph_0 \).

II.9.1.3. Proposition. If \( \kappa \) and \( \lambda \) are cardinals, then \( |\kappa| < |\lambda| \) if and only if \( \kappa < \lambda \).

This is obvious from the definition.

So far, we have not needed the Axiom of Choice. But the Axiom of Choice is crucial in the next result, which is the key fact about cardinals.
II.9.1.4. **Theorem.** (AC) Let $X$ be any set. Then there is a unique cardinal $\kappa$ such that $|X| = |\kappa|$.

**Proof:** By the Well-Ordering Principle, there is a $\sigma \in \Omega$ with $|X| = |\sigma|$. Let $\kappa$ be the smallest such $\sigma$. Then $\kappa$ is clearly a cardinal. Uniqueness follows from II.9.1.3.

[This result is actually equivalent to the Well-Ordering Principle, as is easily seen.]

II.9.1.5. **Definition.** If $X$ is a set, then the **cardinality** of $X$, denoted $\text{card}(X)$, is the unique cardinal $\kappa$ with $|X| = |\kappa|$.

II.9.1.6. **Examples.**

(i) If $X$ is a finite set with $n$ elements, then $\text{card}(X) = n$.

(ii) If $X$ is countably infinite, then $\text{card}(X) = \aleph_0$.

(iii) If $\kappa$ is a cardinal, then $\text{card}(\kappa) = \kappa$.

II.9.1.7. If $Y \subseteq X$, then $\text{card}(Y) \leq \text{card}(X)$. We can have $\text{card}(Y) = \text{card}(X)$ even if $Y$ is a proper subset of $X$, provided $X$ and $Y$ are infinite. If $\sigma$ and $\tau$ are ordinals, and $\tau < \sigma$, then $\text{card}(\tau) \leq \text{card}(\sigma)$. We can have $\text{card}(\tau) = \text{card}(\sigma)$; for example, $\text{card}(\omega) = \text{card}(\omega + 1) = \aleph_0$. We have $\text{card}(\sigma) \leq \sigma$ for any ordinal $\sigma$.

II.9.1.8. If $\{\kappa_i : i \in I\}$ is a set of cardinals, there is a smallest cardinal $\kappa$ such that $\kappa_i \leq \kappa$ for all $i \in I$. This $\kappa$ is denoted $\lim\{\kappa_i : i \in I\}$ (it is the same as $\lim\{\kappa_i : i \in I\}$ in the ordinal sense.)

II.9.1.9. **Theorem.** If $\sigma$ is any ordinal, then there is a cardinal $\kappa$ with $\sigma < \kappa$.

This is easy to prove using the Axiom of Choice: we can take $\kappa = \text{card}(\mathcal{P}(\sigma))$. However, it can be proved without the Axiom of Choice. We first prove a lemma:

II.9.1.10. **Lemma.** Let $\sigma$ be an ordinal. Then the class $Z(\sigma) = \{\tau \in \Omega : |\tau| = |\sigma|\}$ is a set.

**Proof:** Let $s$ be a set with $|s| = |\sigma|$ (we could take $s = \sigma$.) If $\tau \in Z(\sigma)$, then there is a well-ordering on $s$ making $s$ order-isomorphic to $\tau$; thus the collection $\mathcal{R}_{\tau}$ of all well orderings on $s$ order-isomorphic to $\tau$ is nonempty. $\mathcal{R}_{\tau}$ is contained in the set of all relations on $s$, which can be identified with $\mathcal{P}(s \times s)$. If $\tau, \rho \in Z(\sigma)$, $\tau \neq \rho$, then $\mathcal{R}_{\tau}$ and $\mathcal{R}_{\rho}$ are disjoint and thus distinct. Thus $\tau \mapsto \mathcal{R}_{\tau}$ is an injective map from $Z(\sigma)$ to $\mathcal{P}(\mathcal{P}(s \times s))$, which is a set. 

185
II.9.1.11. **Corollary.** Let \( \sigma \) be an infinite ordinal, and \( \kappa = |Z(\sigma)| \). Then \( \kappa \) is a cardinal; \( |\sigma| < \kappa \), and \( \kappa \) is the smallest cardinal greater than \( \text{card}(\sigma) \). In fact, \( \kappa = \{ \tau \in \Omega : |\tau| \leq |\sigma| \} \).

**Proof:** The last formula is easy to verify, and the other statements follow immediately (note that \( \kappa \notin \kappa \)).

II.9.1.12. **Corollary.** The class of cardinals is not a set.

II.9.1.13. **Definition.** For each ordinal \( \sigma \), we (inductively) define \( \aleph_\sigma \) to be the smallest infinite cardinal (aleph) greater than \( \{ \aleph_\tau : \tau < \sigma \} \).

By II.9.1.11, \( \aleph_\sigma \) is defined for every ordinal \( \sigma \). This gives a one-to-one order-preserving correspondence \( \sigma \leftrightarrow \aleph_\sigma \) between the ordinals and the infinite cardinals (alephs).

II.9.1.14. **Definition.** The cardinal \( \aleph_\sigma \) is a **successor cardinal** if \( \sigma \) is a successor ordinal, and a **limit cardinal** if \( \sigma \) is a limit ordinal.

By this definition, \( \aleph_0 \) and \( \aleph_\omega \) are examples of limit cardinals, and \( \aleph_1 \) is a successor cardinal.

II.9.1.15. Since every cardinal is an ordinal, the function \( \sigma \mapsto \aleph_\sigma \) can be regarded as a map from \( \Omega \) to \( \Omega \). It is easy to prove by induction that \( \sigma \leq \aleph_\sigma \) for every \( \sigma \), and intuitively it seems that \( \aleph_\sigma \) is much bigger than \( \sigma \). Put another way: if \( \sigma \) is an ordinal, then it seems intuitively that \( \{ \kappa : \kappa \text{ a cardinal, } \kappa < \sigma \} \) should be quite a small subset of \( \sigma \), i.e. the cardinals should be sparsely distributed among the ordinals. However, it is not hard to show (Exercise II.9.7.10.) that there is a \( \sigma \) for which \( \aleph_\sigma = \aleph_\sigma \). (Such a \( \sigma \) is obviously a cardinal.) We discuss related matters in ().

II.9.2. **General Cardinals and Alephs**

II.9.2.1. We have so far only defined cardinals of sets which can be well ordered; these cardinals, if infinite, are called **alephs**. In the absence of the Axiom of Choice, there will be sets which cannot be well ordered and whose cardinal is as yet undefined. As described in the introduction, we want to pick a “model set” to serve as the cardinal of such a set. This can only be done rigorously in the presence of the Axiom of Regularity, and even then in a not entirely satisfactory way without the Axiom of Choice. However, even without the Axiom of Regularity it is possible to use the whole cardinal terminology as simply shorthand for statements about sets which would otherwise be cumbersome and inelegant. For example, II.9.7.11.(a) can be phrased without the language of cardinals as follows:

“Let \( X \) be a set containing a countably infinite subset. If \( Y \) is any set disjoint from \( X \) such that \( X \cup Y \) is equipotent with \( \mathcal{P}(X) \), then \( Y \) is equipotent with \( \mathcal{P}(X) \).”

We will thus be slightly imprecise and assume that \( \text{card}(X) \) has been defined for every set \( X \), so that we can write such statements as “Let \( \kappa \) be a cardinal.” The usual “ordering” gives a partial ordering on the class of all cardinals (the antisymmetric property follows from the Schröder-Bernstein Theorem.)
II.9.2.2. Infinite cardinals which are not alephs (if they exist) are not comparable with alephs in general. Although infinite cardinals, alephs are “small” in the sense that any infinite cardinal dominated by an aleph is again an aleph. However, there is no cardinal larger than all the alephs, since the class of alephs do not form a set (II.9.1.12.) Thus the statements in the previous section must be modified in the absence of the Axiom of Choice by interpreting “cardinal” to mean “cardinal of a well ordered set”, i.e. a natural number or aleph. For example, $\aleph_\sigma$ is the smallest aleph greater than $\{\aleph_\tau : \tau < \sigma\}$: there could be another cardinal $\kappa$ greater than all these alephs but incomparable with $\aleph_\sigma$. There could even be an infinite cardinal which is incomparable with $\aleph_0$! 

II.9.2.3. One different way “cardinality” of a set could be defined is to associate to a set $X$ the partially ordered set $S(X)$ of equipotence classes of subsets of $X$. This partially ordered set always has a largest element, and, if $X$ is infinite, contains a hereditary subset order-isomorphic to $\omega$. The set $S(X)$ is totally ordered if and only if $S$ can be well ordered; thus the AC is equivalent to the statement that $S(X)$ is always totally ordered. In this case, $S(X)$ is well ordered; if $X$ has cardinality $\aleph_\alpha$, then $S(X) \cong \omega + \alpha + 1$. However, in the absence of AC it is unclear whether $S(X) \cong S(Y)$ implies that $X$ and $Y$ are equipotent. It would be interesting to characterize which partially ordered sets occur as $S(X)$ for some $X$ (in the absence of AC).

II.9.3. Cardinal Arithmetic

Cardinal arithmetic is easy to define. However, it must be kept in mind that it is not the same as ordinal arithmetic for infinite cardinals (alephs), and one must always carefully distinguish whether cardinal or ordinal arithmetic is being used. The distinction is usually clear from the context; but if there is any possibility of confusion we will use $+_c$ and $+_o$ for cardinal and ordinal addition respectively, and similarly $\cdot_c$ and $\cdot_o$. We can also use the vertical arrow notation for exponentiation to distinguish between cardinal and ordinal exponentiation (where the distinction is more crucial), writing $\sigma \uparrow_o \tau$ for $\sigma^\tau$ in the ordinal sense, and $\kappa \uparrow_c \lambda$ for cardinal exponentiation.

II.9.3.1. Definition. Let $\kappa$ and $\lambda$ be cardinals, and let $X$ and $Y$ be disjoint sets (see Exercise II.5.6.15.) with $\text{card}(X) = \kappa$, $\text{card}(Y) = \lambda$. Then

- $\kappa + \lambda = \kappa +_c \lambda = \text{card}(X \cup Y)$.
- $\kappa \cdot \lambda = \kappa \cdot_o \lambda = \text{card}(X \times Y)$.
- $\kappa^\lambda = \kappa \uparrow_c \lambda = \text{card}(X^Y)$ (where $X^Y$ denotes the set of functions from $Y$ to $X$.)

It is clear that this definition does not depend on the choice of the sets $X$ and $Y$.

The definition of cardinal exponentiation gives the explanation for the notation $\text{card}(\mathcal{P}(\mathbb{N})) = \text{card}(\{0, 1\}^\mathbb{N}) = 2^{\aleph_0}$, since for set theorists $2 = \{0, 1\}$.

Cardinal addition and multiplication agree with ordinary addition and multiplication for finite cardinals. Cardinal addition and multiplication are not very interesting for infinite cardinals, at least for alephs:

II.9.3.2. Theorem. Let $\kappa$ and $\lambda$ be nonzero cardinals of well-ordered sets, not both finite. Then

$\kappa + \lambda = \kappa \cdot \lambda = \max(\kappa, \lambda)$.

Note that $()$ and $()$ are special cases.
II.9.3.3. Exponentiation of cardinals is very interesting, however, and is quite different from ordinal exponentiation (for example, \( \omega^\omega = \omega \uparrow \omega \) is a countable ordinal, hence \( \text{card}(\omega^\omega) = \aleph_0 \), but \( \aleph_0^{\aleph_0} = \aleph_0 \uparrow \aleph_0 \) is an uncountable cardinal.)

Cardinal addition, multiplication, and exponentiation satisfy the usual algebraic rules (Exercise ().) However, subtraction and division are another matter: they are usually not well defined.

II.9.3.4. The sum of an infinite set of cardinals can also be defined. If \( \{\kappa_i : i \in I\} \) is an indexed set of cardinals, and \( \{X_i : i \in I\} \) is a collection of disjoint sets (see Exercise ()) with \( \text{card}(X_i) = \kappa_i \) (e.g. \( X_i = \{i\} \times \kappa_i \)), then \( \sum_i \kappa_i = \text{card}(\bigcup_i X_i) \). If \( \kappa = \lim \{\kappa_i : i \in I\} \) is an aleph and \( \text{card}(I) \leq \kappa \) (in particular, if the \( \kappa_i \) are all distinct), then \( \sum_{i \in I} \kappa_i = \kappa \). Infinite products can be defined similarly.

II.9.4. The Role of the Axiom of Choice

In this subsection, we explore what can and cannot be proved about cardinals without assuming the Axiom of Choice (AC).

II.9.4.1. If \( \aleph \) is an aleph, then \( \aleph + \aleph = \aleph \) and \( \aleph^2 = \aleph \aleph = \aleph \). It cannot be proved without AC that \( \kappa + \kappa = \kappa \) or \( \kappa^2 = \kappa \) for every infinite cardinal \( \kappa \). In fact, the statement that \( \kappa^3 = \kappa \) for every infinite cardinal \( \kappa \) implies (hence is equivalent to) AC [?, XVI.2 Theorem 6]. The statement that \( \kappa + \kappa = \kappa \) for all infinite \( \kappa \) is strictly weaker than AC ([?]; cf. Exercise II.9.7.4.). It can be proved without AC that some infinite cardinals not provably alephs, such as \( \kappa = 2^{\aleph_0} \), satisfy \( \kappa + \kappa = \kappa^2 = \kappa \); see Exercise (). [?, XVI.2] contains several other similar statements equivalent to AC (see Exercise ().)

If AC is not assumed, the class of cardinals is not totally ordered by \( \leq \) (in fact, \( \leq \) being a total order is equivalent to AC, cf. II.9.7.1.). In the absence of AC, there is another interesting and potentially different “ordering” on cardinals:

II.9.4.2. Definition. Let \( \kappa = \text{card}(X) \) and \( \lambda = \text{card}(Y) \) be cardinals. Then \( \kappa \not\lesssim \lambda \) if there is a surjective function from \( Y \) to \( X \).

The relation \( \not\lesssim \) is clearly well defined on cardinals, and transitive. If \( 0 \neq \kappa \leq \lambda \), then \( \kappa \not\lesssim \lambda \) (Exercise ());

if AC is assumed, \( \leq \) and \( \not\lesssim \) coincide (except that \( 0 \not\lesssim \kappa \) if \( \kappa \neq 0 \).) In the absence of AC, it cannot be proved that \( \not\lesssim \) is antisymmetric (i.e. there is no analog of the Schröder-Bernstein Theorem; see Exercise ()(b).) It is provable without AC that \( \kappa \not\lesssim \lambda \) implies \( 2^\kappa \leq 2^\lambda \) (Exercise ()).

II.9.4.3. Proposition. Let \( \kappa = \text{card}(I) \) and \( \lambda = \text{card}(Y) \) be cardinals. Then \( \kappa \not\lesssim \lambda \) if and only if \( Y \) can be written as \( \bigcup_{i \in I} Y_i \), with the \( Y_i \) nonempty and disjoint.

Proof: If \( f : Y \to I \) is surjective, let \( Y_i = f^{-1}(\{i\}) \). Conversely, if \( Y = \bigcup Y_i \), define \( f : Y \to I \) by \( f(y) = i \) if \( y \in Y_i \).
II.9.4.4. If $\kappa$ is a cardinal, then it is not true that $\aleph_\sigma \leq \kappa$ for all $\sigma$. Thus there is a smallest aleph $\aleph$ such that $\aleph \leq \kappa$ is not true. This aleph is denoted $\aleph^+(\kappa)$. (Some authors such as [?] use the notation $\aleph(\kappa)$, but this is confusing since $\aleph^+(\aleph_\sigma) = \aleph_{\sigma+1}$, not $\aleph_\sigma$.) It is easily checked that, if $\kappa$ is infinite,

$$\aleph^+(\kappa) = \{ \sigma \in \Omega : \text{card}(\sigma) \leq \kappa \} .$$

II.9.4.5. Theorem. Let $\kappa$ be an infinite cardinal. Then $\aleph^+(\kappa) \leq 2^{2^\kappa}$, and hence $\aleph^+(\kappa) < 2^{\aleph^+(\kappa)} \leq 2^{2^{2^\kappa}}$.

For the proof, note that if $X$ is a set with $\text{card}(X) = \kappa$, then each subset of $\mathcal{P}(X)$ (element of $\mathcal{P}(\mathcal{P}(X))$) has a natural partial order induced by set inclusion.

II.9.4.6. Lemma. For each ordinal $\sigma < \aleph^+(\kappa)$, there is a subset of $\mathcal{P}(X)$ (element of $\mathcal{P}(\mathcal{P}(X))$) which is well ordered of order type $\sigma$.

Proof: Let $f$ be a bijection from $\sigma$ to a subset $Y$ of $X$. For $\rho \leq \sigma$, let $Y_\rho = \{ f(\tau) : \tau < \rho \}$. Then $\rho \to Y_\rho$ is an order-embedding of $\sigma$ into $\mathcal{P}(X)$.

Proof: We now prove Theorem II.9.4.5. Construct a function $f : \mathcal{P}(\mathcal{P}(X)) \to \aleph^+(\kappa)$ as follows. If $S \in \mathcal{P}(\mathcal{P}(X))$ is well ordered of order type $\tau$ for some $\sigma < \aleph^+(\kappa)$, set $f(S) = \sigma$; otherwise set $f(S) = 0$. By the lemma, $f$ is surjective. The last statement follows from (? and (?).

II.9.4.7. Remark. If we instead let $\Sigma^+(\kappa)$ be the set of all order types of well ordered elements of $\mathcal{P}(\mathcal{P}(X))$, then it is easily checked that $\Sigma^+(\kappa)$ is an ordinal $\geq \aleph^+(\kappa)$. But it is not obvious without AC that $\Sigma^+(\kappa)$ is a cardinal, or that $\text{card}(\Sigma^+(\kappa)) = \aleph^+(\kappa)$ (although the last statement is asserted without proof in [?, ]). Using the Axiom of Choice, if $f : \sigma \to A_\sigma$ is an order-preserving bijection, we can choose an element $x_\tau \in A_{\tau+1} \setminus A_\tau$ for each $\tau < \sigma$, and it follows easily that $\Sigma^+(\kappa) = \aleph^+(\kappa)$.

It cannot be proved without AC that $\aleph^+(\kappa) \leq 2^{2^\kappa}$ (but see Exercise (?).)

II.9.4.8. If $\kappa$ is finite, then $\aleph^+(\kappa) = \aleph_0$. Without AC, it is conceivable that there could be infinite $\kappa$ for which $\aleph^+(\kappa) = \aleph_0$, i.e. $\aleph_0 \not\leq \kappa$. It is even conceivable that there could be infinite $\kappa$ for which $\aleph_0 \not\leq \kappa$. Thus, without AC, there are three possible definitions of infinite sets or cardinals, which are successively more restrictive:

II.9.4.9. Definition. Let $\kappa = \text{card}(X)$ be a cardinal.

$X$ is an infinite set $(\kappa$ is an infinite cardinal) if $\kappa \neq n$ for every $n \in \aleph$.

$X$ or $\kappa$ is countably decomposable if $\aleph_0 \not\leq \kappa$, i.e. if $X$ can be decomposed as a disjoint union of a countably infinite number of disjoint nonempty subsets.

$X$ or $\kappa$ is infinite in the sense of Dedekind if $\aleph_0 \leq \kappa$, i.e. if $X$ contains a countably infinite subset.

Dedekind’s definition was actually that a set is infinite if it can be put in one-one correspondence with a proper subset of itself. It is easily seen (?) that this condition is equivalent to the presence of a countably infinite subset.
It can be easily shown by induction () that for any \( \kappa \), either \( \kappa = n \) for some \( n \in \mathbb{N} \) or else \( n < \kappa \) for all \( n \in \mathbb{N} \). Thus \( \kappa \) is infinite if and only if \( n < \kappa \) for all \( n \in \mathbb{N} \).

It is obvious that a countably decomposable set is infinite, since there is no surjective function from \( n \) to \( \mathbb{N} \) ().

II.9.4.10. **PROPOSITION.** Let \( X \) be a set, and \( \kappa = \text{card}(X) \). The following are equivalent:

(i) \( X \) (or \( \kappa \)) is infinite.

(ii) \( \aleph_0 \nless 2^\kappa \).

(iii) \( 2^{\aleph_0} \leq 2^{2^\kappa} \).

(iv) \( 2^{\aleph_0} < 2^{2^\kappa} \).

**Proof:** (i) \( \Rightarrow \) (ii) is Exercise (), and (ii) \( \Rightarrow \) (iii) is Exercise ()(b) (cf. Exercise ()(b).) (iv) \( \Rightarrow \) (iii) \( \Rightarrow \) (i) is obvious since (iii) implies that \( 2^{2^\kappa} \) is infinite. To show (iii) \( \Rightarrow \) (iv), it suffices to show that \( 2^{\aleph_0} \neq 2^{2^\kappa} \) for any \( \kappa \). If \( 2^{\aleph_0} = 2^{2^\kappa} \), we have \( \kappa < 2^\kappa < 2^{2^\kappa} = 2^{\aleph_0} \), contradicting Exercise ().

II.9.4.11. It can be shown (Exercise ()) that \( X \) is countably decomposable if and only if \( X \) can be written as a union of countably many distinct subsets (Exercise ()). It cannot be shown without some form of AC (Countable AC suffices) that every infinite cardinal is countably decomposable; but any infinite cardinal which is comparable with \( 2^{\aleph_0} \) is countably decomposable (Exercise ()). We have:

II.9.4.12. **PROPOSITION.** Let \( X \) be a set and \( \kappa = \text{card}(X) \). The following are equivalent:

(i) \( X \) (or \( \kappa \)) is countably decomposable.

(ii) \( \mathcal{P}(X) \) is infinite in the sense of Dedekind, i.e. \( \aleph_0 \leq 2^\kappa \).

(iii) \( 2^{\aleph_0} \leq |\mathcal{P}(X)| = 2^\kappa \).

**Proof:** (i) \( \Rightarrow \) (iii) is Exercise (), and (ii) \( \Rightarrow \) (i) is Exercise () since then there is a countably infinite set of distinct subsets of \( X \), whose union is \( X \) since \( X \) can be added to the collection of subsets. (iii) \( \Rightarrow \) (ii) is trivial since \( \aleph_0 < 2^{\aleph_0} \).

It cannot be shown without some form of AC (Countable AC suffices) that every countably decomposable set is infinite in the sense of Dedekind. The next proposition gives some alternate characterizations of infiniteness in the sense of Dedekind.

190
II.9.4.13. **Proposition.** Let \( X \) be a set, and \( \kappa = \text{card}(X) \). The following are equivalent:

(i) \( X \) is infinite in the sense of Dedekind.

(ii) \( \kappa = \kappa + \aleph_0 \).

(iii) \( \kappa = \kappa + 1 \).

(iv) If \( \kappa = \lambda + 1 \), then \( \lambda = \kappa \).

(v) If \( Y \) is any set obtained from \( X \) by adding or removing finitely many points, then \( \text{card}(Y) = \kappa \).

(vi) There is a proper subset \( Y \) of \( X \) which is equipotent with \( X \).

**Proof:** (i) \( \Rightarrow \) (ii), (i) \( \Rightarrow \) (iii), (i) \( \Rightarrow \) (iv), (i) \( \Rightarrow \) (v) are all proved the same way: if \( Z \) is a countably infinite subset of \( X \), and \( W \) is \( Z \) with a finite number of elements removed, or a finite or countable number of points added, then \( |Z| = |W| \) and \( |X| = |(X \setminus Z) \cup Z| = |(X \setminus Z) \cup W| \).

It is obvious that any of (ii), (iii), (iv), (v) imply (vi).

(vi) \( \Rightarrow \) (i): Let \( Y \) be a proper subset of \( X \) and \( f : X \to Y \) a bijection. Fix \( x \in X \setminus Y \), and let \( x_n = f^{(n)}(x) \), where \( f^{(n)} = f \circ f \circ \cdots \circ f \) (\( n \) times.) Then \( \{x_n : n \in \mathbb{N}\} \) is a countably infinite subset of \( X \).

II.9.5. The Continuum Hypothesis

If \( X \) is any set, and \( \text{card}(X) = \kappa \), then \( \text{card}(\mathcal{P}(X)) = \text{card}(\{0, 1\}^X) = 2^\kappa \). By Cantor’s Theorem (\( \dagger \)), \( \kappa < 2^\kappa \).

In aleph notation, \( \aleph_{\sigma + 1} \leq 2^{\aleph_{\sigma}} \) for every \( \sigma \). (Without AC, it can only be proved that \( \aleph_{\sigma + 1} \preceq 2^{\aleph_{\sigma}} \) (Exercise (\( \dagger \)).) In particular, \( \aleph_1 \leq 2^{\aleph_0} \). Do we have equality? This is equivalent (under AC) to the question whether every uncountable subset of \( \mathbb{R} \) has cardinality \( 2^{\aleph_0} \).

II.9.5.1. **Continuum Hypothesis (CH):** \( 2^{\aleph_0} = \aleph_1 \).

II.9.5.2. It was a big mathematical industry in the first part of the 20th century (actually beginning with Cantor in the 19th century) to try to prove (or, sometimes, to disprove) this hypothesis. Perhaps surprisingly, it turns out to be independent of ZFC, i.e. it cannot be either proved or disproved in ZFC!\(^{12}\)

Mathematicians to this day have had various opinions about whether the CH “should be” true, and it is much more customary than with AC to carefully note any use of the CH in proofs and to avoid using it whenever possible.

The Axiom of Choice is also independent of ZF+CH. However, the CH implies a weak version of AC: \( \mathbb{R} \) can be well ordered since it is equipotent with \( \omega_1 \). This in turn implies that there is a choice function for \( \mathcal{P}(\mathbb{R}) \) (\( \dagger \)). But the CH does not even imply the Countable Axiom of Choice.

If the AC is not assumed, then there is a weaker version of the Continuum Hypothesis which is not equivalent to the one above:

\(^{12}\)This statement is again under the assumption that ZF is consistent.
II.9.5.3. **Weak Continuum Hypothesis:** There is no cardinal strictly between $\aleph_0$ and $2^{\aleph_0}$, i.e. if $X \subseteq P(\mathbb{N})$ (or $X \subseteq \mathbb{R}$), then either $X$ is countable or $|X| = |P(\mathbb{N})| = |\mathbb{R}|$.

In fact there are many inequivalent ways to phrase the CH in the absence of the AC. See [http://math.stackexchange.com/questions/404807/how-to-formulate-continuum-hypothesis-without-the-axiom-of-choice?rq=1](http://math.stackexchange.com/questions/404807/how-to-formulate-continuum-hypothesis-without-the-axiom-of-choice?rq=1) for a discussion.

There is a generalized version of the Continuum Hypothesis:

II.9.5.4. **Generalized Continuum Hypothesis (Version 1):** $2^{\aleph_\sigma} = \aleph_{\sigma+1}$ for every $\sigma$.

This is also independent of ZFC (?). However, without the Axiom of Choice there is another version analogous to the Weak Continuum Hypothesis:

II.9.5.5. **Generalized Continuum Hypothesis (Version 2):** If $\kappa$ is any infinite cardinal, then there is no cardinal strictly between $\kappa$ and $2^\kappa$.

II.9.5.6. Note that Version 2 is not really weaker than Version 1, since it is an assertion about all sets, not just those which can be well ordered. In fact, it turns out that Version 2 implies the Axiom of Choice, and thus also Version 1 (Exercise ()).

The Continuum Hypothesis does not imply the Generalized Continuum Hypothesis Version 1. There are intermediate hypotheses, saying $2^{\aleph_\sigma} = \aleph_{\sigma+1}$ for every $\sigma$ up to some point but not beyond.

II.9.6. **Large Cardinals**

We will give only the briefest introduction to the bizarre world of large cardinals, emphasizing the measurable cardinals (as is appropriate in a book on real analysis.) In this section, “cardinal” means “cardinal of a well ordered set”; we may as well assume the Axiom of Choice.

II.9.6.1. **Definition.** Let $\kappa$ be a cardinal. Then $\kappa$ is regular if $\kappa$ is not equal to $\sum_{i \in I} \kappa_i$ for any set $\{\kappa_i : i \in I\}$ with $\text{card}(I) < \kappa$ and $\kappa_i < \kappa$. Otherwise $\kappa$ is singular.

Equivalently, $\kappa$ is regular if a set of cardinality $\kappa$ cannot be written as a union of fewer than $\kappa$ subsets, each of cardinality less than $\kappa$. Among the finite cardinals, only 0, 1, and 2 are regular. Among infinite cardinals, every successor cardinal is regular; $\aleph_0$ is regular, but “most” limit cardinals are singular, for example $\aleph_\omega = \sum_{n \in \mathbb{N}} \aleph_n$.

II.9.6.2. **Definition.** An infinite cardinal $\kappa$ is weakly inaccessible if it is an uncountable regular limit cardinal.

II.9.6.3. A weakly inaccessible cardinal cannot be reached from below by taking successor cardinals or sums of smaller sets of smaller cardinals. The set of cardinals less than a weakly inaccessible cardinal $\kappa$ has cardinality $\kappa$, the same as the set of ordinals less than $\kappa$ (i.e. $\kappa = \aleph_\kappa$), so the cardinals less than $\kappa$ are in this sense not so sparsely distributed among the ordinals. (But $\kappa = \aleph_\kappa$ does not imply that $\kappa$ is weakly inaccessible (Exercise ())).
II.9.6.4. There is one potential way to reach a weakly inaccessible cardinal: in the absence of the Continuum Hypothesis, even $2^\alpha$ might be so huge as to be weakly inaccessible, or exceed a weakly inaccessible cardinal. In fact, it appears to be consistent with ZFC to assume this. So we strengthen the definition of inaccessibility:

II.9.6.5. Definition. A cardinal $\kappa$ is inaccessible, or strongly inaccessible, if it is weakly inaccessible and $\lambda < \kappa$ implies $2^\lambda < \kappa$.

If the Generalized Continuum Hypothesis is assumed, there is no difference between weak and strong inaccessibility.

II.9.6.6. The question then becomes: do (weakly) inaccessible cardinals exist?

Inaccessible cardinals cannot be reached by any of the operations of set theory, and thus their existence cannot be proved in ZFC. For if there does exist an inaccessible cardinal in some model of ZFC, let $\kappa$ be the smallest inaccessible cardinal. Then the set $V_\kappa$ of Exercise () can be taken to be the universe of a model for ZFC in which there are no inaccessible cardinals. On the other hand, it appears to be consistent with ZFC to assume that there exists an inaccessible cardinal.

II.9.6.7. Note that the cardinals immediately larger than an inaccessible cardinal are not inaccessible. In fact, if there is a second inaccessible cardinal, it must be vastly larger than the first one. The same proof as in the previous paragraph shows that even if an inaccessible cardinal is assumed to exist, it cannot be proved in ZFC that a second one also exists. Thus the inaccessible cardinals are (seemingly) very sparsely distributed even among all cardinals, let alone among all ordinals.

II.9.6.8. Inaccessible cardinals are often called large cardinals. (Set theorists make a technical distinction between inaccessible cardinals and “large cardinals”, which have no precise widely-accepted definition, but inaccessible cardinals are large cardinals by any reasonable definition, and the classes of large cardinals which have been studied are inaccessible cardinals.) There is an enormous hierarchy of types of large cardinals which have been considered. For an analyst, the most interesting class is the class of measurable cardinals, discussed in the next section. See [Kan03] for a full discussion of all types of large cardinals, or [Ruc82] for a readable semitechnical description of some of them.

Large cardinals may seem far removed from the “real world”, but it turns out that existence axioms for certain kinds of large cardinals have close connections with natural questions about subsets of $\mathbb{R}$ and even $\mathbb{N}$. See () for a discussion of a few of these; [Kan03] has a full treatment.

II.9.7. Exercises

II.9.7.1. (a) Show that the AC (Well-Ordering Principle) implies that $\leq$ is a total order (in fact, well order) on the class of all cardinals.

(b) Conversely, suppose $\leq$ is a total order on the class of all cardinals. If $\kappa$ is a cardinal, show that $\kappa \leq \aleph^+ (\kappa)$ (II.9.4.4.), and hence $\kappa$ is an aleph. Conclude that AC holds.

Thus the AC is equivalent to the statement that the class of cardinals is totally ordered.
II.9.7.2. (a) If $\kappa$ is an infinite cardinal (aleph), then $\text{card}(\kappa_{\text{ev}}) = \text{card}(\kappa_{\text{odd}}) = \kappa$ (II.8.7.7). Thus $\kappa + \kappa = \kappa$.
(b) Conclude that if $\kappa$ and $\lambda$ are infinite cardinals (alephs), then $\kappa + \lambda = \max(\kappa, \lambda)$.
(c) Show that if $\kappa$ is an infinite cardinal (aleph), then $\kappa + c n = \kappa$ for each finite cardinal $n$.

II.9.7.3. Let $\kappa$ be an infinite cardinal (aleph). Define an ordering on $\kappa \times \kappa$ by setting $(\pi, \rho) < (\sigma, \tau)$ if $\max(\pi, \rho) < \max(\sigma, \tau)$, or if $\max(\pi, \rho) = \max(\sigma, \tau)$ and $\pi < \sigma$, or if $\max(\pi, \rho) < \max(\sigma, \tau)$, $\pi = \sigma$, and $\rho < \tau$.
(a) Show that this is a well ordering on $\kappa \times \kappa$. Draw a picture illustrating the ordering.
(b) Assume that $\lambda \cdot \lambda < \kappa$ for all cardinals $\lambda < \kappa$. Show that every element of $\kappa \times \kappa$ has fewer than $\kappa$ predecessors under this ordering, so if $\sigma$ is the order type of the well ordering, then $\sigma \leq \kappa$. Conclude that $\text{card}(\kappa \cdot \kappa) \leq \kappa$. (The opposite inequality also obviously holds.)
(c) Prove by transfinite induction on $\kappa$ that $\kappa \cdot \kappa = \kappa$ if $\kappa$ is an aleph.
(d) Conclude that if $\lambda \neq 0$ is finite or an aleph, then $\kappa \cdot \lambda = \max(\kappa, \lambda)$.

II.9.7.4. (a) Let $\kappa$ be a cardinal. If $\kappa + \kappa = \kappa$, show that $\aleph_0 \cdot \kappa = \kappa$. [Let $X$ be a set with $|X| = \kappa$ and $f$ and $g$ one-to-one functions from $X$ to $X$ with disjoint ranges. Consider the functions $g \circ g \circ \ldots \circ g \circ f$.]
(b) Show that $\text{AC}$ implies that $\kappa + \kappa = \kappa$ for every infinite cardinal $\kappa$. The converse implication does not hold [].
(c) Assume $\kappa + \kappa = \kappa$ for all $\kappa \geq \aleph_0$. Show (without $\text{AC}$) that every infinite cardinal is Dedekind-infinite, i.e. $\geq \aleph_0$ [].

II.9.7.5. Suppose $X$ is a set of cardinality $\chi$, and there is a purely nonatomic (countably additive) $\{0,1\}$-valued measure $\mu$ on $(X, \mathcal{P}(X))$ with $\mu(X) = 1$.
(a) Suppose, for some $\kappa < \chi$, there are sets $\{A_i : i \in I\}$ with each $A_i \subseteq X$ and $\text{card}(I) = \kappa$, such that $\mu(A_i) = 0$ for all $i$ but $\mu(\bigcup_{i \in I} A_i) = 1$, and suppose $\kappa$ is the smallest cardinal for which this happens. If $E \subseteq I$, define $\nu(E) = \mu(\bigcup_{i \in E} A_i)$. Then $\nu$ is a $\{0,1\}$-valued measure on $I$ with $\nu(\{i\}) = 0$ for all $i \in I$ and $\nu(I) = 1$. Also, $\nu$ is $\kappa$-additive by minimality of $\kappa$, so $\kappa$ is measurable.
(b) If no $\kappa < \chi$ is measurable, conclude that $\mu$ is $\chi$-additive, so $\chi$ is measurable.
(c) If $\chi$ is the first measurable cardinal, and $\kappa$ is a cardinal, use the argument of (a) to show that every $\{0,1\}$-valued measure (on $(Y, \mathcal{P}(Y))$ for some set $Y$) is $\kappa$-additive if and only if $\kappa < \chi$.

II.9.7.6. [?] Suppose $X$ is a set, and $\nu$ is a purely nonatomic probability measure on $(X, \mathcal{P}(X))$. Show that there is a purely nonatomic $\{0,1\}$-valued measure $\mu$ on $(X, \mathcal{P}(X))$ with $\mu(X) = 1$. Conclude that $\text{card}(X)$ dominates a measurable cardinal. (This requires that $2^{\aleph_0}$ does not dominate an inaccessible cardinal.)
II.9.7.7.  Let \( \kappa \) and \( \lambda \) be cardinals.

(a) Show (without AC) that if \( \kappa \leq \lambda \), then \( \kappa \preceq \lambda \). [Mimic the proof of II.5.4.1.]

(b) Show (without AC) that if \( \kappa \preceq \lambda \), then \( 2^\kappa \leq 2^\lambda \). [If \( \text{card}(X) = \kappa \) and \( \text{card}(Y) = \lambda \), and \( f : Y \to X \), define \( f^*: \mathcal{P}(X) \to \mathcal{P}(Y) \) by \( f^*(A) = f^{-1}(A) \). If \( f \) is surjective, then \( f^* \) is injective.]

(c) Use (b) to show that if \( \kappa \) is any cardinal, then \( 2^\kappa \npreceq \kappa \). This also follows directly from the proof of II.5.3.3.

II.9.7.8.  (a) Show (without AC) that if \( \kappa \) is any infinite cardinal, then \( \aleph_0 \npreceq 2^\kappa \). [If \( \text{card}(X) = \kappa \) and \( n \in \mathbb{N} \), the set of subsets of \( X \) of cardinality \( n \) is nonempty. Define \( f : \mathcal{P}(X) \to \{0\} \cup \mathbb{N} \cup \{\infty\} \) by \( f(A) = \text{card}(A) \) if \( A \subseteq X \) is finite, and \( f(A) = \infty \) otherwise.]

(b) Conclude from II.9.7.7. (b) that \( 2^{\aleph_0} \leq 2^\kappa \). Explicitly describe a subset of \( \mathcal{P}(\mathcal{P}(X)) \) of cardinality \( 2^{\aleph_0} \).

[For \( S \subseteq \mathbb{N} \), consider \( \{A \subseteq X : \text{card}(A) \in S\} \}.]

II.9.7.9.  (a) Show (without AC or CH) that \( \aleph_1 \npreceq 2^{\aleph_0} \). [Define \( f : \mathcal{P}(\mathbb{Q}) \to \aleph_1 = \omega_1 \) as follows. If \( A \subseteq \mathbb{Q} \), set \( f(A) = \sigma \) if \( A \) is well ordered (in the induced order from \( \mathbb{Q} \)) and order-isomorphic to \( \sigma \); set \( f(A) = 0 \) if \( A \) is not well ordered.]

(b) \[?] If \( \aleph_1 \) and \( 2^{\aleph_0} \) are not comparable (i.e. if \( \aleph_1 \npreceq 2^{\aleph_0} \)), then there is a cardinal \( \kappa \) satisfying \( \kappa > 2^{\aleph_0} \) but \( \kappa \npreceq 2^{\aleph_0} \). [Set \( \kappa = \aleph_1 + 2^{\aleph_0} \). Let \( f : [0,1] \to \aleph_1 \) be surjective, and \( g : \mathbb{R} \setminus [0,1] \to \mathcal{P}(\mathbb{N}) \) be a bijection. Then \( f, g \) give a surjective map from \( \mathbb{R} \) to \( \aleph_1 \cup \mathcal{P}(\mathbb{N}) \). Then \( 2^\kappa = 2^{2^{\aleph_0}} \). It cannot be proved in ZF that \( \aleph_1 \leq 2^{\aleph_0} \).]

II.9.7.10.  Set \( \kappa_0 = \aleph_0, \kappa_{n+1} = \kappa_{\kappa_n} \) for each \( n \), and \( \kappa = \lim \{\kappa_n\} \). Show that \( \kappa = \aleph_\sigma \) for some \( \sigma \). Since \( \tau \leq \aleph_\tau \) for all \( \tau \) by (\( \cdot \)), \( \sigma \leq \kappa \). If \( \sigma < \kappa \), then \( \sigma < \kappa_n \) for some \( n \), so \( \aleph_\sigma < \aleph_{\kappa_n} = \kappa_{n+1} \leq \kappa \).

II.9.7.11.  (a) Show (without AC) that if \( \kappa \) is a cardinal with \( \aleph_0 \leq \kappa \), and \( \lambda \) is a cardinal with \( \kappa + \lambda = 2^\kappa \), then \( \lambda = 2^\kappa \). [This is a hard problem; see [?], IX.5 for a solution.]

(b) Show (without AC) that if \( \kappa \) is a cardinal with \( \aleph_0 \leq \kappa \), then \( 2^\kappa + 2^\kappa = 2^\kappa \). [It follows from \( \aleph_0 \leq \kappa \) that \( \kappa = 1 + \kappa \), so \( 2^\kappa = 2^{1+\kappa} = 2 \cdot 2^\kappa \).]

(c) Using (a), show (without AC) that if the GCH2 (\( \cdot \)) is assumed, then every cardinal is dominated by an aleph, hence is an aleph, yielding the Axiom of Choice. [If \( \kappa_0 \) is an infinite cardinal, set \( \kappa = \kappa_0 + \aleph_0 \), and \( \lambda = \kappa + \aleph_\kappa (\cdot) \). Then \( 2^{2^\kappa} + \lambda \leq 2^{2^\kappa} \) by (\( \cdot \)) and (b). Conclude from (a) and the GCH2 that either \( \lambda = 2^{2^\kappa} \), in which case by (a), \( \aleph_\kappa (\cdot) = 2^{2^\kappa} \); or else \( \lambda \leq 2^{2^\kappa} \). If \( \lambda \leq 2^{2^\kappa} \), then \( 2^\kappa + \lambda \leq 2^{2^\kappa} \), so by the same argument either \( \aleph_\kappa (\cdot) = 2^{2^\kappa} \) or \( \lambda \leq 2^{2^\kappa} \); if the latter, apply (a) and the GCH2 again to conclude that \( 2^\kappa = \aleph_\kappa (\cdot) \).]

II.9.7.12.  Show (without AC) that for any infinite cardinal \( \kappa \), we have \( \aleph_\kappa (\cdot) \leq 2^{2^\kappa} \).[Mimic the proof of II.9.1.10.]

II.9.7.13.  [?], VIII.2 Ex. 2 Show (without AC) that if \( \kappa \) is infinite and \( \kappa \leq 2^{\aleph_0} \), then \( \aleph_0 \npreceq \kappa \) (and hence \( 2^{\aleph_0} \leq 2^\kappa \) by (\( \cdot \)), as follows. (This appears to be a curious result: it apparently says that if \( \kappa \) is infinite and “not too large”, then \( \kappa \) is “not too small”.)
(a) Fix an enumeration \((r_1, r_2, \ldots)\) of \(\mathbb{Q}\). If \(X\) is an infinite subset of \(\mathbb{R}\), let \(r_n\) be the first rational number \(r\) such that there are \(a, b \in X\) with \(a \leq r < b\). Then, if \(Y = X \cap \{x \in \mathbb{R} : x \leq r_n\}\) and \(Z = X \setminus Y\), \(Y\) and \(Z\) are disjoint and nonempty, and \(X = Y \cup Z\). At least one of \(Y\), \(Z\) is infinite.

(b) Use the procedure in (a) inductively, beginning with an infinite subset \(X\) of \(\mathbb{R}\): write \(X = X_1 \cup Y_1\) with \(X_1\) nonempty, \(Y_1\) infinite, and \(X_1, Y_1\) disjoint. Similarly decompose \(Y_1 = X_2 \cup Y_2\), \(\ldots\), \(Y_n = X_{n+1} \cup Y_{n+1}\).

(c) Set \(X_{\infty} = \bigcap_n Y_n = X \setminus \bigcup_n X_n\). If \(X_{\infty} \neq \emptyset\), then \(X\) is the disjoint union
\[
X = X_1 \cup X_2 \cup \ldots \cup X_{\infty}
\]
of \(\aleph_0\) nonempty sets, and otherwise \(X = \bigcup_n X_n\) is a disjoint union of \(\aleph_0\) nonempty sets.

(d) Conclude that if \(\kappa\) is a cardinal and \(2^\kappa < 2^{\aleph_0}\), then \(\kappa\) is finite.

It cannot be proved without some form of Choice (Countable AC suffices) that an infinite subset of \(\mathbb{R}\) contains a countably infinite subset \(\emptyset\).

II.9.7.14. \(\Box\) Show (without AC) that if \(\kappa\) and \(\lambda\) are cardinals \(\geq 2\), at least one of which is infinite, and \(\kappa \leq \lambda\), then \(\kappa^\lambda = \lambda^\max\). In particular, if \(\kappa\) is infinite, then \(\kappa^2 \leq 2^\kappa\). (We can have \(\kappa^\lambda = \lambda^\kappa\) even if \(\kappa < \lambda\) and both are infinite. For example, if \(\kappa = \text{lim}\{\aleph_0, 2^{\aleph_0}, 2^{2^{\aleph_0}}, \ldots\}\), then \(2^\kappa = \aleph_0^\aleph_0 = \kappa^{\aleph_0} = \kappa^\kappa\) [?, VIII.3].)

II.9.7.15. (a) Show (without AC) that cardinal addition and multiplication satisfy the associative, commutative, and distributive laws.

(b) Show (without AC) that cardinal exponentiation satisfies the usual rules of exponents: if \(\kappa, \lambda, \mu\) are cardinals, then \(\kappa^{\lambda \mu} = (\kappa^\lambda)^\mu\) and \(\kappa^{\mu \lambda} = (\kappa^\mu)^\lambda\).

(c) Show (without AC) that if \(\kappa_1 \leq \kappa_2\) and \(\lambda_1 \leq \lambda_2\), then \(\kappa_1 + \lambda_1 \leq \kappa_2 + \lambda_2\), \(\kappa_1 \lambda_1 \leq \kappa_2 \lambda_2\), and \(\kappa_1^{\lambda_1} \leq \kappa_2^{\lambda_2}\).

(d) If \(\kappa_1 < \kappa_2\) and \(\lambda_1 \leq \lambda_2\), it is not necessarily true that \(\kappa_1 + \lambda_1 < \kappa_2 + \lambda_2\) and \(\kappa_1 \lambda_1 < \kappa_2 \lambda_2\), even with AC: we have \(\aleph_0 + \aleph_0 = \aleph_1 + \aleph_1 = \aleph_1\) and \(\aleph_0 \aleph_1 = \aleph_1^\aleph_1 = \aleph_1\). If \(\kappa_1 < \kappa_2\) and \(\lambda_1 < \lambda_2\), and the Axiom of Choice is assumed, then \(\kappa_1 + \lambda_1 < \kappa_2 + \lambda_2\) and \(\kappa_1 \lambda_1 < \kappa_2 \lambda_2\). (This cannot be proved without AC; in fact, each of these is equivalent to AC [?, XVI.2]. [Let \(\kappa\) be an infinite cardinal and \(\lambda = \aleph_0 \kappa\); then \(2\lambda = \lambda\). If \(\lambda \leq \aleph^+(\lambda)\), then \(\lambda < \lambda + \aleph^+(\lambda)\) and \(\aleph^+(\lambda) < \lambda + \aleph^+(\lambda)\), so
\[
\lambda + \aleph^+(\lambda) < 2\lambda + 2\aleph^+(\lambda) = \lambda + \aleph^+(\lambda)
\]
which is a contradiction. Thus \(\kappa \leq \lambda \leq \aleph^+(\lambda)\) and \(\kappa\) is an aleph. The argument for the second inequality is similar, using \(\lambda = \aleph_0 \aleph_0\}.])

(e) Even if \(\kappa_1 < \kappa_2\) and \(\lambda_1 < \lambda_2\), and the Axiom of Choice is assumed, it is not necessarily true that \(\kappa_1^{\lambda_1} < \kappa_2^{\lambda_2}\): if \(\kappa\) is as in Exercise (), then \(\kappa^2 = \kappa\), and we have \((2^\kappa)^\kappa = 2^{\kappa^2} = 2^\kappa = \kappa^{\aleph_0}\) (A. Tarski; cf. [?, VIII.3]).]

II.9.7.16. (a) [?, VI.6 Ex. 3] Show (without AC) that if a set \(X\) is a union of a sequence of distinct subsets, then \(X\) is a union of a sequence of disjoint nonempty subsets and hence \(\aleph_0 < \text{card}(X)\). [If \(X = \bigcup X_n\), for each \(x \in X\) define a sequence \((s_n(x))\) of 0’s and 1’s by \(s_n(x) = 1\) if and only if \(x \in X_n\). There are infinitely many resulting sequences since the \(X_n\) are distinct. Divide this set of sequences into \(\aleph_0\) disjoint nonempty subsets using Exercise (.)]

(b) If \(\kappa\) is a cardinal and \(\aleph_0 < \kappa\), then \(\aleph_0 < \kappa\) and hence \(2^{\aleph_0} < 2^\kappa\). In particular, if \(\kappa\) is any infinite cardinal, then \(\aleph_0 < 2^\kappa\) and \(2^{\aleph_0} < 2^{2^\kappa}\) (Exercise (.)]
II.9.7.17. Suppose \( \{X_i : i \in I\} \) is an indexed collection of sets. Let \( X = \bigcup_{i \in I} X_i \), and for each \( i \) let \( Y_i = \{i\} \times X_i \subseteq I \times X \). Then \( \{Y_i : i \in I\} \) is an indexed collection of disjoint sets with \( |Y_i| = |X_i| \) for each \( i \).

II.9.7.18. Fix an ordinal \( \sigma \). Let \( \omega_\sigma \) be \( \aleph_\sigma \) regarded as an ordinal. Let \( Q_\sigma \) be the set of all sequences from \( \omega_\sigma \) which are eventually 0. Give \( Q_\sigma \) the lexicographic ordering.

(a) Show that \( Q_0 \) is order-isomorphic to \( \mathbb{Q} \cap [0, \infty) \).

(b) Show that \( \operatorname{card}(Q_\sigma) = \aleph_\sigma \).

(c) Show that \( Q_\sigma \) has a cofinal subset order-isomorphic to \( \omega_\sigma \), and an explicit order-isomorphism from \( Q_\sigma \) to each half-open segment between consecutive elements of this cofinal subset. [Consider the set of sequences which are 0 after the first term.]

(d) If \( \alpha \) is an ordinal with \( \operatorname{card}(\alpha) \leq \aleph_\sigma \), show that there is a cofinal subset of \( \alpha \) of order type \( \leq \omega_\sigma \), with the half-open segments between consecutive elements of the subset of order type \( < \alpha \). [If \( \operatorname{card}(\alpha) = \aleph_\sigma \), let \( \{\beta_\tau : \tau < \omega_\sigma\} \) be an enumeration of the elements of \( \alpha \). For each \( \rho < \omega_\sigma \), let \( \gamma_\rho = \beta_\tau \) for the first \( \tau \) for which \( \beta_\tau \) is larger than \( \gamma_\pi \) for all \( \pi < \rho \), if there is one.]

(e) Using (c) and (d), define by transfinite induction a specific order-embedding of \( \alpha \) into \( Q_\sigma \), for each ordinal \( \alpha \) with \( \operatorname{card}(\alpha) \leq \aleph_\sigma \).

(f) Show (without AC or CH), by the argument of Exercise () using \( Q_\sigma \) in place of \( Q_\sigma \), that \( 2^{\aleph_\sigma} \simeq \mathfrak{c} \) (A. Tarski []).

*****Does this actually work without AC? In (d), must choose a bijection between \( \alpha \) and \( \omega_\sigma \).

II.9.7.19. Let \( \chi \) be the first measurable cardinal. This problem will show that \( \chi \) is inaccessible.

(a) Use problem II.9.7.5.(c) to show that, if \( \{\kappa_i : i \in I\} \) is a set of cardinals with \( \kappa_i < \chi \) for all \( i \) and \( \operatorname{card}(I) < \chi \), then \( \kappa = \lim \{\kappa_i\} < \chi \). [If \( X \) has cardinality \( \kappa \), write \( X = \bigcup_{i \in I} X_i \), where \( \operatorname{card}(X_i) = \kappa_i \).]

(b) If \( \kappa < \chi \), show that \( 2^\kappa < \chi \) as follows. Let \( X \) be a set of cardinality \( \kappa \), and \( \mu \) a \( \{0, 1\}\)-valued measure on \( (\mathcal{P}(X), \mathcal{P}(\mathcal{P}(x))) \). For each \( x \in X \), let

\[
A_x = \{Y \subseteq X : x \in Y\}, \quad B_x = \{Y \subseteq X : x \notin Y\}.
\]

Then \( A_x \) and \( B_x \) are complementary subsets of \( \mathcal{P}(X) \), so either \( \mu(A_x) = 1 \) or \( \mu(B_x) = 1 \). Set

\[
S = \{x \in X : \mu(A_x) = 1\}
\]

\[
S = \bigcap_{x \in S} A_x \cap \bigcap_{x \notin S} B_x.
\]

(i) Show that \( \mu(S) = 1 \). [Consider the complement, and use the fact from Problem 8(c) that \( \mu \) is \( \kappa \)-additive.]

(ii) Show that \( S = \{S\} \).

(iii) Conclude that \( 2^\kappa < \chi \).

(c) If \( \kappa < \chi \), use (b) to conclude that the successor of \( \kappa \) is also less than \( \chi \). Conclude that \( \chi \) is inaccessible.
II.10. Measurable Cardinals

II.10.1. Introduction

In this section, we discuss two fascinating set-theoretic problems which originally arose in the development of Lebesgue measure. Throughout this section, we will need to assume the Axiom of Choice, which will be used without comment.

II.10.1.1. In Lebesgue’s original work, he asked whether every subset of \( \mathbb{R} \) is Lebesgue measurable, or if Lebesgue measure can at least be extended to a translation-invariant measure defined on all subsets of \( \mathbb{R} \). Vitali’s example of a nonmeasurable set (XIII.3.9.5.) gave a negative answer (if AC is assumed).

Banach weakened the question to just ask: is there a measure defined on all subsets of \( \mathbb{R} \), not translation-invariant, which extends Lebesgue measure? More generally, is there a finite nonzero measure on \([0,1]\), or any set \( X \), defined on all subsets of \( X \), in which every singleton has measure 0? It is obvious that the answer to this question for a set \( X \) depends only on the cardinality of \( X \).

II.10.1.2. Definition. Let \( X \) be a set. A measure \( \mu \) on \((X, \mathcal{P}(X))\) is a full real-valued measure on \( X \) if it is a nonzero finite measure in which \( \mu(\{x\}) = 0 \) for every \( x \in X \). A full \( \{0,1\}\)-valued measure is a full real-valued measure taking only the values 0 and 1.

In set theory, a full real-valued measure on a set \( X \) is usually just called a real-valued measure, but this term is ambiguous in a measure-theory context (the main point, of course, is that a full real-valued measure is defined for all subsets). A full real-valued measure \( \mu \) can be, and usually is, renormalized so that \( \mu(X) = 1 \) (a full real-valued probability measure).

We then can phrase Banach’s question as:

II.10.1.3. Question. Does \([0,1]\) (or \( \mathbb{R} \)) have a full real-valued measure? Does there exist a set \( X \) with a full real-valued measure on \( X \)?

It is obvious from countable additivity that a set with a full real-valued measure must be uncountable.

II.10.1.4. Definition. Let \( \kappa \) be a cardinal. A measure \( \mu \) on a set \((X, \mathcal{P}(X))\) is \( \kappa^+ \)-additive if, whenever \( \{A_i : i \in I\} \) is an indexed collection of pairwise disjoint subsets of \( X \), with \( |I| \leq \kappa \), then

\[
\mu(\bigcup_{i \in I} A_i) = \sum_{i \in I} \mu(A_i) .
\]

The measure \( \mu \) is \( \kappa \)-additive if it is \( \lambda^+ \)-additive for all \( \lambda < \kappa \).

This terminology is a little confusing and somewhat counterintuitive, but is standard in set theory and the theory of large cardinals. Note that “\( \aleph_2^+ \)-additive” and “\( \aleph_1 \)-additive” both mean “countably additive”; “\( \aleph_0 \)-additive” is the same as “finitely additive.”

II.10.1.5. Proposition. Let \( \kappa \) be a cardinal, \( X \) a set of cardinality \( \kappa \), and \( \mu \) a finite (or \( \sigma \)-finite) measure on \((X, \mathcal{P}(X))\). Then the following are equivalent:

(i) Whenever \( \{A_i : i \in I\} \) is a collection of subsets of \( X \) with \( |I| \leq \kappa \) and \( \mu(A_i) = 0 \) for all \( i \), we have \( \mu(\bigcup_{i \in I} A_i) = 0 \).
(ii) Whenever \( \{ A_i : i \in I \} \) is a collection of pairwise disjoint subsets of \( X \) with \( |I| \leq \kappa \) and \( \mu(A_i) = 0 \) for all \( i \), we have \( \mu(\bigcup_{i \in I} A_i) = 0 \).

(iii) \( \mu \) is \( \kappa^+ \)-additive.

**Proof:** (i) \( \Rightarrow \) (ii) and (iii) \( \Rightarrow \) (ii) are trivial.

(ii) \( \Rightarrow \) (i): Suppose \( \mu \) satisfies (ii), and \( \mu(A_i) = 0 \) for \( i \in I \). Fix a well ordering on \( I \), and for each \( i \) let \( B_i = A_i \setminus \bigcup_{j < i} A_j \) (set \( B_{i_0} = A_{i_0} \) if \( i_0 \) is the first element of \( I \)). Then the \( B_i \) are pairwise disjoint, \( \mu(B_i) = 0 \) since \( B_i \subseteq A_i \), and
\[
\mu(\bigcup_{i \in I} A_i) = \mu(\bigcup_{i \in I} B_i) = \sum_{i \in I} \mu(B_i) = 0 .
\]

(ii) \( \Rightarrow \) (iii): Suppose \( \mu \) satisfies (ii), and that \( \{ A_i : i \in I \} \) is a collection of pairwise disjoint subsets of \( X \) with \( |I| \leq \kappa \). Then \( J = \{ i \in I : \mu(A_i) > 0 \} \) is countable by (i), and we have \( \mu(\bigcup_{i \in I \setminus J} A_i) = 0 \) by (ii), since \( |I \setminus J| \leq \kappa \). Thus
\[
\mu(\bigcup_{i \in I} A_i) = \mu(\bigcup_{i \in J} A_i) + \mu(\bigcup_{i \in I \setminus J} A_i) = \sum_{i \in J} \mu(A_i) + 0 = \sum_{i \in I} \mu(A_i) .
\]

So, if \( \mu \) is a full real-valued measure on \( X \), then \( \mu \) is \( \kappa \)-additive if and only if the union of fewer than \( \kappa \) sets of measure zero has measure zero.

A key observation made by Banach was

**II.10.1.6.** **Proposition.** Let \( \kappa \) be the smallest cardinal for which there exists a set of cardinality \( \kappa \) with a full real-valued measure, and let \( \mu \) be a full real-valued measure on a set \( X \) (not necessarily of cardinality \( \kappa \)). Then \( \mu \) is \( \kappa \)-additive.

**Proof:** Suppose that \( \{ A_i : i \in I \} \) is an indexed collection of pairwise disjoint subsets of \( X \) with \( \mu(A_i) = 0 \) for all \( i \) and \( |I| < \kappa \). Let \( A = \bigcup_{i \in I} A_i \). If \( \mu(A) > 0 \), for \( S \subseteq I \) let \( \nu(S) = \mu(\bigcup_{i \in S} A_i) \). Then it is easy to check that \( \nu \) is a full real-valued measure on \( I \), contradicting minimality of \( \kappa \). Thus \( \mu(A) = 0 \) and \( \mu \) is \( \kappa \)-additive.

**II.10.2. Real-Valued Measurable Cardinals**

In light of **II.10.1.6.**, we make the following definition:

**II.10.2.1. Definition.** A cardinal \( \kappa \) is real-valued measurable if there is a \( \kappa \)-additive full real-valued measure on a set of cardinality \( \kappa \).

Note that if \( \kappa \) is any cardinal larger than a real-valued measurable cardinal, then there is a full real-valued measure on a set of cardinality \( \kappa \) (supported on a subset of real-valued measurable cardinality), but the measure will not be \( \kappa \)-additive in general. But **II.10.1.6.** says that if \( \kappa \) is the smallest cardinal of a set supporting a full real-valued measure, then \( \kappa \) is a real-valued measurable cardinal. Thus there exists a set with a full real-valued measure if and only if there exists a real-valued measurable cardinal.
II.10.2.2. Proposition. Let $\kappa$ be a real-valued measurable cardinal. Then $\kappa$ is an uncountable regular cardinal.

Proof: We have already observed that $\kappa$ is uncountable.

Let $X$ be a set of cardinality $\kappa$ and $\mu$ a $\kappa$-additive full real-valued measure on $X$. Note that if $A$ is a subset of $X$ with $|A| < \kappa$, then $\mu(A) = 0$ by $\kappa$-additivity. So if $\{A_i : i \in I\}$ is an indexed collection of pairwise disjoint subsets of $X$ with $|A_i| < \kappa$ for all $i$ and $|I| < \kappa$, then $\mu(A_i) = 0$ for all $i$ and hence $\mu(\bigcup_{i \in I} A_i) = 0$, so we cannot have that $X = \bigcup_{i \in I} A_i$.

Banach and Kuratowski proved that if the Continuum Hypothesis is assumed, there is no full real-valued measure on $\mathbb{R}$ or $[0, 1]$. Then Banach extended the arguments to show that if the Generalized Continuum Hypothesis (GCH) is assumed, then any real-valued measurable cardinal is inaccessible.

The next major contributions were made by S. Ulam. In his Ph.D. dissertation, he showed that every real-valued measurable cardinal is weakly inaccessible without the use of the GCH. The device he used is now called an Ulam matrix. The construction uses cardinal and ordinal notation and terminology; see (i) for an explanation.

II.10.2.3. Lemma. [Ulam Matrix] Let $\lambda$ be a cardinal, and $\kappa$ the successor cardinal of $\lambda$. Regard $\lambda$ and $\kappa$ as sets of ordinals. Then there are subsets $\{A_{\alpha}^\gamma : \alpha < \kappa, \gamma < \lambda\}$ of $\kappa = \{\sigma : \sigma < \kappa\}$ ($\alpha$, $\beta$, $\gamma$, $\sigma$, $\tau$ denote ordinals) such that

(i) If $\alpha < \beta < \kappa$ and $\gamma < \lambda$, then $A_{\alpha}^\gamma \cap A_{\beta}^\gamma = \emptyset$.

(ii) For any $\alpha < \kappa$, $[\kappa \setminus \bigcup_{\gamma < \lambda} A_{\alpha}^\gamma] \subseteq \alpha$, and in particular $|\kappa \setminus \bigcup_{\gamma < \lambda} A_{\alpha}^\gamma| < \kappa$.

The $A_{\alpha}^\gamma$ can be thought of as an array of subsets with $\kappa$ rows and $\lambda$ columns, with $\alpha$ denoting the row and $\gamma$ the column. The conditions say that the sets in each column are pairwise disjoint, and the union of each row is all but a "small" subset of the whole set $\kappa$.

Proof: If $\sigma < \kappa$, then $|\sigma + 1| \leq \lambda$, so there is a surjective function $f_\sigma : \lambda \to \sigma + 1$. Fix such a function for each $\sigma$. If $\alpha < \kappa$ and $\gamma < \lambda$, let

$$A_{\alpha}^\gamma = \{\sigma < \kappa : f_\sigma(\gamma) = \alpha\}.$$  

Property (i) is obvious. For (ii), fix $\alpha < \kappa$. Suppose $\sigma < \kappa$ and $\sigma \notin \bigcup_{\gamma < \lambda} A_{\alpha}^\gamma$. Then there is no $\gamma$ such that $f_\sigma(\gamma) = \alpha$, i.e. $\alpha$ is not in the range of $f_\sigma$, which is $\sigma + 1 = \{\tau : \tau \leq \sigma\}$. Thus $\sigma < \alpha$.

II.10.2.4. Theorem. Let $\kappa$ be a real-valued measurable cardinal. Then $\kappa$ is weakly inaccessible.

Proof: It has already been shown (II.10.2.2) that $\kappa$ is uncountable and regular; it remains to show that it is a limit cardinal. If $\kappa$ were the successor of a cardinal $\lambda$, let $\{A_{\alpha}^\gamma\}$ be an Ulam matrix as in II.10.2.3. If $\mu$ is a $\kappa$-additive full real-valued measure on $\kappa$, set $S = \{(\alpha, \gamma) : \mu(A_{\alpha}^\gamma) > 0\} \subseteq \kappa \times \lambda$. For each $\alpha$, we have $\mu(\kappa \setminus \bigcup_{\gamma < \lambda} A_{\alpha}^\gamma) = 0$ by II.10.2.3.(ii) and $\kappa$-additivity, and hence $\mu(\bigcup_{\gamma < \lambda} A_{\alpha}^\gamma) > 0$; then by $\kappa$-additivity $\mu(A_{\alpha}^\gamma) > 0$ for some $\gamma$, i.e. for each $\alpha < \kappa$ there is at least one $\gamma$ with $(\alpha, \gamma) \in S$. Thus $|S| \geq \kappa$. On the other hand, for each $\gamma < \lambda$ there are at most countably many $\alpha$ such that $(\alpha, \gamma) \in S$ by II.10.2.3.(i) and (i), since $\mu$ is finite. Hence $|S| \leq \aleph_0 \cdot \lambda = \lambda$, a contradiction. Thus $\kappa$ is not a successor cardinal.
More recently, R. Solovay [Sol71] proved that if $\kappa$ is a real-valued measurable cardinal, then the cardinality of the set of weakly inaccessible cardinals less than $\kappa$ is $\kappa$ (Solovay’s result is actually considerably stronger: a real-valued measurable cardinal is weakly Mahlo).

Ulam’s Dichotomy

Ulam then observed that Question II.10.1.3. naturally divides into two rather distinct questions, both of considerable interest. Recall that a set $A \in \mathcal{A}$ in a measure space $(X, \mathcal{A}, \mu)$ is an atom if $\mu(A) > 0$ and for every $B \in \mathcal{A}$, $B \subseteq A$, either $\mu(B) = 0$ or $\mu(A \setminus B) = 0$, and that $(X, \mathcal{A}, \mu)$ is atomless if there are no atoms.

II.10.2.5. Proposition. Let $\mu$ be a full real-valued measure on a set $X$. If $(X, \mathcal{P}(X), \mu)$ has an atom, then there is a full $\{0, 1\}$-valued measure on $X$.

Proof: Let $A$ be an atom in $(X, \mathcal{P}(X), \mu)$. For $B \subseteq X$, define

$$\nu(B) = \frac{\mu(A \cap B)}{\mu(A)}.$$ 

It is easily checked that $\nu$ is a full $\{0, 1\}$-valued measure on $X$.

So Question II.10.1.3. splits into the next two questions:

II.10.2.6. Question. Does there exist an atomless full real-valued measure on a set $X$?

II.10.2.7. Question. Does there exist a full $\{0, 1\}$-valued measure on a set $X$?

II.10.3. Atomless Full Real-Valued Measures

We will discuss Questions II.10.2.6. and II.10.2.7. separately. We first analyze the properties of an atomless full real-valued measure (if one exists). Ulam proved the following theorem:

II.10.3.1. Theorem. Let $\mu$ be an atomless full real-valued measure on a set $X$. Then $\mu$ is not $(2^{\aleph_0})^+\text{-additive}.$

Before we prove this theorem, let us draw the most important consequence:

II.10.3.2. Corollary. Suppose there is a set with an atomless full real-valued measure. Let $\kappa$ be the smallest real-valued measurable cardinal. Then $\kappa \leq 2^{\aleph_0}$.

Proof: Let $X$ be a set with an atomless full real-valued measure $\mu$ on $X$. Then $\mu$ is not $(2^{\aleph_0})^+$-additive by II.10.3.1. But $\mu$ is $\kappa$-additive by II.10.1.6. Thus $\kappa \leq 2^{\aleph_0}$. ✷
This result, combined with II.10.2.4., puts severe set-theoretic limitations on the existence of atomless full real-valued measures: they can only exist if \(2^{\aleph_0}\) is at least as large as the first weakly inaccessible cardinal (in fact, by SOLOVAY’S result, the first weakly Mahlo cardinal). It is believed that this is consistent with ZFC, but it would be in dramatic contradiction to the Continuum Hypothesis and would imply that \(2^{\aleph_0}\) is very large.

The proof of II.10.3.1. mostly consists of the next three lemmas. These results hold for arbitrary atomless finite measures, not just full ones.

II.10.3.3. **Lemma.** Let \((X, \mathcal{A}, \mu)\) be an atomless measure space, and \(Y \in \mathcal{A}\) with \(0 < \mu(Y) < \infty\). For any \(\epsilon > 0\), there is an \(A \in \mathcal{A}\), \(A \subseteq Y\), with \((1 - \epsilon)\mu(Y) < \mu(A) < \mu(Y)\).

**Proof:** Since \(Y\) is not an atom, it decomposes as a disjoint union of sets \(A_1, B_1\) of strictly positive measure. We may assume that \(\mu(A_1) \geq \mu(B_1)\); then \(\mu(A_1) \geq \mu(Y)/2\). Then \(B_1\) decomposes as a disjoint union of \(A_2\) and \(B_2\), of strictly positive measure, with \(\mu(A_2) \geq \mu(B_1)/2\). Continue inductively; for any \(n\) we have
\[
(1 - 2^{-n})\mu(Y) < \mu(\bigcup_{k=1}^{n} A_k) < \mu(Y)
\]
and we can take \(A = \bigcup_{k=1}^{n} A_k\) for \(n\) large enough that \(2^{-n} < \epsilon\).

II.10.3.4. **Lemma.** Let \((X, \mathcal{A}, \mu)\) be an atomless measure space, and \(Y \in \mathcal{A}\) with \(0 < \mu(Y) < \infty\). If \(0 < t < \mu(Y)\), there is a subset \(A\) of \(Y\), \(A \in \mathcal{A}\), with \(\mu(A) = t\).

**Proof:** For countable ordinals \(\sigma\), define subsets \(A_\sigma \in \mathcal{A}\) by transfinite induction as far as possible by setting 
\(A_0 = Y\); if \(\mu(A_\sigma) > t\), let \(A_{\sigma+1}\) be a subset of \(A_\sigma\) with \(t < \mu(A_{\sigma+1}) < \mu(A_\sigma)\) (using II.10.3.3.); and if \(\sigma\) is a (countable) limit ordinal, set \(A_\sigma = \bigcap_{\tau < \sigma} A_\tau\). If \(\mu(A_\sigma) = t\) for some \(\sigma\), terminate the construction and we are done. In fact, this must happen at some countable (limit) ordinal, since the \(\mu(A_\sigma)\) strictly decrease, and if \(\mu(A_\sigma) > t\) for all \(\sigma < \omega_1\) we would have that \(\sigma \mapsto -\mu(A_\sigma)\) would be an order-embedding of \(\omega_1\) into \(\mathbb{R}\), which is impossible. (Alternatively, if for each \(\sigma\) we set \(B_\sigma = A_\sigma \setminus A_{\sigma+1}\), then the \(B_\sigma\) would be an uncountable family of pairwise disjoint subsets of \(Y\) of strictly positive measure.)

II.10.3.5. **Lemma.** Let \((X, \mathcal{A}, \mu)\) be an atomless measure space, and \(Y \in \mathcal{A}\) with \(0 < \mu(Y) < \infty\). Then there are subsets \(\{A_t : 0 \leq t \leq 1\} \subseteq \mathcal{A}\) of \(Y\) such that

(i) \(A_s \subseteq A_t\) for \(s < t\).
(ii) \(A_t = \bigcap_{s > t} A_s\) for \(0 \leq t < 1\) and \(A_1 = Y\).
(iii) \(\mu(A_t) = t \cdot \mu(Y)\) for \(0 \leq t \leq 1\).

**Proof:** Let \(\{r_0, r_1, r_2, \ldots\}\) be an enumeration of \(\mathbb{Q} \cap [0, 1]\) with \(r_0 = 0\) and \(r_1 = 1\). Set \(B_0 = \emptyset\) and \(B_1 = Y\). Inductively define \(B_r\) for \(n \geq 3\) so that \(B_{r_m} \subseteq B_{r_m}\) if \(r_m < r_n\) and \(\mu(B_{r_m}) = r_m \cdot \mu(Y)\), using II.10.3.4. [at stage \(n\), if \(r_p\) and \(r_q\) are the closest numbers with \(r_p < r_n < r_q\) and \(p, q < n\), apply II.10.3.4. to \(B_{r_q} \setminus B_{r_p}\).]
and \( t = (r_n - r_p)\mu(Y) \) and add \( B_{r_p} \). Set \( A_1 = B_1 = Y \) and for \( 0 \leq t < 1 \) set \( A_t = \cap_{r_n > t} B_{r_n} \). Then (i) is obvious, and if \( r_n < t < r_m \), we have \( B_{r_n} \subseteq A_t \subseteq B_{r_m} \), so (ii) and (iii) follow easily.

We now prove Theorem II.10.3.1.

**Proof:** Let \( \mu \) be an atomless full real-valued measure on a set \( X \). Let \( \{A_t : 0 \leq t \leq 1\} \) be a collection of subsets as in II.10.3.5, with \( Y = X \). For each \( t \), set \( C_t = A_t \setminus \cup_{s < t} A_s \). We have that \( \mu(C_t) = 0 \) for each \( t \). If \( x \in X \), let \( t = \inf(s : x \in A_s) \) (note that this set of \( s \) is nonempty since \( x \in A_1 = X \)). Then \( x \in A_t \) by II.10.3.5.(i)–(ii), but \( x \notin A_s \) if \( s < t \), so \( x \in C_t \). Thus \( \cup_{0 \leq t \leq 1} C_t = X \), so \( \mu(\cup_{0 \leq t \leq 1} C_t) > 0 \) and \( \mu \) is not \((2^{\aleph_0})^+\)-additive.

Almost the same proof shows one direction of the following:

**II.10.3.6. Theorem.** There is an extension of Lebesgue measure to a measure on \((\mathbb{R}, \mathcal{P}(\mathbb{R}))\) if and only if there is a set with an atomless full real-valued measure.

**Proof:** Suppose there is an atomless full real-valued probability measure \( \mu \) on a set \( X \). Define the sets \( A_t \) and \( C_t \) as in the proof of II.10.3.1., and define \( f : X \to [0, 1] \) by \( f(x) = t \) if \( x \in C_t \) (note that the \( C_t \) are pairwise disjoint). Set \( \nu = f_*(\mu) \); then \( \nu \) is a full real-valued measure on \([0, 1]\). To see that \( \nu \) extends Lebesgue measure \( \lambda \) on \([0, 1]\), let \( 0 \leq t_1 < t_2 \leq 1 \); then \( f^{-1}((t_1, t_2)) = A_{t_2} \setminus A_{t_1} \), so

\[
\nu((t_1, t_2)) = \mu(A_{t_2} \setminus A_{t_1}) = t_2 - t_1 = \lambda((t_1, t_2))
\]

and thus by () \( \nu \) agrees with \( \lambda \) on Borel subsets of \([0, 1]\). Since for every Lebesgue measurable subset \( E \) of \([0, 1]\) there exist Borel sets \( A \) and \( B \) with \( A \subseteq E \subseteq B \) and \( \lambda(A) = \lambda(E) = \lambda(B) \) (), \( \nu \) must agree with \( \lambda \) on all Lebesgue measurable subsets of \([0, 1]\). Then \( \nu \) can be defined by translation on \([n, n+1]\) for all \( n \) and hence on all of \( \mathbb{R} \), extending Lebesgue measure.

Conversely, suppose \( \mu \) is an extension of \( \lambda \) to all subsets of \( \mathbb{R} \). Then the restriction of \( \mu \) to \([0, 1]\) is a full real-valued measure on \([0, 1]\). It is not obvious that this measure is atomless; however, if it were not there would be a full \([0, 1]\)-valued measure on \([0, 1]\) by II.10.2.5., which is impossible by II.10.4.3..

**II.10.4. Measurable Cardinals**

Now we turn to Question II.10.2.7.. The proof of the next result is essentially identical to the proof of II.10.1.6., and is left to the reader.

**II.10.4.1. Proposition.** Let \( \kappa \) be the smallest cardinal for which there exists a set of cardinality \( \kappa \) with a full \([0, 1]\)-valued measure, and let \( \mu \) be a full \([0, 1]\)-valued measure on a set \( X \) (not necessarily of cardinality \( \kappa \)). Then \( \mu \) is \( \kappa \)-additive.
II.10.4.2. **Definition.** A cardinal is measurable if, on a set $X$ of cardinality $\kappa$, there is a $\kappa$-additive full $\{0,1\}$-valued measure on $X$.

By II.10.4.1., the condition of $\kappa$-additivity is not crucial for the question of existence of a measurable cardinal; but it does ensure that if there is a second measurable cardinal, it is tremendously larger than the first (if this condition were eliminated from the definition, any cardinal larger than a measurable cardinal would be measurable.) The $\kappa$-additivity is very important in the set-theoretic interpretations of measurability.

A measurable cardinal is, of course, a real-valued measurable cardinal. By Ulam’s dichotomy and II.10.3.1., a real-valued measurable cardinal is either measurable or $\leq 2^{\aleph_0}$. Measurable cardinals are larger than $2^{\aleph_0}$ (in fact “much larger”), because of the following fact:

**II.10.4.3. Theorem.** A measurable cardinal is inaccessible.

**Proof:** Let $\kappa$ be a measurable cardinal. Then $\kappa$ is weakly inaccessible by II.10.2.4., so it remains to show that if $\lambda < \kappa$, then $2^\lambda < \kappa$. Fix $\lambda < \kappa$, and suppose $2^\lambda \geq \kappa$. Then there is a $\kappa$-additive full $\{0,1\}$-valued measure $\mu$ on $\mathcal{P}(X)$ for a set $X$ of cardinality $\lambda$ ($\mu$ is supported on a subset of $\mathcal{P}(X)$ of cardinality $\kappa$). For each $x \in X$, let

$A_x = \{ Y \subseteq X : x \in Y \}$, \quad $B_x = \{ Y \subseteq X : x \notin Y \}$.

Then $A_x$ and $B_x$ are complementary subsets of $\mathcal{P}(X)$, so either $\mu(A_x) = 1$ or $\mu(B_x) = 1$. Set

$S = \{ x \in X : \mu(A_x) = 1 \}$

$S = \bigcap_{x \in S} A_x \cap \bigcap_{x \notin S} B_x$.

The complement of $S$ is

$S^c = \bigcup_{x \notin S} A_x \cup \bigcup_{x \in S} B_x$

which is a union of $\lambda$ sets of measure 0, hence $\mu(S^c) = 0$, $\mu(S) = 1$. But it is easily seen that $S = \{ S \}$, and $\mu(T) = 0$ for every singleton $T$, a contradiction.

It turns out that measurable cardinals, if they exist, are enormous:

**II.10.4.4. Theorem.** [Hanf-Tarski] If $\kappa$ is a measurable cardinal, then the cardinality of the set of inaccessible cardinals less than $\kappa$ is $\kappa$.

In fact, “inaccessible” can be replaced by other types of large cardinal conditions weaker than measurability. See II.10.4.11. and II.10.4.12. for stronger statements about the size of measurable cardinals.

In a set $X$ of measurable cardinal $\kappa$, a $\kappa$-additive full $\{0,1\}$-valued measure gives a way of dividing all subsets of $X$ into “large” ones (of measure 1) and “small” ones (of measure 0). If $A$ is any subset of $X$, exactly one of $A$, $X \setminus A$ is “large”. Any subset of cardinality less than $\kappa$ is “small”. 

204
Ultrafilters and Measurable Cardinals

A good alternative description of the principle of the previous paragraph uses the language of ultrafilters. Recall that a filter on a set $X$ is a nonempty subset $\mathcal{F}$ of $\mathcal{P}(X)$ such that

(i) $\mathcal{F}$ is closed under supersets, i.e. if $A \in \mathcal{F}$ and $A \subseteq B \subseteq X$, then $B \in \mathcal{F}$.
(ii) $\mathcal{F}$ is closed under finite intersections.
(iii) $\emptyset \notin \mathcal{F}$.

An ultrafilter on $X$ is a maximal filter on $X$. It is easily seen that a filter $\mathcal{F}$ is an ultrafilter if and only if, for every $A \subseteq X$, either $A \in \mathcal{F}$ or $(X \setminus A) \in \mathcal{F}$. An ultrafilter $\mathcal{F}$ is fixed if $\bigcap_{A \in \mathcal{F}} A$ is nonempty (in this case, we must have $\bigcap_{A \in \mathcal{F}} A = \{x\}$ for some $x \in X$); $\mathcal{F}$ is free if it is not fixed, i.e. if $\bigcap_{A \in \mathcal{F}} A = \emptyset$. $\mathcal{F}$ is free if and only if the complement of any finite subset of $X$ is in $\mathcal{F}$. (Note that AC is needed to show that free ultrafilters exist on any infinite set; in fact, by Zorn’s Lemma, every filter is contained in an ultrafilter, and in particular the filter consisting of complements of finite sets is contained in a free ultrafilter.)

If $\kappa$ is a cardinal, a filter $\mathcal{F}$ on a set $X$ is called $\kappa$-complete if $\mathcal{F}$ is closed under taking the intersection of fewer than $\kappa$ sets. Every fixed ultrafilter is $\kappa$-complete for any $\kappa$.

II.10.4.5. Example. Let $\kappa$ be a measurable cardinal, and $\mu$ a $\kappa$-additive full $\{0,1\}$-valued measure on a set $X$ of cardinality $\kappa$ (e.g. $X = \kappa = \{\sigma : \sigma < \kappa\}$). Let $\mathcal{F} = \{A \subseteq X : \mu(A) = 1\}$. Then $\mathcal{F}$ is a $\kappa$-complete free ultrafilter on $X$.

Conversely, suppose $\mathcal{F}$ is a $\kappa$-complete free ultrafilter on a set $X$ of cardinality $\kappa$. Define $\mu : \mathcal{P}(X) \to \{0,1\}$ by $\mu(A) = 1$ if $A \in \mathcal{F}$ and $\mu(A) = 0$ if $A \notin \mathcal{F}$. It is easily checked that $\mu$ is a $\kappa$-additive full $\{0,1\}$-valued measure on $X$, so $\kappa$ is a measurable cardinal.

So we obtain a rephrasing of the definition of measurable cardinals in the language of ultrafilters:

II.10.4.6. Proposition. Let $\kappa$ be a cardinal. Then $\kappa$ is measurable if and only if $\kappa > \aleph_0$ and there is a $\kappa$-complete free ultrafilter on $\kappa$ (or any set of cardinality $\kappa$).

In fact, there is a natural one-one correspondence between full $\{0,1\}$-valued measures on a set $X$ and free $\aleph_1$-complete ultrafilters on $X$, as in II.10.4.5..

Normal Ultrafilters and Nodal Sets

If $\mathcal{F}$ is an ultrafilter on a set $X$ and $f : X \to X$ is a bijection, then $f(\mathcal{F}) = \{f(A) : A \in \mathcal{F}\}$ is also an ultrafilter on $X$, which is $\kappa$-complete if $\mathcal{F}$ is. Thus if $X$ is a set of measurable cardinality $\kappa$, $\mathcal{F}$ is a $\kappa$-complete free ultrafilter on $X$, $A \in \mathcal{F}$ with $|A| = |X \setminus A| = \kappa$, and $f : X \to X$ is a bijection interchanging $A$ and $X \setminus A$, then $f(\mathcal{F})$ is a $\kappa$-complete free ultrafilter on $X$ with $(X \setminus A) \in f(\mathcal{F})$. Thus the intersection of all $\kappa$-complete free ultrafilters on $X$ is the ($\kappa$-complete) filter of all subsets whose complement has cardinality less than $\kappa$. So there does not appear to be any way to systematically distinguish “size” for sets like $A$ using $\kappa$-complete free ultrafilters.

However, it turns out that if $X = \kappa$, the ordering on $\kappa$ does allow a distinction to be made on the “size” of certain sets $A \subseteq \kappa$ even if $|A| = |\kappa \setminus A| = \kappa$. This is done through the notion of a normal ultrafilter.

A subset of $\kappa$ is cobounded if it contains $\{\sigma : \alpha \leq \sigma < \kappa\}$ for some $\alpha < \kappa$. A filter is cobounded if it contains all cobounded sets; the collection $\mathcal{C}_\kappa$ of all cobounded sets is a filter which is the smallest cobounded filter. A $\kappa$-complete filter on $\kappa$ must be cobounded. Any cobounded filter is free.

205
II.10.4.7. Definition. Let $\kappa$ be a cardinal, and $\mathcal{F}$ a cobounded filter on $\kappa$. Then $\mathcal{F}$ is normal if, whenever $\{S_\alpha : \alpha < \kappa\}$ is an indexed collection of sets in $\mathcal{F}$, we have that $$\Delta_{\alpha < \kappa}S_\alpha = \{\sigma < \kappa : \sigma \in \bigcap_{\alpha < \sigma}S_\alpha\} \in \mathcal{F}.$$ $\Delta_{\alpha < \kappa}S_\alpha$ is called the diagonal intersection of the collection $\{S_\alpha\}$.

By definition, a normal filter is cobounded. It is a little hard to motivate this definition intuitively. It means that for any collection $\{S_\alpha\}$ of sets in $\mathcal{F}$, “most” $\sigma$’s in $\kappa$ belong to $X_\alpha$ for all $\alpha < \sigma$. Normal filters are rather rare. For example, for each $n \in \mathbb{N}_0$ let $S_n = \{m \in \mathbb{N}_0 : m > n + 1\}$. If $\mathcal{F}$ is any cobounded filter on $\mathbb{N}_0$, then this is an indexed set in $\mathcal{F}$; but $\Delta_{n < \mathbb{N}_0}S_n = \emptyset$. Thus there are no normal filters on $\mathbb{N}_0$.

II.10.4.8. Proposition. If there is a normal filter $\mathcal{F}$ on $\kappa$, then $\mathcal{F}$ is $\kappa$-complete.

Proof: Let $\{X_i : i \in I\}$ be an indexed collection of sets in $\mathcal{F}$, with $|I| = \lambda < \kappa$. Let $f : \lambda \to I$ be a bijection; set $S_\alpha = X_{f(\alpha)}$ for $\alpha < \lambda$, and $S_\alpha = \kappa$ for $\alpha \in B := \{\sigma : \lambda \leq \sigma < \kappa\}$. Then $\Delta_{\alpha < \kappa}S_\alpha \in \mathcal{F}$, so $$A := B \cap [\Delta_{\alpha < \kappa}S_\alpha] \in \mathcal{F}$$ since $\mathcal{F}$ is cobounded. But it is easy to see that $A = B \cap \cap_{i \in I}X_i \subseteq \cap_{i \in I}X_i$, so $\cap_{i \in I}X_i \in \mathcal{F}$. \hfill \Box

II.10.4.9. Corollary. If there is a normal ultrafilter on $\kappa$, then $\kappa$ is measurable.

The converse is true also (cf. [?], [Kan03, 5.12]):

II.10.4.10. Theorem. A measurable cardinal has a normal ultrafilter.

Actually, a measurable cardinal may have many normal ultrafilters: it is equiconsistent with the existence of measurable cardinals that there are $2^{2^\kappa}$ normal ultrafilters over each measurable cardinal $\kappa$ ([KP71]; cf. [Kan03, 17.8]) (it is also equiconsistent that the smallest measurable cardinal has only one normal ultrafilter [Kun70]). There are $2^{2^\kappa}$ free ultrafilters on $\kappa$ for any (infinite) cardinal $\kappa$.

Sets which are in the intersection of all normal ultrafilters on a measurable cardinal $\kappa$ are called nodal, and can be considered “large” in a set-theoretic sense. The set of cardinals less than $\kappa$ is intuitively a “small” subset of $\kappa$ (there are intuitively many more ordinals which are not cardinals); however, it turns out that the set of cardinals less than $\kappa$ is a nodal subset of $\kappa$. Much more is true:

II.10.4.11. Theorem. If $\kappa$ is a measurable cardinal, then the set of inaccessible cardinals less than $\kappa$ is a nodal subset of $\kappa$.

This is at first glance surprising, since the inaccessible cardinals are seemingly very sparsely distributed even among the cardinals. The Hanf-Tarski Theorem (II.10.4.4.) is an immediate corollary. There are several much stronger results in [Kan03], replacing “inaccessible” with stronger large cardinal properties. The best known result along this line is the following result of F. Rowbottom (cf. [Kan03, 7.19]):
II.10.4.12. \textbf{Theorem.} Let $\kappa$ be a measurable cardinal. Then the set of Ramsey cardinals less than $\kappa$ is a nodal subset of $\kappa$. Thus the cardinality of the set of Ramsey cardinals less than $\kappa$ is $\kappa$.

This result gives some idea of the enormity of measurable cardinals.

II.10.5. \textbf{Consistency and Equiconsistency Results}

Perhaps remarkably, it appears to be consistent with ZFC to assume the existence of a measurable cardinal. Even more remarkably, even though measurable cardinals seem to be far removed from any aspect of the “real world” (even the “real mathematical world”), the existence of a measurable cardinal has significant implications in mathematical logic about subsets of $\mathbb{N}$! (Specifically, there are subsets of $\mathbb{N}$ which are not “constructible.”)

We list without proof several relative consistency results. All are discussed in detail in [Kan03]. If $A$ and $B$ are theories, then $B$ is of greater consistency strength than $A$ if $A$ can be proved consistent assuming that $B$ is consistent, and $A$ and $B$ are equiconsistent if each is of greater consistency strength than the other. We also use the term strictly greater consistency strength, with the obvious meaning. For example, ZF, ZFC, and ZFC+CH are equiconsistent by the results of Gödel. (Recall the fundamental theorem of model theory: a theory is consistent if and only if it has a model. The proofs that $B$ is of greater consistency strength than $A$ generally proceed by constructing a model for $A$ from a model for $B$.)

II.10.5.1. ZFC is not known to be consistent, and this may not be provable using existing theories. ZFC is presumed to be consistent, though, and all of set theory needs to be drastically altered if it is not. In the rest of this section (and throughout this book), we assume ZFC is consistent.

"God exists since mathematics is consistent, and the Devil exists since we cannot prove it."

\textit{André Weil}\textsuperscript{13}

II.10.5.2. It cannot be proved in ZFC that an inaccessible cardinal exists, i.e.

\[ \text{ZFC+}(\text{There does not exist an inaccessible cardinal}) \]

is equiconsistent with ZFC. This is discussed in (). It cannot even be proved in ZFC that a weakly inaccessible cardinal exists. Moreover, it cannot be proved that existence of an inaccessible cardinal is relatively consistent with ZFC, since existence of such a proof would contradict Gödel’s Incompleteness Theorem (cf. [?]). Thus, unlike the situation with CH,

\[ \text{ZFC+}(\text{There exists an inaccessible cardinal}) \]

is of strictly greater consistency strength than ZFC.

There is no current reason to believe, however, that even the existence of a measurable cardinal is inconsistent with ZFC, or with ZFC+GCH.

II.10.5.3. R. Solovay [Sol70] proved that

\[ \text{ZFC+(There exists an inaccessible cardinal)} \]

is of greater consistency strength than

\[ \text{ZF+DC+(Every subset of } \mathbb{R} \text{ is Lebesgue measurable)} \]

(plus several other properties of } \mathbb{R} \text{). S. Shelah [She84] showed that

\[ \text{ZF+(Countable AC)+(Every subset of } \mathbb{R} \text{ is Lebesgue measurable)} \]

is of greater consistency strength than

\[ \text{ZFC+(There exists an inaccessible cardinal)} \]

and thus all of these are equiconsistent. So, roughly speaking, the necessity of using AC to construct a nonmeasurable subset of } \mathbb{R} \text{ is equivalent to the existence of an inaccessible cardinal.}

II.10.5.4. (Solovay [Sol71]) The following are equiconsistent:

(i) ZFC+(There exists a measurable cardinal).

(ii) ZFC+(\(2^{\aleph_0}\) is real-valued measurable).

II.10.5.5. (J. Silver [Sil71]) If ZFC+(There exists a measurable cardinal) is consistent, so is

\[ \text{ZFC+GCH+(There exists a measurable cardinal)} \]

and thus these two are equiconsistent.

II.10.5.6. The existence of a real-valued measurable cardinal \(\leq 2^{\aleph_0}\) is obviously (from II.10.2.4.) inconsistent with the Continuum Hypothesis. It is also inconsistent with Martin’s Axiom. One version of Martin’s Axiom is a variant of the Baire property:

\text{MARTIN’S AXIOM. If } X \text{ is a compact Hausdorff space with the Countable Chain Condition (every family of pairwise disjoint nonempty open subsets in } X \text{ is countable), then the intersection of fewer than } 2^{\aleph_0} \text{ dense open sets in } X \text{ is dense.}

Martin’s Axiom (MA) can be thought of as a weak version of CH which is more palatable to some set theorists, although it is far from universally accepted. Since CH implies MA, ZFC+MA is equiconsistent with ZFC. See [Fre84] for details about Martin’s Axiom and its consequences.

Incidentally, both real-valued measurability of \(2^{\aleph_0}\) and Martin’s Axiom imply the following curious result: for every cardinal \(\kappa\) with \(\aleph_0 \leq \kappa < 2^{\aleph_0}\), we have \(2^\kappa = 2^{\aleph_0}\).

II.10.5.7. (D. Scott [Sco61]) The existence of a measurable cardinal is inconsistent with Gödel’s constructibility hypothesis \(V = L\) (II.8.7.6.). This result can be interpreted two ways: it can be taken as evidence that measurable cardinals should not exist, or that Gödel’s hypothesis is not reasonable. Most set theorists seem to take the latter view. Thus the existence of a measurable cardinal implies that there is a nonconstructible subset of \(\mathbb{N}\). See [Dev84], [Dev77], and [Dev73] for more on constructibility.
II.11. Categories and Functors

Category theory is a “theory of mathematical theories.” It was originally intended to provide a uniform abstract language for mathematical theories and to formulate and prove properties common to many theories. As often happens in mathematics, abstract category theory not only fulfills this original purpose but also turns out to be applicable to many other settings in mathematics as diverse as group theory, the theory of partially ordered sets, and mathematical physics; there is even a way to base an entire formulation of the foundations of mathematics on category theory rather than set theory ()

Category theory is characterized by a high degree of abstraction, and it is fashionable in some circles to view it pejoratively and call it “abstract nonsense.” However, a knowledge of the bare rudiments (the barest of which we describe here) is very useful in understanding the general nature of mathematical theories and how different parts of mathematics can be viewed as parts of a common whole.

A value-neutral nutshell description of category theory is “the theory of arrow-theoretic results.” The standard reference for category theory is [ML98].

Mathematical Theories

A mathematical theory generally consists of two parts:

1. A collection of objects which are sets with additional structure (algebraic, topological, etc.)
2. Functions between the objects which preserve the structure.

There are many familiar examples, some of which are described in more detail in this book. Here are a few:

- Vector spaces (over a fixed field, e.g. \( \mathbb{R} \)) and linear transformations
- Groups and group homomorphisms
- Metric spaces and continuous functions
- Topological spaces and continuous functions
- Partially ordered sets and order-preserving functions

There is an all-inclusive theory: sets (with no additional structure) and arbitrary functions between them.

In order to really understand a mathematical theory such as group theory, one must understand not only the objects (groups) but also the structure-preserving functions between them (group-homomorphisms.)

Categories

A category \( \mathcal{C} \) consists of:

- A collection \( \text{Ob}(\mathcal{C}) \) of objects.
- For each pair \((A, B)\) of objects, a collection \( \text{Hom}(A, B) \) of morphisms.

For all objects \( A, B, C \), a rule for composing morphisms, i.e. a function from \( \text{Hom}(B, C) \times \text{Hom}(A, B) \) to \( \text{Hom}(A, C) \), written \((g, f) \mapsto g \circ f\). Composition must be associative, i.e. for any objects \( A, B, C, D \), and any \( f \in \text{Hom}(A, B) \), \( g \in \text{Hom}(B, C) \), \( h \in \text{Hom}(C, D) \), we must have \( h \circ (g \circ f) = (h \circ g) \circ f \).
For any object $A$, an identity morphism $i_A$ satisfying $f \circ i_A = f$ for all $B$ and all $f \in \text{Hom}(A, B)$, and $i_A \circ g = g$ for all $B$ and all $g \in \text{Hom}(B, A)$.

These requirements are reasonable in light of the examples to be modeled, and are the minimum amount of structure needed for a satisfactory theory. In practically all the applications we will consider in this book, the objects will be sets and the morphisms certain (allowable) functions between them, with “composition” the usual composition of functions. The requirements are then that a composition of allowable functions in the theory is again an allowable function, and that the identity function from any set in the theory to itself is always an allowable function. Associativity of composition is automatic in this case. Such a category is called a category of sets and functions.

The examples described earlier give standard categories:

**Set**: Sets and functions (i.e. the objects of Set are all sets, and $\text{Hom}(X, Y)$ is the set of all functions from $X$ to $Y$)

**Vect$_R$**: Real vector spaces and linear transformations

**Gp**: Groups and group homomorphisms

**Ab**: Abelian groups and group homomorphisms

**MSp**: Metric spaces and continuous functions

**Top**: Topological spaces and continuous functions

**POSet**: Partially ordered sets and order-preserving functions

There is, however, no requirement that the morphisms of a category be functions. Some interesting categories in which the morphisms are not functions are given in the exercises.

When categories are defined within standard set theory, the collection of objects need not be a set (although it is a class, i.e. the objects themselves are sets); but $\text{Hom}(A, B)$ must be a set for every $A, B$. A category $C$ in which $\text{Ob}(C)$ is a set is called a small category. None of the examples above are small categories; but one could construct small categories from them by limiting the size of the underlying set (by restricting the underlying set to be a subset of some large fixed set.)

**Functors**

**Natural Transformations**

**Adjoint Functors**

**The Category of Small Categories**

Functors may be regarded as “morphisms” between categories. We may thus try to go to one further level of abstraction by regarding the collection of all categories as one supercategory, whose objects are categories and for which $\text{Hom}(C, D)$ is the collection of (covariant) functors from $C$ to $D$.

When working within set theory, this construction almost works, but not quite. We run into a version of Russell’s Paradox if we try to take all categories as objects, and we also violate the condition that $\text{Hom}(C, D)$ be a set for any $C$ and $D$. But these logical difficulties disappear if we take as our objects only small categories. Thus we may define a category $\text{SCat}$ whose objects are all small categories, and for which $\text{Hom}(C, D)$ is the set(!) of all functors from $C$ to $D$. 

210
Higher Categories

One can instead think of the collection of all categories as a “second-order category.” There is more structure than just a category: the objects are collections of objects with morphisms between them, and there are morphisms (functors) between the second-level objects preserving the first-order structure. One can formalize the notion of a second-order category.

Why stop there? The second-order category of all categories has morphisms between functors: natural transformations. One can define third-order categories by abstracting this. The process can be repeated indefinitely, apparently even transfinitely.

Categories as a Foundation of Mathematics

Categories were first defined by Eilenberg and MacLane in 1945 to provide a setting for studying natural transformations and formulating parts of algebraic topology and, later, homological algebra. They began to be more than just a language with Grothendieck’s 1957 paper recasting algebraic geometry in category terms. Lawvere in his 1963 Ph.D. thesis began an attempt to reformulate the foundations of mathematics in terms of categories rather than sets.

Lawvere’s idea was that instead of focusing on membership, which is the basic concept of set theory, one should focus on structure as encoded in the transformations between objects. This represents a “top-down” approach to the foundations of mathematics where it is not relevant what the objects of study (e.g. numbers) “are”, but rather what properties they have, rather than the “bottom-up” approach of set theory, which attempts to build up all the objects of mathematics from fundamental building blocks. This is arguably more in line with the way most mathematicians who are not logicians or set-theorists approach mathematics, and it can even be interpreted as being in line with logic and set theory, e.g. we don’t normally worry about what sets are, but only about how to work with them structurally. A great deal of mainstream mathematics, if not all, can (apparently) be done from this point of view without ever involving set theory.

The notion of a topos (plural often written topos as if it were a Greek word even though it isn’t), invented by Grothendieck, can be used in a foundational way. A topos is a category with extra structure (limits, colimits, products, quotients, etc.) which is similar enough to the category of sets and functions that it can be used in a similar way to define and describe all the standard structures of mathematics. They can even encode alternative logics such as intuitionist logic. (Grothendieck viewed topos as generalizations of topological spaces in his original work, which is another valid point of view; the fact that topos so nicely generalize set theory and topology makes them even more appealing as foundational structures.)

There has been much work on recasting the foundations of mathematics on category theory rather than set theory. However, this work is incomplete: there are still substantial gaps in what might be called the “foundations of category theory,” including avoiding potential paradoxes similar to the paradoxes of naive set theory which caused so much consternation in the early twentieth century. The potential, though, is to give a better foundation to the full spectrum of mathematics as it is actually practiced.

II.11.1. Exercises

1. Let $R$ be a transitive, reflexive relation on a set $X$. Define a category $C$ with $\text{Ob}(C) = X$, and such that $\text{Hom}(x, y)$ has exactly one element if $xRy$, and $\text{Hom}(x, y) = \emptyset$ if $x$ is not related to $y$. Composition is defined in the only possible way: if $xRy$ and $yRz$, and $f$ and $g$ are the unique elements of $\text{Hom}(x, y)$ and $\text{Hom}(y, z)$, then $g \circ f$ is the unique element of $\text{Hom}(x, z)$.

   (a) Show that $C$ is a (small) category.
(b) Let $S$ be another transitive, reflexive relation on a set $Y$, and $D$ the corresponding category. Describe all functors from $C$ to $D$.

2. Let $S$ be the category associated with the partially ordered set $\{0,1\}$ with the ordinary ordering $()$. If $C$ is any category, a functor from $S$ to $C$ is called a commutative square in $C$. Describe commutative squares in words, and draw a picture explaining the terminology (begin with a picture of the category $S$ by placing the objects at vertices of a square and drawing arrows for the morphisms.)

3. (a) Let $G$ be a group. Define a (small) category $G$ with one object $\bullet$, with $\text{Hom}(\bullet, \bullet) = G$. Define composition of morphisms via the group operation.
   (b) Let $H$ be another group, and $H$ the corresponding category. Describe all functors from $G$ to $H$.
   (c) A (necessarily small) category with one object is called a monoid. Describe which monoids arise from groups.

4. Define a category $\text{Mat}_\mathbb{R}$ whose objects are $\mathbb{N}$, and for which the morphisms $\text{Hom}(n, m)$ are the $m \times n$ matrices with real entries. Composition is matrix product. Show that $\text{Mat}_\mathbb{R}$ is a (small) category.

5. Here is a type of algebraic object which is important in algebraic topology and homological algebra. A chain complex is a diagram of the form

$$\cdots \xrightarrow{d_{n+2}} C_{n+1} \xrightarrow{d_{n+1}} C_n \xrightarrow{d_n} C_{n-1} \xrightarrow{d_{n-1}} \cdots$$

where the $C_n$ are abelian groups and $d_n : C_n \to C_{n-1}$ is a group homomorphism, which satisfies $d_n \circ d_{n+1} = 0$ for all $n$, i.e. the image $B_n$ of $d_{n+1}$ is contained in the kernel $Z_n$ of $d_n$ for each $n$. Often, but not always, $C_n = \{0\}$ for $n < 0$. The chain complex can formally be defined as a pair $C = \{(C_n), (d_n)\}$ consisting of the sequence $(C_n)$ together with the sequence $(d_n)$ of maps.

The elements of $C_n$ are called $n$-chains; the elements of $Z_n$ are called $n$-cycles, and the elements of $B_n$ $n$-boundaries (these terms are motivated by standard constructions of chain complexes in topology). The quotient group $Z_n/B_n$ is called the $n$’th homology group of $C$, denoted $H_n(C)$.

(a) Let $C = \{(C_n), (d_n)\}$ and $D = \{(D_n), (d'_n)\}$ be chain complexes. A morphism from $C$ to $D$ is a sequence $f = (f_n)$, where $f_n : C_n \to D_n$ is a group homomorphism making the squares in the following diagram commutative:

$$\begin{array}{cccccc}
\cdots & C_{n+1} & \xrightarrow{d_{n+1}} & C_n & \xrightarrow{d_n} & C_{n-1} & \xrightarrow{d_{n-1}} & \cdots \\
& \downarrow{f_{n+1}} & \quad & \downarrow{f_n} & \quad & \downarrow{f_{n-1}} & \\
\cdots & D_{n+1} & \xrightarrow{d'_{n+1}} & D_n & \xrightarrow{d'_n} & D_{n-1} & \xrightarrow{d'_{n-1}} & \cdots
\end{array}$$

i.e. $d'_n \circ f_n = f_{n-1} \circ d_n$ for each $n$. Morphisms are composed in the obvious way by setting $(g \circ f)_n = g_n \circ f_n$ (check that this makes sense). Show that the chain complexes with these morphisms form a category $\text{Chc}$.

(b) Show that, for fixed $n$, $H_n$ is a functor from $\text{Chc}$ to $\text{Ab}$. [Here $H_n$ sends the chain complex $C$ to the group $H_n(C)$. If $f \in \text{Hom}(C, D)$, show that there is a natural group homomorphism $H_n(f) : H_n(C) \to H_n(D)$ with the right properties.]

There is also a theory of cochain complexes, where the horizontal arrows are reversed and the subscripts written as superscripts. In an abstract algebraic sense, there is only a notational difference between chain complexes and cochain complexes, but they are used in a somewhat different and complementary way in
topology. Chain and cochain complexes can be defined also over an arbitrary ring $R$ (as diagrams of left $R$-modules). The algebra involved in the study of chain complexes and related matters is quite extensive. See books on homological algebra such as [2], or on algebraic topology such as [3], for a full treatment.

6. Here is a “paradox” concerning Gödel’s Incompleteness Theorem along the lines of the Berry Paradox (8). We work with the following somewhat informal version of Gödel’s Theorem:

**Theorem.** If $T$ is a consistent theory which is finitely describable and contains Peano arithmetic, then there is a statement in $T$ which is neither provable nor disprovable in $T$.

Fix a model for Peano arithmetic, e.g. the standard model ([4]), and let $T$ be the theory whose language is the language of Peano arithmetic and whose axioms are all the statements in Peano arithmetic which are true in the given model. Then $T$ is complete since every statement in $T$ or its negation is an axiom of $T$; $T$ is consistent since it has a model; $T$ obviously contains Peano arithmetic; and $T$ is finitely describable since we just gave a finite description!

Give a resolution of this “paradox.” (Note that the standard model for Peano arithmetic is finitely describable in ZF set theory, which is itself a finitely describable theory in the technical sense used by Gödel, so the demolition of the paradox must lie elsewhere.)
Chapter III

The Numbers of Analysis

The most basic object of study in analysis is the set of real numbers (along with functions on this set). The various number sets culminating in the real numbers (and, one step farther, the complex numbers) are generally familiar, at least informally. In this chapter, we will be fairly careful in describing these number systems through sets of axioms which characterize them and which can be used to develop all their properties and prove the theorems of analysis, while at the same time trying to avoid getting bogged down in set-theoretic technicalities. In the first section we describe the real numbers axiomatically, and then take a constructive approach in later sections beginning with the natural numbers and successively constructing the integers, rational numbers, real numbers, and complex numbers. The axiomatic approach of the first section may be sufficient for many readers, at least temporarily.

III.1. The Real Numbers – Axiomatic Approach

“Mathematics is fundamentally an egalitarian subject. It should in principle be possible for anyone to check the correctness of any argument; nothing needs to be taken on trust. This is the philosophy. The reality is that some parts of mathematics are much harder to grasp than others.”

J. K. Truss

There are two common ways the set \( \mathbb{R} \) of real numbers is specified as a basis for analysis. In the more complete approach, the real numbers are constructed from “scratch” beginning with the natural numbers. This approach is taken in succeeding sections. While this approach is the “right” one from a logical standpoint, it is complicated and time-consuming and is probably not the best way for a beginning analysis student to proceed.

The other approach is to simply begin with a list of reasonable assumptions about \( \mathbb{R} \), called axioms, which reflect the properties of the real numbers one expects from the informal approach seen in calculus and precalculus, and which are comprehensive enough that all the results of analysis can be developed from them. It is pretty easy for a beginning student to accept on faith that there is a number system satisfying the axioms, and it can be shown without too much difficulty that there is only one such number system.

\[1\] [Tru97, p. v]
(in a sense which will be precisely specified). A student who has any doubts about such an acceptance can
look at later sections to whatever extent necessary to convince him/her/self that the number system can
be carefully constructed. While in principle no part of mathematics should be simply accepted on faith,
in practice it may be prudent to postpone working through the full justification of some complicated parts
of mathematics which appear reasonable. (The history of mathematics is full of such temporary leaps of
faith, which have sometimes lasted for centuries! There is, of course, a danger in doing this, especially at
the frontiers of knowledge: one can never be entirely sure the details will work out as expected until they
are actually done.)

In this section, we take an axiomatic approach to the real numbers. We will not attempt to justify the
reasonableness of most of the axioms, which we hope will be self-evident in light of previous experience, nor
will we try to motivate the specific choice of axioms from among all possible statements we would expect
to be true about \( \mathbb{R} \) – after the fact it will become clear that we can get anything we might want as a
logical consequence of the axioms we have chosen. The one axiom we will discuss and motivate is the crucial
Completeness Axiom, which is the most complicated and least obvious of the axioms (and, for analysis,
arguably the most important).

Throughout this section, the real numbers \( \mathbb{R} \) will be assumed to be a set with various algebraic operations
and an ordering, satisfying properties specified in the axioms.

### III.1.1. The Algebraic Axioms of \( \mathbb{R} \)

The axioms for the real numbers come in three groups: the algebraic axioms, the order axioms, and one
additional axiom called the Completeness Axiom. In this subsection, we list the algebraic axioms and derive
the usual rules of algebra from them.

#### III.1.1.1. There are four standard algebraic operations on \( \mathbb{R} \): addition, subtraction, multiplication,
and division (other algebraic operations such as exponentiation can be defined in terms of these). In fact,
subtraction and division can be defined in terms of addition and multiplication respectively, so addition and
multiplication are the operations which need to be specified in the axioms.

#### III.1.1.2. The Algebraic Axioms

(Op) There are two binary operations + (addition) and \( \cdot \) (multiplication) on \( \mathbb{R} \) associating to each
pair \((x, y)\) of elements of \( \mathbb{R} \) elements \( x + y \) and \( x \cdot y \) of \( \mathbb{R} \) (\( x \cdot y \) is usually written \( xy \)).

(A1) The binary operation + is associative: \( x + (y + z) = (x + y) + z \) for all \( x, y, z \in \mathbb{R} \).

(A2) The binary operation + is commutative: \( x + y = y + x \) for all \( x, y \in \mathbb{R} \).

(A3) There is an element \( 0 \in \mathbb{R} \) such that \( 0 + x = x \) for all \( x \in \mathbb{R} \).

(A4) For every \( x \in \mathbb{R} \) there is an element \( -x \in \mathbb{R} \) with \( x + (-x) = 0 \).

(M1) The binary operation \( \cdot \) is associative: \( x(yz) = (xy)z \) for all \( x, y, z \in \mathbb{R} \).

(M2) The binary operation \( \cdot \) is commutative: \( xy = yx \) for all \( x, y \in \mathbb{R} \).

(M3) There is an element \( 1 \in \mathbb{R} \), \( 1 \neq 0 \), such that \( 1 \cdot x = x \) for all \( x \in \mathbb{R} \).

(M4) For every \( x \in \mathbb{R} \), \( x \neq 0 \), there is an element \( x^{-1} \in \mathbb{R} \) with \( xx^{-1} = 1 \).
(D) The operation \( \cdot \) distributes over \(+\): \( x(y + z) = xy + xz = (xy) + (xz) \) for all \( x, y, z \in \mathbb{R} \).

Axiom (D) is called the distributive law or distributive property.

All of the usual rules of arithmetic and algebra can be proved from the algebraic axioms. The next proposition gives some of the most important and often-used ones. We write out parts of the proof in excruciating detail to illustrate the techniques.

**III.1.1.3. Proposition.**

(i) If \( x, y, z \in \mathbb{R} \) and \( x + z = y + z \), then \( x = y \). (Additive Cancellation)

(ii) If \( x, y, z \in \mathbb{R} \), \( z \neq 0 \), and \( xz = yz \), then \( x = y \). (Multiplicative Cancellation)

(iii) If \( x \in \mathbb{R} \), then \( 0 \cdot x = 0 \).

(iv) If \( x, y \in \mathbb{R} \), then \( (-x)y = -(xy) \).

(v) If \( x \in \mathbb{R} \), then \( (-1)x = -x \).

(vi) If \( x \in \mathbb{R} \), then \( -(x) = x \).

(vii) If \( x, y \in \mathbb{R} \), then \( (-x)(-y) = xy \). In particular, \( (-1)(-1) = 1 \).

(viii) If \( x, y \in \mathbb{R} \), \( x \neq 0 \), and \( y \neq 0 \), then \( xy \neq 0 \) and \( (xy)^{-1} = (x^{-1})(y^{-1}) \).

**Proof:** (i): If \( x + z = y + z \), then \( (x + z) + (-z) = (y + z) + (-z) \). But

\[
(x + z) + (-z) = x + (z + (-z)) \text{ by (A1)}
\]

\[
= x + 0 \text{ by (A4) (definition of } -z)
\]

\[
= 0 + x \text{ by (A2)}
\]

\[
= x \text{ by (A3)}.
\]

By a similar argument, \( (y + z) + (-z) = y \). Thus \( x = y \).

(ii): The proof is almost identical to the proof of (i), and is left to the reader (Exercise (i)).

(iii): We have

\[
0 \cdot x + x = 0 \cdot x + 1 \cdot x \text{ by (M3)}
\]

\[
= x \cdot 0 + x \cdot 1 \text{ by (M2)}
\]

\[
= x(0 + 1) \text{ by (D)}
\]

\[
= x \cdot 1 \text{ by (A3)}
\]

\[
= 1 \cdot x \text{ by (M2)}
\]

\[
= x \text{ by (M3)}
\]

\[
= 0 + x \text{ by (A3)}.
\]

Thus we conclude that \( 0 \cdot x = 0 \) by (i) (applied to \( (0 \cdot x, 0, x) \) in place of \( (x, y, z) \)).
(iv): We have
\[(\neg x) y + (xy) = y(\neg x) + (yx) \quad \text{by (M2)}\]
\[= y((\neg x) + x) \quad \text{by (D)}\]
\[= y(x + (\neg x)) \quad \text{by (A2)}\]
\[= y \cdot 0 \quad \text{by (A4) (definition of } -x\text{)}\]
\[= 0 \cdot y \quad \text{by (M2)}\]
\[= 0 \quad \text{by (iii)}\]
\[= (xy) + (-xy)) \quad \text{by (A4) (definition of } -(xy)\text{)}\]
\[= (-xy)) + (xy) \quad \text{by (A2)}\]

Therefore, we have \((-x)y = -(xy)\) by (i).

(v): By (iv), \((-1)x = -(1 \cdot x)\). But \(1 \cdot x = x\) by (M3).

(vi): We abbreviate the argument (as we will from now on). We have
\[
[-(\neg x)] + (-x) = 0 = x + (-x)
\]
and so \((-\neg x) = x\) by (i).

(vii): We have
\[
(-x)(-y) = -[x(-y)] = -[-(xy)] = xy \quad \text{by (vi)}.
\]

(viii): We have
\[
(xy)[(x^{-1})(y^{-1})] = [(xy)x^{-1}](y^{-1}) = [x(yx^{-1})](y^{-1}) = [x(x^{-1}y)](y^{-1}) = [(xx^{-1})y](y^{-1}) = yy^{-1} = 1.
\]

If \(xy = 0\), then \((xy)[(x^{-1})(y^{-1})] = 0 \cdot (x^{-1}y^{-1}) = 0\) by (iii); but \(1 \neq 0\) by (M3), a contradiction. Thus \(xy \neq 0\). We then have \((xy)[(x^{-1})(y^{-1})] = 1 = (xy)[(x^{-1})(y^{-1})]\), so \((xy)^{-1} = (x^{-1})(y^{-1})\) by (ii).

III.1.1.4. By repeated application of the associative laws, a sum or product of three or more factors is unambiguously defined, so we may unambiguously write \(x + y + z\), \(xyz\), etc., for sums and products of real numbers. In particular, if \(x \in \mathbb{R}\), the product \(x \cdot x \cdots x\) \((n\text{ factors})\) is unambiguously defined; write \(x^n\) for this product. By repeated application of III.1.1.3.(viii), \((x^n)^{-1} = (x^{-1})^n\) for any nonzero \(x \in \mathbb{R}\) and any \(n\); write \(x^{-n}\) for this real number. (The last two arguments are a little too informal; they can be done carefully by induction (Exercise III.1.13.2.).) The usual rules of exponents hold (III.1.13.2.).

III.1.1.5. All the usual rules of algebra (with the exception of existence of roots; cf. III.1.12.) can be similarly derived from the algebraic axioms of \(\mathbb{R}\). In the future, we will generally use standard operations of algebra without comment. However, the reader should be sure he/she is able to write out the complete tedious proof of any algebraic formula if required, along the lines of the proofs in III.1.1.3.

From now on, we will also use standard algebraic notation: if \(x, y \in \mathbb{R}\), we will write \(x - y\) for \(x + (-y)\) and \(\frac{x}{y}\) for \(xy^{-1}\) (if \(y \neq 0\)). We will also group multiplication before addition in the usual way: \(xy + z\) means \((xy) + z\), etc.
III.1.1.6. A set with two binary operations satisfying (A1)–(A4), (M1)–(M4), and (D) is called a field, and these axioms are often called the field axioms. There are many fields with quite varied properties; see III.4.3.1. and III.4.3.5.(c), or books on abstract algebra for more details. Since the algebraic properties of \( \mathbb{R} \) are proved just using the field axioms, they are valid in any field.

III.1.2. The Order Axioms for \( \mathbb{R} \)

In addition to the algebraic structure, there is an ordering on the real numbers which (among other things) allows \( \mathbb{R} \) to be pictured geometrically as a line.

III.1.2.1. There are two equivalent ways the ordering on \( \mathbb{R} \) can be axiomatized: either directly, or by describing the set of positive numbers. Each is useful in different contexts. We will begin with the direct approach:

\((\text{Ord})\) There is a relation (strict total order) \( < \) on \( \mathbb{R} \), such that

(O1) If \( x, y \in \mathbb{R} \), then exactly one of \( x < y \), \( y < x \), \( x = y \) holds. (Trichotomy)

(O2) If \( x, y, z \in \mathbb{R} \), \( x < y \), and \( y < z \), then \( x < z \). (Transitivity)

(O3) If \( x, y, z \in \mathbb{R} \) and \( x < y \), then \( x + z < y + z \). (Translation Invariance)

(O4) If \( x, y, z \in \mathbb{R} \), \( x < y \), and \( 0 < z \), then \( xz < yz \). (Homogeneity or Scaling Invariance)

III.1.2.2. We will freely use the usual extensions of the order notation. We write \( x \leq y \) to mean \( x < y \) or \( x = y \). Write \( x > y \) to mean \( y < x \), and \( x \geq y \) to mean \( y \leq x \), i.e. \( x > y \) or \( x = y \).

As with the algebraic axioms, there are many standard order results which can be proved from the axioms. Here are some of the basic ones:

III.1.2.3. Proposition.

(i) If \( x, y \in \mathbb{R} \) and \( x < y \), then \( -y < (-x) \).

(ii) If \( x, y \in \mathbb{R} \), \( x < y \), and \( z < 0 \), then \( yz < xz \).

(iii) \( 0 < 1 \).

(iv) If \( x \in \mathbb{R} \) and \( 0 < x \), then \( 0 < x^{-1} \).

(v) If \( x, y \in \mathbb{R} \), \( 0 < x \), and \( x < y \), then \( y^{-1} < x^{-1} \).

(vi) If \( x, y, z, w \in \mathbb{R} \), \( x < y \), and \( z < w \), then \( x + z < y + w \).

(vii) If \( x, y, z, w \in \mathbb{R} \), \( 0 < x < y \), and \( 0 < z < w \), then \( xz < yw \).

Proof: (i): If \( x < y \), by (O3) we have \(-y = x - x - y < y - x - y = -x\).

(ii): If \( x < y \) and \( z < 0 \), by (i) we have \( 0 < (-z) \), so \(-(xz) = x(-z) < y(-z) = -(yz) \), and hence \( yz < xz \).

by (i).
(iii): Since $1 \neq 0$ by (M3), either $0 < 1$ or $1 < 0$. If $1 < 0$, we have $0 < (-1)$ by (i), so $0 < (-1)(-1) = 1$ by (O4), a contradiction.

(iv): We have $x^{-1} \neq 0$. If $x^{-1} < 0$, then we have

$$1 = xx^{-1} < x0 = 0$$

by (O4), contradicting (iii).

(v): We have $0 < x^{-1}$ and $0 < y^{-1}$ by (iv), so $1 = x^{-1}x < x^{-1}y$ by (O4), and hence $y^{-1} = y^{-1}1 < x^{-1}yy^{-1} = x^{-1}$ again by (O4).

(vi): We have $x + z < y + z < y + w$ by two applications of (O3). The proof of (vii) is almost identical. 

III.1.2.4. Transitivity also holds with $\leq$, and with $>$ and $\geq$:

If $x \leq y$ and $y \leq z$, then $x \leq z$.

If $x < y$ and $y \leq z$, then $x < z$.

If $x \leq y$ and $y < z$, then $x < z$.

If $x > y$ and $y > z$, then $x > z$.

The results of III.1.2.3. with $<$ replaced by $\leq$ throughout also hold. The simple proofs, checking case-by-case, are left to the reader.

Note, however, that transitivity only holds for inequalities going the same direction: for example, if $x < y$ and $y > z$, then no relation between $x$ and $z$ can be concluded. Thus the direction of inequalities must always be carefully noted.

III.1.2.5. Instead of using (Ord) as the axiomatization of the order structure on $\mathbb{R}$, one can equivalently use an axiom describing the positive numbers:

(Pos) There is a nonempty subset $P$ of $\mathbb{R}$ such that

(P1) If $x, y \in P$, then $x + y \in P$.

(P2) If $x, y \in P$, then $xy \in P$.

(P3) $0 \notin P$.

(P4) If $x \in \mathbb{R}$, $x \neq 0$, then either $x \in P$ or $(-x) \in P$, but not both.

In the presence of the algebraic axioms, it is easy to derive the (Ord) axioms from (Pos), and vice versa. The arguments are good examples of how properties are proved from the axioms.
III.1.2.6. Suppose we assume the axiom (Pos), along with the algebraic axioms. We then define the relation < by saying 

\[ x < y \text{ if (and only if)} (y-x) \in P. \]

We verify the axioms (O1)–(O4) from (Pos):

(O1): If \( x, y \in \mathbb{R} \), then from (P3) and (P4) we conclude that exactly one of \( y - x = 0 \), \( (y-x) \in P \), \(-y = -(y-x) \in P \) holds. Thus exactly one of \( x = y \), \( x < y \), or \( y < x \) holds.

(O2): If \( x < y \) and \( y < z \), i.e. \((y-x) \in P \) and \((z-y) \in P \), then \((z-x) = (y-x) + (z-y) \in P \) by (P1).

(O3): \((y+z) - (x+z) = y-x.\)

(O4): If \( x < y \) and \( 0 < z \), i.e. \((y-x) \in P \) and \( z \in P \), then \( yz - xz = z(y-x) \in P \) by (P2).

III.1.2.7. Now assume (Ord), along with the algebraic axioms. Define \( P = \{ x \in \mathbb{R} : 0 < x \} \). We verify that axioms (P1)–(P4) hold for this \( P \):

(P1): If \( x, y \in P \), i.e. \( 0 < x \) and \( 0 < y \), then we have, using (O3) and the algebraic axioms,

\[ 0 = 0 + 0 < x + 0 < x + y \]

so \( x + y \in P \).

(P2): This is very similar to (P1). If \( x, y \in P \), i.e. \( 0 < x \) and \( 0 < y \), by (O4) and III.1.1.3.(iii) we have

\[ 0 = 0 \cdot y < x \cdot y. \]

(P3): By (O1), we do not have \( 0 < 0 \).

(P4): If \( x \neq 0 \), then by (O1) we have \( 0 < x \) or \( x < 0 \), but not both. If \( 0 < x \), then \( x \in P \). If \( x < 0 \), then \( 0 = x + (-x) < 0 + (-x) = -x \) by (O3) (and (A3)–(A4)), so \((-x) \in P \).

III.1.2.8. Thus we are free to assume either (Pos) or (Ord), along with the algebraic axioms; exactly the same results can be obtained in each case. We will sometimes use (Pos) and sometimes (Ord), depending on which is more convenient at the time.

III.1.2.9. A field additionally satisfying (Ord) (or, equivalently, (Pos)) is called an ordered field. Ordered fields look somewhat more like \( \mathbb{R} \) than general fields, but there are still many ordered fields besides \( \mathbb{R} \); see, for example, III.5.3.3.(d) and III.10.2.21.. The results of III.1.2.3. and III.1.2.4. hold in a general ordered field since they are just proved from the axioms.

The final axiom, the Completeness Axiom, is what distinguishes \( \mathbb{R} \) from all other ordered fields. But before discussing this axiom, we describe some standard sets of numbers and their properties.

III.1.3. Absolute Value

III.1.4. The Natural Numbers

III.1.4.1. The first set of numbers developed, going back to prehistoric times, is the natural numbers or counting numbers, also described as the positive integers. This set is usually called \( \mathbb{N} \). Thus, as it is often described or defined,

\[ \mathbb{N} = \{1, 2, 3, \ldots \}. \]

Unfortunately, this “description” is totally inadequate as a definition of \( \mathbb{N} \): it is entirely unclear what the “\( \ldots \)” means (if you think you know, try giving a precise formulation of the meaning!)

Instead, we make the following careful definition (assuming we already have \( \mathbb{R} \)):
III.1.4.2. \textbf{Definition}. \( \mathbb{N} \) is the smallest subset of \( \mathbb{R} \) containing 1 and which is closed under adding 1, i.e. if \( n \in \mathbb{N} \), then \( (n+1) \in \mathbb{N} \).

To see that there is such a smallest subset of \( \mathbb{R} \), we could alternately define \( \mathbb{N} \) to be the intersection of all subsets \( S \) of \( \mathbb{R} \) with the property that 1 \( \in S \) and, whenever \( n \in S \), \( n+1 \) is also in \( S \). There is at least one such subset \( S \), namely \( \mathbb{R} \) itself.

III.1.4.3. One mathematically minor point needs to be addressed. There is no general agreement among mathematicians about whether \( \mathbb{N} \) includes 0; some mathematicians include it, and others do not. We will not. The question of whether to work with \( \mathbb{N} \) or \( \mathbb{N} \cup \{0\} \) as the basic set is strictly a matter of taste, since it is mathematically trivial to go from either to the other. See III.2.1.2. for further comments.

We now derive some of the basic properties of \( \mathbb{N} \) directly from its definition.

III.1.4.4. \textbf{Proposition}. \( \mathbb{N} \) is closed under addition, i.e. if \( n, k \in \mathbb{N} \), then \( (n + k) \in \mathbb{N} \).

\textbf{Proof}: Fix \( k \in \mathbb{N} \), and let \( S_k = \{ n \in \mathbb{N} : n + k \in \mathbb{N} \} \). Then \( 1 \in S_k \) since \( k + 1 \in \mathbb{N} \). If \( n \in S_k \), then \( n \in \mathbb{N} \) and \( n + k \in \mathbb{N} \), so \( n + 1 \in \mathbb{N} \) and \( (n+1) + k = (n+k) + 1 \in \mathbb{N} \), and hence \( n + 1 \in S_k \). Thus \( S_k = \mathbb{N} \). \( \Diamond \)

III.1.4.5. \textbf{Proposition}. \( \mathbb{N} \) is closed under multiplication, i.e. if \( n, k \in \mathbb{N} \), then \( nk \in \mathbb{N} \).

\textbf{Proof}: Fix \( k \in \mathbb{N} \), and let \( S_k = \{ n \in \mathbb{N} : nk \in \mathbb{N} \} \). Then \( 1 \in S_k \) since \( 1 \cdot k = k \in \mathbb{N} \). If \( n \in S_k \), then \( n \in \mathbb{N} \) and \( nk \in \mathbb{N} \). Then \( n + 1 \in \mathbb{N} \), and \( (n+1)k = nk + n \in \mathbb{N} \) by III.1.4.4., so \( n + 1 \in S_k \). Thus \( S_k = \mathbb{N} \). \( \Diamond \)

III.1.4.6. \textbf{Proposition}. If \( n \in \mathbb{N} \), then either \( n = 1 \) or \( n - 1 \in \mathbb{N} \).

\textbf{Proof}: Let \( S = \{ n \in \mathbb{N} : n = 1 \) or \( n - 1 \in \mathbb{N} \} \). Then \( 1 \in S \), and if \( n \in S \), then \( n + 1 \in \mathbb{N} \) and \( (n+1) - 1 = n \in \mathbb{N} \), so \( n + 1 \in S \). Thus \( S = \mathbb{N} \). \( \Diamond \)

III.1.4.7. \textbf{Proposition}. If \( m, n \in \mathbb{N} \) and \( m < n \), then \( n - m \in \mathbb{N} \).

\textbf{Proof}: Let \( S \) be the set of all \( k \in \mathbb{N} \) such that \( n \in \mathbb{N} \), \( n > k \) implies \( n - k \in \mathbb{N} \). Then \( 1 \in S \) by III.1.4.6.. If \( k \in S \) and \( n > k + 1 \), then \( n > k \), so \( n - k \in \mathbb{N} \), and \( n - k > 1 \) since \( n > k + 1 \); thus \( (n-k)-1 = n - (k+1) \in \mathbb{N} \) by III.1.4.6.. Thus \( k + 1 \in S \). So \( S = \mathbb{N} \). \( \Diamond \)

III.1.4.8. \textbf{Proposition}. If \( n \in \mathbb{N} \), then \( n \geq 1 \).

\textbf{Proof}: Let \( S = \{ n \in \mathbb{N} : n \geq 1 \} \). Then \( 1 \in S \), and if \( n \in S \), then \( n + 1 \in S \); so \( S = \mathbb{N} \). \( \Diamond \)

221
III.1.4.9. Proposition. If \( m, n \in \mathbb{N} \) and \( m \neq n \), then \( |m - n| \geq 1 \).

Proof: We may assume \( m < n \). Then \( n - m \in \mathbb{N} \), so \( n - m \geq 1 \). ☐

III.1.4.10. Definition. Let \( n \in \mathbb{N} \). An \( m \in \mathbb{N} \) is a predecessor of \( n \) if \( m < n \).

III.1.4.11. Proposition. Every \( n \in \mathbb{N} \) has only finitely many predecessors in \( \mathbb{N} \). (To avoid circularity, we interpret this statement to mean that the set of predecessors of any \( n \in \mathbb{N} \) is a finite set in the sense of II.5.2.6.)

Proof: Let \( S \) be the set of all \( n \in \mathbb{N} \) with only finitely many predecessors in \( \mathbb{N} \). Then \( 1 \in S \) since 1 has no predecessors in \( \mathbb{N} \) (III.1.4.8). Suppose \( n \in S \). If \( m \in \mathbb{N} \) is a predecessor of \( n + 1 \), i.e. \( m < n + 1 \), then \( (n + 1) - m \in \mathbb{N} \), so \( (n + 1) - m \geq 1 \). If \( (n + 1) - m = 1 \), then \( m = n \); otherwise \( (n + 1) - m > 1 \) (III.1.4.8.) and \( n > m \), i.e. \( m \) is a predecessor of \( n \). Thus the set of predecessors of \( n + 1 \) is \( \{n\} \cup \{ \text{predecessors of } n \} \), which is a finite set, so \( n + 1 \in S \). Thus \( S = \mathbb{N} \). ☐

III.1.4.12. Proposition. Every nonempty subset of \( \mathbb{N} \) has a smallest element (\( \mathbb{N} \) is well ordered (\( ))).

Proof: Let \( S \) be a nonempty subset of \( \mathbb{N} \), and let \( n \in S \). The set \( A \) of all elements of \( S \) which are predecessors of \( n + 1 \) is finite by III.2.6.10., and nonempty since \( n \in A \). But any finite nonempty subset of \( \mathbb{R} \) has a smallest element (II.5.2.12.). ☐

III.1.5. Induction and Recursion

The properties of \( \mathbb{N} \) we have developed lead to an important method of proof of statements involving natural numbers:

III.1.5.1. [Principle of Induction] Suppose \( P(n) \) is a statement for each \( n \in \mathbb{N} \). Suppose the following two statements hold:

(i) \( P(1) \) is true.

(ii) For every \( n \in \mathbb{N} \), if \( P(n) \) is true, then \( P(n + 1) \) is true.

Then \( P(n) \) is true for all \( n \in \mathbb{N} \).

We could have called this a Theorem, but the statement is not precise enough to qualify. One reason is that we have not been precise about the meaning of the term “statement”, since to be so would require an extensive excursion into set theory and mathematical logic. We have also been imprecise about what it means to say a statement is “true”; this should be interpreted to mean provable, i.e. a Theorem in the theory being considered, or occasionally “true in a given model.” Many books on mathematical logic such as [?] contain careful discussions of these points. But any type of mathematical statement or interpretation of truth likely to be made by a working mathematician comes within the scope of the principle.
III.1.5.2. To see why the Principle of Induction holds, set

\[ S = \{ n \in \mathbb{N} : P(n) \text{ is true} \} . \]

We have that \( 1 \in S \) by (i), and if \( n \in S \) we have \( n + 1 \in S \) by (ii). Thus \( S = \mathbb{N} \).

III.1.5.3. Proofs by induction have been described as knocking over a sequence of dominoes. The “inductive step” (ii) in the procedure amounts to showing that, for each \( n \), if the \( n \)'th domino falls, it knocks over the \( (n + 1) \)'st also. But you still have to push over the first domino by showing (i).

III.1.5.4. Careful proofs of many algebraic formulas can, and should, be done by induction. One example, the subject of a famous (but possibly apocryphal) story, is a formula for the sum of the first \( n \) natural numbers.

According to the story, when C. F. GAUSS, one of the greatest mathematicians in history, was a boy in the late 18th century, his schoolteacher became annoyed with his class and told the children to add the (natural) numbers from 1 to 100. The teacher soon saw GAUSS sitting quietly, not working, and told him to get busy. He replied that he had already finished, and the teacher found that he had the correct answer. When asked how he did it so quickly, GAUSS replied that he had written the numbers in increasing order on one line, in decreasing order on the next line, and added them vertically first pairwise to obtain a sum with all terms the same, which can be computed by multiplication, giving twice the desired sum. Symbolically, he wrote

\[
\begin{align*}
1 & + 2 + \cdots + 99 + 100 = s \\
100 & + 99 + \cdots + 2 + 1 = s \\
101 & + 101 + \cdots + 101 + 101 = 2s
\end{align*}
\]

He then computed the sum in the last line to be \((100)(101) = 10100\), so \( s = 10100/2 = 5050 \).

This clever argument can be easily modified to develop a formula for the sum of the natural numbers from 1 to \( n \), for any \( n \):

\[
\begin{align*}
1 & + 2 + \cdots + (n-1) + n = s \\
(n+1) & + (n+1) + \cdots + (n+1) + (n+1) = 2s
\end{align*}
\]

and the last sum is \( n(n+1) \), yielding the formula

\[ s = \frac{n(n+1)}{2} . \]

However, although this argument is a good way to derive (or, more accurately, guess) the correct formula, it is not precise enough to constitute a rigorous proof, primarily because of the \( \cdots \) in each row. To give a careful proof, we proceed by induction, taking, for each \( n \),

\[ P(n) : \sum_{k=1}^{n} k = \frac{n(n+1)}{2} . \]
To carry out the proof, we must (i) verify $P(1)$, which is easy: both sides of the equation are 1. Then we must show (ii) that $P(n)$ implies $P(n+1)$ for any $n$. So let $n$ be a natural number, and assume that

\[ \sum_{k=1}^{n} k = \frac{n(n+1)}{2}. \]

We then need to show that

\[ \sum_{k=1}^{n+1} k = \frac{(n+1)(n+2)}{2}. \]

But we have

\[ \sum_{k=1}^{n+1} k = \left( \sum_{k=1}^{n} k \right) + (n+1) = \frac{n(n+1)}{2} + (n+1) \]

\[ = \frac{n(n+1) + 2(n+1)}{2} = \frac{(n+2)(n+1)}{2}, \]

which is what was to be shown. By the Principle of Induction, $P(n)$ is true for all $n$, i.e. the formula holds for all $n$.

Proof by induction is used in far more circumstances than just establishing algebraic formulas, however.

**Complete Induction**

A proof procedure which is a variation of ordinary induction is complete induction.

**III.1.5.5.** [Principle of Complete Induction] Suppose $P(n)$ is a statement for each $n \in \mathbb{N}$. Suppose, for each $n \in \mathbb{N}$, the following *inductive implication* holds:

“If $P(m)$ is true for all $m < n$, then $P(n)$ is true.”

Then $P(n)$ is true for all $n \in \mathbb{N}$.

We could have again called this a Theorem, but the statement is also not precise enough to qualify because of the imprecision in the meaning of the terms “statement” and “true.”

**III.1.5.6.** Complete induction is not quite the same as ordinary induction, where statements $P(n)$ indexed by $\mathbb{N}$ are proved for all $n$ by proving $P(1)$ and $[P(n) \Rightarrow P(n+1)]$ for all $n$. Instead, in complete induction, we assume $P(m)$ is true for all $m \in \mathbb{N}$, $m < n$, and deduce $P(n)$. Ordinary induction is a special case of complete induction [if we have that $P(n)$ implies $P(n+1)$, then we certainly have that $P(m)$ for all $m < n+1$ implies $P(n+1)$]; on the other hand, complete induction can be easily deduced from ordinary induction. Indeed, suppose the statements $P(n)$ satisfy the hypotheses of complete induction. For each $n$, set

$Q(n)$: “$P(m)$ is true for all $m < n$.”
Then, for each \( n \geq 2 \), the statement “\( Q(n) \) implies \( P(n) \)” is logically equivalent to “\( Q(n) \) implies \( Q(n+1) \).” We have that \( Q(1) \) is automatically true since there are no \( m < 1 \), so by ordinary induction we obtain that \( Q(n) \) is true for all \( n \), which implies that \( P(n) \) is true for all \( n \).

Complete induction is useful where there is no simple relationship between \( P(n) \) and \( P(n+1) \), but there is a relationship between \( P(n) \) and \( P(m) \) for certain \( m \)’s less than \( n \). The next simple example is a good illustration. (We are slightly ahead of ourselves here, since prime numbers are technically only defined in III.1.6.13., but the definition is well known.)

### III.1.5.7. Proposition

Every natural number can be written as a finite product of prime numbers. [We define the product of an empty set of primes to be 1, and a product of one prime \( p \) to be \( p \).]

**Proof:** For each \( n \in \mathbb{N} \), let \( P(n) \) be the statement “The integer \( n \) can be written as a finite product of prime numbers.” Fix \( n \in \mathbb{N} \), and assume \( P(m) \) is true for all \( m < n \); we must prove that \( P(n) \) is true. There are three cases:

1. \( n = 1 \). Then \( n \) is an empty product of prime numbers.
2. \( n > 1 \) is prime. Then \( n \) is a product of one prime number.
3. \( n > 1 \) is not prime. Then \( n = n_1n_2 \) for some \( n_1, n_2 \in \mathbb{N}, n_1, n_2 > 1 \). Then \( n_1, n_2 < n \), so by assumption \( n_1 \) and \( n_2 \) can each be written as a finite product of prime numbers. Hence so can \( n_1n_2 = n \). ✷

### III.1.5.8. Note that in complete induction, it is not necessary in general to separately prove \( P(1) \), since it is included in the general case. In the case \( n = 1 \), the assumption that \( P(m) \) is true for all \( m < n \) is automatically satisfied since there are no such \( m \)’s (in this case, the hypothesis is said to be *vacuous*.) Of course, it is *allowed* to prove \( P(1) \) as a special case, as was done in the proof of III.1.5.7.

### Infinite Regress

There is an alternate way to phrase a proof by induction or complete induction, based on the fact (III.1.4.12.) that every nonempty subset of \( \mathbb{N} \) has a smallest element.

### III.1.5.9. [Principle of Infinite Regress]

Suppose \( P(n) \) is a statement for each \( n \in \mathbb{N} \). Suppose we have:

“For each \( n \in \mathbb{N} \), if \( P(n) \) is false, then there is an \( m \in \mathbb{N}, m < n \), such that \( P(m) \) is false.”

Then \( P(n) \) is true for all \( n \).

### III.1.5.10. To prove this, let

\[
S = \{ n \in \mathbb{N} : P(n) \text{ is false} \} .
\]

If \( S \) is nonempty, then it has a smallest element \( n \). But if \( n \in S \), the hypothesis insures that there is an \( m \in S \) with \( m < n \), a contradiction. Thus \( S = \emptyset \).
III.1.5.11. Actually, the statement in the Principle of Infinite Regress is just the contrapositive of the statement of Complete Induction, so Infinite Regress is logically equivalent to Complete Induction (and hence to ordinary Induction).

Infinite Regress is sometimes used in a seemingly more perverse way: if for each \( n \) we have a statement \( Q(n) \), and if we can show that if \( Q(n) \) is true, then there is an \( m < n \) such that \( Q(m) \) is true, then it follows that \( Q(n) \) cannot be true for any \( n \)!

To show this, let \( P(n) \) be the negation of \( Q(n) \) for each \( n \), and apply infinite regress to the \( P(n) \).

We often phrase arguments using Infinite Regress in a slightly different way, effectively combining Complete Induction with a proof by contradiction: to prove that \( P(n) \) is true for all \( n \) we assume \( P(n) \) is false for some \( n \), let \( n \) be the smallest natural number for which \( P(n) \) is false, and obtain a contradiction by showing that \( P(m) \) is false for some \( m \in \mathbb{N}, m < n \). “True” and “false” can be interchanged in this statement.

III.1.5.12. As an example of the use of this principle, we redo the proof of III.1.5.7.. Suppose not every element of \( \mathbb{N} \) can be written as a product of prime numbers, and let \( n \) be the smallest natural number which cannot. Then \( n \neq 1 \), since 1 can be written as the empty product of primes, and \( n \) is not prime, since a prime number can be written as a product of length 1. Thus \( n \) can be written as \( n_1 n_2 \), where \( 1 < n_1, n_2 < n \). Then at least one of \( n_1, n_2 \) cannot be written as a product of primes, contradicting that \( n \) is the smallest such number.

This argument is not really simpler when phrased this way, but some arguments do become much simpler or more natural (e.g. III.1.12.6.). In principle, any argument done by induction or complete induction can be rephrased as an infinite regress argument, and conversely.

**Definitions by Induction or Recursion**

Induction (or, technically, recursion) can also be used to define sequences. We will again not be completely precise in defining terms; see, for example, [7, p. 249-250] for a careful treatment.

III.1.5.13. Let \( X \) be a set. Suppose, for each \( n \in \mathbb{N} \), we have a definite procedure or rule \( R_n \) for choosing an \( x_n \in X \); the \( x_n \) may depend on the previous choice of the \( x_m \) for \( m < n \) (but the rule \( R_n \) does not depend on the choice of the \( x_m \) for \( m < n \)). Then

III.1.5.14. **[Principle of Recursion]** There is a unique sequence \((x_n)\) in \( X \) such that, for each \( n \in \mathbb{N} \), \( x_n \) is determined by the specified procedure \( R_n \) applied to \( \{x_m : m < n\} \).

Roughly speaking, if the sequence can be defined “one step at a time” by the rules \( R_n \), then it can be defined “all at once.” The procedure is often used when all the rules \( R_n \) (except \( R_1 \), which just amounts to specification of the first term of the sequence) are the same.

Here is a precise version of the Principle of Recursion:

III.1.5.15. **Theorem.** Let \( X \) be a set, and for each \( n \in \mathbb{N} \) let \( f_n \) be a function from \( X^n \) to \( X \). If \( x_1 \) is any element of \( X \), then there is a unique sequence \((x_n)\) in \( X \) with \( x_{n+1} = f_n(x_1, \ldots, x_n) \) for all \( n \in \mathbb{N} \).

**Proof:** Let \( S \) be the smallest subset of \( \mathbb{N} \times X \) containing \((1, x_1)\), with the property that, for any \( n \in \mathbb{N} \), whenever \( \{(k, y_k) : k \in \mathbb{N}, k \leq n\} \subseteq S \) for \((y_1, \ldots, y_n) \in X^n \), then \((n + 1, f_n(y_1, \ldots, y_n)) \in S \). \( (S \) is the

Recall that

Note that no form of the Axiom of Choice is needed in this proof; in fact, the AC is not needed even for the transfinite version II.4.2.14..

Thus

Note that

For each \( n \in N \), let \( x_n \) be the unique element of \( X \) for which \( (n, x_n) \in S \). Let \( B = \{ n \in N : x_{n+1} = f_n(x_1, \ldots, x_n) \} \). We have \( 1 \in B \) since \( (2, f_1(x_1)) \in S \); and if \( n \in B \), then \( (n + 2, f_{n+1}(x_1, \ldots, x_{n+1})) \in S \), so \( n + 1 \in B \). Thus \( B = N \).

Note that no form of the Axiom of Choice is needed in this proof; in fact, the AC is not needed even for the transfinite version II.4.2.14..

In other words, if a definite rule is specified for each \( n \) for determining the \( (n+1) \)'st term of the sequence from the first \( n \) terms, there is a unique sequence generated beginning with any first term. The rule \( f_n \) can vary with \( n \), but all the \( f_n \) must be specified in advance. The most common situation is that there is one function \( f : X \to X \) such that \( f_n(x_1, \ldots, x_n) = f(x_n) \) for each \( n \), i.e. the next term in the sequence is determined just from the previous term by the same rule each time.

The sequence is said to be defined by induction (or, more correctly, defined by recursion) from \( x_1 \) by the functions \( (f_n) \).

Caution: In definitions by induction or recursion, the rule \( R_n \) can be quite general, but it must be a definite rule giving a specific element as a function of \( \{ x_m : m < n \} \). Thus, for example, a “rule” like “Let \( x_n \) be any element of \( X \setminus \{ x_m : m < n \} \)” is not permissible, even if it is proved that this set is always nonempty (say, by a cardinality argument.) But if \( X \) is well-ordered (), it is permissible to let \( R_n \) be the rule “Let \( x_n \) be the first element of \( X \setminus \{ x_m : m < n \} \)” (provided this set is always nonempty.)

III.1.6. The Integers

The next set of numbers we will consider is the integers, or whole numbers (although historically positive fractions predated the concept of 0 or negative integers). The letter \( \mathbb{Z} \) (from the German Zahl, “number”) is customarily used to denote the set of integers. Thus, very informally,

\[ Z = \{ 0, \pm 1, \pm 2, \ldots \} \]

As with \( \mathbb{N} \), this is too imprecise to be even an informal definition of \( \mathbb{Z} \).

Instead, we define \( \mathbb{Z} \) to be the smallest subset of \( \mathbb{R} \) containing \( \mathbb{N} \) and closed under subtraction, i.e. with the property that if \( m, n \in \mathbb{Z} \), then \( m - n \in \mathbb{Z} \).
We could describe \( \mathbb{Z} \) more precisely as

\[
\mathbb{Z} = \{ m - n : m, n \in \mathbb{N} \}.
\]

Indeed, this set contains \( \mathbb{N} \) and is closed under subtraction; on the other hand, every difference of natural numbers must be contained in \( \mathbb{Z} \).

There is a conceptual problem with defining \( \mathbb{Z} \) to be the set of differences of natural numbers, however. Although this description is technically correct, there is no uniqueness: an integer can be written as a difference of natural numbers in many different ways. Thus it is conceptually clearer to define \( \mathbb{Z} \) the way we did.

There is another standard way to describe \( \mathbb{Z} \): \( \mathbb{Z} \) is the disjoint union of \( \mathbb{N} \), \( \{ 0 \} \), and \( \{-n : n \in \mathbb{N} \} \). It is clear that the union of these three sets is contained in \( \mathbb{Z} \), and is closed under subtraction by checking case-by-case, so equals \( \mathbb{Z} \). To show the sets are disjoint, just note that if \( n \in \mathbb{N} \), then \( n > 0 \), so \( -n < 0 \) and \( -n \notin \mathbb{N} \). Thus we observe

\[
\mathbb{N} = \{ x \in \mathbb{Z} : x > 0 \}.
\]

Since \( \mathbb{Z} \) is closed under subtraction and taking negatives, it is also closed under addition. In fact, it is the smallest subset of \( \mathbb{R} \) containing \( \mathbb{N} \) and closed under addition and taking negatives. (It is not the smallest subset of \( \mathbb{R} \) containing \( \mathbb{N} \) and closed under taking negatives: that would be \( \mathbb{N} \cup (-\mathbb{N}) \).)

It also follows immediately from III.1.6.3. and III.1.1.3.(iv) and (vii) that \( \mathbb{Z} \) is closed under multiplication. Thus \( \mathbb{Z} \) satisfies all the field axioms (III.1.1.2.) except (M4). (In algebraic language, it is a commutative unital ring). In fact, (M4) fails spectacularly: the only elements of \( \mathbb{Z} \) with multiplicative inverses in \( \mathbb{Z} \) are 1 and \(-1\).

Number Theory

All the algebraic properties of \( \mathbb{N} \) have direct analogs in \( \mathbb{Z} \). In fact, except for complications involved with keeping track of signs, the properties are identical. In particular, the Division Algorithm and the Fundamental Theorem of Arithmetic hold in \( \mathbb{Z} \); the statements are obvious modifications of the ones in \( \mathbb{N} \). (In algebraic language, \( \mathbb{Z} \) is a Euclidean Domain.)

Theorem. [Division Algorithm] Let \( n, d \in \mathbb{Z}, d \neq 0 \). Then there are unique \( q, r \in \mathbb{Z} \) such that \( 0 \leq r < |d| \) and \( n = qd + r \).

See III.2.9.4. for the proof if \( n, d \in \mathbb{N} \). The other cases are nearly identical. We say \( d \) divides \( n \), written \( d|n \), if \( r = 0 \), i.e. if \( n = qd \) for some \( q \in \mathbb{Z} \); \( q \) is called the quotient of \( n \) by \( d \), denoted \( \frac{n}{d} \). If \( d \) divides \( n \), then \( d \) also divides \(-n\), and \(-d \) divides \( \pm n \). Every nonzero integer divides 0. If \( n, d \in \mathbb{N} \), then \( q \in \mathbb{N} \), and \( q, d \leq n \), with equality for one if and only if the other is 1. If \( m \) and \( n \) each divide the other, then \( m = \pm n \). If \( d \) divides both \( m \) and \( n \), say \( m = ad \) and \( n = bd \) for \( a, b \in \mathbb{Z} \), then \( m + n = ad + bd = (a + b)d \), so \( d \) divides \( m + n \). Conversely, if \( d \) divides \( m \) and \( m + n \), then \( d \) divides \( (m + n) - m = n \).

With \( \mathbb{Z} \) at our disposal, there is a more efficient approach to the theory of prime numbers and factorization than can be done staying strictly within \( \mathbb{N} \).
III.1.6.8. **Definition.** If \( m, n \in \mathbb{N} \), the number \( d \in \mathbb{N} \) is the *greatest common divisor* for \( m, n \) if \( d \mid m \), \( d \mid n \), and \( c \mid d \) for any \( c \in \mathbb{N} \) which divides both \( m \) and \( n \). Write \( d = \gcd(m, n) \) or \((q) = (m, n)\) (ideal notation).

This definition can be made for general nonzero elements of \( \mathbb{Z} \), but is cleaner if we stick to \( \mathbb{N} \). It is clear that if the greatest common divisor of \( m \) and \( n \) exists, it is unique and is indeed the largest natural number that divides both \( m \) and \( n \), but it is not so clear that the largest such divisor is a greatest common divisor in the sense of the definition, and hence it is unclear that a greatest common divisor exists. However, this turns out to be true:

III.1.6.9. **Theorem.** If \( m \) and \( n \) be natural numbers. Then \( m \) and \( n \) have a (unique) greatest common divisor, which is of the form \( d = am + bn \) for some (nonunique) \( a, b \in \mathbb{Z} \).

**Proof:** Set \( J = \{mx + ny : x, y \in \mathbb{Z}\} \) (\( J \) is an *ideal* in \( \mathbb{Z} \)). Then \( J \cap \mathbb{N} \neq \emptyset \) since \( m, n \in J \). Let \( d \) be the smallest element of \( J \cap \mathbb{N} \), and write \( d = am + bn \) for \( a, b \in \mathbb{Z} \).

We show that \( d \) divides \( m \) and \( n \). In fact, \( d \) divides any \( z \in J \): suppose \( z = mx + ny \in J \), and write \( z = qd + r \) by the Division Algorithm with \( q \in \mathbb{Z} \) and \( 0 \leq r < d \). Then

\[
mx + ny = q(ax + by) + r
\]

and by minimality of \( d \) we have that \( r = 0 \).

If \( c \) divides both \( m \) and \( n \), then \( c \) clearly divides \( am + bn = d \).

III.1.6.10. There is an effective and numerically efficient algorithm (the *Euclidean algorithm*) for finding \( \gcd(m, n) \) for natural numbers \( m \) and \( n \).

III.1.6.11. If \( m, n \in \mathbb{N} \), we say \( m \) and \( n \) are *relatively prime* if \( \gcd(m, n) = 1 \). (This definition, like the notion of greatest common divisor itself, can be extended to pairs of nonzero integers.)

III.1.6.12. **Proposition.** Let \( d, m, n \in \mathbb{N} \). If \( d \) divides \( mn \) and \( d \) and \( m \) are relatively prime, then \( d \) divides \( n \).

**Proof:** If \( d \) and \( m \) are relatively prime, then there are integers \( a \) and \( b \) with \( ad + bm = 1 \). Then

\[
n = 1 \cdot n = (ad + bm)n = adn + bmn
\]

so \( n \) is divisible by \( d \).
III.1.6.13. A $p \in \mathbb{N}$ is a prime number if $p > 1$ and the only natural numbers which divide $p$ are 1 and $p$, i.e. the only integers dividing $p$ are $\pm 1$ and $\pm p$. (To be consistent with the language of abstract algebra, we should also call $-p$ prime, and we should use the term irreducible instead of prime until III.1.6.14. is proved.)

If $p, n \in \mathbb{N}$ and $p$ is prime, then either $p$ divides $n$ or $p$ and $n$ are relatively prime. In particular, if $p$ and $q$ are distinct prime numbers, then $p$ and $q$ are relatively prime. We also have the following corollary of III.1.6.12. (the last part of the statement is proved by induction from the first part):

III.1.6.14. Corollary. Let $p, m, n \in \mathbb{N}$ with $p$ prime. If $p$ divides $mn$, then $p$ divides $m$ or $p$ divides $n$. If $n_1, \ldots, n_r \in \mathbb{N}$ and $p$ divides $n_1 n_2 \cdots n_r$, then $p$ divides at least one of the $n_k$.

We can then state the Fundamental Theorem of Arithmetic:

III.1.6.15. Theorem. [Fundamental Theorem of Arithmetic] Every natural number can be written as a (finite) product of prime numbers, uniquely up to the order of the factors. (The “empty product” 1 and products of length 1 are included. Repeated factors are, of course, allowed.)

Proof: It has already been shown (III.1.5.7.) that every natural number can be written as a product of prime numbers, so we only need to show uniqueness. This can be done by induction on the length of the product, but we phrase the argument alternately by infinite regress.

Suppose

$$n = p_1 p_2 \cdots p_r = q_1 q_2 \cdots q_s$$

is a nonunique factorization with $r$ the smallest possible length for one of the factorizations (hence $r \leq s$). Then $n > 1$, so both $r$ and $s$ are at least 1, and neither can be 1 since the $p_j$ and $q_k$ are prime. Thus $r, s > 1$. We have that $p_1$ divides $q_1 \cdots q_s$, so it divides $q_k$ for some $k$, and since $q_k$ is prime we have $p_1 = q_k$. By reordering the $q$’s we may assume $k = 1$. Thus

$$\frac{n}{p_1} = p_2 \cdots p_r = q_2 \cdots q_s$$

is a nonunique factorization with one product of length $r - 1$, contradicting minimality of $r$. Thus nonunique factorizations do not exist. \(\diamondsuit\)

We conclude our brief introduction to the algebraic theory of $\mathbb{N}$ by noting that there are an infinite number of primes. This observation and its slick proof are due to Euclid. (Actually Euclid never stated that there are infinitely many primes; the ancient Greeks had no notion of infinity.)

III.1.6.16. Theorem. There are infinitely many prime numbers. If $n \in \mathbb{N}$, there is a prime number $p$ with $p > n$.

Proof: Suppose $p_1, \ldots, p_r$ is a finite set of prime numbers. Set $m = 1 + p_1 p_2 \cdots p_r$. Then no $p_k$ divides $m$, so if $p$ is a prime dividing $m$, $p$ is not one of the $p_k$ and no finite list of primes is complete.

The last statement follows from the first and the fact that the set of predecessors of $n$ is finite. As an alternate proof, the number $n! + 1$ (cf. Exercise III.1.13.3.) is not divisible by any natural number $\leq n$ except 1, so any prime number dividing it is greater than $n$. \(\diamondsuit\)
III.1.7. The Rational Numbers

The next step historically in building the number system was the rational numbers, usually denoted \( \mathbb{Q} \) (for “quotient”). Actually at least some simple rational numbers probably predated negative numbers historically.

III.1.7.1. \( \mathbb{Q} \) is the smallest subset of \( \mathbb{R} \) containing \( \mathbb{Z} \) and closed under quotients of nonzero elements.

III.1.7.2. If \( a, b \in \mathbb{R} \) and \( b \neq 0 \), then \( \frac{a}{b} \) is defined to be \( ab^{-1} \). The formulas

\[
\frac{a}{b} + \frac{c}{d} = \frac{ad + bc}{bd}; \quad \frac{a}{b} \cdot \frac{c}{d} = \frac{ac}{bd}; \quad \left( \frac{b}{d} \right)^{-1} = \frac{d}{b}; \quad \frac{a}{b} + \frac{c}{d} = \frac{ad}{bc}
\]

for \( a, b, c, d \in \mathbb{R}, b \neq 0, d \neq 0 \) (and, in the last, \( c \neq 0 \)), provable from the field axioms, show that

\[
\mathbb{Q} = \left\{ \frac{m}{n} : m, n \in \mathbb{Z}, n \neq 0 \right\}
\]

and that \( \mathbb{Q} \) is the smallest subset of \( \mathbb{R} \) containing \( \mathbb{Z} \) and closed under multiplication and reciprocals of nonzero elements; the first formula also shows that \( \mathbb{Q} \) is closed under addition. Since \( -\frac{m}{n} = \frac{-m}{n} = \frac{m}{-n} \) for any \( m, n \) \((n \neq 0)\), we also have that \( \mathbb{Q} \) is closed under subtraction, and that any element of \( \mathbb{Q} \) can be written as \( \frac{m}{n} \), where \( m \in \mathbb{Z}, n \in \mathbb{N} \).

III.1.7.3. Rational numbers are often described as “fractions,” but this is incorrect. Rational numbers are not the same thing as fractions: many fractions such as \( \frac{1}{2} \) and \( \frac{2}{4} \) can represent the same rational number. Instead, a rational number is a number which can be represented as a fraction. Although each rational number does have a standard representation as a fraction in “lowest terms” (III.1.7.4.), when a rational number appears in mathematics it often does not have any natural representation as a fraction (e.g. it could arise as a repeating decimal).

III.1.7.4. Since for \( n, r \neq 0 \) we have \( \frac{mr}{nr} = \frac{m}{n} \) \( r \) and by definition \( \frac{r}{r} = 1 \), we have \( \frac{mr}{nr} = \frac{m}{n} \). Thus, if \( m, n \in \mathbb{N} \) and \( d = gcd(m, n) \), and \( m = ad, n = bd \), we have \( \frac{m}{n} = \frac{a}{b} \), and \( a \) and \( b \) are relatively prime. By the Fundamental Theorem of Arithmetic, the representation of a positive rational number as a quotient of relatively prime natural numbers is unique. (Actually it just follows immediately from III.1.4.12. that any positive rational number has a unique representation as \( \frac{a}{b} \) with \( b \in \mathbb{N} \) minimal, and this must be in lowest terms, i.e. \( a \) and \( b \) have no common factors. The fact that this is the unique representation as \( \frac{m}{n} \) with \( m 

III.1.7.5. The set \( \mathbb{Q} \) of rational numbers with its algebraic operations, and the ordering induced as a subset of \( \mathbb{R} \), satisfies all the axioms of \( \mathbb{R} \) we have discussed so far, i.e. it is an ordered field. (In fact it is the “smallest” ordered field: any ordered field contains a canonical subfield isomorphic to \( \mathbb{Q} \) as an ordered field.) It is, in fact, not so easy to see (but not terribly difficult; see e.g. III.1.12.2. – III.1.12.6.) that \( \mathbb{Q} \) is not all of \( \mathbb{R} \), i.e. that there exist irrational numbers. The axiom which distinguishes \( \mathbb{R} \) from \( \mathbb{Q} \) (and all other ordered fields) is the Completeness Axiom.
III.1.8. The Number Line

The geometric representation of the real numbers as a line is familiar, at least informally, to anyone who has studied analytic geometry or even high-school algebra. The number line should be viewed merely as a convenient picture of the real numbers and not as a rigorous mathematical construction, since it is logically either baseless or circular depending on whether, or how, the relevant geometric objects are defined.

III.1.8.1. DESCARTES was the one to formalize the notion that points on a line can be identified with [real] numbers, but, at least in retrospect, the basic idea really goes back at least to EUCLID (and probably to predecessors such as EUDOXUS). One of the essential features of Euclidean geometry (the name in Greek refers to “measuring the earth”) is that any two points on a line, or in space, have a numerical distance between them, at least once a fixed unit distance has been specified. EUCLID actually refers to “magnitudes” of lines [line segments] instead of numerical distances between points, but discusses equality, addition, subtraction, multiplication, and division of magnitudes, so his magnitudes correspond naturally to [constructible] nonnegative real numbers; indeed, the principal conceptual advance of DESCARTES’ time over ancient Greece was the abstraction of the notion of “magnitude” or “quantity” into “number”. (However, the conception of a line as a collection of points is a subtle one, and was not widely accepted in ancient Greece, or indeed universally accepted even today.) The only thing missing from EUCLID then, besides the abstract concept of number (and perhaps the conception of a line as a collection of points), is the idea of arbitrarily fixing one point on the line and calling it 0, and a unit distance and positive direction, which can be simultaneously specified by giving one additional point on the line to be called +1; once this is done, identifying all other points on the line with numbers, and vice versa, via distance and direction from 0, is almost immediate. (Identifying points in a plane or three-dimensional space with ordered pairs or triples of numbers is not quite so straightforward: not only must an origin and unit distance be chosen, but also a set of perpendicular axes and an orientation.)

III.1.8.2. To do the identification carefully (or at least systematically), we fix a line \( L \) and arbitrarily fix a point on \( L \) which we call 0. Then fix another point on \( L \) which we call 1. We usually draw \( L \) as a horizontal line, with 1 to the right of 0. Successively mark off equally spaced points to the right of 1 (i.e. the same direction from 0 as 1) and call these 2, 3, \ldots. Do the same to the left (the opposite direction from 1) of 0, and call these numbers \(-1, -2, \ldots\). In this way, the numbers in \( \mathbb{Z} \) are identified with points on \( L \). See Figure ( ). (We often mark points on the number line \( L \) by short cross segments, but these are of course not part of \( L \).)

III.1.8.3. Now, for each \( m \in \mathbb{N} \), choose \( m - 1 \) equally spaced points between 0 and 1, and call them \( \frac{1}{m}, \frac{2}{m}, \ldots, \frac{m-1}{m} \) from left to right. Similarly, for each \( n \in \mathbb{Z} \) choose \( m - 1 \) equally spaced points between \( n \) and \( n + 1 \), and call them \( n, n + \frac{1}{m}, \ldots, n + \frac{m-1}{m} \) from left to right. Thus each rational number is associated with a point on \( L \), and the ordering on \( \mathbb{Q} \) is the same as the geometric ordering on \( L \) from left to right. We can thus picture \( \mathbb{Q} \) as a subset of \( L \). Although it is not immediately obvious whether every point of \( L \) corresponds to a rational number (we will see that actually “most” do not), the subset corresponding to \( \mathbb{Q} \) is dense in \( L \), i.e. every subinterval of \( L \), no matter how short, contains a point of \( \mathbb{Q} \), in fact infinitely many. See Figure ( ). (Actually, density of \( \mathbb{Q} \) in the number line, which seems geometrically obvious, takes some proof; see ()..)
III.1.9. Suprema, Infima, and the Completeness Axiom

III.1.9.1. One plausible assumption about a line is that it has no “holes”. A way of expressing this is that any time a line $L$ is split into two disjoint subsets $A$ and $B$, with every point in $A$ to the left of (or, in the usual order, less than) every point of $B$, then there should be a point of $L$ exactly at the boundary of $A$ and $B$, i.e. either $A$ should have a largest (rightmost) point or $B$ should have a smallest (leftmost) point. (Both things cannot happen simultaneously, for then the largest point of $A$ and the smallest point of $B$ would be consecutive points on $L$, which clearly is intuitively impossible.) See Figure (1). The term used for this property, called the completeness property, is that a line is connected, or a continuum. It should be emphasized that the completeness property of a line cannot be proved – it is just a reasonable assumption, although a rather subtle one.

To rephrase this property in terms of the real numbers, we need some terminology:

III.1.9.2. Definition. If $A$ is a nonempty subset of $\mathbb{R}$, a number $b \in \mathbb{R}$ is an upper bound for $A$ if $a \leq b$ for all $a \in A$. If $A$ has an upper bound, then $A$ is bounded above. A number $c \in \mathbb{R}$ is a lower bound for $A$ if $c \leq a$ for all $a \in A$. If $A$ has a lower bound, then $A$ is bounded below. $A$ is bounded if $A$ is bounded above and bounded below.

The real number $s$ is the least upper bound, or supremum, of the nonempty subset $A$, written $s = \sup(A)$ (or sometimes $s = \text{lub}(A)$), if $s$ is an upper bound for $A$ and $s \leq b$ for any upper bound $b$ of $A$. The greatest lower bound, or infimum, of $A$, written $\inf(A)$ or $\text{glb}(A)$, is defined analogously.

III.1.9.3. Note that an upper or lower bound for a set $A$ is not necessarily an element of $A$. Not every subset of $\mathbb{R}$ is bounded above or below: for example, $A = \mathbb{R}$ has no upper or lower bound in $\mathbb{R}$. If $A$ is bounded above, there is nothing unique about an upper bound for $A$: if $b$ is an upper bound for $A$, so is $b'$ for any $b' > b$. Similarly, lower bounds are not unique. But the supremum of $A$, if it exists, is unique; similarly, the infimum of $A$ is unique if it exists. But note that it is not obvious that a set which is bounded above has a supremum, or that a set which is bounded below has an infimum.

We do not define upper or lower bounds, or the supremum or infimum, of the empty set $\emptyset$. (Technically, if Definition III.1.9.2. were applied to $A = \emptyset$, every real number would be both an upper bound and a lower bound for $\emptyset$.)

III.1.9.4. Examples. (i) If a subset $A$ of $\mathbb{R}$ has a maximum $b$, then $b = \sup(A)$ and $A$ is bounded above. If $A$ has a minimum $c$, then $c = \inf(A)$ and $A$ is bounded below. In particular, every finite subset of $\mathbb{R}$ has a supremum and an infimum, which are its largest and smallest elements respectively.

(ii) Let $A$ be the open interval $(0, 1) = \{x \in \mathbb{R} : 0 < x < 1\}$. Then $A$ is bounded above, and $1 = \sup(A)$ (to see this, note that if $b < 1$, then there is an $x \in \mathbb{R}$ with $b < x < 1$); but $A$ has no maximum element, since $1 \notin A$. Similarly, $0 = \inf(A)$, but $A$ has no minimum.

(iii) It is intuitively clear that $0 = \inf\{\frac{1}{n} : n \in \mathbb{N}\}$, but this requires proof; cf. (1).

(iv) If $A \subseteq \mathbb{R}$, set $-A = \{-x : x \in A\}$. Then $-b$ is a lower bound for $-A$ if and only if $b$ is an upper bound for $A$. So $-A$ is bounded below if and only if $A$ is bounded above, and $-A$ has an infimum if and only if $A$ has a supremum, with $\inf(-A) = -\sup(A)$. Thus the upper and lower situations are completely symmetric under taking negatives.
III.1.9.5. Proposition. Let $A$ be a nonempty subset of $\mathbb{R}$, and $s \in \mathbb{R}$. The following are equivalent:

(i) $s = \sup(A)$.

(ii) $x \leq s$ for all $x \in A$, and for any $b \in \mathbb{R}$, $b < s$, there is an $x \in A$ with $x > b$.

(iii) $x \leq s$ for all $x \in A$, and for every $\epsilon \in \mathbb{R}$, $\epsilon > 0$, there is an $x \in A$ with $x > s - \epsilon$.

Proof: (i) $\Rightarrow$ (ii): If $s = \sup(A)$ and $b < s$, then $b$ is not an upper bound for $A$.

(ii) $\Rightarrow$ (i): Under (ii), $s$ is an upper bound for $A$, and no $b < s$ is an upper bound for $A$.

(ii) $\iff$ (iii): Given $b$ as in (ii), set $\epsilon = s - b$; given $\epsilon$ as in (iii), set $b = s - \epsilon$.

III.1.9.6. Proposition. Let $A$ be a nonempty subset of $\mathbb{R}$, and $c \in \mathbb{R}$. Set $c + A = \{c + x : x \in A\}$. Then $c + A$ is bounded above if and only if $A$ is bounded above, and $\sup(c + A) = c + \sup(A)$. Similarly, $c + A$ is bounded below if and only if $A$ is bounded below, and $\inf(c + A) = c + \inf(A)$.

Proof: If $b$ is an upper bound for $A$, then $c + b$ is an upper bound for $c + A$; conversely, if $d$ is an upper bound for $c + A$, then $d - c$ is an upper bound for $A$. If $s = \sup(A)$, then it is clear that $c + s$ is the least upper bound of $c + A$, and conversely.

We can then phrase the Completeness Axiom as follows. This turns out to be equivalent to the completeness property of the real line as described above, but is easier to work with.

III.1.9.7. Completeness Axiom: Every nonempty subset of $\mathbb{R}$ which is bounded above has a supremum.

We will show that the Completeness Axiom is equivalent to the completeness property of the real line, as described in III.1.9.1. We first make a more general observation:

III.1.9.8. Proposition. Let $A$ and $B$ be nonempty subsets of $\mathbb{R}$, with $a \leq b$ for all $a \in A$, $b \in B$. Then $A$ is bounded above, $B$ is bounded below, and $\sup(A) \leq \inf(B)$.

Proof: Every $b \in B$ is an upper bound for $A$. So $A$ is bounded above, and so has a supremum $\sup(A)$ which satisfies $\sup(A) \leq b$ for each $b \in B$ since $\sup(A)$ is the least upper bound of $A$. This means $\sup(A)$ is a lower bound for $B$ (as is each $a \in A$), so $B$ is bounded below, and $\inf(B)$ exists and satisfies $\inf(B) \geq \sup(A)$ since $\inf(B)$ is the greatest lower bound of $B$.

We can then show using the Completeness Axiom that the real line has the completeness property. This is sometimes (cf. [Lan51]) called Dedekind’s Fundamental Theorem, although in our approach it hardly merits Theorem status since it is almost immediate (in other approaches to the real numbers it is a real theorem).
**III.1.9.9. Theorem.** If $A$ and $B$ are nonempty disjoint subsets of $\mathbb{R}$ with $A \cup B = \mathbb{R}$ and $x < y$ for all $x \in A$ and $y \in B$, then either $A$ has a largest element or $B$ has a smallest element, but not both. Alternatively, there is a unique real number $a$ such that \{ $x \in \mathbb{R} : x < a$\} $\subseteq A$ and \{ $y \in \mathbb{R} : a < y$\} $\subseteq B$ ($a$ may be either the largest element of $A$ or the smallest element of $B$).

**Proof:** If such an $a$ exists, it is both an upper bound for $A$ and a lower bound for $B$, and conversely, a number $a$ which is both an upper bound for $A$ and a lower bound for $B$ satisfies the conclusions. So we need to show that there is a unique $a$ with these properties.

By III.1.9.8., $\sup(A)$ and $\inf(B)$ exist and satisfy $\sup(A) \leq \inf(B)$. We cannot have $\sup(A) < \inf(B)$, since then $c = (\sup(A) + \inf(B))/2$ would satisfy $\sup(A) < c < \inf(B)$ and $c$ could not be in either $A$ or $B$. Thus $\sup(A) = \inf(B)$; call this real number $a$. If $b$ is an upper bound for $A$, then $a \leq b$, and if $d$ is a lower bound for $B$, then $d \leq a$. Thus $a$ is the unique number with both properties.

**III.1.9.10.** Conversely, if the real line is assumed to have the completeness property of III.1.9.1., then the Completeness Axiom can be proved, and thus the Completeness Axiom is equivalent to the completeness property. For suppose $C$ is a nonempty subset of $\mathbb{R}$ which is bounded above. We wish to show from the completeness property that $C$ has a supremum. If $C$ has a largest element, the conclusion is obvious. If $C$ has no largest element, i.e. if no element of $C$ is an upper bound for $C$, let $B$ be the set of all upper bounds for $C$ in $\mathbb{R}$, and let $A$ be the set of real numbers which are not upper bounds for $C$. Then $\mathbb{R}$ is the disjoint union of $A$ and $B$. $B$ is nonempty by assumption, and $A$ is nonempty since $C \subseteq A$. We clearly have $x < y$ for all $x \in A$, $y \in B$. Let $a$ be the unique element of $\mathbb{R}$ given by the completeness property. If $a \in A$, then $a$ would be an upper bound for $A$ and hence for $C$, contradicting the definition of $A$; hence $a \in B$ and $a$ is an upper bound for $C$. If $x < a$, then $x \in A$, so $x$ is not an upper bound for $C$; hence $a$ is the least upper bound of $C$.

**III.1.9.11.** The Completeness Axiom is really the cornerstone of analysis. Most of the basic concepts of analysis, e.g. convergence of sequences, limits and continuity of functions, and derivatives, can be equally well defined in the same way in any ordered field such as $\mathbb{Q}$, and many of the standard results about them (e.g. algebraic combinations of limits, rules of differentiation) hold in this setting with the same proofs as in $\mathbb{R}$. But the objects have very different properties from the real case. For example, working on $\mathbb{Q}$, define

$$f(x) = \begin{cases} -1 & \text{ if } x^2 < 2 \\ 1 & \text{ if } x^2 > 2 \end{cases} .$$

Then $f$ is continuous and even differentiable everywhere, and $f'$ is identically 0, but $f$ is not constant and does not satisfy the Intermediate Value Theorem. If

$$g(x) = \begin{cases} x & \text{ if } x^2 < 2 \\ 0 & \text{ if } x^2 > 2 \end{cases}$$

then $g$ is continuous on $[-2, 2]$, but does not satisfy the Extreme Value Theorem. Thus these properties of continuous or differentiable functions on $\mathbb{R}$, which may seem “obvious,” are in fact rather subtle since they depend on the Completeness Axiom.

These points are argued persuasively in [Kör04]. The book begins by asking, “Why do we bother?” and then states:
It is surprising how many people think that analysis consists in the difficult proofs of obvious theorems. All we need know, they say, is what a limit is, the definition of continuity and the definition of the derivative. All the rest is ‘intuitively clear.’ ”

This notion is then well refuted. There is also an interesting discussion of the question, “Is the Intermediate Value Theorem obvious?” In that book, the working definition of analysis is “mathematics based on the Completeness Axiom” (called the fundamental axiom); everything else (of the mathematics covered there) is regarded as “mere algebra.”

**Intervals in \( \mathbb{R} \)**

Using the Completeness Axiom, we can give a clean description of intervals in \( \mathbb{R} \).

**III.1.9.12. Definition.** A subset \( J \) of \( \mathbb{R} \) is an interval if

(i) \( J \) contains more than one real number.

(ii) If \( x, y \in J, x < y \), and \( z \in \mathbb{R}, x < z < y \), then \( z \in J \).

Informally, an interval is a subset of \( \mathbb{R} \) containing all numbers between any two of its elements. We do not regard \( \emptyset \) or singleton sets to be intervals, although they technically satisfy (ii), but we sometimes call these sets *degenerate intervals*.

**III.1.9.13. Examples.** Here are standard examples of intervals, and the standard interval notation used:

Let \( a, b \in \mathbb{R}, a < b \). Set

\[ [a, b] = \{x \in \mathbb{R} : a \leq x \leq b\} \]

\[ [a, b) = \{x \in \mathbb{R} : a \leq x < b\} \]

\[ (a, b] = \{x \in \mathbb{R} : a < x \leq b\} \]

\[ (a, b) = \{x \in \mathbb{R} : a < x < b\} \]

If \( a \in \mathbb{R}, \) set

\[ [a, \infty) = [a, +\infty) = \{x \in \mathbb{R} : x \geq a\} \]

\[ (a, \infty) = (a, +\infty) = \{x \in \mathbb{R} : x > a\} \]

If \( b \in \mathbb{R}, \) set

\[ (-\infty, b] = \{x \in \mathbb{R} : x \leq b\} \]

\[ (-\infty, b) = \{x \in \mathbb{R} : x < b\} \]

Finally, set \( (-\infty, \infty) = (-\infty, +\infty) = \mathbb{R} \).

Intervals of the form \([a, b]\), \([a, \infty)\), and \((-\infty, b]\) are called *closed intervals*, and intervals of the form \((a, b)\), \((a, \infty)\), and \((-\infty, b)\) are called *open intervals*. The interval \((-\infty, \infty)\) is regarded as both a closed interval and an open interval. An interval of the form \([a, b]\) or \((a, b)\) is called a *half-open interval*.  

236
III.1.9.14. PROPOSITION. Every interval $J$ in $\mathbb{R}$ is of one of the forms from III.1.9.13. More specifically, $J$ is of the form $[a,b]$, $[a,b)$, $(a,b)$, or $(a,b)$ if $J$ is bounded, of the form $[a,\infty)$ or $(a,\infty)$ if $J$ is bounded below but not bounded above, of the form $(-\infty,b]$ or $(-\infty,b)$ if $J$ is bounded above but not bounded below, and $J = (-\infty, \infty)$ if $J$ is not bounded above or below.

PROOF: Suppose $J$ is bounded. Set $a = \inf(J)$ and $b = \sup(J)$. Then $a < b$ since $J$ is not a singleton, and $J \subseteq [a,b]$. If $z \in \mathbb{R}$, $a < z < b$, then $z$ is neither an upper or lower bound for $J$, so there are $x, y \in J$ with $x < z < y$. But then $z \in J$ by (ii). So $(a,b) \subseteq J$. The argument if $J$ is unbounded is almost identical. ⬜

III.1.9.15. Without the Completeness Axiom, we could not assert that every interval is of such a simple form. For example, we can formally define intervals in $\mathbb{Q}$ the same way. But then

$$\{x \in \mathbb{Q} : x^2 < 2\}$$

can be easily shown to be an interval in $\mathbb{Q}$; but even though it is a nonempty proper subset of $\mathbb{Q}$, it has no endpoints (in $\mathbb{Q}$) and so cannot be described as either an open or closed interval in the usual way.

Lengths of Intervals

An important consequence of the characterization of intervals in $\mathbb{R}$, sometimes not properly appreciated, is the fact that each interval has a well-defined numerical length:

III.1.9.16. DEFINITION. Let $I$ be an interval in $\mathbb{R}$. If $I$ is not bounded, set $\ell(I) = +\infty$. If $I$ is bounded, then $I$ is of the form $[a,b]$, $[a,b)$, $(a,b)$, or $(a,b)$ for some $a, b \in \mathbb{R}$, $a < b$, and we set $\ell(I) = b - a$. Then $\ell(I)$, called the length of $I$, satisfies $0 < \ell(I) \leq +\infty$.

III.1.9.17. Without the characterization of intervals, it would not be possible to give a numerical length to intervals in general. For example, if our number system were $\mathbb{Q}$, the interval described in III.1.9.15. would not have a well-defined numerical length within our number system.

The following two properties of interval length seem like (and really are) almost no-brainers, but are surprisingly powerful, eventually making possible a nontrivial theory of Lebesgue measure on $\mathbb{R}$.

III.1.9.18. PROPOSITION. (i) Let $I$ and $J$ be intervals in $\mathbb{R}$. If $J \subseteq I$, then $\ell(J) \leq \ell(I)$.

(ii) Let $I$ and $J$ be intervals in $\mathbb{R}$. If $I \cup J$ is an interval (e.g. if $I \cap J \neq \emptyset$), then

$$\ell(I \cup J) \leq \ell(I) + \ell(J).$$

237
**III.1.9.19. Theorem.** [Fundamental Theorem of Interval Length] Let $I_1, \ldots, I_n, J$ be intervals in $\mathbb{R}$. If $J \subseteq I_1 \cup \cdots \cup I_n$, then

$$\ell(J) \leq \sum_{k=1}^{n} \ell(I_k).$$

**Proof:** By induction on $n$. The case $n = 1$ is III.1.9.18.(i). Suppose the statement is true for $n$, and let $J \subseteq I_1 \cup \cdots \cup I_{n+1}$. We may assume $I_1$ is bounded, $I_1 \cap J \neq \emptyset$, and $J \not\subseteq I_1$. Let $a_1$ and $b_1$ be the left and right endpoints of $I_1$. Then either $a_1$ or $b_1$ is in $J$. Suppose $a_1 \in J$. (1) If $a_1 \notin I_1$, then there is an $I_k$ with $a_1 \in I_k$ and $I_1 \cup I_k$ is an interval. (2) If $a_1 \in I_1$ and $J$ contains a $c < a_1$, then there is one of the intervals $I_k$ with endpoints $a_k, b_k$ with $a_k < a_1$ and $b_k \geq a_1$ since there are only finitely many $I_k$ [if not, $d = \max\{b_k : a_k < a_1\} < a_1$ and $x \in J \setminus I_k$ for $d < x < a_1$]; then also $I_1 \cup I_k$ is an interval. The case where $b_1 \in J$ is similar. We must be in either case (1) or (2) for at least one of $a_1$ and $b_1$ since $J \not\subseteq I_1$.

Thus there must be an $I_k$ such that $I_1 \cup I_k$ is an interval. By renumbering, we may assume $k = n + 1$. Set $I'_1 = I_1 \cup I_{n+1}$. Then $J \subseteq I'_1 \cup I_2 \cup \cdots \cup I_n$, and $\ell(I'_1) \leq \ell(I_1) + \ell(I_{n+1})$ by III.1.9.18.(ii). Thus, by the inductive hypothesis,

$$\ell(J) \leq \ell(I'_1) + \sum_{k=2}^{n} \ell(I_k) \leq \sum_{k=1}^{n+1} \ell(I_k).$$

**III.1.10. The Archimedean Property and Density of $\mathbb{Q}$**

Using the Completeness Axiom, we now show that the Archimedean property (cf. (i)) also holds in $\mathbb{R}$:

**III.1.10.1. Theorem.** Let $a, b \in \mathbb{R}$ with $a > 0$. Then there is an $n \in \mathbb{N}$ with $b < na$.

**Proof:** Suppose $na \leq b$ for all $n \in \mathbb{N}$, i.e. $b$ is an upper bound for $A = \{na : n \in \mathbb{N}\}$. Then $A$ is bounded above, so by the Completeness Axiom $A$ has a supremum. Set $s = \sup(A)$. Then $s - a$ is not an upper bound for $A$ since $a > 0$, so there is an $n \in \mathbb{N}$ with $na > s - a$. But then $(n + 1)a \in A$ and $(n + 1)a = na + a > (s - a) + a = s$, contradicting the fact that $s$ is an upper bound for $A$. Thus the assumption that $na \leq b$ for all $n \in \mathbb{N}$ is false.

**III.1.10.2. Corollary.** Let $b \in \mathbb{R}$. Then there is an $n \in \mathbb{N}$ with $b < n$. ($\mathbb{N}$ is not bounded above in $\mathbb{R}$.)

**Proof:** Apply III.1.10.1. with $a = 1$.

**III.1.10.3. Corollary.** $\inf \{\frac{1}{n} : n \in \mathbb{N}\} = 0$, i.e. if $\epsilon \in \mathbb{R}$, $\epsilon > 0$, there is an $n \in \mathbb{N}$ with $\frac{1}{n} < \epsilon$.

**Proof:** $0$ is a lower bound for $\{\frac{1}{n} : n \in \mathbb{N}\}$, so $\inf \{\frac{1}{n} : n \in \mathbb{N}\}$ exists. If $\epsilon \in \mathbb{R}$, $\epsilon > 0$, then there is an $n \in \mathbb{N}$ with $\frac{1}{n} < \epsilon$. For this $n$, $\frac{1}{n} < \epsilon$. Thus $\epsilon$ is not a lower bound for $\{\frac{1}{n} : n \in \mathbb{N}\}$.

There is a tightening of III.1.10.2. which is an important observation:

238
**III.1.10.4.** Proposition. Let $x \in \mathbb{R}$, then there is a unique $n \in \mathbb{Z}$ with $n \leq x < n + 1$. The integer $n$ is called the integer part of $x$, denoted $\lfloor x \rfloor$.

**Proof:** Suppose first $x \geq 0$. Then $\{n \in \mathbb{N} : x < n\}$ is nonempty; let $m$ be the smallest element of this set, and set $n = m - 1$. Then $n \leq x < n + 1$. If $x < 0$, there is an $r \in \mathbb{N}$ such that $r \leq -x < r + 1$, so $-(r + 1) < x \leq -r$. If $x = -r$, set $n = -r$; otherwise set $n = -(r + 1)$.

The $n$ is unique since if $n \leq x < n + 1$ and $m \leq x < m + 1$, we have $-(m + 1) < x \leq -m$, so $n - (m + 1) < 0 < (n + 1) - m$, $-1 < m - n < 1$, $m - n = 0$.

We then get the density of $\mathbb{Q}$ in $\mathbb{R}$:

**III.1.10.5.** Theorem. Let $a, b \in \mathbb{R}$, $a < b$. Then there is an $r \in \mathbb{Q}$ with $a < r < b$.

In fact, by applying the theorem repeatedly to the intervals $(a, b)$, $(a, r)$, $(r, b)$, etc., it is readily shown that there are infinitely many rational numbers in the interval $(a, b)$.

**Proof:** By III.1.10.3, there is an $n \in \mathbb{N}$ with $\frac{1}{n} < b - a$. For this $n$, there is an $m \in \mathbb{Z}$ with $m - 1 \leq na < m$. We have $a < \frac{m}{n}$. Also, $m - na \leq 1$, $m \leq na + 1$, so

\[
\frac{m}{n} \leq a + \frac{1}{n} < a + (b - a) = b .
\]

**III.1.10.6.** Corollary. Let $a \in \mathbb{R}$, and set $A = \{r \in \mathbb{Q} : r < a\}$. Then $\sup(A) = a$.

**Proof:** $A$ is nonempty ($-n \in A$ for some $n \in \mathbb{N}$), and $a$ is an upper bound for $A$, so $s = \sup(A)$ exists and satisfies $s \leq a$. If $s < a$, then there is an $r \in \mathbb{Q}$ with $s < r < a$. But then $r \in A$, contradicting that $s$ is an upper bound for $A$. Thus $s = a$.

**III.1.11. Uniqueness of $\mathbb{R}$**

We can now prove that the real numbers are uniquely determined by the axioms, i.e. that any two structures satisfying the axioms for $\mathbb{R}$ are the same up to a renaming of the elements. Specifically:

**III.1.11.1.** Theorem. Let $\mathbb{R}$ and $\mathbb{R}'$ be sets with addition, multiplication, and order satisfying the algebraic, order, and completeness axioms. Then there is a unique function $\phi : \mathbb{R} \to \mathbb{R}'$ which is one-to-one and onto, such that for all $x, y \in \mathbb{R}$,

\[
\phi(x + y) = \phi(x) + \phi(y) \\
\phi(xy) = \phi(x)\phi(y) \\
\phi(x) < \phi(y) \text{ if and only if } x < y
\]
Similarly, define \( \phi \) and \( \phi' \) of adding 1, rational numbers. Let \( \phi, \phi' \) of III.1.11.2. and hence \( \phi(0) = 0' \) by additive cancellation in \( \mathbb{R}' \). Similarly,
\[
\phi(1) \cdot \phi(1) = \phi(1 \cdot 1) = \phi(1) = 1' \cdot \phi(1)
\]
and, since \( \phi(1) \neq \phi(0) = 0' \) because \( \phi \) is one-to-one, we have \( \phi(1) = 1' \) by multiplicative cancellation.

III.1.11.2. Now note that \( \mathbb{R} \) and \( \mathbb{R}' \) (in fact, any ordered field) each contain a “copy” (model) of the rational numbers. Let \( \mathbb{N} \) be the smallest subset of \( \mathbb{R} \) containing its multiplicative identity 1 and closed under adding 1, \( \mathbb{Z} \) the smallest subset of \( \mathbb{R} \) containing \( \mathbb{N} \) and closed under subtraction, and \( \mathbb{Q} \) the smallest subset of \( \mathbb{R} \) containing \( \mathbb{Z} \) and closed under division by nonzero elements; similarly, let \( \mathbb{N}' \) be the smallest subset of \( \mathbb{R}' \) containing its multiplicative identity 1' and closed under adding 1', and \( \mathbb{Z}' \) and \( \mathbb{Q}' \) the corresponding subsets of \( \mathbb{R}' \) closed under subtraction and division.

III.1.11.3. We will define \( \phi : \mathbb{R} \rightarrow \mathbb{R}' \) and its inverse \( \psi : \mathbb{R}' \rightarrow \mathbb{R} \) in stages. We begin by defining \( \phi \) and \( \psi \) inductively (recursively) on \( \mathbb{N} \) and \( \mathbb{N}' \). Define \( \phi(1) = 1' \), and if \( \phi(n) \) has been defined, define \( \phi(n + 1) = \phi(n) + 1' \). (We should write \( +', ' \), \( <' \) for the algebraic operations and order relation in \( \mathbb{R}' \), but we will not do so to avoid becoming overprimed.) This defines \( \phi \) on all of \( \mathbb{N} \), with range contained in \( \mathbb{N}' \). Similarly, define \( \psi : \mathbb{N}' \rightarrow \mathbb{N} \) inductively by \( \psi(1') = 1 \) and \( \psi(n' + 1') = \psi(n') + 1 \).

III.1.11.4. Lemma. We have \( \psi(\phi(n)) = n \) and \( \phi(\psi(n')) = n' \) for all \( n \in \mathbb{N}, n' \in \mathbb{N}' \). Thus \( \phi \) and \( \psi \) are mutually inverse bijections between \( \mathbb{N} \) and \( \mathbb{N}' \).

Proof: This is an easy proof by induction. We have \( \psi(\phi(1)) = \psi(1') = 1 \). If \( \psi(\phi(n)) = n \), then
\[
\psi(\phi(n + 1)) = \psi(\phi(n) + 1') = \psi(\phi(n)) + 1 = n + 1
\]
so \( \psi(\phi(n)) = n \) for all \( n \in \mathbb{N} \). The other formula is proved similarly by induction on \( \mathbb{N}' \).

III.1.11.5. Lemma. If \( n, m \in \mathbb{N} \), then \( \phi(n + m) = \phi(n) + \phi(m) \) and \( \phi(nm) = \phi(n)\phi(m) \).

Proof: For a fixed \( n \in \mathbb{N} \), we prove the formula by induction on \( m \). We have \( \phi(n + 1) = \phi(n) + 1' = \phi(n) + \phi(1) \), so the formula holds for \( m = 1 \). If \( \phi(n + m) = \phi(n) + \phi(m) \), then
\[
\phi(n + (m + 1)) = \phi((n + m) + 1) = \phi(n + m) + 1' = (\phi(n) + \phi(m)) + 1' = \phi(n) + (\phi(m) + 1') = \phi(n) + \phi(m + 1)
\]
so the formula holds for all \( m \). The formula for multiplication is proved similarly.
III.1.11.6. Lemma. If \( n, m \in \mathbb{N} \), then \( \phi(n) < \phi(m) \) if and only if \( n < m \).

Proof: We have \( n < m \) if and only if there is a \( p \in \mathbb{N} \) with \( m = n + p \). Then
\[
\phi(m) = \phi(n + p) = \phi(n) + \phi(p)
\]
so \( \phi(n) < \phi(m) \). The argument also works for \( \psi \), giving the converse. \( \blacksquare \)

III.1.11.7. We now extend \( \phi \) and \( \psi \) to \( \mathbb{Z} \) and \( \mathbb{Z}' \). If \( x \in \mathbb{Z} \), write \( x = n - m \) for \( n, m \in \mathbb{N} \), and define \( \phi(x) = \phi(n) - \phi(m) \). This is well defined since if \( n - m = q - p \), i.e. \( n + p = m + q \), we have
\[
\phi(n) + \phi(p) = \phi(n + p) = \phi(m + q) = \phi(m) + \phi(q)
\]
and thus \( \phi(q) - \phi(p) = \phi(n) - \phi(m) \). Alternatively, write \( \mathbb{Z} \) as the disjoint union of \( \mathbb{N} \), \( \{0\} \) and \( -\mathbb{N} \), and \( \mathbb{Z}' \) as the disjoint union of \( \mathbb{N}' \), \( \{0'\} \), and \( -\mathbb{N}' \), and define \( \phi(0) = 0' \) and \( \phi(-n) = -\phi(n) \) for \( n \in \mathbb{N} \). Define \( \psi : \mathbb{Z}' \rightarrow \mathbb{Z} \) in the same manner. It is obvious, especially from the second definition, that \( \psi \) is the inverse for \( \phi \), so \( \phi \) and \( \psi \) are bijections between \( \mathbb{Z} \) and \( \mathbb{Z}' \).

The next result is just a simple but somewhat tedious calculation checking case-by-case:

III.1.11.8. Lemma. If \( x, y \in \mathbb{Z} \), then \( \phi(x+y) = \phi(x) + \phi(y) \) and \( \phi(xy) = \phi(x)\phi(y) \). We have \( \phi(x) < \phi(y) \) if and only if \( x < y \).

III.1.11.9. Now we extend \( \phi \) and \( \psi \) to \( \mathbb{Q} \) and \( \mathbb{Q}' \). If \( x \in \mathbb{Q} \), write \( x = \frac{m}{n} \) for \( m, n \in \mathbb{Z} \), \( n \neq 0 \), and set \( \phi(x) = \frac{\phi(m)}{\phi(n)} \in \mathbb{Q}' \). This makes sense since \( \phi(n) \neq 0 \). Then \( \phi \) is well defined since, if \( \frac{m}{n} = \frac{p}{q} \), i.e. \( mq = np \), we have
\[
\phi(m)\phi(q) = \phi(mq) = \phi(np) = \phi(n)\phi(p)
\]
so \( \frac{\phi(m)}{\phi(n)} = \frac{\phi(p)}{\phi(q)} \). Similarly define \( \psi : \mathbb{Q}' \rightarrow \mathbb{Q} \). It is clear that \( \psi \) is the inverse of \( \phi \), so \( \phi \) and \( \psi \) are bijections.

III.1.11.10. Lemma. If \( x, y \in \mathbb{Q} \), then \( \phi(x+y) = \phi(x) + \phi(y) \) and \( \phi(xy) = \phi(x)\phi(y) \). We have \( \phi(x) < \phi(y) \) if and only if \( x < y \).

Proof: Write \( x = \frac{m}{n}, y = \frac{p}{q} \) with \( m, p \in \mathbb{Z} \) and \( n, q \in \mathbb{N} \). Then
\[
\phi(x+y) = \phi \left( \frac{m}{n} + \frac{p}{q} \right) = \phi \left( \frac{mq + np}{nq} \right) = \frac{\phi(m)\phi(q) + \phi(n)\phi(p)}{\phi(n)\phi(q)} = \frac{\phi(m)}{\phi(n)} + \frac{\phi(p)}{\phi(q)} = \phi(x) + \phi(y)
\]
\[
\phi(xy) = \phi \left( \frac{m}{n} \cdot \frac{p}{q} \right) = \phi \left( \frac{mp}{nq} \right) = \frac{\phi(mp)}{\phi(nq)} = \frac{\phi(m)\phi(p)}{\phi(n)\phi(q)} = \frac{\phi(m)}{\phi(n)} \cdot \frac{\phi(p)}{\phi(q)} = \phi(x)\phi(y).
\]
If \( x < y \), then \( mq < np \), so
\[
\phi(m)\phi(q) = \phi(mq) < \phi(np) = \phi(n)\phi(p)
\]
so we have \( \phi(x) = \frac{\phi(m)}{\phi(n)} < \frac{\phi(p)}{\phi(q)} = \phi(y) \), and the argument is reversible. \( \blacksquare \)
III.1.11.11. It is clear from the requirement that $\phi(0) = 0'$ and $\phi(1) = 1'$ that the definition of $\phi$ and its inverse $\psi$ between $N$ and $N'$ can only be made in the manner of III.1.11.3., i.e. there are unique functions $\phi$ and $\psi$ between $N$ and $N'$ with the specified properties. The extensions to $\mathbb{Z}$ and $\mathbb{Q}$ are then forced by the properties of $\phi$ needed, i.e. the uniqueness statement applies to functions from $\mathbb{Q}$ to $\mathbb{Q}'$ also.

III.1.11.12. So far, we have only used the algebraic and order axioms, so the arguments work for any ordered fields: if $F$ and $F'$ are ordered fields, then the smallest subfields of $F$ and $F'$ are naturally isomorphic (and isomorphic to $\mathbb{Q}$). Thus we may naturally regard $\mathbb{Q}$ as a subfield of any ordered field.

Now we use the Completeness Axiom and density of $\mathbb{Q}$ in $\mathbb{R}$, and density of $\mathbb{Q}'$ in $\mathbb{R}'$, to extend $\phi$ and $\psi$ to $\mathbb{R}$ and $\mathbb{R}'$.

III.1.11.13. Definition. Let $x \in \mathbb{R}$. Let $\phi(x) = \sup\{\phi(r) : r \in \mathbb{Q}, r < x\}$. If $x' \in \mathbb{R}'$, define $\psi(x') = \sup\{\psi(r') : r' \in \mathbb{Q}', r' < x'\}$.

It follows immediately from III.1.10.6. applied in both $\mathbb{R}$ and $\mathbb{R}'$ that if $x \in \mathbb{Q}$, $x' \in \mathbb{Q}'$, this definition of $\phi(x)$ and $\psi(x')$ agrees with the previous one, and that $\psi$ is the inverse of $\phi$ in general, so $\phi$ and $\psi$ are mutually inverse bijections between $\mathbb{R}$ and $\mathbb{R}'$.

III.1.11.14. Lemma. If $x, y \in \mathbb{R}$, then $x < y$ if and only if $\phi(x) < \phi(y)$.

Proof: Suppose $x < y$. Let $t \in \mathbb{Q}$, $x < t < y$. Then $\phi(t) \leq \phi(y)$ by definition of $\phi(y)$, and $\phi(t) \neq \phi(y)$ since $\phi$ is injective, so $\phi(t) < \phi(y)$. Also, $\phi(r) < \phi(t)$ for every $r < x$, so $\phi(t)$ is an upper bound for $\{\phi(r) : r \in \mathbb{Q}, r < x\}$ and therefore $\phi(x) \leq \phi(t)$ (even $\phi(x) < \phi(t)$ since $\phi$ is injective). So $\phi(x) < \phi(y)$ by transitivity. The same argument works for $\psi$, giving the converse.

III.1.11.15. Corollary. If $x \in \mathbb{R}$, then $\phi(x) = \inf\{\phi(r) : r \in \mathbb{Q}, x < r\}$.

Proof: Set $b' = \inf\{\phi(r) : r \in \mathbb{Q}, x < r\}$. Since $\phi(x)$ is a lower bound for this set, $\phi(x) \leq b'$. If $\phi(x) < b'$, let $r' \in \mathbb{Q}'$ with $\phi(x) < r' < b'$. Then $r' = \phi(r)$ for some $r \in \mathbb{Q}$, $x < r$, contradicting that $b'$ is a lower bound. Thus $b' = \phi(x)$.

III.1.11.16. Corollary. If $x \in \mathbb{R}$, then $\phi(-x) = -\phi(x)$.

It remains to show that $\phi$ preserves addition and multiplication.
III.1.11.17.  **Lemma.** Let \( x, y \in \mathbb{R} \). Then \( \phi(x + y) = \phi(x) + \phi(y) \) and \( \phi(xy) = \phi(x)\phi(y) \).

**Proof:** Suppose \( a \in \mathbb{Q} \). Then, if \( r \in \mathbb{Q} \), we have \( a + r < a + y \) if and only if \( r < y \), so

\[
\phi(a + y) = \sup\{\phi(a + r) : r \in \mathbb{Q}, r < y\} = \sup\{\phi(a) + \phi(r) : r \in \mathbb{Q}, r < y\}.
\]

By III.1.9.6., the last supremum equals

\[
\phi(a) + \sup\{\phi(r) : r \in \mathbb{Q}, r < y\} = \phi(a) + \phi(y).
\]

Then we have

\[
\phi(a) + \phi(y) = \phi(a + y) < \phi(x + y)
\]

for every \( a \in \mathbb{Q} \), \( a < x \), and

\[
\phi(x + y) < \phi(b + y) = \phi(b) + \phi(y)
\]

for every \( b \in \mathbb{Q} \), \( x < b \). But by III.1.11.15. and III.1.9.6., we have

\[
\phi(x) + \phi(y) = \sup\{\phi(a) + \phi(y) : a \in \mathbb{Q}, a < x\} = \inf\{\phi(b) + \phi(y) : b \in \mathbb{Q}, x < b\}
\]

and so \( \phi(x + y) = \phi(x) + \phi(y) \).

The proof that \( \phi(xy) = \phi(x)\phi(y) \) is very similar if \( x \) and \( y \) are positive. The proof for general \( x, y \) then follows from this and III.1.11.16.

III.1.11.18. By the density of \( \mathbb{Q} \) in \( \mathbb{R} \) and of \( \mathbb{Q}' \) in \( \mathbb{R}' \), the values of \( \phi \) and \( \psi \) are completely determined by their values on \( \mathbb{Q} \) and \( \mathbb{Q}' \) respectively. Since the functions between \( \mathbb{Q} \) and \( \mathbb{Q}' \) are unique (III.1.11.1.), we obtain the uniqueness of the function \( \phi \) (and \( \psi \)) with the specified properties.

This completes the proof of Theorem III.1.11.1.

III.1.12.  **Existence of Roots**

Although we will later get more general results, we show here using the Completeness Axiom that every positive real number has arbitrary roots. We first need an estimate:

III.1.12.1.  **Proposition.** Let \( a, b \in \mathbb{R} \). Set \( c = \max(|a|, |b|) \). If \( n \in \mathbb{N} \), then

\[
|b^n - a^n| \leq nc^{n-1}|b - a|.
\]

**Proof:** This is easily proved using the Mean Value Theorem, but there is an elementary proof: it follows immediately from the identity (for \( n > 1 \))

\[
b^n - a^n = (b - a) \sum_{k=0}^{n-1} a^k b^{n-k-1}
\]
which is easily verified by an algebraic calculation. Then we have, by the triangle inequality,

$$|b^n - a^n| = |b - a|\left|\sum_{k=0}^{n-1} a^k b^{n-k-1}\right| \leq |b - a| \sum_{k=0}^{n-1} |a|^k |b|^{n-k-1} \leq |b - a| \cdot nc^{n-1}.$$  

\* III.1.12.2.  **Theorem.** Let $a \in \mathbb{R}$, $a \geq 0$, and $n \in \mathbb{N}$. Then there is a unique $x \in \mathbb{R}$, $x \geq 0$, with $x^n = a$.

**Proof:** If there is a solution, it is unique since by the identity in the proof of III.1.12.1., if $0 < x < y$, then $x^n < y^n$. If $a = 0$, the unique solution is $x = 0$. For existence, it suffices to consider the case $0 < a < 1$ since if $a > 1$, so $\frac{1}{a} < 1$, and $x^n = \frac{1}{a}$, then $\left(\frac{1}{x}\right)^n = a$, and the case $a = 1$ is obvious.

Set 

$$A = \{ r \in \mathbb{R} : r > 0, r^n < a \}.$$  

$A$ is nonempty since there is an $k \in \mathbb{N}$ with $\frac{1}{k} < a$, and for this $k$ we have $\frac{1}{k^n} \leq \frac{1}{k} < a$. Also, $A$ is bounded: 1 is an upper bound for $A$. Thus $x = \sup(A)$ exists, and $x \leq 1$.

We claim $x^n = a$. First suppose $x^n > a$, and choose $k \in \mathbb{N}$ with $\frac{1}{k} < x$ and $\frac{1}{k} < \frac{a^n - a}{x^n}$. Then, by III.1.12.1.,

$$x^n - \left(x - \frac{1}{k}\right)^n \leq nx^{n-1} \frac{1}{k} \leq n \frac{1}{k} < x^n - a$$

and so $(x - \frac{1}{k})^n > a$ and $x - \frac{1}{k}$ is an upper bound for $A$, contradicting that $x$ is the least upper bound of $A$. Thus $x^n \leq a$.

So $x < 1$ since $a < 1$. If $x^n < a$, choose $k \in \mathbb{N}$ so that $x + \frac{1}{k} < 1$ and $\frac{1}{k} < \frac{a - x^n}{a}$. Then, by III.1.12.1.,

$$\left(x + \frac{1}{k}\right)^n - x^n \leq n \left(x + \frac{1}{k}\right)^{n-1} \frac{1}{k} < n \frac{1}{k} < a - x^n$$

so $(x + \frac{1}{k})^n < a$, contradicting that $x$ is an upper bound for $A$. Thus $x^n = a$.

If $n$ is odd, then negative real numbers have $n$’th roots too:

III.1.12.3. **Corollary.** Let $n \in \mathbb{N}$ be odd, and $a \in \mathbb{R}$. Then there is a unique $x \in \mathbb{R}$ with $x^n = a$.

**Proof:** If $a \geq 0$, existence comes from III.1.12.2. If $a < 0$, then by III.1.12.2. there is an $x \in \mathbb{R}$ with $x^n = -a$. Then, since $n$ is odd, $(-x)^n = -x^n = a$. Uniqueness follows as in the beginning of the proof of III.1.12.2.

III.1.12.4. If $n$ is even and $a < 0$, there is no solution to $x^n = a$ in $\mathbb{R}$, since if $n = 2m$, then $x^n = (x^m)^2 \geq 0$ for any $x \in \mathbb{R}$ (. If $a > 0$, there are two solutions, one positive and one negative. As usual, we will denote the positive solution as $\sqrt[n]{a}$. If $n$ is odd, then for any $a$ we denote the unique solution by $\sqrt[n]{a}$. When $n = 2$ (square root), we just write $\sqrt{a}$ for the nonnegative root when $a \geq 0$. 

244
III.1.12.5. So every positive real number has a square root. In particular, there is a real number $\sqrt{2}$ whose square is 2. Since there is no rational number whose square is 2 (I.5.5.), $\sqrt{2}$ is a real number which is not rational (an irrational number). It turns out that “most” real numbers are irrational ()

The classical proof that $\sqrt{2}$ is irrational is given in I.5.5.. Here is a more general result; the special case $d = 2$ gives another pretty proof for $\sqrt{2}$ which is even simpler than the classic one.

III.1.12.6. Theorem. If $d \in \mathbb{N}$, then $\sqrt{d}$ is either a natural number or irrational.

Proof: Suppose $\sqrt{d}$ is not a natural number. Since $\sqrt{d} > 1$ (because $(\sqrt{d})^2 > 1^2$; cf. III.1.2.3.(vii)), there is a $q \in \mathbb{N}$ with $q < \sqrt{d} < q + 1$, i.e. $0 < \sqrt{d} - q < 1$ (III.1.10.4.). (If $d = 2$, then $q = 1$.)

Now suppose $\sqrt{d}$ is rational. Then there is a natural number $n$ such that $n\sqrt{d}$ is an integer, i.e.

$$A = \{ n \in \mathbb{N} : n\sqrt{d} \in \mathbb{Z} \}$$

is nonempty. By III.1.4.12., $A$ has a smallest element $n$. But then

$$m := (\sqrt{d} - q)n = n\sqrt{d} - nq \in \mathbb{Z}$$

and $m > 0$ since $\sqrt{d} - q > 0$; hence $m \in \mathbb{N}$. Also,

$$m\sqrt{d} = (d - q\sqrt{d})n = dn - q(n\sqrt{d}) \in \mathbb{Z}$$

so $m \in A$. But $m < n$ since $\sqrt{d} - q < 1$, contradicting that $n$ is the smallest element of $A$. 

This proof is due to Dedekind. See III.1.13.6. for another version of the proof, and III.9.5.4. for a generalization.

III.1.12.7. One can significantly extend III.1.12.3. using the notions of limits and continuity, and the Intermediate Value Theorem. For example, it can be easily shown (V.2.3.6.) that every polynomial of odd degree with real coefficients has a root in $\mathbb{R}$ (III.1.12.3. is the special case of the polynomial $x^n - a$).

III.1.12.8. An ordered field in which every positive element has a square root and every polynomial of odd degree has a root is called a real-closed field. There are many other equivalent characterizations of real-closed fields. The theory of real-closed fields turns out to be exactly the first-order theory of $\mathbb{R}$, i.e. any statement true in $\mathbb{R}$ which has a first-order formulation (not allowing quantification over subsets) is true in every real-closed field. There are many real-closed fields other than $\mathbb{R}$, including countable examples (actually, the field of real algebraic numbers is a countable example). Other examples include any model for the hyperreal numbers of nonstandard analysis (), and the Levi-Civita numbers. See () for a description of the theory of real-closed fields.

III.1.13. Exercises

III.1.13.1. Prove by induction on $n$ that if $\{x_k, y_k : 1 \leq k \leq n \}$ is a set of real numbers, then

$$\sum_{k=1}^{n}(x_k + y_k) = \sum_{k=1}^{n}x_k + \sum_{k=1}^{n}y_k .$$
III.1.13.2.  (a) Let \( x \in \mathbb{R} \). Show how to define \( x^n \) for each \( n \in \mathbb{N} \) by recursion.
(b) Prove by induction that if \( x, y \in \mathbb{R} \) and \( m, n \in \mathbb{N} \), then \((xy)^n = x^ny^n\), \( x^mx^n = x^{m+n} \), \((x^m)^n = x^{mn}\), and, if \( y \neq 0 \), \((y^n)^{-1} = (y^{-1})^n\), \((\frac{x}{y})^n = x^n y^{-n}\) and \(\frac{y^m}{y^n} = y^{m-n}\). Extend these rules of exponents to arbitrary integer powers, with appropriate hypotheses.

III.1.13.3.  Show how to carefully define \( n! = 1 \cdot 2 \cdot 3 \cdots n \) for all \( n \in \mathbb{N} \) by recursion.

III.1.13.4.  Define the Fibonacci sequence \( (x_n) \) by \( x_1 = 1 \), \( x_2 = 1 \), \( x_n = x_{n-1} + x_{n-2} \) for \( n > 2 \).
(a) Show that this definition can be phrased as a proper recursive definition under III.1.5.15.
(b) Prove by induction that any two consecutive terms in the sequence are relatively prime.
(c) Rephrase the argument of (b) as an Infinite Regress argument. Which way is simpler?

III.1.13.5.  Carefully prove the assertions in III.1.7.2. and III.1.7.4.

(a) Suppose \( \sqrt{d} \) is not an integer, but is rational. Write \( \sqrt{d} = \frac{a}{b} \) in lowest terms (e.g. with \( b \) minimal in \( \mathbb{N} \)), with \( a, b \in \mathbb{N} \). Then also \( \sqrt{d} = \frac{d}{\sqrt{d}} = \frac{db}{a} \).
(b) Since \( \frac{db}{a} = \frac{a}{b} \), the fractional parts (which are nonzero since \( \sqrt{d} \notin \mathbb{N} \)) are equal. Thus there are \( p, q \in \mathbb{N} \) with \( p < a \) and \( q < b \) and \( \frac{p}{a} = \frac{q}{b} \).
(c) From \( \frac{p}{a} = \frac{q}{b} \) we get \( \frac{p}{q} = \frac{a}{b} = \sqrt{d} \), contradicting that \( \frac{a}{b} \) is in lowest terms.
(d) If \( r \) is a positive rational number and \( r = \frac{a}{b} \) with \( b \) minimal in \( \mathbb{N} \), then the fraction \( \frac{a^n}{b^n} \) is also the representation of \( a^{n-1}r \) with minimal denominator in \( \mathbb{N} \) (cf. III.1.7.4.).
(e) Using (d), prove that if \( d, n \in \mathbb{N} \), then \( \sqrt{d} \) is either an integer or irrational (cf. III.9.5.4.). [Use that \( \sqrt{d} = \frac{d}{(\sqrt{d})^{n-1}r} \).]
III.2. The Natural Numbers

We now begin the construction of the number systems from scratch, beginning with the natural numbers.

III.2.1. Introduction

III.2.1.1. The first set of numbers developed, going back to prehistoric times, is the natural numbers or counting numbers, also described as the positive integers. This set is usually called \( \mathbb{N} \). Thus, as it is often described or defined,

\[ \mathbb{N} = \{1, 2, 3, \ldots \} \]

Unfortunately, this “description” is totally inadequate as a definition of \( \mathbb{N} \), even an informal one, for two reasons. Most importantly, it is entirely unclear what the “…” means (if you think you know, try giving a precise formulation of the meaning!) And even if this point is specified, this description says nothing about the operations of arithmetic which are an essential part of the structure.

III.2.1.2. One mathematically minor point needs to be addressed. There is no general agreement among mathematicians about whether \( \mathbb{N} \) includes 0; some mathematicians include it, and others do not. We will not. Set theorists generally include it, since from the point of view of the set-theoretic construction of \( \mathbb{N} \) it is natural to do so. However, in my opinion 0 should not be called a “natural number.” The positive integers historically far predate the emergence of the concept of 0, and there are important societies, and even some modern-day societies, that never developed 0; the notion of 0 is far more abstract and subtle than that of numbers such as 1 and 2. (On the other hand, I acknowledge that it is also historically questionable whether “large” positive integers should be regarded as “natural numbers,” since there is a practical limit to the size of numbers which occur “naturally,” and in addition the development of notation which allows one to even contemplate numbers such as \( 10^{10^{10}} \) is relatively recent compared even to the concept of 0.) However, it is useful to have a notation for the set \( \mathbb{N} \cup \{0\} \) of nonnegative integers; we will use the notation \( \mathbb{N}_0 \) for this set. The question of whether to work with \( \mathbb{N} \) or \( \mathbb{N}_0 \) as the basic set is strictly a matter of taste, since it is mathematically trivial to go from either to the other.

III.2.2. Axiomatic Characterization of \( \mathbb{N} \)

III.2.2.1. Rather than trying to define what \( \mathbb{N} \) is, it is more useful to list a set of basic properties that \( \mathbb{N} \) has, from which all the usual structure can be derived, and then to show there is an essentially unique mathematical structure having these properties. The basic axiom scheme was first developed by G. Peano in 1889, although the actual construction of \( \mathbb{N} \) along these lines which motivated the axiomatization had already been done by R. Dedekind.

**Peano Axioms for \( \mathbb{N} \):**

(P1) There is a natural number 1.

(P2) Every natural number \( n \) has a successor \( S(n) \).

(P3) 1 is not the successor of any natural number.

(P4) If \( m, n \in \mathbb{N} \) and \( S(m) = S(n) \), then \( m = n \).

(P5) (Axiom of Induction) If \( A \subseteq \mathbb{N} \), 1 \( \in \) \( A \), and \( n \in A \) implies \( S(n) \in A \), then \( A = \mathbb{N} \).
The Axiom of Induction can be equivalently rephrased: “The smallest subset of \( \mathbb{N} \) containing 1 and closed under taking successors is all of \( \mathbb{N} \).” To make precise the notion of “smallest,” note that if \( \{ A_i \} \) is a collection of subsets of \( \mathbb{N} \) each containing 1 and closed under taking successors, then \( \bigcap_i A_i \) also contains 1 and is closed under taking successors. Thus the intersection of all subsets which contain 1 and are closed under taking successors is clearly the smallest such set.

**III.2.2.2.** This theory is technically a second-order theory since in the Axiom of Induction, there is quantification over subsets of \( \mathbb{N} \). There is a corresponding first-order theory, but it is not as strong and has infinitely many axioms replacing the Axiom of Induction. See books on mathematical logic and model theory, such as (), for an explanation of first-order Peano arithmetic and the difference between first-order and second-order theories.

Here are some simple observations. The first is a “converse” to axiom (P3):

**III.2.2.3.** Proposition. If \( n \in \mathbb{N} \), \( n \neq 1 \), then there is an \( m \in \mathbb{N} \) with \( n = S(m) \).

Proof: Let \( A \) be the set of all \( n \in \mathbb{N} \) such that either \( n = 1 \) or there is an \( m \in \mathbb{N} \) with \( n = S(m) \). We trivially have \( 1 \in A \). If \( n \in A \) (actually, if just \( n \in \mathbb{N} \)), then obviously \( S(n) \in A \). By axiom (P5), \( A = \mathbb{N} \). \( \square \)

**III.2.2.4.** Proposition. \( \mathbb{N} \) is infinite (in the sense of Dedekind (II.5.2.1.).)

Proof: The function \( S : \mathbb{N} \to \mathbb{N} \) is injective by axiom (P4), but not surjective by axiom (P3). \( \square \)

Sets and Models

“The definitions of number are very numerous and of great variety . . . We must not be surprised that there are so many. If any one of them was satisfactory we should not get any new ones.”

*H. Poincaré*

There are some logical subtleties in regarding \( \mathbb{N} \) as a “set”, which we now discuss briefly.

**III.2.2.5.** Definition. A *model* for Peano arithmetic is a triple \( (\mathbb{N}, e, s) \), where \( \mathbb{N} \) is a set, \( e \in \mathbb{N} \), and \( s \) is a function from \( \mathbb{N} \) to \( \mathbb{N} \) satisfying

(P3) \( s(x) \neq e \) for every \( x \in \mathbb{N} \).

(P4) If \( x, y \in \mathbb{N} \) and \( s(x) = s(y) \), then \( x = y \) (i.e. \( s \) is injective).

(P5) If \( A \subseteq \mathbb{N} \), \( e \in A \), and \( x \in A \) implies \( s(x) \in A \), then \( A = \mathbb{N} \).

(Of course, Peano axioms (P1) and (P2), suitably renamed, also hold tautologically in \( (\mathbb{N}, e, s) \).)
There is a “standard” model for Peano arithmetic in ZF set theory or the equivalent, the set $\omega$ of finite ordinals. Ordinals are discussed more carefully in ( ), but here we briefly outline the construction of $\omega$, which is originally due to J. von Neumann. Begin with $\emptyset$, which plays the role of 1 (or, more commonly, 0 in $\mathbb{N}_0$; set theorists often call this set 0). Define the successor of $\alpha$ to be $S(\alpha) = \alpha \cup \{\alpha\}$. Thus the successor of $\emptyset$ is $S(\emptyset) = \{\emptyset\} = \{0\}$ (note that $\{\emptyset\} \neq \emptyset$) Set theorists usually call this set 1. Then $S(1) = S(S(\emptyset)) = \{\emptyset, \{\emptyset\}\} = \{0, 1\}$ (called 2 in set theory). Continuing,

$$S(2) = S(S(S(\emptyset))) = \{\emptyset, \{\emptyset\}, \{\emptyset, \{\emptyset\}\}\} = \{0, 1, 2\}$$

(called 3 in set theory), etc. The Axiom of Infinity then gives the set $\omega$.

There is a logical subtlety in this model: it is open to question whether second-order Peano arithmetic can be constructed in ZF set theory, but it can. (There is a further logical subtlety in that it apparently cannot be proved that ZF set theory is consistent; cf. ( ).) We do not discuss these questions further, but simply refer the reader to books on mathematical logic such as ( ), and we agree not to be bothered by them from now on and accept $\omega$ as a valid model for $\mathbb{N}$.

Set theorists generally define $\mathbb{N}$ (or $\mathbb{N}_0$) to be $\omega$. However, this leads to logical difficulties: technically, the natural number 1, the integer 1, the rational number 1, the real number 1, and the complex number 1 are all different objects (sets) as defined in set theory, and they must somehow, and somewhat awkwardly, be identified together (cf. III.2.2.9).

“If numbers are sets, then they must be particular sets, for each set is some particular set. But if the number 3 is really one set rather than another, it must be possible to give some cogent reason for thinking so; for the position that this is an unknowable truth is hardly tenable.”

Paul Benacerraf

It is hard to conceive that the principles of logic entail that we must inevitably conclude that the number 3 (whether regarded as natural, integer, rational, real, or complex) must be the set $\{\emptyset, \{\emptyset\}, \{\emptyset, \{\emptyset\}\}\}$, or any other specific set.

Another approach to defining natural numbers is frequently considered, reflecting their use as counting numbers (cardinal numbers): the number $n$ is defined to be the class of all sets with exactly $n$ elements (this can be carefully phrased in a non-circular manner, e.g. by fixing a model for $\mathbb{N}$ such as $\omega$ and taking $n$ to be the class of all sets equipotent with the corresponding element of the model). Thus, for example, the number 1 is defined to be the class of all singleton sets. This approach has logical difficulties, since these objects cannot themselves be sets (e.g. there is an obvious one-one correspondence between the class of all singleton sets and the class of all sets), and anyway does not avoid the problem that there is no obvious way to extend the definition coherently to negative integers or rational numbers, let alone irrational numbers (attempts to do this logically, such as in [?], become unmanageably complicated and convoluted).

It is simpler, although perhaps less satisfying logically, not to precisely define $\mathbb{N}$ as a set. This approach will carry through also when the number system is extended, i.e. we will not define individual numbers to be any particular sets. This will not cause any difficulties in the actual use of the number systems in analysis. Anyone who is uncomfortable with this approach can be comforted by the knowledge that the number system can, in a somewhat arbitrary and awkward way, be precisely constructed within set theory.

“Questions about the true ‘nature’ of mathematical objects – such as whether \( \sqrt{2} \) is a set – are always irrelevant to mathematical practice. In mathematics one is exclusively concerned with abstract relationships rather than with the ‘internal constitution’ of objects.”

\[ \text{Martin Davis}^4 \]

### III.2.2.9. Technically, what we can do is assume that within set theory we have a sufficient supply of atoms (\( \varepsilon \)), and whenever each new collection of numbers is defined as a set, a collection of additional atoms is designated to name those numbers not already named. The operations of set theory and arithmetic can then be transferred to this set of atoms. Thus we will regard \( \mathbb{N} \) (and, later, \( \mathbb{Z}, \mathbb{Q}, \mathbb{R}, \) and \( \mathbb{C} \)) as sets, with \( \mathbb{N} \subseteq \mathbb{Z} \subseteq \mathbb{Q} \subseteq \mathbb{R} \subseteq \mathbb{C} \), but we will not regard individual numbers as sets.

The (second-order) Peano axioms uniquely determine the structure of \( \mathbb{N} \), up to a simple renaming of its elements, in the following sense:

### III.2.2.10. Theorem. Let \((N,e,s)\) and \((N',e',s')\) be models of the Peano axioms. Then there is a unique bijection \( \phi : N' \to N \) with \( \phi(e') = e \) and \( \phi(s'(x)) = s(\phi(x)) \) for all \( x \in N' \). (Such a \( \phi \) is called an isomorphism of \((N',e',s')\) and \((N,e,s)\).

\[ \text{Proof:} \] It suffices to assume that \((N',e',s') = (\omega,0,S)\), where \( S \) is the ordinal successor function \( S(\alpha) = \alpha \cup \{ \alpha \} \). If \( \phi : \omega \to N \) and \( \psi : \omega \to N' \) are successor-preserving bijections, then so is \( \phi \circ \psi^{-1} : N' \to N \).

Inductively define a function \( \phi \) from \( \omega \) to \( N \) by \( \phi(0) = e \) and \( \phi(S(\alpha)) = s(\phi(\alpha)) \). This function \( \phi \) preserves successors by construction. If \( R \subseteq N \) is the range of \( \phi \), then \( e \in R \), and if \( x = \phi(\alpha) \in R \), then so is \( s(x) = \phi(S(\alpha)) \). Thus \( R = N \) by axiom (P5), and \( \phi \) is surjective.

To show that \( \phi \) is injective, let \( A \) be the set of all \( x \in N \) such that \( x \) has a unique preimage. If \( \phi(\alpha) = e \), then \( \alpha = 0 \) since otherwise \( \alpha = S(\beta) \) for some \( \beta \) (III.2.2.3.), and \( e = \phi(\alpha) = \phi(S(\beta)) = s(\phi(\beta)) \), contradicting axiom (P3). Thus \( e \in A \). Now suppose \( x \in A \), and suppose \( \alpha, \beta \in \omega \) with \( \phi(\alpha) = \phi(\beta) = s(x) \). Then \( \alpha = S(\sigma) \) and \( \beta = S(\tau) \) for some \( \sigma, \tau \in \omega \). We have

\[
\phi(\sigma) = \phi(S(\sigma)) = \phi(S(\alpha)) = s(s(x)) = s(\phi(\tau))
\]

and so \( \phi(\sigma) = s(\phi(\tau)) \) by axiom (P4). Thus \( \sigma = \tau \) since \( x \) has unique preimage, and hence \( \alpha = \beta \), i.e. \( s(x) \in A \). Thus \( A = N \) by axiom (P5) and \( \phi \) is injective.

There is no such theorem for first-order Peano arithmetic; in fact, by general facts about first-order logic (the Lowenheim-Skolem Theorem), there are models of first-order Peano arithmetic of arbitrary infinite cardinality.

### III.2.2.11. In particular, every model for Peano arithmetic is isomorphic to \( \omega \). Thus, by slight abuse of language, we can talk about the set of natural numbers even though we technically do not define \( \mathbb{N} \) precisely within set theory (i.e. to be any specific model).

Since we have not defined \( \mathbb{N} \) as a particular set, we must technically identify \( \mathbb{N} \) with a specific model to define functions in or out; such definitions are independent of the choice of model in an evident way, so we will freely use \( \mathbb{N} \) as a domain or range for functions as though it were an honest set (this is logically justifiable by the procedure of III.2.2.9.).
III.2.3. Induction and Recursion

We will not reiterate here the full content of (indeed we cannot yet). Note that with the careful construction of \( \mathbb{N} \), we can give a more direct and complete justification for the principles of induction and recursion. We do not yet have addition on \( \mathbb{N} \), so we cannot phrase things using “\( n + 1 \)” and we must instead use the successor function. We also do not yet have the ordering on \( \mathbb{N} \) so we cannot phrase Complete Induction or Infinite Regress.

III.2.3.1. [Principle of Induction] Suppose \( P(n) \) is a statement for each \( n \in \mathbb{N} \). Suppose the following two statements hold:

(i) \( P(1) \) is true.

(ii) For every \( n \in \mathbb{N} \), if \( P(n) \) is true, then \( P(S(n)) \) is true.

Then \( P(n) \) is true for all \( n \in \mathbb{N} \).

III.2.3.2. To see why the Principle of Induction holds, set

\[ A = \{ n \in \mathbb{N} : P(n) \text{ is true} \} . \]

We have that \( 1 \in A \) by (i), and if \( n \in A \) we have \( S(n) \in A \) by (ii). Thus \( A = \mathbb{N} \).

Definitions by Induction or Recursion

We will write sequences, which are really functions on \( \mathbb{N} \), using functional notation. The following theorem is not quite as general as III.1.5.15., but is the version we will use at present. The proof is similar to the proof of III.1.5.15., but somewhat more complicated since we have less machinery available.

III.2.3.3. Theorem. Let \( X \) be a set, and let \( g \) be a function from \( X \) to \( X \). If \( x_1 \) is any element of \( X \), then there is a unique function \( f : \mathbb{N} \rightarrow X \) with \( f(1) = x_1 \) and \( f(S(n)) = g(f(n)) \) for all \( n \in \mathbb{N} \).

Proof: Let \( B \) be the smallest subset of \( \mathbb{N} \times X \) containing \( (1, x_1) \), with the property that, whenever \( (n, x) \in B \), then \( (S(n), g(x)) \in B \). (\( B \) is the intersection of all subsets of \( \mathbb{N} \times X \) with these two properties; there is at least one such subset, \( \mathbb{N} \times X \) itself.)

We first show that for every \( n \in \mathbb{N} \), there is at least one \( x \in X \) with \( (n, x) \in B \). Set

\[ A = \{ n \in \mathbb{N} : \exists x \in X \text{ with } (n, x) \in B \} . \]

Then \( 1 \in A \) since \( (1, x_1) \in B \). If \( n \in A \), and \( (n, x) \in B \), then \( (S(n), g(x)) \in B \) so \( S(n) \in A \). Thus \( A = \mathbb{N} \).

Next we show that \( B \) is a function, i.e. if \( (n, x) \) and \( (n, y) \) are in \( B \), then \( x = y \). Let

\[ A' = \{ n \in \mathbb{N} : (n, x) \in B \text{, } (n, y) \in B \text{ imply } x = y \} . \]

First we show \( 1 \in A' \). Set

\[ B' = \{(1, x_1)\} \cup \{(n, x) \in B : n \neq 1\} \]

251
and note that $B' \subseteq B$, $(1, x_1) \in B'$, and $(n, x) \in B'$ implies $(S(n), g(x)) \in B'$; hence $B' = B$ and $1 \in A'$. Now suppose $n \in A'$, i.e. there is a unique $x_n \in X$ with $(n, x_n) \in B$. Set

$$B'' = \{(S(n), g(x_n)) \cup \{(m, x) \in B : m \neq S(n)\}$$

and note that $B'' \subseteq B$, $(1, x_1) \in B''$, and $(m, x) \in B''$ implies $(S(m), g(x)) \in B''$ [if $m \neq n$ we have $S(m) \neq S(n)$ so the result is obvious; if $m = n$ then $x = x_n$ so the result holds too]. Thus $B'' = B$ and $S(n) \in A'$. So $A' = \mathbb{N}$ and $B$ is a function, i.e. for each $n \in \mathbb{N}$ we can set $f(n) = x_n$, where $x_n$ is the unique element of $X$ such that $(n, x_n) \in B$.

We need to show that $f$ is unique. If $f'$ is another function from $\mathbb{N}$ to $X$ with $f'(1) = x_1$ and $f'(S(n)) = g(f'(n))$ for all $n \in \mathbb{N}$, set

$$A'' = \{n \in \mathbb{N} : f(n) = f'(n)\}.$$

We have $1 \in A''$ since $f(1) = f'(1) = x_1$. Suppose $n \in A''$. Then

$$f(S(n)) = g(f(n)) = g(f'(n)) = f'(S(n))$$

so $S(n) \in A''$, and thus $A'' = \mathbb{N}$, $f = f'$.

A version of this theorem is used in defining algebraic operations on $\mathbb{N}$:

**III.2.3.4. Corollary.** Let $g$ be a function from $\mathbb{N} \times \mathbb{N}$ to $\mathbb{N}$, and $h$ a function from $\mathbb{N}$ to $\mathbb{N}$. Then there is a unique function $f$ from $\mathbb{N} \times \mathbb{N}$ to $\mathbb{N}$ satisfying $f(m, 1) = h(m)$ and $f(m, S(n)) = g(m, f(m, n))$ for all $m, n \in \mathbb{N}$.

**Proof:** Fix $m \in \mathbb{N}$, and let $g_m$ be the function from $\mathbb{N}$ to $\mathbb{N}$ given by $g_m(n) = g(m, n)$. Define a function $f_m : \mathbb{N} \rightarrow \mathbb{N}$ recursively by $f_m(1) = h(m)$ and $f_m(S(n)) = g_m(f_m(n))$. Set $f(m, n) = f_m(n)$ for each $n$. This gives a well-defined function $f : \mathbb{N} \times \mathbb{N} \rightarrow \mathbb{N}$, and we have $f(m, 1) = f_m(1) = h(m)$ and

$$f(m, S(n)) = f_m(S(n)) = g_m(f_m(n)) = g(m, f(m, n))$$

for $m, n \in \mathbb{N}$. Uniqueness is also obvious from the uniqueness of the $f_m$.

**III.2.4. Algebraic Structure of $\mathbb{N}$**

There is no explicit mention of algebraic operations on $\mathbb{N}$ in the Peano axioms. But addition and multiplication can be defined inductively in terms of the successor function:

**III.2.4.1. Definition.** Let $(\mathbb{N}, 1, S)$ be the natural numbers (or, technically, a model for the natural numbers). Define a function $+ : \mathbb{N} \times \mathbb{N} \rightarrow \mathbb{N}$ inductively (recursively) as follows:

(a) $+(m, 1) = S(m)$.

(b) If $m \in \mathbb{N}$, then $+(m, S(n)) = S(+(m, n))$.

This is done from III.2.3.4. by setting $h(m) = S(m)$ and $g(m, n) = S(n)$ for all $m, n$.

Then define a function $\times : \mathbb{N} \rightarrow \mathbb{N}$ by

252
(c) If $m \in \mathbb{N}$, then $\times (m, 1) = m$.

(d) If $m \in \mathbb{N}$, then $\times (m, S(n)) = +(m, \times (m, n))$ for all $y \in \mathbb{N}$.

This is done from III.2.4. by setting $h(m) = m$ and $g(m, n) = +(m, n)$ for all $m, n$.

We normally write $m + n$ for $+(m, n)$, and $mn$ instead of $\times (m, n)$. We will suppress the notations $+(m, n)$ and $\times (m, n)$ from now on, and use $m + n$ and $mn$ instead. We also adopt the standard convention that multiplication is grouped before addition, i.e. that $mn + r$ means $(mn) + r$, etc.

III.2.4.2. Proposition. The functions $+$ and $\times$ are well defined on all of $\mathbb{N} \times \mathbb{N}$.

PROOF: This is an immediate consequence of III.2.3.4. \hfill \Box

We can then prove the associative and commutative laws for addition.

III.2.4.3. Theorem. The binary operation $+$ is associative and commutative on $\mathbb{N}$, i.e.

(i) [Associative Law] We have $(x + y) + z = x + (y + z)$ for all $x, y, z \in \mathbb{N}$.

(ii) [Commutative Law] We have $x + y = y + x$ for all $x, y \in \mathbb{N}$.

PROOF: (i): Fix $m, n \in \mathbb{N}$. Let $A_{m,n}$ be the set of all $r \in \mathbb{N}$ such that $(m + n) + r = m + (n + r)$. By (a) and (b),

$$(m + n) + 1 = S(m + n) = m + S(n) = m + (n + 1)$$

so $1 \in A_{m,n}$. Now suppose $r \in A_{m,n}$. We have, by (b),

$$(m + n) + S(r) = S((m + n) + r) = S(m + (n + r)) = m + S(n + r) = m + (n + S(r))$$

and thus $S(r) \in A_{m,n}$. So $A_{m,n} = \mathbb{N}$, i.e. $(m + n) + r = m + (n + r)$ for all $r$. Since $m$ and $n$ are arbitrary, (i) is proved.

(ii): Let $C$ be the set of $n \in \mathbb{N}$ such that $n + 1 = 1 + n$. Trivially $1 \in C$. If $n \in C$, then by (a) and (b)

$$1 + S(n) = S(1 + n) = S(n + 1) = S(n) + 1$$

so $S(n) \in C$. Thus $C = \mathbb{N}$. Now fix $m \in \mathbb{N}$, and let $D_m$ be the set of $n \in \mathbb{N}$ such that $m + n = n + m$. We have $1 \in D_m$ by the first part of the proof. Now suppose $n \in D_m$. Then

$$m + S(n) = S(m + n) = (m + n) + 1 = 1 + (m + n) = 1 + (n + m) = (1 + n) + m = (n + 1) + m = S(n) + m$$

by (i) and the first part of the proof, so $S(n) \in D_m$. Thus $D_m = \mathbb{N}$, i.e. $m + n = n + m$ for all $n$. Since $m$ is arbitrary, this is true for all $m, n \in \mathbb{N}$ \hfill \Box

We now show that multiplication is associative, commutative, and distributive over addition.
III.2.4.4. Theorem.

(i) [Associative Law] We have \((mn)r = m(nr)\) for all \(m, n, r \in \mathbb{N}\).

(ii) [Commutative Law] We have \(mn = nm\) for all \(m, n \in \mathbb{N}\).

(iii) [Distributive Law] We have \(m(n + r) = mn + mr\) (and \((m + n)r = mr + nr\)) for all \(m, n, r \in \mathbb{N}\).

Proof: The proof is similar in form to the previous ones. We first prove the first (left) distributive law (iii).

First note that if \(m, n \in \mathbb{N}\), we have, by (c), (d), and commutativity of addition,

\[ m(n + 1) = mS(n) = m + mn = mn + m = mn + m1. \]

Fix \(m, n \in \mathbb{N}\), and let \(A_{m,n}\) be the set of all \(r \in \mathbb{N}\) such that \(m(n + r) = mn + mr\). We have \(1 \in A_{m,n}\) by the first part of the proof. Now let \(r \in A_{m,n}\). Then

\[ m(n + S(r)) = mS(n + r) = m + m(n + r) = m + (mn + mr) \]

\[ = (mn + mr) + m = mn + (mr + m1) = mn + m(r + 1) = mn + mS(n) \]

by (c), (d), associativity and commutativity of addition, and the first part of the proof applied to \(m\) and \(r\).

Thus \(A_{m,n} = \mathbb{N}\) and the first distributive law is proved.

The right distributive law \((m + n)r = mr + nr\) for all \(m, n, r \in \mathbb{N}\) will follow from the left distributive law and commutativity of multiplication. But we will need a special case of the right distributive law to prove commutativity of multiplication: \((1 + n)r = 1r + nr\) for all \(n, r \in \mathbb{N}\). To prove this, fix \(n \in \mathbb{N}\) and let \(B_n\) be the set of all \(r \in \mathbb{N}\) such that the formula holds.

\[ (1 + n)1 = 1 + n = 11 + n1 \]

by (c), \(1 \in B_n\). If \(r \in B_n\), then

\[ (1 + n)S(r) = (1 + n) + (1 + n)r = (1 + n) + (1r + nr) = (1r + 1) + (n + nr) \]

\[ = (1r + 1) + (n + nr) = 1(r + 1) + nS(r) = 1S(r) + nS(r) \]

by (d), the associative and commutative laws of addition, and the left distributive law. Thus \(S(r) \in B_n\), \(B_n = \mathbb{N}\), and \((1 + n)r = 1r + nr\) for all \(n, r \in \mathbb{N}\).

(i): To show that \(\times\) is associative, fix \(m, n \in \mathbb{N}\) and let \(C_{m,n}\) be the set of all \(r \in \mathbb{N}\) such that \((mn)r = m(nr)\). Since \((mn)1 = mn = m(n1)\) by (c), \(1 \in B_{m,n}\). If \(r \in A_{m,n}\), then

\[ (mn)S(r) = mn + (mn)r = mn + m(nr) = m(n + nr) = m(nS(r)) \]

by (d) and the (left) distributive law. So \(S(r) \in C_{m,n}\). Thus \(C_{m,n} = \mathbb{N}\) and the associative law is proved.

(ii): For the commutative law, let \(D\) be the set of \(n\) for which \(1n = n\). We have \(1 \in D\) by (c). If \(n \in D\), then

\[ 1S(n) = 1 + 1n = 1 + n = n + 1 = S(n) \]

by (d), (a), and commutativity of addition. So \(S(n) \in D\) and \(D = \mathbb{N}\), i.e. \(1n = n\) for all \(n \in \mathbb{N}\).

Now fix \(m \in \mathbb{N}\), and let \(E_m\) be the set of all \(n \in \mathbb{N}\) such that \(mn = nm\). By (c) and the previous argument, \(1 \in E_m\). If \(n \in E_m\), then

\[ mS(n) = m + mn = m + nm = 1m + nm = (1 + n)m = (n + 1)m = S(n)m \]

254
by (d), the previous calculation, and the special case of the right distributive law. Thus $E_m = \mathbb{N}$ and the commutative law is proved.

Among the many algebraic properties of $\mathbb{N}$ which can be proved from the Peano axioms, here are two which are particularly important:

### III.2.4.5. Proposition. There do not exist $m, n \in \mathbb{N}$ with $m + n = m$.

**Proof:** Let $A$ be the set of all $m \in \mathbb{N}$ such that there is no $n \in \mathbb{N}$ with $m + n = n$. We have $1 \in A$, since $1 + n = 1 = S(n)$, contradicting axiom (P3). Let $m \in A$, and suppose there is $n \in \mathbb{N}$ with $S(m) + n = S(m)$. Then

\[ S(m + n) = S(n + m) = n + S(m) = S(m) + n = S(m) \]

by III.2.4.1.(b) and commutativity of addition. Thus $m + n = m$ by Axiom (P4), contradicting that $m \in A$. So $S(m) \in A$, $A = \mathbb{N}$.

### III.2.4.6. Proposition. [Cancellation] Let $m, n, r \in \mathbb{N}$. If $m + r = n + r$, then $m = n$.

**Proof:** The proof follows the usual scheme. Let $A$ be the set of all $r \in \mathbb{N}$ such that $m + r = n + r$ implies $m = n$ for all $m, n \in \mathbb{N}$. We have $1 \in A$ by axiom (P4). If $r \in A$, let $m, n \in \mathbb{N}$ with $m + S(r) = n + S(r)$. Then

\[ S(m + r) = m + S(r) = n + S(r) = S(n + r) \]

by III.2.4.1.(b). Thus $m + r = n + r$ by axiom (P4), hence $m = n$ since $r \in A$; so $S(r) \in A$ and $A = \mathbb{N}$.

There is also cancellation for multiplication, but it takes more work to prove (III.2.6.7.).

### III.2.5. Algebraic Axiomatization of $\mathbb{N}$

#### III.2.5.1. An alternate axiomatization of $\mathbb{N}$ can be given which is much closer to the way $\mathbb{N}$ is thought of and used. We have shown that $\mathbb{N}$ satisfies the following set of axioms:

- (N1) $\mathbb{N}$ contains an element 1.
- (N2) $\mathbb{N}$ has an associative binary operation +.
- (N3) There is no $n \in \mathbb{N}$ with $n + 1 = 1$.
- (N4) For any $m, n \in \mathbb{N}$, $m + 1 = n + 1$ implies $m = n$.
- (N5) If $A \subset \mathbb{N}$, $1 \in A$, and $A$ is closed under adding 1 (i.e. if $n \in A$ implies $n + 1 \in A$), then $A = \mathbb{N}$. 255
III.2.5.2. Theorem. Let \((N, e, +)\) be a model for axioms \((N1)\)–\((N5)\), i.e. \(e \in N\), + is a binary operation on \(N\), there is no \(x \in N\) with \(x + e = e\), \(x + e = y + e\) implies \(x = y\), and a subset \(A\) of \(N\) containing \(e\) and closed under adding \(e\) is all of \(N\). For \(x \in N\), define \(s(x) = x + e\). Then \((N, e, s)\) is a model for Peano arithmetic.

Proof: This is quite obvious, since axioms \((N3)\), \((N4)\), and \((N5)\) are simple rephrasings of axioms \((P3)\), \((P4)\), and \((P5)\) respectively.

If we start with a model \((N, e, S)\) for Peano arithmetic, define + on \(N\) as in III.2.4.1., and then define \(s\) as in III.2.5.2. from +, it is obvious that \(s\) coincides with \(S\). One can go the other way too:

III.2.5.3. Proposition. Let \((N, e, +)\) be a model for axioms \((N1)\)–\((N5)\). Define \(s\) as in III.2.5.2., and define +′ on \(N\) from \(s\) as in III.2.4.1.. Then +′ coincides with +.

Proof: We need only check that \(e + e = s(e)\), \(s(x) + e = s(x + e)\) for all \(x \in N\), and \(x + s(y) = s(x + y)\) for all \(x, y \in N\), since these formulas with + replaced by +′ characterize +′ by III.2.4.1.. We have \(e + e = s(e)\) by definition of \(s\). For any \(x \in N\), we have

\[
s(x) + e = (x + e) + e = s(x + e)
\]

also by definition of \(s\). Finally, if \(x, y \in N\), we have

\[
x + s(y) = x + (y + e) = (x + y) + e = s(x + y).
\]

Putting together III.2.5.3., III.2.5.2., and III.2.2.10., we obtain:

III.2.5.4. Corollary. If \((N, e, +)\) and \((N′, e′, +′)\) are models for \((N1)\)–\((N5)\), then there is a bijection \(\phi : N \to N′\) such that \(\phi(e) = e′\) and \(\phi(x + y) = \phi(x) +′ \phi(y)\) for all \(x, y \in N\).

Proof: Let \(\phi\) be as in III.2.2.10. for the successor operations \(s\) and \(s′\). Let \(A\) be the set of all \(y \in N\) such that \(\phi(x + y) = \phi(x) +′ \phi(y)\) for all \(x \in N\). We have that \(e \in A\) by III.2.2.10.. If \(y \in A\), then

\[
\phi(x + s(y)) = \phi(s(x + y)) = s′(\phi(x + y)) = s′(\phi(x) +′ \phi(y)) = \phi(x) +′ s′(\phi(y)) = \phi(x) +′ \phi(s(y))
\]

and so \(s(y) \in A\), \(A = N\).

III.2.5.5. Corollary. If \((N, e, +)\) is a model for axioms \((N1)\)–\((N5)\), then the binary operation + is commutative.
III.2.5.6. Remarks. (i) Note that multiplication does not explicitly enter into this algebraic characterization of \( \mathbb{N} \). This is because multiplication is completely determined by addition and property (d) of III.2.4.1. In fact, if \( * \) is an associative binary operation on \( \mathbb{N} \) which distributes over addition (i.e. \( x \ast (y + z) = (x \ast y) + (x \ast z) \) and \( (x + y) \ast z = (x \ast z) + (y \ast z) \)) and for which \( 1 \ast 1 = 1 \), then \( * \) must agree with multiplication since it must satisfy III.2.4.1.(a)–(c).

(ii) An examination of the proof of III.2.5.2. shows that associativity of \( + \) is not used. Thus, if we modify \( (\mathbb{N}^2) \) to \( (\mathbb{N}^2)' \) by deleting the word “associative,” and take \( (\mathbb{N}1)' \), \( (\mathbb{N}3)' \), \( (\mathbb{N}4)' \), \( (\mathbb{N}5)' \) to be identical to \( (\mathbb{N}1) \), \( (\mathbb{N}3) \), \( (\mathbb{N}4) \), \( (\mathbb{N}5) \) respectively, and if \( (\mathbb{N}, e, +) \) is a model for \( (\mathbb{N}1)'–(\mathbb{N}5)' \) with \( + \) nonassociative, we can still define \( s \) as in III.2.5.2. and obtain a model of Peano arithmetic. But the conclusion of III.2.5.3. will fail for this model, and hence the corollaries will also fail. There are such models with nonassociative \( + \): see Exercise (i).

III.2.5.7. All of the theorems of elementary number theory (e.g. unique factorization of natural numbers into products of prime numbers) can be proved directly from the Peano axioms. See books on number theory, e.g. (i).

III.2.6. Order Structure of \( \mathbb{N} \)

There is also a natural order structure on \( \mathbb{N} \). This order structure can either be transferred from the set containment order on \( \omega \) (i), or defined directly from the addition. We take the latter approach since it is more elementary.

III.2.6.1. Definition. Let \( m, n \in \mathbb{N} \). Set \( m < n \) if there is an \( r \in \mathbb{N} \) with \( m + r = n \).

III.2.6.2. Proposition. Let \( m, n, r \in \mathbb{N} \). If \( m < n \) and \( n < r \), then \( m < r \) (the relation \( < \) is transitive).

Proof: We have \( m + s = n \) and \( n + t = r \) for some \( s, t \in \mathbb{N} \). Then \( m + (s + t) = r \).

The next simple fact is essentially a rephrasing of III.2.2.3.:  

III.2.6.3. Proposition. For any \( n \in \mathbb{N}, n \neq 1 \), we have \( 1 < n \).

Proof: If \( n \in \mathbb{N}, n \neq 1 \), then by III.2.2.3. \( n = S(m) \) for some \( m \in \mathbb{N}, \) so \( 1 + m = n \) and \( 1 < n \).

The next result is the basic fact about <:
III.2.6.4.  **Theorem.** If \( m, n \in \mathbb{N} \), then exactly one of the following is true: \( m < n \), \( m = n \), \( n < m \).

**Proof:** If \( m = n \), we cannot have \( m < n \) by III.2.4.5. Similarly, if \( m < n \) and \( n < m \), we have \( m + r = n \) and \( n + s = m \) for some \( r, s \in \mathbb{N} \); then \( m + (r + s) = m \), contradicting III.2.4.5. Thus, for any \( m \) and \( n \), at most one of \( m < n \), \( m = n \), \( n < m \) is true.

To show that at least one is true, let \( A \) be the set of \( m \in \mathbb{N} \) such that, for every \( n \in \mathbb{N} \), either \( m < n \), \( m = n \), or \( n < m \) is true. We have \( 1 \in A \) by III.2.6.3.. If \( m \in A \), and \( n \in \mathbb{N} \), then either \( n < m \), \( n = m \), or \( m < n \). If \( n = m \), then \( S(m) = n + 1 \) so \( n < S(m) \). Similarly, if \( n < m \), i.e. \( n + r = m \) for some \( r \in \mathbb{N} \), then \( S(m) = n + (r + 1) \), so \( n < S(m) \). If \( m < n \), then \( n = m + r \) for some \( r \in \mathbb{N} \). If \( r = 1 \), then \( n = S(m) \); otherwise \( r = 1 + s \) for some \( s \in \mathbb{N} \), in which case \( n = (m + 1) + s = S(m) + s \), so \( S(m) < n \). Thus \( S(m) \in A \), \( A = \mathbb{N} \).

III.2.6.5.  Combining III.2.6.4. and III.2.6.2., we obtain that the relation \( < \) is a **strict total order** \( () \) on \( \mathbb{N} \). As is customary, we will write \( m \leq n \) if \( m < n \) or \( m = n \). We will also write \( n > m \) if \( m < n \) and \( n \geq m \) if \( m \leq n \).

Another important property of \( < \) is translation-invariance:

III.2.6.6.  **Theorem.** Let \( m, n \in \mathbb{N} \).
(i) If \( m < n \), then \( m + r < n + r \) for all \( r \in \mathbb{N} \). If \( m + r < n + r \) for some \( r \in \mathbb{N} \), then \( m < n \).
(ii) If \( m < n \), then \( mr < nr \) for all \( r \in \mathbb{N} \). If \( mr < nr \) for some \( r \in \mathbb{N} \), then \( m < n \).

**Proof:** (i): If \( m < n \), i.e. there is an \( s \in \mathbb{N} \) with \( m + s = n \), then for any \( r \in \mathbb{N} \) we have \( (m + r) + s = (m + s) + r = n + r \), i.e. \( m + r < n + r \) for some \( s \in \mathbb{N} \). Conversely, suppose \( m + r < n + r \) for some \( r \), i.e. \( (m + r) + s = n + r \) for some \( s \in \mathbb{N} \). Then \( m + s = n \) by cancellation (III.2.4.6.), i.e. \( m < n \).

(ii): If \( m < n \), write \( n = m + s \) for some \( s \in \mathbb{N} \). Then for any \( r \in \mathbb{N} \) we have \( mr + sr = (m + s)r = nr \), i.e. \( mr < nr \). For the converse, we cannot use multiplicative cancellation which is not yet proved, so we need a different argument (this argument could also have been used for addition). Suppose \( mr < nr \) for some \( r \). We have either \( m < n \), \( m = n \), or \( m > n \). If \( m = n \), we have \( mr = nr \), contradicting III.2.6.4., and if \( n < m \) we would have \( nr < mr \) by the first part of the proof, again contradicting III.2.6.4.. Thus we must have \( m < n \).

As a corollary, we get cancellation for multiplication:

III.2.6.7.  **Corollary.** Let \( m, n, r \in \mathbb{N} \). If \( mr = nr \), then \( m = n \).

**Proof:** We have either \( m < n \), \( m = n \), or \( n < m \). If \( m < n \), we would have \( mr < nr \) by III.2.6.6., contradicting III.2.6.4.. Similarly, we cannot have \( n < m \).
III.2.6.8. Because of cancellation, we can replace $<$ by $\leq$ throughout III.2.6.6.

We also obtain:

III.2.6.9. Corollary. If $m, n \in \mathbb{N}$ and $mn = 1$, then $m = n = 1$.

Proof: Suppose $n \neq 1$. Then $n > 1$, so $mn \geq m1 = m \geq 1$, a contradiction. So $n = 1$, and hence $m = 1$ too.

There is one more important basic fact about the ordering on $\mathbb{N}$. If $m, n \in \mathbb{N}$, we say $m$ is a predecessor of $n$ if $m < n$.

III.2.6.10. Theorem. Every $n \in \mathbb{N}$ has only finitely many predecessors in $\mathbb{N}$. (To avoid circularity, we interpret this statement to mean that the set of predecessors of any $n \in \mathbb{N}$ is a finite set in the sense of II.5.2.6.)

Proof: Let $A$ be the set of all $n \in \mathbb{N}$ such that the set of predecessors of $n$ is finite. By III.2.6.3., the set of predecessors of $1$ is $\emptyset$, which is finite (), so $1 \in A$. Let $n \in A$. If $m$ is a predecessor of $S(n)$, then either $m$ is a predecessor of $n$ or $m = n$ [if $n < m$, i.e. $n + r = m$ for some $r$, we have $n + r < S(n) = n + 1$, so $r < 1$ by III.2.6.6., contradicting III.2.6.3.]. Thus, if $P$ is the set of predecessors of $n$, the set of predecessors of $S(n)$ is $P \cup \{n\}$, which is finite since $P$ is finite. Thus $S(n) \in A$, $A = \mathbb{N}$.

III.2.6.11. Corollary. If $A$ is a nonempty subset of $\mathbb{N}$, then $A$ has a smallest element ($\mathbb{N}$ is well-ordered ()).

Proof: Let $n$ be an element of $A$. If $n$ is the smallest element of $A$, we are done. Otherwise, the set of predecessors of $n$ which are in $A$ is a nonempty finite totally ordered set, hence has a smallest element (II.5.2.12.), which must be the smallest element of $A$ since $A$ is totally ordered.

III.2.7. Subtraction and Division in $\mathbb{N}$

III.2.7.1. Subtraction and division can be partially defined on $\mathbb{N}$. If $m, n \in \mathbb{N}$, we say $m - n$ is defined in $\mathbb{N}$ if there is an $r \in \mathbb{N}$ with $m = n + r$; if such a $r$ exists, it is unique by cancellation, and we set $m - n = r$.

We have that $m - n$ is defined in $\mathbb{N}$ if and only if $n < m$, and we have $m - n = (m + r) - (n + r)$ for any $r \in \mathbb{N}$. If $m, n, r, s \in \mathbb{N}$ and $m - n$ and $r - s$ are defined, then $(m + r) - (n + s)$ is defined, and $(m + r) - (n + s) = (m - n) + (r - s)$.

Similarly, if $m, n \in \mathbb{N}$, we say $m$ is divisible by $n$ in $\mathbb{N}$ if there is a (necessarily unique) $r \in \mathbb{N}$ with $m = nr$. We then say $r$ is the quotient of $m$ divided by $n$, written $r = \frac{m}{n}$. We have, for all $n \in \mathbb{N}$, that $m$ is divisible by 1 and $\frac{m}{n} = n$, and $n$ is divisible by $n$ and $\frac{n}{n} = 1$. If $m$ is divisible by $n$, we necessarily have $n \leq m$. If $m$ is divisible by $n$ and $r$ is divisible by $s$, then $m r$ is divisible by $n s$ and $\frac{m r}{n s} = \frac{m}{n} \frac{r}{s}$. In particular, if $m$ is divisible by $n$, then $m r$ is divisible by $m r$ for any $r \in \mathbb{N}$, and $\frac{m r}{m} = \frac{m}{n}$. 259
III.2.7.2. The fact that subtraction is only partially defined on \( \mathbb{N} \) leads to the expansion of \( \mathbb{N} \) to a larger number system \( \mathbb{Z} \) in which subtraction is everywhere defined. Similarly, the fact that division is only partially defined leads to the expansion of \( \mathbb{N} \) (or \( \mathbb{Z} \)) to the system of rational numbers \( \mathbb{Q} \). There is a choice of which order to do the extensions: in the following sections we will first expand to \( \mathbb{Z} \) to get subtraction defined everywhere, and then expand \( \mathbb{Z} \) to \( \mathbb{Q} \) to get division (except division by 0) everywhere defined. We could instead proceed by expanding \( \mathbb{N} \) to the positive rational numbers \( \mathbb{Q}_+ \) to get division defined everywhere, and then construct \( \mathbb{Q} \) from \( \mathbb{Q}_+ \) to make subtraction everywhere defined.

III.2.8. Axiomatization of \( \mathbb{N}_0 \)

III.2.8.1. We can also axiomatize \( \mathbb{N}_0 \). Actually, the Peano axioms (P1)–(P5) give an axiomatization of \( \mathbb{N}_0 \) if 1 is replaced by 0 throughout. But the addition (and multiplication) must be defined differently (Exercise ()). We can give an algebraic axiomatization of \( \mathbb{N}_0 \):

\[
\begin{align*}
(\mathbb{N}_01) & \quad \mathbb{N}_0 \text{ contains elements 0 and 1.} \\
(\mathbb{N}_02) & \quad \mathbb{N}_0 \text{ has an associative binary operation } +. \\
(\mathbb{N}_03) & \quad \text{If } n \in \mathbb{N}_0, \text{ then } n + 1 \neq 0. \\
(\mathbb{N}_04) & \quad m, n \in \mathbb{N}_0, \ n + 1 = n + 1 \text{ implies } m = n. \\
(\mathbb{N}_05) & \quad A \subset \mathbb{N}_0, \ 0 \in A, \text{ and } A \text{ is closed under adding } 1 \text{ (i.e. if } n \in A \text{ implies } n + 1 \in A), \text{ then } A = \mathbb{N}_0. \\
(\mathbb{N}_06) & \quad 0 \neq 1.
\end{align*}
\]

III.2.8.2. There is a model (in the obvious sense) for (\( \mathbb{N}_01 \))–(\( \mathbb{N}_06 \)): take \( \mathbb{N} \) (or, more precisely, any model for \( \mathbb{N} \)), let 0 be any object not in \( \mathbb{N} \), let \( \mathbb{N}_0 = \mathbb{N} \cup \{0\} \), and extend + from \( \mathbb{N} \) to \( \mathbb{N}_0 \) by setting \( 0 + x = x + 0 = 0 \) for all \( x \in \mathbb{N}_0 \). The axioms are easily checked.

Conversely, let \( (\mathbb{N}_0, 0, 1, +) \) be a model for (\( \mathbb{N}_01 \))–(\( \mathbb{N}_05 \)) (\( \mathbb{N}_06 \) is not needed here). If we define \( S(x) = x + 1 \) for \( x \in \mathbb{N}_0 \), then \( (\mathbb{N}_0, 0, S) \) is a model for Peano arithmetic.

III.2.8.3. Lemma. Let \( (\mathbb{N}_0, 0, 1, +) \) be a model for (\( \mathbb{N}_01 \))–(\( \mathbb{N}_06 \)). Then \( 0 + 1 = 1 \).

Proof: This proof is somewhat more complex than the others in this section. Define a sequence in \( \mathbb{N}_0 \) (function from \( \mathbb{N} \) to \( \mathbb{N}_0 \)) by setting \( x_1 = 0 + 1 \) and \( x_{S(n)} = x_n + 1 \) (we have avoided writing \( n + 1 \) for \( S(n) \) since in this proof + will denote the operation in \( \mathbb{N}_0 \)). We have that \( x_n \neq 0 \) for all \( n \) by (\( \mathbb{N}_03 \)). The set \( \{0\} \cup \{x_n : n \in \mathbb{N}\} \) contains 0 and is closed under adding 1, hence equals \( \mathbb{N}_0 \) by (\( \mathbb{N}_05 \)). Thus \( 1 = x_n \) for some \( n \in \mathbb{N} \) (since \( 1 \neq 0 \) by (\( \mathbb{N}_06 \))). Suppose \( n = S(m) \) for some \( m \in \mathbb{N} \). Then we have

\[
(0 + x_m) + 1 = 0 + (x_m + 1) = 0 + x_n = 0 + 1
\]

and hence \( 0 + x_m = 0 \) by (\( \mathbb{N}_04 \)). If \( m = S(r) \) for some \( r \in \mathbb{N} \), then

\[
0 = 0 + x_m = 0 + (x_r + 1) = (0 + x_r) + 1
\]

which contradicts (\( \mathbb{N}_03 \)); thus \( m = 1 \), i.e. \( 0 + x_1 = 0 \). But then

\[
(0 + 0) + 1 = 0 + (0 + 1) = 0 + x_1 = 0
\]

which again contradicts (\( \mathbb{N}_03 \)). So the assumption \( n = S(m) \) for some \( m \in \mathbb{N} \) is false, i.e. \( n = 1, 1 = x_1 = 0 + 1 \). \( \Box \)
III.2.8.4. We then get \(0 + 1 = 0 + (0 + 1) = (0 + 0) + 1\), so \(0 = 0 + 0\) by (N04). Then \((1 + 0) + 1 = 1 + (0 + 1) = 1 + 1\), so \(1 + 0 = 1\) by (N04). If \(A\) is the set of \(x \in N_0\) for which \(x + 0 = x\), we have \(0 \in A\), and if \(x \in A\), then \((x + 1) + 0 = x + (1 + 0) = x + 1\), so \(x + 1 \in A\); thus \(A = N_0\). Similarly, if \(B\) is the set of \(x \in N_0\) such that \(0 + x = x\), we have \(0 \in B\), and if \(x \in B\) then \(0 + (x + 1) = (0 + x) + 1 = x + 1\), so \(x + 1 \in B\); thus \(B = N_0\). So \(0 + x = x + 0 = x\) for all \(x \in N_0\).

It follows from (N03) by induction (in the usual way) that \(x + y \neq 0\) for any \(x, y \in N_0\), \(y \neq 0\). Thus \((N_0 \setminus \{0\}, 1, +)\) (we need \((N_01)\) to have \(1 \in N_0 \setminus \{0\}\)) is a model for (N1)–(N5), so this set may be identified with \(N\). From III.2.2.10. we then obtain:

III.2.8.5. Theorem. Let \((N, 0, 1, +)\) and \((N', 0', 1', +')\) be models for (N01)–(N06). Then there is a bijection \(\phi : N' \rightarrow N\) with \(\phi(0') = 0\), \(\phi(1') = 1\), and \(\phi(x +' y) = \phi(x) + \phi(y)\) for all \(x, y \in N'\).

III.2.8.6. So we may (again with slight abuse of language) talk about the structure \(N_0\), and regard \(N\) as a subset of \(N_0\). It follows that + is commutative on \(N_0\). We may also define multiplication on \(N_0\) by extending the multiplication on \(N\) by setting \(n0 = 0n = 0\) for all \(n \in N_0\). This definition is forced by the distributive law and cancellation: if \(n \in N\), then \(0 + n = n = 1n = (0 + 1)n = 0n + 1n = 0n + n\) for any \(n\), and the argument for \(n0\) is similar. It is easily checked that the extended multiplication is associative, commutative, and distributive over addition (\(\cdot\)), and \(mn = 0\) if and only if \(m = 0\) or \(n = 0\). We also have:

III.2.8.7. Proposition. Let \(m, n \in N_0\). Then there are unique \(r, s \in N_0\) such that \(m + r = n + s\) and at least one of \(r, s\) is 0.

III.2.8.8. We can extend the ordering on \(N\) to \(N_0\) by setting \(0 < n\) for all \(n \in N\). It is easily checked that III.2.6.4. and III.2.6.6.(i) continue to hold, and that III.2.6.6.(ii) holds with \(r \neq 0\).

III.2.8.9. It should be noted that we could have replaced axiom (N06) by

\[(N06')\quad 0 + 1 = 1.\]

Indeed, this axiom along with (N03) implies that \(0 \neq 1\). The proof of Theorem III.2.8.5. is streamlined using this axiom since Lemma III.2.8.3. is not needed. Note that either (N06) or (N06') (or some substitute) is necessary: \((N, 1, 1, +)\) is a model for (N01)–(N05).

III.2.9. Further Properties of \(N\)

Many more detailed properties of \(N\) can be proved. Much of the detailed algebraic theory of \(N\) is beyond the scope of an analysis text, but we will cover a few of the essentials here.

Complete Induction, Infinite Regress, and Recursion

III.2.9.1. First, now that we have the necessary algebraic and order structure on \(N\), we can formulate and justify the principles of Complete Induction, Infinite Regress, and Definition by Recursion as described in (). We will not repeat them here.
Divisibility and the Division Algorithm

If \( m, n, r \in \mathbb{N} \) and \( r \) divides both \( m \) and \( n \), then an application of the distributive law shows that \( r \) divides \( m + n \). There is a partial converse:

**III.2.9.2. Proposition.** Let \( m, n, r \in \mathbb{N} \). If \( r \) divides both \( m \) and \( m + n \), then \( r \) also divides \( n \).

**Proof:** Write \( m = ar \) and \( m + n = br \) for \( a, b \in \mathbb{N} \). We have \( ar = m < m + n = br \), so \( a < b \) by **III.2.6.6.(ii).** Thus \( b - a = c \) is defined in \( \mathbb{N} \). We have \( a + c = b \), so

\[
m + cr = ar + cr = br = m + n
\]

so \( cr = n \) by cancellation and \( r \) divides \( n \).

**III.2.9.3.** Now let \( n, d \in \mathbb{N} \). We want to “divide” \( n \) by \( d \) and get a “quotient” and a “remainder.” Since the numbers \( \{md : m \in \mathbb{N}\} \) are all distinct, only finitely many are less than or equal to \( n \), hence there is a largest such \( m \); call it \( q \). (There may not be any such \( m \), i.e. we could have \( d > n \); in this case set \( q = 0 \).) We then have \( q \in \mathbb{N}_0 \) and \( qd \leq n < (q + 1)d \). Then \( q \) is clearly the unique \( m \in \mathbb{N}_0 \) such that \( md \leq n < (m + 1)d \).

We call \( q \) the quotient of \( n \) by \( d \); if \( d \) divides \( n \) in the sense of **III.2.7.1.**, this definition of quotient agrees with the definition there.

We now define the remainder. If \( qd = n \), i.e. \( d \) divides \( n \), set \( r = 0 \). If \( qd < n \), then \( r = n - qd \) is defined in \( \mathbb{N} \). In either case we have \( n = qd + r \). We have \( 0 \leq r \) since \( r \in \mathbb{N}_0 \), and we have

\[
qd + r = n < (q + 1)d = qd + d
\]

so we obtain \( r < d \) by **III.2.6.6.(i).** Then \( r \) is called the remainder of \( n \) divided by \( d \). (Also, \( d \) is often called the divisor and \( n \) the dividend.)

We summarize the construction:

**III.2.9.4. Theorem.** [Division Algorithm] Let \( n, d \in \mathbb{N} \). Then there are unique \( q, r \in \mathbb{N}_0 \) such that \( 0 \leq r < d \) and \( n = qd + r \).

**Proof:** We only need to observe uniqueness. If we also have \( n = q'd + r' \) with \( 0 \leq r' < d \), then

\[
q'd \leq n = q'd + r' < q'd + d = (q' + 1)d
\]

and so \( q' = q \) by the uniqueness of \( q \) with this property, and hence \( r' = r \) by cancellation.
Prime Numbers and Factorization

III.2.9.5. A number $p \in \mathbb{N}$ is normally defined to be prime if $p > 1$ and $p$ cannot be written as a product $mn$ of natural numbers except by taking $m$ or $n$ to be 1.

Although this is the standard definition of a prime number, and we will use it, it should be noted that this definition is not the same as the usual definition in abstract algebra of a prime element of a ring (the abstract algebra definition of a prime element is one satisfying the conclusion of III.2.9.6.; an element which cannot be factored in a nontrivial way is called an irreducible element. In $\mathbb{N}$, or $\mathbb{Z}$ (or, more generally, a Unique Factorization Domain), irreducible elements and prime elements turn out to be the same thing, but this is false in general rings.)

By III.1.5.7., every natural number can be written as a product of prime numbers. We will eventually show (III.2.9.8.) that this product is unique.

III.2.9.6. Theorem. Let $p$ be a prime number, and $m, n \in \mathbb{N}$. If $p$ divides $mn$, then $p$ divides $m$ or $p$ divides $n$.

Proof: This can be proved somewhat more easily after $\mathbb{Z}$ is constructed (cf. III.1.6.12.), but we give a direct proof from the Peano axioms and the machinery we have already constructed from them. The proof is a multiple infinite regress.

Suppose there is a prime $p$ for which there are $m, n \in \mathbb{N}$ not divisible by $p$ for which $p$ divides $mn$. Let $p$ be the smallest such prime. For this $p$, let $m$ be the smallest natural number not divisible by $p$ for which there is an $n \in \mathbb{N}$, not divisible by $p$, such that $mn$ is divisible by $p$, and for this $m$ let $n$ be the smallest natural number satisfying these conditions.

Write $m = ap + r$, $n = bp + s$ with $a, b, r, s \in \mathbb{N}_0$ and $r, s < p$ by the Division Algorithm. We have $r \neq 0$ and $s \neq 0$ since $p$ does not divide $m$ or $n$; hence $r, s \in \mathbb{N}$. We have

$$mn = (ap + r)(bp + s) = abp^2 + aps + bpr + rs$$

and since $mn$ and $abp^2 + aps + bpr$ are divisible by $p$, we have that $rs$ is divisible by $p$ by (9). But $r$ and $s$ are not divisible by $p$ since they are less than $p$. Since $r \leq m$ and $s \leq n$, we have $r = m$ and thus $s = n$ by minimality of $m$ and $n$. Thus $m < p$ and $n < p$.

Write $mn = kp$ for some $k \in \mathbb{N}$. We have $k < p$ since $mn < p^2$. If $k = 1$, we have $p = mn$, contradicting that $p$ is prime. If $k > 1$, let $q$ be a prime number dividing $k$. Then $q < p$, and $q$ divides $mn$, so $q$ divides $m$ or $q$ divides $n$ by minimality of $p$. Suppose $q$ divides $m$, and write $m = qd$ and $k = qt$. Then $qdn = qtp$, so $dn = tp$ and $p$ divides $dn$. But $p$ does not divide $d$ since it does not divide $m$, and $d < m$, contradicting minimality of $m$. If $q$ divides $n$, a similar contradiction is obtained.

A simple induction proof then shows:

III.2.9.7. Corollary. Let $p$ be a prime number, and $n_1, \ldots, n_r \in \mathbb{N}$. If $p$ divides $n_1n_2\cdots n_r$, then $p$ divides at least one of the $n_k$.

We then obtain one of the most important facts about the natural numbers:

263
III.2.9.8. Theorem. [Fundamental Theorem of Arithmetic] Every natural number can be written as a (finite) product of prime numbers, uniquely up to the order of the factors. (The “empty product” 1 and products of length 1 are included. Repeated factors are, of course, allowed.)

Proof: It has already been shown (III.1.5.7.) that every natural number can be written as a product of prime numbers, so we only need to show uniqueness. This can be done by induction on the length of the product, but we phrase the argument alternately by infinite regress.

Suppose \( n \) is the smallest natural number for which there are two distinct factorizations

\[
 n = p_1 p_2 \cdots p_r = q_1 q_2 \cdots q_s .
\]

Then \( n > 1 \) by III.2.6.9., so both \( r \) and \( s \) are at least 1, and neither can be 1 since the \( p_j \) and \( q_k \) are prime. Thus \( r, s > 1 \). We have that \( p_1 \) divides \( q_1 \cdots q_s \), so it divides \( q_k \) for some \( k \), and since \( q_k \) is prime we have \( p_1 = q_k \). By reordering the \( q \)’s we may assume \( k = 1 \). Thus

\[
 \frac{n}{p_1} = p_2 \cdots p_r = q_2 \cdots q_s
\]

and \( \frac{n}{p_1} \) has two distinct factorizations. But \( \frac{n}{p_1} < n \), contradicting minimality of \( n \). Thus there is no such \( n \).

We conclude our brief introduction to the algebraic theory of \( \mathbb{N} \) by noting that there are an infinite number of primes. This observation and its slick proof are due to Euclid.

III.2.9.9. Theorem. There are infinitely many prime numbers. If \( n \in \mathbb{N} \), there is a prime number \( p \) with \( p > n \).

Proof: Suppose \( p_1, \ldots, p_r \) is a finite set of prime numbers. Set \( m = 1 + p_1 p_2 \cdots p_r \). Then no \( p_k \) divides \( m \), so if \( p \) is a prime dividing \( m \), \( p \) is not one of the \( p_k \) and no finite list of primes is complete.

The last statement follows from the first and the fact that the set of predecessors of \( n \) is finite. As an alternate proof, the number \( n! + 1 \) is not divisible by any number \( \leq n \) except 1, so any prime number dividing it is greater than \( n \).

III.2.10. Summary

III.2.10.1. The Peano axioms for the natural numbers, like all axiom systems in mathematics, cannot be proved. They are accepted as a set of basic assumptions mathematicians make about the natural numbers, for several reasons:

1. All of the axioms, with the arguable exception of P5, are statements which are “obviously” true about the natural numbers we learn about and use starting as children.

2. Assuming consistency of some appropriate form of set theory, e.g. ZF, it can be rigorously shown that there is a mathematical structure, and (up to an obvious renaming of elements) only one, which satisfies the axioms, and which furthermore has uniquely determined arithmetic operations, definable directly from the axioms, which capture all the properties and facts we would expect about the natural numbers and no obviously false ones.
All the standard properties of the natural numbers can be systematically and rigorously (if somewhat tediously) proved from the axioms.

From the resulting mathematical structure, a rigorous construction can be made of larger number systems, \( \mathbb{Z}, \mathbb{Q}, \mathbb{R}, \) and \( \mathbb{C} \), which again have all the properties one would expect in these number systems. The constructed system \( \mathbb{R} \) also allows a rigorous development of analysis. (Analysis is complicated enough that it cannot be said that there are no “surprises”; however, there are no known contradictions or paradoxes resulting from the development from the Peano axioms, and even the surprises make sense and become unsurprising when thoroughly thought through.)

(1)–(3) have been discussed in this section, and part of (4) will be treated in succeeding sections. The part of (4) about analysis, however, will occupy the rest of the book (and more)!

III.2.11. Exercises

III.2.11.1. Show that the ordering on \( \mathbb{N} \) defined in III.2.6.1. coincides with the set containment order on \( \omega \) (using the standard identification of \( \mathbb{N} \) with \( \omega \)).

III.3. The Integers

III.3.1. Introduction and Axiomatization of \( \mathbb{Z} \)

III.3.1.1. The next set of numbers we will consider is the integers, or whole numbers (although historically positive fractions predated the concept of 0 or negative integers). The letter \( \mathbb{Z} \) (from the German Zahl, “number”) is customarily used to denote the set of integers. Thus, very informally,

\[
\mathbb{Z} = \{0, \pm 1, \pm 2, \ldots \}
\]

As with \( \mathbb{N} \), this is too imprecise to be even an informal definition of \( \mathbb{Z} \).

III.3.1.2. There are several equivalent ways to axiomatize \( \mathbb{Z} \), and unlike with \( \mathbb{N} \) there is no generally accepted standard axiomatization. We will describe a few of the possibilities here. One efficient way is the following set of axioms:

(A) \( \mathbb{Z} \) has an associative binary operation \(+\).

(B) There is an element \( 0 \in \mathbb{Z} \) such that \( x + 0 = 0 + x = x \) for all \( x \in \mathbb{Z} \).

(C) For every \( x \in \mathbb{Z} \) there is an element \( -x \in \mathbb{Z} \) with \( x + (-x) = (-x) + x = 0 \).

(D) There is an element \( 1 \in \mathbb{Z} \) such that, if \( A \subseteq \mathbb{Z}, 1 \in A, \) and \( x \in A \) implies \( x + 1 \in A \) and \( (-x) \in A \), then \( A = \mathbb{Z} \).

(E) If \( P \) is the smallest subset of \( \mathbb{Z} \) containing 1, such that \( x \in P \) implies \( x + 1 \in P \), then \( 0 \notin P \).

A model for (A)–(E) is called a group. A group satisfying (D) is called a cyclic group, and a cyclic group satisfying (E) is a free cyclic group. There is a vast theory of groups, which is a large portion of the modern subject of abstract algebra.
III.3.2. Models for $\mathbb{Z}$

There is a standard model for $\mathbb{Z}$, which can be constructed from either $\mathbb{N}$ or $\mathbb{N}_0$. The construction is slightly simpler notationally starting from $\mathbb{N}_0$, so we will do it this way. The motivation for the construction is that every integer can be written as a difference of natural numbers. However, the representation is not unique, so it takes some work to handle the nonuniqueness: the idea is that $x_1 - y_1 = x_2 - y_2$ if and only if $x_1 + y_2 = x_2 + y_1$.

III.3.2.1. Definition. Define a relation on $\mathbb{N}_0 \times \mathbb{N}_0$ by setting $(x_1, y_1) \sim (x_2, y_2)$ if $x_1 + y_2 = x_2 + y_1$.

III.3.2.2. Proposition. (i) The relation $\sim$ is an equivalence relation ($\sim$) on $\mathbb{N}_0 \times \mathbb{N}_0$.

(ii) If $(x_1, y_1) \sim (x_2, y_2)$ and $(z_1, w_1) \sim (z_2, w_2)$, then $(x_1 + z_1, y_1 + w_1) \sim (x_2 + z_2, y_2 + w_2)$.

Proof: (i): If $(x_1, y_1) \sim (x_2, y_2)$, it is trivial that $(x_2, y_2) \sim (x_1, y_1)$. It is also trivial that $(x, y) \sim (x, y)$ for any $x, y$. If $(x_1, y_1) \sim (x_2, y_2)$ and $(x_2, y_2) \sim (x_3, y_3)$, we have

$$(x_1 + y_3) + (x_2 + y_2) = (x_1 + y_2) + (x_2 + y_3) = (x_2 + y_1) + (x_3 + y_2) = (x_3 + y_1) + (x_2 + y_2)$$

by the associative and commutative laws, and hence $x_1 + y_3 = x_3 + y_1$ by cancellation. Thus $(x_1, y_1) \sim (x_3, y_3)$.

(ii): By the associative and commutative laws, we have

$$(x_1 + z_1) + (y_2 + w_2) = (x_1 + y_2) + (z_1 + w_2) = (x_2 + y_1) + (z_2 + w_1) = (x_2 + z_2) + (y_1 + w_1).$$

We will write $[(x, y)]$ for the equivalence class of the pair $(x, y)$. We will think of $[(x, y)]$ as representing the integer $x - y$; the equivalence relation $\sim$ is designed so that every representative of the equivalence class represents the same integer.

III.3.2.3. Definition. Let $\mathcal{Z}$ be the set of equivalence classes of ordered pairs. For $[(x, y)], [(z, w)] \in \mathcal{Z}$, define

$$[(x, y)] + [(z, w)] = [(x + z, y + w)].$$

Note that $+$ is well defined on $\mathcal{Z}$ by III.3.2.2.(ii).

III.3.2.4. Theorem. If $\mathcal{N}_0 = \{(x, 0) : x \in \mathbb{N}_0\}$, then $(\mathcal{N}_0, [(0, 0)], [(1, 0)], +)$ is a model for $\mathbb{N}_0$, and $(\mathcal{Z}, +, [(0, 0)], [(1, 0)])$ is a model for $\mathbb{Z}$. Addition in $\mathcal{Z}$ is commutative.

Proof: It is obvious that once we know that addition of equivalence classes is well defined, it inherits associativity (and also commutativity) from addition in $\mathbb{N}_0$. It is also obvious that $\mathcal{N}_0$ is closed under addition, and the map $\phi : \mathbb{N}_0 \to \mathcal{N}_0$ defined by $\phi(x) = [(x, 0)]$ satisfies $\phi(x + y) = \phi(x) + \phi(y)$ for all $x, y \in \mathbb{N}_0$. Also, $\phi(x) = \phi(y)$ if and only if $(x, 0) \sim (y, 0)$, i.e. if and only if $x = y$. Thus $\mathcal{N}_0$ is a model for $\mathbb{N}_0$, with 0-element $\phi(0) = [(0, 0)]$ and 1-element $\phi(1) = [(1, 0)]$.

We now check the $\mathbb{Z}$-axioms for $\mathcal{Z}$. (G1) is already checked. We have $[(0, 0)] + [(x, y)] = [(0 + x, 0 + y)] = [(x, y)]$ for all $x, y \in \mathbb{N}_0$, and similarly $[(x, y)] + [(0, 0)] = [(x, y)]$ for all $x, y$; thus (G2) holds. For $x, y \in \mathbb{N}_0$, 266
In the first case.

Proof:

(iii) If III.3.3.3. (G3). We will not prove this (cf. ()) since we will deduce commutativity of addition in another way.

There are noncommutative groups (). Commutativity of addition does follow from (Cyc), along with (G1)–(G2).

III.3.3.2. Here are some basic consequences of the axioms (G1)–(G3).

Z

We could have done the whole construction using N instead of N₀. In this case, the 0 element is [(1, 1)], and the 1-element is [(1 + 1, 1)]. The natural number n is represented by [(n + 1, 1)]. The approach of III.3.2.5. can also be done using N; details are left to the reader.

III.3.3.1. Here are some basic consequences of the axioms (G1)–(G3).

(i) [CANCELLATION] If x, y, z ∈ Z and x + z = y + z, then x = y: we have

\[ x = x + 0 = x + (z + (-z)) = (x + z) + (-z) = (y + z) + (-z) = y + (z + (-z)) = y + 0 = y. \]

Similarly, if z + x = z + y, then x = y. Since 0 + 0 = 0 = 0 + (−0) by (G2), we have −0 = 0.

(ii) If x, y ∈ Z and x + y = 0, then y = −x. In particular, −(−x) = x.

(iii) If x, y ∈ Z, then −(x + y) = −(y) + (−x): streamlining manipulations with the associative law, we have

\[ (x + y) + [(-y) + (-x)] = x + (y + (-y)) + (-x) = x + 0 + (-x) = x + (-x) = 0. \]

III.3.3.2. One property of Z which does not follow just from (G1)–(G3) is commutativity of addition: there are noncommutative groups (). Commutativity of addition does follow from (Cyc), along with (G1)–(G3). We will not prove this (cf. (i)) since we will deduce commutativity of addition in another way.

III.3.3.3. THEOREM. Let (Z, +, 0, 1) be a model for Z, and let P ⊆ Z be the set defined in (Fr). Then

(i) P is closed under addition, i.e. if x, y ∈ P, then x + y ∈ P.

(ii) (P, 1, +) is a model for N. Thus + is commutative on P.

(iii) If −P = {−x : x ∈ P}, then Z is the disjoint union of P, −P, and {0}.

Proof: (i): Let A be the set of all y ∈ P such that x + y ∈ P for all x ∈ P. Since x ∈ P implies x + 1 ∈ P, we have 1 ∈ A. If y ∈ A, then for any x ∈ P, we have x + (y + 1) = (x + y) + 1 ∈ P, so y + 1 ∈ A. So A is
a subset of \( Z \) containing 1 and closed under adding 1; thus \( P \subseteq A \) since \( P \) is the smallest such set. Since \( A \subseteq P \), we have \( A = P \).

(ii) Axiom (N1) holds by (i), and axiom (N2) is trivial. Since \( 0 + 1 = 1 \) and \( 0 \notin P \), we have \( x + 1 \neq 1 \) for all \( x \in P \) by cancellation, so axiom (N3) holds. Axiom (N4) holds by cancellation. Axiom (N5) also holds by an argument similar to the proof of (i). It follows from III.2.5.5. that \( + \) is commutative on \( P \).

(iii) We have \( \{0\} \cap P = \emptyset \) by (Fr), and similarly \( \{0\} \cap (\neg P) = \emptyset \) since \( -0 = 0 \). If \( x \in P \cap (\neg P) \), so \( x = -y \) for some \( y \in P \), then \( 0 = x + y \in P \) by (i), a contradiction; thus \( P \cap (\neg P) = \emptyset \). If \( x, y \in P \), then by (ii) and III.2.6.4. either \( x = y \), or there is a \( z \in P \) with \( x + z = y \), or there is a \( w \in P \) with \( x = y + w \). Now let \( A = P \cup (\neg P) \cup \{0\} \). We have \( 0 \in A \), and if \( x \in A \), then \( \neg x \in A \). If \( x \in A \), we show \( x + 1 \in A \). If \( x = 0 \) or \( x \in P \), this is obvious. If \( x \in (\neg P) \), then \( x = (\neg y) \) for some \( y \in P \). If \( y = 1 \), then \( x + 1 = 0 \in A \); if \( y = z + 1 = 1 + z \) for some \( z \in P \), then \( x = (\neg y) = (\neg z) + (\neg 1) \), so \( x + 1 = (\neg z) \in A \). Thus \( A = Z \) by (Cyc).

### III.3.4. Proposition. If \((Z, +, 0, 1)\) is a model for \( Z \), then \(+\) is commutative.

**Proof:** Addition is commutative on \( P \) by III.3.3.(ii), and we have \( 0 + x = x + 0 \) for any \( x \in Z \) by axiom (G2). It remains to show that \( x + (\neg y) = (\neg y) + x \) for \( x, y \in P \). Fix \( x, y \in P \). We have

\[
y + [x + (\neg y)] = (y + x) + (\neg y) = (x + y) + (\neg y) = x + [y + (\neg y)] = x = [y + (\neg y)] + x = y + [(\neg y) + x]
\]

and so \( x + (\neg y) = (\neg y) + x \) by cancellation. \( \diamondsuit \)

### III.3.5. Theorem. If \((Z, +, 0, 1)\) and \((Z', +', 0', 1')\) are models for \( Z \), then there is a bijection \( \phi : Z \to Z' \) such that \( \phi(0) = 0', \phi(1) = 1' \), and \( \phi(x + y) = \phi(x) +' \phi(y) \) for all \( x, y \in Z \).

**Proof:** Let \( P \) and \( P' \) be the subsets of \( Z \) and \( Z' \) respectively defined in (Fr). Since \( P \) and \( P' \) are models for Peano arithmetic, there is a bijection \( \phi : P \to P' \) with \( \phi(1) = 1' \) and \( \phi(x + y) = \phi(x) +' \phi(y) \) for all \( x, y \in P \) (III.2.5.4.). Extend \( \phi \) by setting \( \phi(0) = 0' \) and \( \phi(-x) = -\phi(x) \) for \( x \in P \). By III.3.3.3., \( \phi \) is well defined and bijective. We need only check that \( \phi \) preserves addition. Fix \( x, y \in P \). We know that \( \phi(x + y) = \phi(x) +' \phi(y) \). We also have

\[
\phi(-x) + (\neg y) = \phi(-y + x) = -\phi(y + x) = -((\neg y) +' \phi(x)) = [-\phi(x)] + [-\phi(y)].
\]

Finally, we either have \( x = y \), or \( x + z = y \) for some \( z \in P \), or \( x = y + w \) for some \( w \in P \). If \( x = y \), we have

\[
\phi(x + (\neg y)) = \phi(0) = \phi(x) +' [-\phi(y)] = \phi(x) +' \phi(-y).
\]

If \( x = y + w \), we have \( x + (-y) = w \) (using commutativity of addition). Then

\[
\phi(x) +' \phi(-y) = \phi(x) +' [-\phi(y)] = \phi(y + w) +' [-\phi(y)] = \phi(y) +' \phi(w) +' [-\phi(y)] = \phi(w) = \phi(x + (\neg y)).
\]

The argument if \( x + z = y \) is almost identical. \( \diamondsuit \)
III.3.3.6. So, as with \( \mathbb{N}_0 \) and \( \mathbb{N} \), we may talk about the set (or structure) \( \mathbb{Z} \) without defining it precisely as a set. We will identify \( \mathbb{N} \) with the subset \( P \), called the set of positive integers, and hence identify \( \mathbb{N}_0 \) with the set \( \mathbb{N} \cup \{0\} \) of nonnegative integers.

III.3.3.7. Note that the element 0 in \( \mathbb{Z} \) is uniquely determined by the algebraic structure: since \( x+0=x \) for any \( x \), by cancellation 0 is the unique \( x \in \mathbb{Z} \) with the property that \( x+x=x \). However, 1 is not completely determined by the algebraic (additive) structure of \( \mathbb{Z} \): if \( (\mathbb{Z}, +, 0, 1) \) is a model for \( \mathbb{Z} \), then \( (\mathbb{Z}, +, 0, -1) \) is also a model for \( \mathbb{Z} \).

In group-theoretic language, a free cyclic group has two generators. The axioms for \( \mathbb{Z} \) determine its algebraic (additive) structure: since any element \( x \) can be uniquely written in the form \( (x-x) + x \) where \( x-x \) is an integer, the rest of the structure then follows uniquely.

III.3.4. Ordering and Subtraction in \( \mathbb{Z} \)

III.3.4.1. We may also define a total ordering on \( \mathbb{Z} \) extending the order on \( \mathbb{N}_0 \) by setting \((-n) < 0 \) for \( n \in \mathbb{N} \), and \((-n) < (-m) \) if \( n, m \in \mathbb{N} \) and \( m < n \). It is easily checked that this is a total order and that \( x < y \) implies \( x+z < y+z \) for \( x, y, z \in \mathbb{Z} \). We will also use the symbols \( >, \leq, \geq \) with their usual (obvious) meaning.

III.3.4.2. We define the absolute value of an \( x \in \mathbb{Z} \) by \( |x| = x \) if \( x \geq 0 \) and \( |x| = -x \) if \( x < 0 \), i.e. \( |0| = 0 \) and \( |x| = |x| \) for \( x \in \mathbb{P} \). We obviously then have \( |x| \geq 0 \) and \( |x| = |x| \) for all \( x \in \mathbb{Z} \).

We also define the signum \( \text{sgn}(x) \) to be 1 if \( x \in \mathbb{P} \) and \(-1 \) if \( x \in \mathbb{N}_0 \); \( \text{sgn}(0) \) is not defined.

III.3.4.3. Proposition. [Triangle Inequality] If \( x, y \in \mathbb{Z} \), then \( |x| - |y| \leq |x+y| \leq |x| + |y| \).

The proof is a straightforward but tedious case-by-case check. The result is called the “triangle inequality” in analogy with the vector version (1).

III.3.4.4. We may define subtraction in \( \mathbb{Z} \) by \( x-y = x+(-y) \) for \( x, y \in \mathbb{Z} \). This operation extends the partially defined subtraction in \( \mathbb{N} \). Subtraction is a binary operation on \( \mathbb{Z} \), but is not associative or commutative. We have \( (x+z) - (y+w) = (x-y) + (z-w) \) (and in particular \( x-y = (x+z) - (y+z) \)) and \( y-x = -(x-y) \) for \( x, y, z, w \in \mathbb{Z} \). We then have \( |x-y| = |y-x| \) for all \( x, y \in \mathbb{Z} \).

III.3.5. Multiplication and Division in \( \mathbb{Z} \)

III.3.5.1. We now discuss multiplication in \( \mathbb{Z} \). We define multiplication on \( \mathbb{N}_0 \) as in III.2.8.6. There is only one way to extend this multiplication to \( \mathbb{Z} \) so that the distributive laws hold: since

\[
0 \cdot 0 = 0 = 0(x+(-x)) = 0x + 0(-x) = 0 + 0(-x) = 0(-x)
\]

for \( x \in \mathbb{N}_0 \), we must have \( 0y = 0 \) for all \( y \in \mathbb{Z} \). Similarly, \( y0 = 0 \) for all \( y \in \mathbb{Z} \). Then, if \( x, y \in \mathbb{Z} \),

\[
0 = x0 = x(y + (-y)) = xy + x(-y)
\]

so we must have \( x(-y) = -(xy) \) for all \( x, y \). Similarly, \( (-x)y = -(xy) \) for all \( x, y \in \mathbb{Z} \). Thus the following definition of multiplication is forced by the distributive laws:
III.3.5.2. **Definition.** If \( x, y \in \mathbb{N} \), define \( x(-y) = (-x)y = -(xy) \), \( (-x)(-y) = xy \), and \( x0 = 0x = 0 \).

It is obvious that this gives a well-defined binary operation on \( \mathbb{Z} \). Despite the use of the distributive law in motivating the definition of multiplication, the associative, commutative, and distributive laws must still be checked. The commutative law is obvious, and the proof of the distributive law is essentially the reversal of the argument in III.3.5.1. The associative law is a simple but tedious calculation checking case-by-case, using the associative law in \( \mathbb{N} \). Thus we obtain:

III.3.5.3. **Theorem.** Multiplication in \( \mathbb{Z} \) is associative, commutative, and distributes over addition, and is uniquely determined by these properties and the requirement that \( 11 = 1 \).

The last statement follows from III.3.5.1 and III.2.5.6(i).

The next results are easy consequences of the definitions, and the proofs are left to the reader.

III.3.5.4. **Proposition.** If \( x, y, z \in \mathbb{Z} \), \( z \neq 0 \), and \( xz = yz \), then \( x = y \). If \( xy = 0 \), then \( x = 0 \) or \( y = 0 \).

III.3.5.5. **Proposition.** If \( x, y \in \mathbb{Z} \), then \( |xy| = |x||y| \). If \( x, y \neq 0 \), then \( \text{sgn}(xy) = \text{sgn}(x)\text{sgn}(y) \).

III.3.5.6. **Proposition.** Let \( x, y, z \in \mathbb{Z} \) with \( x < y \). If \( z > 0 \), then \( xz < yz \). If \( z < 0 \), then \( xz > yz \).

III.3.5.7. We may define division in \( \mathbb{Z} \) as in \( \mathbb{N} \): if \( x, y \in \mathbb{Z} \), \( y \neq 0 \), we say \( x \) is divisible by \( y \) in \( \mathbb{Z} \) if there is a (necessarily unique) \( z \in \mathbb{Z} \) with \( x = yz \). We then say \( z \) is the quotient of \( x \) divided by \( y \), written \( z = \frac{x}{y} \). If \( x, y \in \mathbb{N} \), this notion coincides with divisibility and quotient in \( \mathbb{N} \). We have, for all \( x \in \mathbb{Z} \), that \( x \) is divisible by 1 and \( \frac{x}{1} = x \), and if \( x \neq 0 \), then \( x \) is divisible by \( x \) and \( \frac{x}{x} = 1 \). If \( x \) is divisible by \( y \) and \( z \) is divisible by \( w \), then \( xz \) is divisible by \( yw \) and \( \frac{xz}{yw} = \frac{x}{y} \frac{z}{w} \). In particular, if \( x \) is divisible by \( y \), then \( xz \) is divisible by \( yz \) for any \( z \in \mathbb{Z} \), \( z \neq 0 \), and \( \frac{xz}{yz} = \frac{x}{y} \). If \( x \neq 0 \), then no meaning can be attached to \( \frac{x}{0} \) since there is no \( z \) with \( z0 = x \). We also can give no usable definition of \( \frac{0}{v} \).

Quite apart from the impossibility of dividing by 0, which is insurmountable, division is still only partially defined on \( \mathbb{Z} \). It is thus desirable to expand \( \mathbb{Z} \) to a larger number system \( \mathbb{Q} \) in which division (except division by 0) is everywhere defined.

III.3.6. **Ring Axiomatization of \( \mathbb{Z} \)**

We give here an alternate axiomatization of \( \mathbb{Z} \). This axiomatization is not as “efficient” as the previous one, since it postulates existence of multiplication and its properties which can be deduced from the previous axioms, and also postulates commutativity of addition. However, this axiom scheme is commonly used, and natural subsets of these axioms define structures which are important in abstract algebra.
III.3.6.1. Ring Axioms for $\mathbb{Z}$:

(Op) There are two binary operations $+$ and $\cdot$ on $\mathbb{Z}$.

(A1) The binary operation $+$ is associative.

(A2) The binary operation $+$ is commutative.

(A3) There is an element $0 \in \mathbb{Z}$ such that $x + 0 = 0 + x = x$ for all $x \in \mathbb{Z}$.

(A4) For every $x \in \mathbb{Z}$ there is an element $(-x) \in \mathbb{Z}$ with $x + (-x) = (-x) + x = 0$.

(M1) The binary operation $\cdot$ is associative.

(M2) The binary operation $\cdot$ is commutative.

(M3) There is an element $1 \in \mathbb{Z}$ such that $x \cdot 1 = 1 \cdot x = x$ for all $x \in \mathbb{Z}$.

(D) The operation $\cdot$ distributes over addition.

(Cyc) If $A \subseteq \mathbb{Z}$, $1 \in A$, and $x \in A$ implies $x + 1 \in A$ and $(-x) \in A$, then $A = \mathbb{Z}$.

(Fr) If $P$ is the smallest subset of $\mathbb{Z}$ containing $1$, such that $x \in P$ implies $x + 1 \in P$, then $0 \notin P$.

We have seen that a set $Z$ with a binary operation $+$ satisfying (A1), (A3), (A4), and with an element $1$ satisfying (Cyc) and (Fr) is a model for $\mathbb{Z}$, hence also satisfies (A2), and there is a unique multiplication on $Z$ for which the rest of the axioms are satisfied. Thus from III.3.3.5. we obtain:

III.3.6.2. Theorem. Let $(\mathbb{Z}, +, \cdot, 0, 1)$ be a model for the ring axioms of $\mathbb{Z}$. then there is a bijection $\phi : \mathbb{Z} \to \mathbb{Z}$ with $\phi(0) = 0, \phi(1) = 1, \phi(x + y) = \phi(x) + \phi(y)$, and $\phi(x \cdot y) = \phi(x)\phi(y)$, where $\mathbb{Z}$ has its previously defined addition, multiplication, 0, and 1.

III.3.6.3. Definition. A set $R$ with two binary operations $+$ and $\cdot$ satisfying (A1)–(A4) [with $\mathbb{Z}$ replaced by $R$ in the statements], (M1), and (D) is called a ring. A ring is commutative if it also satisfies (M2). A ring is unital if it also satisfies (M3) (an explicit assumption is usually made that $1 \neq 0$ in a unital ring; it is unnecessary to explicitly include this in our axiomatization of $\mathbb{Z}$ since it is an automatic consequence of (Fr)).

Several examples of rings are given in the Exercises, including commutative nonunital rings, noncommutative unital rings, and noncommutative nonunital rings. Note that the term commutative, when applied to a ring, refers to multiplication; addition is always commutative in a ring. Ring theory is an extensive and important part of abstract algebra, with many applications.

We will not develop the general theory of rings here, but we need one basic proposition:

III.3.6.4. Proposition. Let $R$ be a ring. Then

(i) $R$ has cancellation for addition.

(ii) If $x \in R$, then $x0 = 0x = 0$.

(iii) If $R$ is unital and contains more than one element, then $1 \neq 0$.

Proof: The proof of (i) is the same as for $\mathbb{Z}$ (III.3.3.1.(i)), which uses only (G1)–(G3), which are the same as (A1), (A3), (A4). (Actually cancellation holds in any group by this proof.)

For (ii), for any $x \in R$ we have $0 + 0x = 0x = (0 + 0)x = 0x + 0x$, so $0x = 0$. Similarly, $x0 = 0$.

(iii) follows immediately from (ii): if $x \in R$, $x \neq 0$, then $0x = 0 \neq x = 1x$. 🌟
III.3.6.5. The axiom (Cyc) is often replaced by the following axiom:

(Pos) There is a nonempty subset $P'$ of $\mathbb{Z}$, closed under addition and multiplication, such that $\mathbb{Z}$ is the disjoint union of $P'$, $\{0\}$, and $-P' = \{-x : x \in P'\}$.

It is obvious that (Pos) follows from the ring axioms for $\mathbb{Z}$ (taking $P' = P$). To show that (Pos) $\Rightarrow$ (Cyc) in the presence of the other axioms, we first need:

III.3.6.6. Proposition. Let $(\mathbb{Z}, +, \cdot, 0, 1)$ be a model for the ring axioms of $\mathbb{Z}$ with (Cyc) replaced by (Pos). Then $1 \in P'$.

Proof: Since $\mathbb{Z}$ is a unital ring and $P' \neq \emptyset$, we have $0 \neq 1$ in $\mathbb{Z}$ by III.3.6.4.(iii). Thus either $1 \in P'$ or $(-1) \in P'$. If $(-1) \in P'$, then $1 = (-1)(-1) \in P'$. (In fact, $(-1) \notin P'$ since then $1 \in P' \cap (-P')$.)

Once we know that $1 \in P'$, it follows from the proof of III.3.3.3. that $P = P'$ and that (Cyc) holds. So we get that the following set of axioms characterize $\mathbb{Z}$:

III.3.6.7. Ordered Ring Axioms for $\mathbb{Z}$:

(Op) There are two binary operations $+$ and $\cdot$ on $\mathbb{Z}$.

(A1) The binary operation $+$ is associative.

(A2) The binary operation $+$ is commutative.

(A3) There is an element $0 \in \mathbb{Z}$ such that $x + 0 = 0 + x = x$ for all $x \in \mathbb{Z}$.

(A4) For every $x \in \mathbb{Z}$ there is an element $(-x) \in \mathbb{Z}$ with $x + (-x) = (-x) + x = 0$.

(M1) The binary operation $\cdot$ is associative.

(M2) The binary operation $\cdot$ is commutative.

(M3) There is an element $1 \in \mathbb{Z}$ such that $x \cdot 1 = 1 \cdot x = x$ for all $x \in \mathbb{Z}$.

(D) The operation $\cdot$ distributes over addition.

(Pos) There is a nonempty subset $P$ of $\mathbb{Z}$ such that

(P1) If $x, y \in P$, then $x + y \in P$.

(P2) If $x, y \in P$, then $xy \in P$.

(P3) $0 \notin P$.

(P4) If $x \in \mathbb{Z}$, $x \neq 0$, then either $x \in P$ or $(-x) \in P$, but not both.

(Min$_\mathbb{Z}$) $P$ is the smallest subset $A$ of $\mathbb{Z}$ containing $1$, such that $x \in A$ implies $x + 1 \in A$.

III.3.6.8. The ordering on $\mathbb{Z}$ can be cleanly expressed in terms of these axioms: $x < y$ if and only if $(y - x) \in P$. The specification of the ordering via (Pos) can be done alternately by the axiom

(Ord) There is a relation (strict total order) $<$ on $\mathbb{Z}$, such that

(O1) If $x, y \in \mathbb{Z}$, then exactly one of $x < y$, $y < x$, $x = y$ holds. (Trichotomy)

(O2) If $x, y, z \in \mathbb{Q}$, $x < y$, and $y < z$, then $x < z$. (Transitivity)
(O3) If \( x, y, z \in \mathbb{Z} \) and \( x < y \), then \( x + z < y + z \). (Translation Invariance)

(O4) If \( x, y, z \in \mathbb{Z} \), \( x < y \), and \( 0 < z \), then \( xz < yz \). (Homogeneity or Scaling Invariance)

It is easily seen that in the presence of the other axioms \([\text{Min}_2]\) is not needed, \((\text{Pos})\) is equivalent to \((\text{Ord})\); if \((\text{Ord})\) is assumed, \( P \) is defined to be \( \{x \in \mathbb{Z} : 0 < x\} \). It is a matter of taste whether the ordering is axiomatized using \((\text{Pos})\) or \((\text{Ord})\); both are used in the literature.

A commutative ring satisfying \((\text{Pos})\) (or, equivalently, \((\text{Ord})\)) is called an ordered ring.

III.3.6.9. REMARK. The axioms \((\text{P}3)\) and \((\text{P}4)\) can be replaced by

\[(\text{P}3')\] If \( x \in P \), then \(-x \notin P\).

\[(\text{P}4')\] If \( x \in \mathbb{Z}, x \neq 0 \), then either \( x \in P \) or \(-x \in P\).

It is obvious that \((\text{P}3)\) and \((\text{P}4)\) imply \((\text{P}3')\) and \((\text{P}4')\), and that \((\text{P}3')\) and \((\text{P}4')\) imply \((\text{P}4)\). Note also that if \((\text{P}3')\) is assumed, then we cannot have \( 0 \in P \): if \( 0 \in P \), then \((-0) \notin P\) by \((\text{P}3')\), but \(-0 = 0\), a contradiction. Thus \((\text{P}3')\) implies \((\text{P}3)\).

III.3.7. Exercises

III.3.7.1. Show that the set of even integers, with its usual addition and multiplication, is a nonunital commutative ring.

III.3.7.2. Fix \( n \in \mathbb{N} \), and let \( M_n(\mathbb{R}) \) be the set of all \( n \times n \) matrices with real entries. Give \( M_n(\mathbb{R}) \) the usual matrix addition and multiplication. Show that \( M_n(\mathbb{R}) \), with this addition and multiplication, is a unital ring, which is not commutative if \( n > 1 \). Do the same for \( M_n(\mathbb{Z}), M_n(\mathbb{Q}), \) and \( M_n(\mathbb{C}) \).

III.3.7.3. Let \( R \) be the set of all sequences of \( 2 \times 2 \) matrices (with real entries) which are eventually 0. Add and multiply sequences coordinatewise. Show that \( R \) with these operations is a noncommutative nonunital ring.

III.3.7.4. Let \( R \) be a ring. A subset \( J \) of \( R \) is an ideal of \( R \) if \( J \) is closed under addition, \( 0 \in J \), \( x \in J \) implies \((-x) \in J \), and \( x \in J, y \in R \) imply that \( xy, yx \in J \) (cf. II.6.4.12).

(a) Fix \( n \in \mathbb{N} \), and let \( n\mathbb{Z} \) be the set of all integers divisible by \( n \). Show that \( n\mathbb{Z} \) is an ideal in \( \mathbb{Z} \). Show that every ideal of \( \mathbb{Z} \) other than \( \{0\} \) is of this form.

(b) Let \( J \) be an ideal in a ring \( R \). If \( x, y \in R \), set \( x \sim y \) if \((y - x) \in J \). Show that \( \sim \) is an equivalence relation.

(c) Let \( R/J \) be the set of \( \sim \)-equivalence classes \( \{[x] : x \in R\} \) (cf. (b)). Show that \([x] + [y] = [x + y] \) and \([x][y] = [xy] \) give well-defined binary operations on \( R/J \) making it into a ring, which is commutative [resp. unital] if \( R \) is commutative [resp. unital]. \( R/J \) is called the quotient ring of \( R \) by \( J \), pronounced “\( R \) mod \( J \)”.

III.3.7.5. Use the notation and terminology of Exercise III.3.7.4.

(a) Show that the quotient ring \( \mathbb{Z}/n\mathbb{Z} \) can be identified with the ring \( \mathbb{Z}_n \) of “integers mod \( n \),” whose elements are \( \{0, 1, 2, \ldots, n-1\} \) and where addition and multiplication are done modulo \( n \).

(b) Show that \((\mathbb{Z}_n, 1, +)\) is a model for \( \mathbb{N} \) with axiom \((\text{N}3)\) deleted.

(c) Show that \((\mathbb{Z}_n, +, 0, 1)\) is a model for \( \mathbb{Z} \) with axiom \((\text{Fr})\) deleted.

273
This problem gives an extension of Theorem III.3.6.2. Let $R$ be a unital ring. Define a function $\phi : \mathbb{Z} \to R$ by $\phi(0) = 0$, $\phi(1) = 1$, and $\phi(x + 1) = \phi(x) + 1$ and $\phi(-x) = -\phi(x)$ for $x \in \mathbb{N}$.

(a) Show that $\phi(x + y) = \phi(x) + \phi(y)$ and $\phi(xy) = \phi(x)\phi(y)$ for all $x, y \in \mathbb{Z}$ (\(\phi\) is a ring-homomorphism).

(b) Show that $\phi(\mathbb{Z}) = \{\phi(x) : x \in \mathbb{Z}\}$ is a subring of $R$ (a subset closed under addition and multiplication which is itself a ring), and is the smallest subring of $R$ containing 1.

(c) Show that $J = \{x \in \mathbb{Z} : \phi(x) = 0\}$ is an ideal of $\mathbb{Z}$, and that $\phi$ gives a ring-isomorphism (bijective ring-homomorphism) from $\mathbb{Z}/J$ to $\phi(\mathbb{Z})$. Thus, either $\phi$ is injective and $\phi(\mathbb{Z})$ is isomorphic to $Z$ as a ring, or $J = n\mathbb{Z}$ for some $n \in \mathbb{N}$, in which case $\phi(\mathbb{Z})$ is isomorphic to $Z_n$ as a ring.

III.3.7.7. The Grothendieck Group. Let $(S, \ast)$ be an abelian semigroup, a set $S$ with an associative, commutative binary operation $\ast$. There is a standard construction of an abelian group $G(S)$ which is virtually identical to the construction of $\mathbb{Z}$ from $\mathbb{N}$ or $\mathbb{N}_0$. The only change is that the equivalence relation must be modified to account for possible lack of cancellation in $(S, \ast)$.

(a) Define a relation $\sim$ on $S \times S$ by setting $(x_1, y_1) \sim (x_2, y_2)$ if there is a $z \in S$ with

$$x_1 \ast y_2 \ast z = x_2 \ast y_1 \ast z.$$ 

Show that $\sim$ is an equivalence relation on $S \times S$.

(b) Let $G(S)$ be the set of $\sim$-equivalence classes $\{(x, y) : x, y \in S\}$. Show that $\mathbb{Z}$ is a group (a subset closed under addition and multiplication which is itself a ring), and is the smallest subgroup of $R$ containing 1.

(c) Show that $\{[(x, y)] : x, y \in S\}$ for any $x, y \in S$, and that this class gives an additive identity.

(d) If $[(x, y)] = [(y, x)]$, show that $G(S)$ is an abelian (commutative) group, i.e. satisfies axioms (A1)--(A4).

(e) Show that $[(x \ast y, y)] = [(x \ast z, z)]$ for any $x, y, z \in S$. Show that the map $\iota : S \to G(S)$ defined by $\iota(x) = [(x \ast x, x)]$ is a (group-)homomorphism, i.e. $\iota(x \ast y) = \iota(x) \ast \iota(y)$ for all $x, y \in S$. Show that $\iota$ is injective if and only if $S$ has cancellation.

(f) Show that this construction, applied to $(\mathbb{N}, \cdot)$, gives the positive rational numbers with multiplication.

(g) Show that the group $G(S)$ is universal in the sense that if $H$ is any abelian group and $\phi : S \to H$ is a homomorphism, there is a unique homomorphism $\psi : G(S) \to H$ such that $\phi = \psi \circ \iota$.

(h) Show that $S \to G(S)$ is a functor (\() from the category of abelian semigroups to the category of abelian groups. Part of showing this is to show that if $S$ and $S'$ are abelian semigroups, and $\phi : S \to S'$ is a homomorphism, there is a corresponding induced homomorphism from $G(S)$ to $G(S')$.

The term abelian, as a synonym for commutative, is used for groups and semigroups (and also for rings by some authors; abelian categories, functions, and varieties also use this name) in honor of the Norwegian mathematician Niels Henrik Abel, who made important contributions to both algebra and analysis before his death at age 26 from tuberculosis.

III.3.7.8. An element $x$ in a commutative ring $R$ is a zero divisor if $x \neq 0$ and there exists $y \in R$, $y \neq 0$, with $xy = 0$.

(a) Show that $xz = yz$ implies $x = y$ in a commutative ring $R$ if and only if $z$ is not a zero divisor. [Consider $(x - y)z$]

(b) A unital commutative ring is an integral domain if it contains no zero divisors. Show that every unital subring of a field is an integral domain. Show that the polynomial ring $\mathbb{R}[X]$ (Exercise ()) is an integral domain.
III.4. The Rational Numbers

III.4.1. Introduction and Axiomatization of \(\mathbb{Q}\)

The next step in building the number system is the construction of the rational numbers, usually denoted \(\mathbb{Q}\) (for “quotient”). We will follow the usual process of listing a set of axioms satisfied by \(\mathbb{Q}\), and then showing that there is a model for the axioms and that the model is essentially unique.

III.4.1.1. Rational numbers are often described as “fractions,” but this is incorrect. Rational numbers are not the same thing as fractions: many fractions such as \(\frac{1}{2}\) and \(\frac{2}{4}\) can represent the same rational number. It is more correct to say that a rational number is a number which can be represented as a fraction. (A similar distinction can be made for integers: an integer is a number that can be represented as a difference of natural numbers, but integers are not the same thing as differences of natural numbers.) Saying that rational numbers are fractions leads to other logical problems. For example, is \(\cos \frac{\pi}{2}\) a rational number? What about \(\sum_{k=0}^{\infty} \frac{1}{3^k}\)?

III.4.1.2. The axioms satisfied by \(\mathbb{Q}\) are very similar to the ones satisfied by \(\mathbb{Z}\), along with an additional axiom stating that every nonzero element of \(\mathbb{Q}\) has a multiplicative inverse. We state them in the ordered field form in analogy with III.3.6.7. (These are not the most efficient axioms, but are the ones most commonly used.)

**Ordered Field Axioms for \(\mathbb{Q}\)**

(Op) There are two binary operations \(+\) and \(\cdot\) on \(\mathbb{Q}\).

(A1) The binary operation \(+\) is associative.

(A2) The binary operation \(+\) is commutative.

(A3) There is an element \(0 \in \mathbb{Q}\) such that \(x + 0 = 0 + x = x\) for all \(x \in \mathbb{Q}\).

(A4) For every \(x \in \mathbb{Q}\) there is an element \((-x) \in \mathbb{Q}\) with \(x + (-x) = (-x) + x = 0\).

(M1) The binary operation \(\cdot\) is associative.

(M2) The binary operation \(\cdot\) is commutative.

(M3) There is an element \(1 \in \mathbb{Q}\) such that \(x \cdot 1 = 1 \cdot x = x\) for all \(x \in \mathbb{Q}\).

(M4) For every \(x \in \mathbb{Q}\), \(x \neq 0\), there is an element \(x^{-1} \in \mathbb{Q}\) with \(x^{-1} x = xx^{-1} = 1\).

(D) The operation \(\cdot\) distributes over addition.

(Pos) There is a nonempty subset \(P\) of \(\mathbb{Q}\) such that

(P1) If \(x, y \in P\), then \(x + y \in P\).

(P2) If \(x, y \in P\), then \(xy \in P\).

(P3) \(0 \notin P\).

(P4) If \(x \in \mathbb{Q}\), \(x \neq 0\), then either \(x \in P\) or \((-x) \in P\), but not both.

(Min\(\mathbb{Q}\)) \(P\) is the smallest subset \(A\) of \(\mathbb{Q}\) containing 1, such that \(x \in A\) implies \(x + 1 \in A\) and \(x \in A\) implies \(x^{-1} \in A\).

As with \(\mathbb{Z}\), the axiom (Ord) may be used in place of (Pos):
There is a nonempty relation (strict total order) \(<\) on \(\mathbb{Q}\), such that

(O1) If \(x, y \in \mathbb{Q}\), then exactly one of \(x < y\), \(y < x\), \(x = y\) holds.  \((\text{Trichotomy})\)

(O2) If \(x, y, z \in \mathbb{Q}\), \(x < y\), and \(y < z\), then \(x < z\).  \((\text{Transitivity})\)

(O3) If \(x, y, z \in \mathbb{Q}\) and \(x < y\), then \(x + z < y + z\).  \((\text{Translation Invariance})\)

(O4) If \(x, y, z \in \mathbb{Q}\), \(x < y\), and \(0 < z\), then \(xz < yz\).  \((\text{Homogeneity or Scaling Invariance})\)

III.4.1.3. A set with two binary operations satisfying (A1)–(A4), (M1)–(M4), and (D), and in which

\(0 \neq 1\), is called a field. A field satisfying (Pos) is an ordered field (note that an ordered field contains more

than one element by (Pos), so \(0 \neq 1\) automatically by III.3.6.4.(iii)).

A field is just a unital commutative ring in which every nonzero element has a multiplicative inverse. There are fields with finitely many elements (Exercise III.4.3.1.). An ordered field looks more like \(\mathbb{Q}\) (Exercise III.4.3.7.), but there are many other ordered fields such as \(\mathbb{R}\); see also Exercises III.5.3.1. and III.5.3.3.(d). See also Exercise III.6.3.2. for an interesting fieldlike ring which is not commutative.

III.4.2. The Standard Model of \(\mathbb{Q}\)

We can form a standard model for \(\mathbb{Q}\) in much the same manner as for \(\mathbb{Z}\), although the construction will be

slightly more complicated since we must explicitly extend both addition and multiplication. The idea is that rational numbers can be represented by equivalence classes of fractions \(\frac{x}{y}\), where \(x \in \mathbb{Z}\), \(y \in \mathbb{N}\), and \(\frac{x}{y} = \frac{z}{w}\) if and only if \(xw = yz\).

III.4.2.1. Definition. Define a relation \(\sim\) on \(\mathbb{Z} \times \mathbb{N}\) by \((x_1, y_1) \sim (x_2, y_2)\) if \(x_1y_2 = x_2y_1\).

We think of \((x, y)\) as representing the rational number \(\frac{x}{y}\). We could just as well work on \(\mathbb{Z} \times (\mathbb{Z} \setminus \{0\})\).

III.4.2.2. Proposition. (i) The relation \(\sim\) is an equivalence relation on \(\mathbb{Z} \times \mathbb{N}\).

(ii) If \((x_1, y_1) \sim (x_2, y_2)\) and \((z_1, w_1) \sim (z_2, w_2)\), then \((x_1w_1 + y_1z_1, y_1w_1) \sim (x_2w_2 + y_2z_2, y_2w_2)\) and \((x_1z_1, y_1w_1) \sim (x_2z_2, y_2w_2)\).

Proof: This is a straightforward calculation and is left to the reader. ⊥

The operations in (ii) are motivated by the informal (at this point) relations

\[
\frac{x}{y} + \frac{z}{w} = \frac{xw + yz}{yw} \quad \text{and} \quad \frac{x}{y} \frac{z}{w} = \frac{xz}{yw}.
\]

We use these relations to define addition and multiplication:

III.4.2.3. Definition. Let \(\mathbb{Q}\) be the set of equivalence classes for \(\sim\). If \([x, y], [z, w] \in \mathbb{Q}\), define

\([x, y] + [z, w] = [(xw + yz, yw)]\) \quad \text{and} \quad \([x, y] [z, w] = [(xz, yw)]\).
III.4.2.4. **Proposition.** Addition and multiplication are well-defined binary operations on $\mathbb{Q}$ making $\mathbb{Q}$ into a field.

**Proof:** Addition and multiplication are well defined by III.4.2.2.(ii). The associative law for multiplication, and the commutative laws for addition and multiplication, are obvious. The associative law for addition and the distributive law are straightforward calculations from the ring axioms of $\mathbb{Z}$, and are left to the reader.

The 0 element is $[(0,1)]$; it is obvious that $[(0,1)] + [(x,y)] = [(x,y)] + [(0,1)] = [(x,y)]$ for all $x,y$. Similarly, the negative of $[(x,y)]$ is $[(-x,y)]$, as is easily verified.

The 1 element is $[(1,1)]$. If $x \in \mathbb{N}$ (and of course $y \in \mathbb{N}$), then $[(x,y)]^{-1} = [(y,x)]$; if $(-x) \in \mathbb{N}$, then $[(x,y)]^{-1} = [(-y,-x)]$. These formulas can be easily verified by the reader. $lacksquare$

### III.4.3. Exercises

**III.4.3.1.** Let $\mathbb{Z}_n$ be as in Exercise III.3.7.5. Show that $\mathbb{Z}_n$ is a field if and only if $n$ is prime. [If $n > 1$ is not prime, there are $x,y \in \mathbb{Z}_n$ with $x \neq 0$ and $y \neq 0$ but $xy = 0$. If $n$ is prime, show that, for any $x \in \mathbb{Z}_n$, $x \neq 0$, the function $\phi_x : \mathbb{Z}_n \to \mathbb{Z}_n$ given by $\phi_x(y) = xy$ is injective. Use finiteness of $\mathbb{Z}_n$ to conclude that $\phi_x$ is also surjective.]

In particular, $\mathbb{Z}_2$ is a field with only two elements.

**III.4.3.2.** Let $F$ be a field. Let $\phi$ be the ring-homomorphism from $\mathbb{Z}$ to $F$ defined in Exercise III.3.7.6. (a) If the ideal $J$ of III.3.7.6.(c) is $\{0\}$, show that the injective ring-homomorphism $\phi$ extends to an injective ring-homomorphism from $\mathbb{Q}$ to $F$, also denoted $\phi$. Show that $\phi(\mathbb{Q})$ is the smallest subfield of $F$.

(b) If the ideal $J$ is $n\mathbb{Z}$, show that $n$ is prime, and $\phi(\mathbb{Z}) \cong \mathbb{Z}_n$ is the smallest subfield of $F$. [Use Exercises III.4.3.1. and III.3.7.6.(c).]

The number $n$ in case (b) is called the characteristic of $F$. In case (a), $F$ is said to have characteristic zero. Thus, for example, $\mathbb{Z}_p$ has characteristic $p$ and the fields of analysis, including $\mathbb{Q}$, $\mathbb{R}$, and $\mathbb{C}$, have characteristic zero.

**III.4.3.3.** (a) Show that $\mathbb{Z} + \mathbb{Z}\sqrt{2} = \{x + y\sqrt{2} : x,y \in \mathbb{Z}\}$ is a subring of $\mathbb{R}$.

(b) Show that $\mathbb{Q} + \mathbb{Q}\sqrt{2} = \{x + y\sqrt{2} : x,y \in \mathbb{Q}\}$ is a subfield of $\mathbb{R}$.

(c) Do the same for the subsets $\mathbb{Z} + \mathbb{Z}i$ and $\mathbb{Q} + \mathbb{Q}i$ of $\mathbb{C}$. Generalize. What if $\sqrt{2}$ is replaced by $\sqrt{2}$? By $\pi$?

(d) If $\mathbb{Q} + \mathbb{Q}\sqrt{2}$ is regarded as a subset of $\mathbb{R}$, the ordering on $\mathbb{R}$ induces an ordering on $\mathbb{Q} + \mathbb{Q}\sqrt{2}$ making it into an ordered field. Can $\mathbb{Q} + \mathbb{Q}i$ be made into an ordered field? [If $P$ is a positive cone in $\mathbb{Q} + \mathbb{Q}i$, then either $i \in P$ or $(-i) \in P$; in either case $(-1) \in P$.]

**III.4.3.4.** **Rings of Fractions.** Here is a construction which generalizes the construction of $\mathbb{Q}$ from $\mathbb{Z}$. Let $R$ be a commutative ring, and $D$ a nonempty subset of $R$ which is closed under multiplication and which does not contain 0 or any zero divisor (the construction can be done more generally, but then becomes rather artificial and degenerate). We will embed $R$ into a larger unital commutative ring $D^{-1}R$, in which the elements of $D$ have multiplicative inverses.

(a) Put a relation $\sim$ on $R \times D$ by setting $(x_1,y_1) \sim (x_2,y_2)$ if $x_1y_2 = x_2y_1$. Show that $\sim$ is an equivalence relation. [Use Exercise 14.]
Let $D^{-1}R$ be the set of $\sim$-equivalence classes. Show that $[(x, y)] + [(z, w)] = [(xw + yz, yw)]$ and $[(x, y)][(z, w)] = [(xz, yw)]$ give well-defined binary operations making $D^{-1}R$ into a unital commutative ring. [Think of $[(x, y)]$ as representing $\frac{x}{y}$.]

(c) Show that $\iota : R \to D^{-1}R$ given by $\iota(x) = [(xy, y)]$ for $y \in D$ is a well-defined injective ring-homomorphism.

(d) Show that every element of $D$ has a multiplicative inverse in $D^{-1}R$.

The ring $D^{-1}R$ is called the ring of fractions of $R$ with denominator $D$. In the special case where $R$ is an integral domain (Exercise III.3.7.8.) and $D$ is the set of nonzero elements of $R$, $D^{-1}R$ is a field, called the quotient field, or field of fractions, of $R$.

III.4.3.5. Use the notation and terminology of Exercise III.4.3.4.

(a) Describe $D^{-1}Z$, where $D$ is the set of powers of 2 in $\mathbb{N}$. This ring is called the ring of dyadic rationals.

(b) Describe $D^{-1}Z$, where $D$ is the set of odd numbers in $\mathbb{N}$. This ring is called the ring of integers localized at 2.

(c) Describe the quotient field of the ring $\mathbb{R}[X]$ of Exercise III.6.3.3. (cf. Exercise ()). This quotient field, usually denoted $\mathbb{R}(X)$, is, by slight abuse of language, called the field of rational functions in one variable with real coefficients. Explain why it is a slight abuse of language to call the elements of this field “functions.” [Consider the “functions” $f(X) = X + 1$ and $g(X) = \frac{X^2 + 1}{X - 1}$.]

III.4.3.6. Show that a field $F$ can be made into an ordered field if and only if 0 is not a sum of nonzero squares in $F$ (such an $F$ is said to be formally real). [The set $S$ of all quotients of sums of nonzero squares is closed under addition, multiplication, and reciprocals. Using Zorn’s Lemma, embed $S$ into a maximal set closed under addition, multiplication, and reciprocals, and not containing 0.] This is a version of the Artin-Schreier Theorem: every formally real field can be embedded in a real-closed field.

III.4.3.7. If $F$ is an ordered field, show that the homomorphism $\phi : Z \to F$ of Exercise III.3.7.6. is injective, and hence by Exercise III.4.3.2.(a) extends to an embedding of $\mathbb{Q}$ into $F$. Show that the induced ordering on $\mathbb{Q}$ is the ordinary one.
III.5. The Real Numbers

III.5.1. Construction of $\mathbb{R}$: the Dedekind Cut Approach

There are two standard approaches to the construction of the real numbers: via Dedekind cuts or via Cauchy sequences. (There is another nice approach using nonstandard analysis (III.10.8.12.).) Both are worthwhile, and each has uses and leads to insights about $\mathbb{R}$ not as easily obtainable from the other. The Dedekind cut approach (originally due, not surprisingly, to R. Dedekind in ()) is arguably slightly simpler, so we describe it first, in this section.

III.5.1.1. The idea is that if $a$ is a real number, then $a$ "cuts" the set of rational numbers into two sets $L_a = \{ x \in \mathbb{Q} : x < a \}$ and $U_a = \{ x \in \mathbb{Q} : x \geq a \}$ (if $a$ is irrational, then $U_a = \{ x \in \mathbb{Q} : x > a \}$; if $a$ is rational, we arbitrarily put it in $U_a$ instead of $L_a$). Every element of $L_a$ is smaller than every element of $U_a$, and we have $\sup(L_a) = \inf(U_a) = a$ (). Conversely, if $(L, U)$ is a division of $\mathbb{Q}$ into two nonempty subsets with each element of $L$ less than every element of $U$, by completeness there will be a real number $a$, e.g. $a = \sup(L) = \inf(U)$, so that $L = L_a$ (provided $L$ has no largest element) and $U = U_a$. Thus there is a one-one correspondence between real numbers and such pairs of subsets of $\mathbb{Q}$, which are called Dedekind cuts.

We may turn this argument around to define real numbers to be Dedekind cuts. (Technically, this will give us a model for $\mathbb{R}$.) In fact, the entire algebraic and order structure on $\mathbb{R}$ can be described directly in terms of the cuts in a fairly simple manner.

It turns out to be technically much easier to work only with positive numbers at first, i.e. to construct a model $\mathcal{P}$ of the set $\mathbb{P}$ of positive real numbers using Dedekind cuts in the set $\mathbb{Q}^+$ of positive rational numbers. The model for the whole set of real numbers is then constructed from $\mathcal{P}$ in a manner similar to the construction of $\mathbb{Z}$ from $\mathbb{N}$. (This approach is used in [Lan51].)

III.5.1.2. Definition. (i) A subset $S$ of $\mathbb{Q}^+ = \{ x \in \mathbb{Q} : x > 0 \}$ is hereditary if $x \in S$, $y \in \mathbb{Q}^+$, $y < x$ imply $y \in S$.

(ii) A lower set in $\mathbb{Q}^+$ is a nonempty hereditary subset of $\mathbb{Q}^+$ which is bounded above and has no largest element.

(iii) An upper set in $\mathbb{Q}^+$ is a subset $U$ of $\mathbb{Q}^+$ such that $\mathbb{Q}^+ \setminus U$ is a lower set in $\mathbb{Q}^+$.

(iv) A Dedekind cut in $\mathbb{Q}^+$ is a pair $(L, U)$, where $L$ is a lower set in $\mathbb{Q}^+$ and $U = \mathbb{Q}^+ \setminus L$.

The next simple observation is obvious, but important.

III.5.1.3. Proposition. If $(L, U)$ is a Dedekind cut in $\mathbb{Q}^+$, $x \in L$, and $y \in U$, then $x < y$.

Proof: We must have $x < y$ since $L$ is hereditary.
III.5.1.4. **Examples.** (i) If \( a \in \mathbb{Q}_+ \), set \( L_a = \{ x \in \mathbb{Q}_+ : x < a \} \) and \( U_a = \{ x \in \mathbb{Q}_+ : x \geq a \} = \mathbb{Q}_+ \setminus L_a \). \( L_a \) is nonempty since \( \frac{1}{n} < a \) for some \( n \in \mathbb{N} \) by (i), and \( L_a \) is bounded above by \( a \). \( L_a \) has no largest element since if \( x \in L_a \), then \( y = (a + x)/2 \in L_a \) and \( x < y \). \( L_a \) is hereditary by transitivity of \(<\). Thus \( L_a \) is a lower set, \( U_a \) is an upper set, and \((L_a, U_a)\) is a Dedekind cut in \( \mathbb{Q}_+ \). The set \( L_a \) is often denoted \( a^* \).

(ii) It is not *a priori* obvious that there are Dedekind cuts in \( \mathbb{Q}_+ \) not of the form \((L_a, U_a)\) for \( a \in \mathbb{Q}_+ \), but it turns out that there are very many which are not. Here is an example which is at least not obviously of this form. Let

\[
L = \{ x \in \mathbb{Q}_+ : x^2 < 2 \}
\]

and \( U = \mathbb{Q}_+ \setminus L \). \( L \) is hereditary since if \( 0 < y < x \), then \( y^2 < x^2 \). \( 1 \in L \), so \( L \) is nonempty, and \( L \) is bounded above since if \( x \in L \), we have \( x < 2 \) since \( x^2 < 2^2 \).

We show that \( L \) has no largest element. If \( x \in L \), set \( z = \frac{4 + \sqrt{2x}}{3 + 2x} \). Then

\[
z - x = \frac{4 - 2x^2}{3 + 2x} > 0 \quad \text{and} \quad 2 - z^2 = \frac{2 - x^2}{(3 + 2x)^2} > 0
\]

by a simple computation; thus \( x < z \) and \( z \in L \).

Although there is no obvious \( a \in \mathbb{Q}_+ \) for which \( L = L_a \), it takes a little work to show that in fact there is no such \( a \) (I.5.5.).

(iii) The only hereditary subset of \( \mathbb{Q}_+ \) which is not bounded above is all of \( \mathbb{Q}_+ \). For if \( S \) is such a set, and \( y \in \mathbb{Q}_+ \), then \( y \) is not an upper bound for \( S \), so there is an \( x \in S \) with \( y < x \). But then \( y \in S \) since \( S \) is hereditary, so \( S = \mathbb{Q}_+ \). Therefore a nonempty proper subset of \( \mathbb{Q}_+ \) which is hereditary and has no largest element is automatically a lower set.

(iv) An arbitrary union or intersection of hereditary subsets of \( \mathbb{Q}_+ \) is hereditary. An arbitrary union of lower sets is either \( \mathbb{Q}_+ \) or a lower set. A finite intersection of lower sets is a lower set. However, an arbitrary intersection of lower sets is not necessarily a lower set: it can be empty (e.g. \( \cap_n L_{1/n} = \emptyset \)) or it may have a largest element (e.g. \( \cap_n L_{1+1/n} \)).

(v) If \( S \) is a (necessarily proper) hereditary subset of \( \mathbb{Q}_+ \) which has a largest element \( a \), let \( L = S \setminus \{a\} \). Then \( L \) is nonempty (\( \frac{1}{n} \in L \) for sufficiently large \( n \)), bounded above (by \( a \)), and hereditary. \( L \) also has no largest element since if \( x \in L \), then \( y = (x + a)/2 \) is in \( L \) and \( x < y \). Thus \( L \) is a lower set. In fact, \( L \) is exactly \( L_a \) of (i).

Here is a useful technical fact about Dedekind cuts:

III.5.1.5. **Theorem.** Let \((L, U)\) be a Dedekind cut in \( \mathbb{Q}_+ \), and \( \epsilon \in \mathbb{Q}_+ \). Then there exist \( x \in L \) and \( y \in U \), \( y \) not minimal in \( U \), with \( y - x = \epsilon \).

**Proof:** Fix \( a \in L \) and \( b \in U \). The set \( \{a + n\epsilon : n \in \mathbb{N}\} \) is unbounded in \( \mathbb{Q}_+ \) by (), hence there is an \( n \) with \( a + n\epsilon > b \), and \( a + n\epsilon \in U \) for this \( n \). Thus there is a smallest \( n \) for which \( a + n\epsilon \in U \). For this smallest \( n \), set \( x = a + (n - 1)\epsilon \) and \( y = n\epsilon \). To insures that \( y \) is not the smallest element of \( U \), replace \( x \) and \( y \) by \( x + \frac{1}{m} \) and \( y + \frac{1}{m} \), where \( m \in \mathbb{N} \) is large enough that \( x + \frac{1}{m} \in L \). \( \square \)

280
We now make our main definition:

III.5.1.6. Definition. \( \mathcal{P} \) denotes the set of all lower subsets of \( \mathbb{Q}^+ \).

Ordering on \( \mathcal{P} \)

III.5.1.7. \( \mathcal{P} \) is naturally ordered by inclusion. If \( L, L' \in \mathcal{P} \), write \( L \leq L' \) if \( L \subseteq L' \), and \( L < L' \) if \( L \subseteq L' \) and \( L \neq L' \), i.e. if \( L \) is a proper subset of \( L' \). This ordering is antisymmetric: if \( L \leq L' \) and \( L' \leq L \), then \( L = L' \), or alternatively, at most one of \( L = L' \), \( L < L' \) and \( L' < L \) holds.

Transitivity of this ordering is obvious.
As usual, we will also write \( L' \geq L \) if \( L \leq L' \), and \( L' > L \) if \( L < L' \).

III.5.1.8. Proposition. The ordering \( \leq \) is a total ordering on \( \mathcal{P} \), i.e. if \( L, L' \in \mathcal{P} \), then either \( L \leq L' \) or \( L' \leq L \). Alternatively, exactly one of \( L < L' \), \( L = L' \), \( L' < L \) holds.

Proof: If \( L = L' \), there is nothing to prove. Suppose there is an \( a \in L' \) with \( a \notin L \). Thus \( a \in \mathbb{Q}^+ \setminus L \), so \( x < a \) for all \( x \in L \) by III.5.1.3.. But any such \( x \) is in \( L' \) since \( L' \) is hereditary, so \( L \subseteq L' \).

Completeness of this ordering is deceptively simple:

III.5.1.9. Proposition. If \( \mathcal{L} = \{ L_i : i \in I \} \) is a nonempty subset of \( \mathcal{P} \) which is bounded above, then \( \mathcal{L} \) has a supremum (least upper bound) in \( \mathcal{P} \).

Proof: \( \mathcal{L} \) is bounded above if (and only if) there is an \( L' \in \mathcal{P} \) with \( L_i \subseteq L' \) for all \( i \in I \). Fix such an \( L' \). Let \( L = \bigcup_{i \in I} L_i \). Since \( L \subseteq L' \), \( L \) is a proper subset of \( \mathbb{Q}^+ \), hence is a lower set by III.5.1.4.(iii)–(iv). We have \( L_i \leq L \) for all \( i \), and if \( L'' \in \mathcal{P} \) with \( L_i \leq L'' \) for all \( i \), then \( L \leq L'' \), so \( L \) is the least upper bound of \( \mathcal{L} \) in \( \mathcal{P} \).

Infima can be done similarly, but there is a slight technical glitch:

III.5.1.10. Proposition. If \( \mathcal{L} = \{ L_i : i \in I \} \) is a nonempty subset of \( \mathcal{P} \) which is bounded below, then \( \mathcal{L} \) has an infimum (greatest lower bound) in \( \mathcal{P} \).

Proof: \( \mathcal{L} \) is bounded below if (and only if) there is an \( L' \in \mathcal{P} \) with \( L' \subseteq L_i \) for all \( i \in I \). Fix such an \( L' \). Let \( S = \bigcap_{i \in I} L_i \). Since \( L' \subseteq S \), \( S \) is nonempty, and is a proper hereditary subset of \( \mathbb{Q}^+ \). But \( S \) could have a largest element. If \( S \) has no largest element, set \( L = S \), and if \( S \) has a largest element \( a \), set \( L = S \setminus \{ a \} \). In either case \( L \) is a lower set (cf. III.5.1.4.(v)). We have \( L \leq L_i \) for all \( i \), and if \( L'' \in \mathcal{P} \) with \( L'' \leq L_i \) for all \( i \), then \( L'' \leq L \), so \( L \) is the greatest lower bound of \( \mathcal{L} \) in \( \mathcal{P} \).

III.5.1.11. So far, we could have equally well worked with Dedekind cuts on all of \( \mathbb{Q} \), and defined \( \mathbb{R} \) as an ordered set; restriction to positive numbers only has no advantages to this point. But defining the algebraic operations on \( \mathbb{R} \) is a little messy, and it is much cleaner and easier to work with \( \mathcal{P} \) instead.
Algebraic Operations on $\mathcal{P}$

We first make a general definition of sums and products of subsets of $\mathbb{Q}_+$:

III.5.1.12. Definition. Let $A$ and $B$ be subsets of $\mathbb{Q}_+$. Define

\[
A + B = \{x + y : x \in A, y \in B\}
\]
\[
AB = \{xy : x \in A, y \in B\}.
\]

Note that $A + B$ and $AB$ are subsets of $\mathbb{Q}_+$ since $\mathbb{Q}_+$ is closed under addition and multiplication.

III.5.1.13. Caution: Some authors, especially in older references or in the context of Boolean algebras, write $A + B$ for $A \cup B$ and $AB$ for $A \cap B$. We will never use these meanings of $A + B$ and $AB$. Note that $A + B$ (as we have defined it) and $A \cup B$ are quite different in general, as are $AB$ and $A \cap B$.

III.5.1.14. Proposition. Let $L$ and $L'$ be lower sets in $\mathbb{Q}_+$. Then $L + L'$ and $LL'$ are lower sets in $\mathbb{Q}_+$.

Proof: $L + L'$ and $LL'$ are clearly nonempty. If $m$ and $n$ are upper bounds for $L$ and $L'$ respectively, then $m + n$ and $mn$ are upper bounds for $L + L'$ and $LL'$ respectively by ().

We show $L + L'$ is hereditary. If $z \in L + L'$ and $w \in \mathbb{Q}_+$, $w < z$, write $z = x + y$ for $x \in L, y \in L'$. If $w \leq y$, there is an $n \in \mathbb{N}$ such that $\frac{1}{n} < w$ and $\frac{1}{n} < x$; then $\frac{1}{n} \in L$ and $0 < w - \frac{1}{n} < y$, so $y - \frac{1}{n} \in L'$ and $w = \frac{1}{n} + (w - \frac{1}{n}) \in L + L'$. On the other hand, if $y < w$, we have $0 < w - y < z - y = x$, so $(w - y) \in L$, and $w = (w - y) + y \in L + L'$ again.

The proof that $LL'$ is hereditary is easier. If $z \in LL'$ and $w \in \mathbb{Q}_+$, $w < z$, write $z = xy$ for $x \in L, y \in L'$. Then $w < xy$, so $0 < \frac{w}{y} < x$ and hence $\frac{w}{y} \in L$ and $w = \frac{w}{y}y \in LL'$.

Finally, we show that $L + L'$ and $LL'$ have no maximal elements. Let $z \in L + L'$, and write $z = x + y$ for $x \in L, y \in L'$. Since $L$ has no largest element, there is an $r \in L$ with $x < r$. Then $r + y \in L + L'$, and $z < r + y$. The proof for $LL'$ is similar.

It is now clear how to define addition and multiplication in $\mathcal{P}$:

III.5.1.15. Definition. Define binary operations $+$ and $\cdot$ on $\mathcal{P}$ to be sum and product as defined in III.5.1.12.

As usual, we will write the product of $L$ and $L'$ either as $L \cdot L'$ or $LL'$. We will use the usual convention of grouping multiplication before addition, e.g. $LL' + L'' = (LL') + L''$.

The usual algebraic properties of addition and multiplication in $\mathcal{P}$ follow easily from those in $\mathbb{Q}$:
III.5.1.16. Proposition. Let \( L, L', L'' \in \mathcal{P} \). Then

(i) \((L + L') + L'' = L + (L' + L'')\) and \((LL')L'' = L(LL'')\). (Associative Law)

(ii) \(L + L' = L' + L\) and \(LL' = L'L\). (Commutative Law)

(iii) \(L(L' + L'') = LL' + LL''\). (Distributive Law)

Proof: The proofs are quite easy, and all are essentially identical. We prove the associative law for addition, and leave the others to the reader. We have

\[
(L + L') + L'' = \{x + y + z : x \in L, y \in L', z \in L''\}
\]

\[
L + (L' + L'') = \{x + (y + z) : x \in L, y \in L', z \in L''\}
\]

and by the associative law in \(\mathbb{Q}\) (A1), these two subsets of \(\mathbb{Q}_+\) are identical.

III.5.1.17. Proposition. The element \(1^* = L_1 = \{x \in \mathbb{Q}_+ : x < 1\}\) is a multiplicative identity for \(\mathcal{P}\), i.e. \(1^* \cdot L = L\) for any \(L \in \mathcal{P}\).

Proof: Let \(L \in \mathcal{P}\). Since \(L\) is hereditary, it is clear that \(1^* \cdot L \leq L\). On the other hand, if \(x \in L\), choose \(y \in L\) with \(x < y\) (since \(L\) has no largest element); then \(\frac{x}{y} < 1\), so \(\frac{x}{y} \in 1^*\), and \(x = \frac{x}{y} \in 1^* \cdot L\).

On the lower sets coming from elements of \(\mathbb{Q}_+\) as in III.5.1.4(i), addition and multiplication in \(\mathcal{P}\) agree with addition and multiplication in \(\mathbb{Q}_+\):

III.5.1.18. Proposition. Let \(a, b \in \mathbb{Q}_+\), and \(L_a = \{x \in \mathbb{Q}_+ : x < a\}\) and \(L_b = \{x \in \mathbb{Q}_+ : x < b\}\) the corresponding elements of \(\mathcal{P}\). Then \(L_a + L_b = L_{a+b}\) and \(L_aL_b = L_{ab}\).

Proof: It is obvious from (i) that \(L_a + L_b \leq L_{a+b}\). By \(L_a + L_b\), i.e. \(z < a + b\), set \(d = a + b - z\). Then \(x = a - \frac{d}{2} \in L_a\) and \(y = b - \frac{d}{2} \in L_b\), and \(z = x + y \in L_{a+b}\).

For the product, it follows from (i) that \(L_aL_b \leq L_{ab}\). If \(z \in L_{ab}\), we have \(\frac{z}{2} < a\). Choose \(x \in \mathbb{Q}_+\) with \(\frac{z}{2} < x < a\), so \(x \in L_a\). Then \(\frac{z}{2} < b\), so \(y = \frac{z}{2} \in L_b\), and \(z = xy \in L_{ab}\).

Multiplicative Inverses

III.5.1.19. Every element of \(\mathcal{P}\) has a multiplicative inverse, but the argument has a slight subtlety. Suppose \(L \in \mathcal{P}\), and \(U = \mathbb{Q}_+ \setminus L\) is the corresponding upper set. Since inversion reverses order (i), we should have

\[
L^{-1} = \{x^{-1} : x \in U\}.
\]

However, this may not be a lower set since it might have a largest element. In fact, this will happen if and only if \(L = L_a\) for some \(a \in \mathbb{Q}_+\) (we then obtain the set \(\{x \in \mathbb{Q}_+ : x \leq a^{-1}\}\)). In this case, we take \(L^{-1} = \{x \in \mathbb{Q}_+ : x < a^{-1}\} = L_{a^{-1}}\). Thus we define \(L^{-1}\) differently depending on whether or not \(L = L_a\) for some \(a \in \mathbb{Q}_+\).
III.5.1.20. \textbf{Proposition.} If $L \in \mathcal{P}$, and $L^{-1}$ is defined as above, then $L^{-1}$ is a lower set and $LL^{-1} = 1$.

\textbf{Proof:} Clearly $L^{-1}$ is nonempty. Suppose $x \in L^{-1}$, $y \in \mathbb{Q}_+$, and $y < x$. Then $x^{-1} < y^{-1}$ and since $x \notin L$, we have $y \notin L$ also since $L$ is hereditary. Thus $y \in U$ and $y^{-1} \in L^{-1}$. So $L^{-1}$ is hereditary. If $x \in L$, then $y^{-1} < x^{-1}$ for all $y \in U$ by (b) and III.5.1.3; hence $x^{-1}$ is an upper bound for $L^{-1}$. If $S = \{x^{-1} : x \in U\}$ has a largest element $b$, then $L^{-1} = S \setminus \{b\}$. If $x \in L^{-1}$, i.e. $x^{-1} \in U$ and $x < b$, and $y \in \mathbb{Q}_+$ with $x < y < b$ (e.g. $y = (x + b)/2$), then $y^{-1} > b^{-1}$, so $y \in S$, and $y \neq b$, so $y \in L^{-1}$; thus $L^{-1}$ has no largest element in any case. So $L^{-1} \in \mathcal{P}$.

If $x \in L$ and $y \in L^{-1}$, then $y^{-1} \in U$, so $x < y^{-1}$ and therefore $y < x^{-1}$, so $xy < xx^{-1} = 1$. Thus $LL^{-1} \leq 1$.

The opposite inequality is trickier. We use III.5.1.5. Fix $a \in L$. If $z < 1$, choose $x \in L$ and $y \in U$, $y$ not minimal in $U$, with $y - x = a(1 - z)$. Then $\frac{z}{y} \in LL^{-1}$, and

$$1 - \frac{x}{y} = \frac{a}{y}(1 - z) < 1 - z$$

since $a < y$. Thus $z < \frac{z}{y}$ and $z \in LL^{-1}$.

There are no additive inverses in $\mathcal{P}$. There is not even an additive identity:

III.5.1.21. \textbf{Proposition.} Let $L, L' \in \mathcal{P}$. Then $L < L + L'$.

\textbf{Proof:} If $x \in L$ and $y \in L'$, then $x < x + y \in L + L'$, so $x \in L + L'$ and $L \leq L + L'$. Set $U = \mathbb{Q}_+ \setminus L$. Fix $z \in L'$, and by III.5.1.5. choose $x \in L$, $y \in U$ with $y - x = z$. Then $y = x + z \in L + L'$, but $y \notin L$.

\textbf{Cancellation}

Cancellation for multiplication follows immediately from the existence of inverses:

III.5.1.22. \textbf{Proposition.} If $L, L', L'' \in \mathcal{P}$ and $LL' = LL''$, then $L' = L''$.

\textbf{Proof:} We have $L^{-1}(LL') = L^{-1}(LL'')$. But we have

$$L^{-1}(LL') = (L^{-1}L)L' = 1^* \cdot L' = L'$$

and similarly $L^{-1}(LL'') = L''$, so $L' = L''$.

Additive cancellation takes more work since there are no additive inverses. We first show that $<$ is translation-invariant:
III.5.1.23. **Proposition.** Let \( L, L', L'' \in P \). If \( L < L' \), then \( L + L'' < L' + L'' \).

**Proof:** It is obvious that \( L + L'' \leq L' + L'' \). Fix \( a \in L' \setminus L \), and \( b \in L' \) with \( a < b \). Let \( U'' = \mathbb{Q}_+ \setminus L'' \), and \( x \in L'' \), \( y \in U'' \) with \( y - x = b - a \) (III.5.1.5.). Then \( z = b + x \in L' + L'' \), but if \( z = s + t \) for \( s \in L \), \( t \in L'' \), we have \( s < a \), so \( b - s > b - a = y - x \), so \( t = z - s = (b - s) + x > (y - x) + x = y \), a contradiction. Thus \( z \in (L' + L'') \setminus (L + L'') \).

Additive cancellation then follows:

III.5.1.24. **Corollary.** Let \( L, L', L'' \in P \). If \( L + L'' < L' + L'' \), then \( L < L' \). If \( L + L'' = L' + L'' \), then \( L = L' \).

**Proof:** Either \( L < L' \), \( L = L' \), or \( L > L' \). In these cases \( L + L'' < L' + L'' \), \( L + L'' = L' + L'' \), and \( L + L' > L' + L'' \) respectively.

**Subtraction**

We also get subtraction defined to the extent possible in light of III.5.1.21.:

III.5.1.25. **Proposition.** Let \( L, L' \in P \). If \( L < L' \), then there is a unique \( L'' \in P \) such that \( L + L'' = L' \).

**Proof:** Uniqueness follows immediately from III.5.1.24. We show existence. Set \( U = \mathbb{Q}_+ \setminus L \), and let

\[
L'' = \{ x - y : x \in L', \ y \in U, \ y < x \} .
\]

We show \( L'' \) is a lower set. If \( y \in L' \setminus L \) and \( x \in L' \), \( y < x \), then \( x - y \in L'' \), so \( L'' \) is nonempty. If \( x \in L' \), \( y \in U \), and \( z \notin L' \), then \( x - y < x < z \), so \( z \notin L'' \) and \( L'' \) is bounded. If \( t \in L'' \) and \( 0 < s < t \), write \( t = x - y \) for \( x \in L' \), \( y \in U \), \( y < x \); then \( s + y < t + y \in L' \), and \( s = (s + y) - y \), so \( s \in L'' \). Thus \( L'' \) is hereditary. Finally, if \( t \in L'' \) with \( t = x - y \) for \( x \in L'' \), \( y \in U \), \( y < x \), let \( w \in L' \), \( x < w \); then \( s = w - y \in L'' \) and \( t < s \), so \( L'' \) has no largest element. Thus \( L'' \in P \).

If \( z \in L + L'' \), write \( z = w + (x - y) \) with \( w \in L \), \( x \in L' \), \( y \in U \), \( y < x \). Then \( w < y \), so \( z < w + (x - w) = x \in L' \), so \( z \in L' \). Thus \( L + L'' \leq L' \).

If \( z \in L' \), let \( b \in L' \), \( z < b \), and by III.5.1.5. choose \( x \in L \) and \( y \in U \) with \( y - x = b - z \). Then \( z - x = b - y \in L'' \), and \( z = x + (z - x) \in L + L'' \), \( L' \leq L + L'' \).

**Notation**

We now streamline our notation for elements of \( P \), eliminating the clumsy \( L, L' \), etc.

III.5.1.26. By III.5.1.18., the map \( \phi : \mathbb{Q}_+ \to P \) given by \( \phi(a) = L_a \) preserves addition and multiplication.

It is obvious that \( \phi \) is also order-preserving, i.e. if \( a < b \), then \( L_a < L_b \). We will identify \( \mathbb{Q}_+ \) with its image in \( P \), and just write \( a \) instead of \( \phi(a) \), \( L_a \), or \( a^* \), unless there is possibility of confusion.
III.5.1.27. Proposition. The image of $\mathbb{Q}_+$ is order-dense in $\mathcal{P}$, i.e. if $L, L' \in \mathcal{P}$ with $L < L'$, then there is an $a \in \mathbb{Q}_+$ with $L < a < L'$.

Proof: Let $L < L'$. Then $L$ is a proper subset of $L'$. Let $b \in L' \setminus L$, and let $a \in L'$ with $b < a$. Then $b \in L_a \setminus L$, so $L < L_a$, and $a \in L' \setminus L_a$, so $L_a < L'$.

III.5.1.28. With this identification, we can say that if $L \in \mathcal{P}$, then $L = \{x \in \mathbb{Q}_+: x < L\}$. (This statement seems strangely circular, but is not actually logically circular since it is not used as a definition of $L$.)

III.5.1.29. From now on, we will use lower-case letters to denote elements of $\mathcal{P}$ instead of $L$'s. Thus we will write $a, b, x, y \in \mathcal{P}$, etc.; the $a, b, x, y$ may denote elements of $\mathbb{Q}_+$, thought of as a subset of $\mathcal{P}$, or of $\mathbb{Q}_+ = \mathcal{P} \setminus \mathbb{Q}_+$, called the set of positive irrational numbers. (We have not yet shown that this set is nonempty.) So, if $a \in \mathcal{P}$, we officially have

$$a = \{x \in \mathbb{Q}_+: x < a\}$$

whether or not $a$ itself is rational. (This statement is technically logically inconsistent if $a$ is rational, since $a$ has previously been defined to be something else, but we will gloss over this technicality since we are not regarding individual numbers as being any specific set-theoretic objects.)

Construction of the Model for $\mathbb{R}$ from $\mathcal{P}$

We now essentially copy the construction of $\mathbb{Z}$ from $\mathbb{N}$ to obtain a model for $\mathbb{R}$.

III.5.1.30. The construction is notationally easier if we adjoin the rational number 0 (which is not in $\mathcal{P}$) to $\mathcal{P}$. Write $\mathcal{P}_0$ for $\mathcal{P} \cup \{0\}$. We define $0 + x = x + 0 = x$ and $0 \cdot x = x \cdot 0 = 0$ for all $x \in \mathcal{P}_0$. This extends the addition and multiplication on $\mathbb{Q}_+ \cup \{0\}$, and the associative, commutative, and distributive laws continue to hold in $\mathcal{P}_0$. We also extend the ordering on $\mathcal{P}$ to $\mathcal{P}_0$ by setting $0 < x$ for all $x \in \mathcal{P}$.

III.5.1.31. Definition. Define a relation on $\mathcal{P}_0 \times \mathcal{P}_0$ by setting $(x_1, y_1) \sim (x_2, y_2)$ if $x_1 + y_2 = x_2 + y_1$.

III.5.1.32. Proposition. (i) The relation $\sim$ is an equivalence relation on $\mathcal{P}_0 \times \mathcal{P}_0$.

(ii) If $(x_1, y_1) \sim (x_2, y_2)$ and $(z_1, w_1) \sim (z_2, w_2)$, then $(x_1 + z_1, y_1 + w_1) \sim (x_2 + z_2, y_2 + w_2)$.

(iii) If $(x_1, y_1) \sim (x_2, y_2)$ and $(z_1, w_1) \sim (z_2, w_2)$, then $(x_1 z_1 + y_1 w_1, x_1 w_1 + y_1 z_1) \sim (x_2 z_2 + y_2 w_2, x_2 w_2 + y_2 z_2)$.

(iv) $(x_1, y_1) \sim (x_2, y_2)$ and $(z_1, w_1) \sim (z_2, w_2)$, and $x_1 + w_1 < z_1 + y_1$, then $x_2 + w_2 < z_2 + y_2$.

Proof: (i): If $(x_1, y_1) \sim (x_2, y_2)$, it is trivial that $(x_2, y_2) \sim (x_1, y_1)$. It is also trivial that $(x, y) \sim (x, y)$ for any $x, y$. If $(x_1, y_1) \sim (x_2, y_2)$ and $(x_2, y_2) \sim (x_3, y_3)$, we have

$$(x_1 + y_3) + (x_2 + y_2) = (x_1 + y_2) + (x_2 + y_3) = (x_2 + y_1) + (x_3 + y_2) = (x_3 + y_1) + (x_2 + y_2)$$

by the associative and commutative laws, and hence $x_1 + y_3 = x_3 + y_1$ by cancellation. Thus $(x_1, y_1) \sim (x_3, y_3)$.

(ii): By the associative and commutative laws, we have

$$(x_1 + z_1) + (y_2 + w_2) = (x_1 + y_2) + (z_1 + w_2) = (x_2 + y_1) + (z_2 + w_1) = (x_2 + z_2) + (y_1 + w_1).$$
(iii): We have
\[(x_1 z_1 + y_1 w_1, x_1 w_1 - y_1 z_1) \sim (x_1 z_1 + y_2 z_1 + x_2 w_1 + y_1 w_1, x_1 w_1 + x_2 w_1 + y_2 z_1 + y_1 z_1)\]
\[= ((x_1 + y_2) z_1 + (x_2 + y_1) w_1, x_1 w_1 + x_2 w_1 + y_2 z_1 + y_1 z_1) = ((x_2 + y_1) z_1 + (x_1 + y_2) w_1, x_1 w_1 + x_2 w_1 + y_2 z_1 + y_1 z_1)\]
\[= (x_2 z_1 + y_1 z_1 + x_1 w_1 + y_2 w_1, x_1 w_1 + x_2 w_1 + y_2 z_1 + y_1 z_1) \sim (x_2 z_1 + y_2 w_1, x_2 w_1 + y_2 z_1) .\]

An almost identical argument shows \((x_2 z_2 + y_2 w_1, x_2 w_1 + y_2 z_2) \sim (x_2 z_2 + y_2 w_2, x_2 w_2 + y_2 z_2)\).

(iv): We have
\[x + y = (x_1 + y_1) + (z_1 + w_1) = (x_1 + z_1) + (y_1 + w_1) \]
\[< (z_1 + y_1) + (y_1 + z_1) = (z_2 + z_2) + (y_1 + z_1) \]
so \(x + w < z + y\) by cancellation.

We will write \([x, y]\) for the equivalence class of the pair \((x, y)\). We will think of \([x, y]\) as representing the real number \(x - y\); the equivalence relation \(\sim\) is designed so that every representative of the equivalence class represents the same real number.

**III.5.1.33.** **Definition.** Let \(\mathcal{R}\) be the set of equivalence classes of ordered pairs. For \([x, y], [z, w] \in \mathcal{R}\), define
\[[x, y] + [z, w] = [(x + z, y + w)]\]
\[[x, y] \cdot [z, w] = [(xz + yw, xw + yz)]\]
\[[x, y] < [z, w] \text{ if } x + w < z + y .\]

Note that +, ·, and < are well defined on \(\mathcal{R}\) by **III.5.1.32**.

**III.5.1.34.** **Theorem.** (\(\mathcal{R}, +, [(0, 0)], [(1, 0)]\)) is a model for \(\mathbb{R}\).

**Proof:** It is obvious that once we know that addition and multiplication of equivalence classes is well defined, \(\mathcal{R}\) inherits associativity, commutativity, and the distributive law from \(\mathcal{P}_0\).

We have \([0, 0] + [x, y] = [(0 + x, 0 + y)] = [(x, y)]\) for all \(x, y \in \mathcal{P}_0\), and similarly \([x, y] + [(0, 0)] = [(x, y)]\) for all \(x, y\); thus (A3) holds with 0-element \((0, 0)\). For \(x, y \in \mathcal{P}_0\), we have \([x, y] + [(y, x)] = [(x + y, y + x)] = [(0, 0)]\), and similarly \([y, x] + [(x, y)] = [(0, 0)]\), so (A4) holds with \(-[(x, y)] = [(y, x)]\).

Suppose \(A \subseteq \mathcal{Z}\) contains \([(0, 0)]\), is closed under adding \([(1, 0)]\) and under negations. Then \(A \cap \mathcal{N}_0 = \mathcal{N}_0\) since \(\mathcal{N}_0\) is a model for \(\mathbb{N}_0\), so \([(x, 0)] \in A\) for all \(x \in \mathbb{N}_0\). Then also \(-[(x, 0)] = [(0, x)] \in A\) for all \(x \in \mathbb{N}_0\). If \(x, y \in \mathbb{N}_0\), either \(x = y\), or there is a \(z \in \mathbb{N}_0\) with \(x + z = y\), or there is a \(w \in \mathbb{N}_0\) with \(x = y + w\). In the first case \([(x, y)] = [(0, 0)] \in A\). If \(x + z = y\), then \([(x, y)] = [(0, z)] \in A\). And if \(x = y + w\), then \([(x, y)] = [(w, 0)] \in A\). Thus (Cyc) holds.

It is obvious that (Fr) holds, since we have shown that \([(x, 0)] \neq [(0, 0)]\) for any \(x \in \mathbb{N}_0, x \neq 0\). \(\blacksquare\)

**III.5.1.35.** Note that each equivalence class in \(\mathcal{R}\) contains exactly one pair \((x, y)\), where either \(x\) or \(y\) (or both) is 0. Thus we could have taken this set of ordered pairs as our model of \(\mathbb{R}\). This model has the advantage that the elements are more concrete; they are specific ordered pairs rather than equivalence classes. But defining addition and proving associativity are somewhat messy in this approach.
III.5.1.36. We could have done the whole construction using $P$ instead of $P_0$. In this case, the 0 element is $[(1, 1)]$, and the 1-element is $[(1 + 1, 1)]$. The positive real number $x$ is represented by $[(x + 1, 1)]$. The approach of III.5.1.35. can also be done using $P$; details are left to the reader.

III.5.2. Construction of $\mathbb{R}$: the Cauchy Sequence Approach

The other standard construction of $\mathbb{R}$ is via equivalence classes of Cauchy sequences of rational numbers. This approach was pioneered by Cantor.

III.5.2.1. The idea behind this construction is that every real number is the limit of a convergent sequence of rational numbers. Cauchy found a criterion for convergence of a sequence which involves only the terms of the sequence, with no explicit reference to the limit; a sequence satisfying this criterion is called a Cauchy sequence. Many different sequences can converge to the same limit, and Cauchy also found a criterion involving only the terms of the sequence for when this happens; Cauchy sequences satisfying this criterion are called equivalent. There is thus a one-one correspondence between real numbers and equivalence classes of Cauchy sequences of rational numbers.

The argument can be turned around to define real numbers to be equivalence classes of Cauchy sequences of rational numbers (this was Cantor’s idea). The algebraic and order properties of real numbers can also be cleanly expressed in terms of these equivalence classes.

We first recall the definition of a convergent sequence. We will phrase it in terms of rational numbers, since we do not assume we have yet constructed anything beyond $\mathbb{Q}$. For a fuller discussion and motivation of the definition, see (). Recall that $\mathbb{Q}_+ = \{x \in \mathbb{Q} : x > 0\}$.

III.5.2.2. Definition. Let $(x_n)$ be a sequence in $\mathbb{Q}$, and $x \in \mathbb{Q}$. Then $(x_n)$ converges to $x$, or $x$ is the limit of the sequence $(x_n)$, written $x_n \to x$ or $x = \lim_{n \to \infty} x_n$, if for every $\epsilon \in \mathbb{Q}_+$ there is a $K \in \mathbb{Q}$ such that $|x_n - x| < \epsilon$ for all $n \in \mathbb{N}, n > K$.

A general sequence in $\mathbb{Q}$ need not converge; in fact, “most” sequences do not converge. It can be readily proved () that a sequence cannot have more than one limit, justifying reference to the limit of a convergent sequence.

Cauchy’s observation is that convergent sequences have an intrinsic property expressible involving only the terms of the sequence:

III.5.2.3. Definition. Let $(x_n)$ be a sequence in $\mathbb{Q}$. Then $(x_n)$ is a Cauchy sequence if, for every $\epsilon \in \mathbb{Q}_+$, there is a $K \in \mathbb{Q}$ such that $|x_n - x_m| < \epsilon$ for all $n, m > K$.

III.5.2.4. Proposition. Let $(x_n)$ be a sequence in $\mathbb{Q}$. If $(x_n)$ converges, then $(x_n)$ is a Cauchy sequence.

Proof: Suppose $x_n \to x$. Let $\epsilon \in \mathbb{Q}_+$. Then there is a $K \in \mathbb{Q}$ such that $|x_n - x| < \frac{\epsilon}{2}$ for all $n > K$. If $n, m > K$, then by the triangle inequality we have

$$|x_n - x_m| \leq |x_n - x| + |x - x_m| < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon.$$
III.5.2.5. Cauchy’s idea was that, conversely, every Cauchy sequence should converge. This turns out to be true in \( \mathbb{R} \) by completeness, but is false in \( \mathbb{Q} \) (although this is not entirely obvious). Thus the idea is to define real numbers to be limits of Cauchy sequences of rational numbers.

However, we also need to specify when two sequences \((x_n)\) and \((y_n)\) should converge to the same limit. This should happen if and only if \(x_n\) and \(y_n\) become arbitrarily close to each other as \(n\) becomes large. So we define:

III.5.2.6. Definition. Let \((x_n)\) and \((y_n)\) be sequences in \(\mathbb{Q}\) (not necessarily Cauchy sequences). Then \((x_n)\) and \((y_n)\) are equivalent, written \((x_n) \sim (y_n)\), if for every \(\epsilon \in \mathbb{Q}_+\) there is a \(K \in \mathbb{Q}\) such that \(|x_n - y_n| < \epsilon\) for all \(n > K\).

The term “equivalent” is justified:

III.5.2.7. Proposition. The relation \(\sim\) is an equivalence relation on the set of all sequences in \(\mathbb{Q}\).

Proof: It is trivial that \(\sim\) is reflexive and symmetric. To prove transitivity, suppose \((x_n), (y_n), \) and \((z_n)\) are sequences in \(\mathbb{Q}\) with \((x_n) \sim (y_n)\) and \((y_n) \sim (z_n)\). Let \(\epsilon \in \mathbb{Q}_+\). There is a \(K_1 \in \mathbb{Q}\) such that \(|x_n - y_n| < \frac{\epsilon}{2}\) for all \(n > K_1\), and a \(K_2 \in \mathbb{Q}\) with \(|y_n - z_n| < \frac{\epsilon}{2}\) for all \(n > K_2\). Set \(K = \max(K_1, K_2)\). If \(n > K\), then by the triangle inequality

\[
|x_n - z_n| \leq |x_n - y_n| + |y_n - z_n| < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon.
\]

If \((x_n)\) and \((y_n)\) are sequences and \(x_n = y_n\) for all but finitely many \(n\), then \((x_n) \sim (y_n)\): take \(K = \max\{n \in \mathbb{N} : x_n \neq y_n\}\).

Equivalent sequences converge to the same limit, and conversely:

III.5.2.8. Proposition. Let \((x_n)\) and \((y_n)\) be sequences in \(\mathbb{Q}\). If \((x_n) \sim (y_n)\) and \(x_n \to x\), then \(y_n \to x\). Conversely, if \(x_n \to x\) and \(y_n \to x\), then \((x_n) \sim (y_n)\).

Proof: Let \(\epsilon \in \mathbb{Q}_+\). There is a \(K_1 \in \mathbb{Q}\) such that \(|x_n - x| < \frac{\epsilon}{2}\) for all \(n > K_1\), and there is a \(K_2 \in \mathbb{Q}\) such that \(|x_n - y_n| < \frac{\epsilon}{2}\) for all \(n > K_2\). Set \(K = \max(K_1, K_2)\). If \(n > K\), then

\[
|y_n - x| \leq |y_n - x_n| + |x_n - x| < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon.
\]

Conversely, suppose \(y_n \to x\). Let \(\epsilon \in \mathbb{Q}_+\), and let \(K_1\) be as above. There is also a \(K_2\) such that \(|y_n - x| < \frac{\epsilon}{2}\) for all \(n > K_3\). Set \(K' = \max(K_1, K_3)\). If \(n > K'\), then

\[
|x_n - y_n| \leq |x_n - x| + |x - y_n| < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon.
\]

Since a constant sequence clearly converges to its constant value \(\), we obtain:
III.5.2.9. **Corollary.** Let \((x_n)\) be a sequence of rational numbers. Then \((x_n)\) converges to the rational number \(r\) if and only if \((x_n)\) is equivalent to the constant sequence \((r)\).

A variation of III.5.2.8. for Cauchy sequences is useful:

III.5.2.10. **Proposition.** Let \((x_n)\) and \((y_n)\) be sequences in \(\mathbb{Q}\). If \((x_n) \sim (y_n)\) and \((x_n)\) is a Cauchy sequence, then \((y_n)\) is also a Cauchy sequence.

**Proof:** Let \(\epsilon \in \mathbb{Q}_+\). There is a \(K_1 \in \mathbb{Q}\) such that \(|x_n - x_m| < \frac{\epsilon}{3}\) for all \(n, m > K_1\), and there is a \(K_2 \in \mathbb{Q}\) such that \(|x_n - y_n| < \frac{\epsilon}{3}\) for all \(n > K_2\). Set \(K = \max(K_1, K_2)\). If \(n, m > K\), then
\[
|y_n - y_m| \leq |y_n - x_n| + |x_n - x_m| + |x_m - y_m| < \frac{\epsilon}{3} + \frac{\epsilon}{3} + \frac{\epsilon}{3} = \epsilon.
\]

We now make our main definition:

III.5.2.11. **Definition.** Let \(\mathbb{R}\) be the set of equivalence classes of Cauchy sequences of rational numbers. Denote the class of a Cauchy sequence \((x_n)\) by \([ (x_n) ]\). Denote by \(\mathbb{Q}\) the set of equivalence classes of constant sequences.

There is an obvious one-one correspondence between \(\mathbb{Q}\) and \(\mathbb{Q}\).

**Order Structure of \(\mathbb{R}\)**

The key to the order structure of \(\mathbb{R}\) is the next result:

III.5.2.12. **Proposition.** Let \((x_n)\) and \((y_n)\) be Cauchy sequences of rational numbers. If \((x_n)\) and \((y_n)\) are not equivalent, then there are \(r, s \in \mathbb{Q}\) with \(r < s\), and \(K \in \mathbb{Q}\), such that either \(x_n < r\) and \(y_n > s\) for all \(n > K\) or \(y_n < r\) and \(x_n > s\) for all \(n > K\).

**Proof:** If \((x_n)\) and \((y_n)\) are not equivalent, then there is an \(\epsilon \in \mathbb{Q}_+\) such that, for every \(K \in \mathbb{Q}\), there is an \(n > K\) with \(|x_n - y_n| \geq \epsilon\). For this \(\epsilon\), fix \(K\) such that \(|x_n - x_m| < \frac{\epsilon}{3}\) and \(|y_n - y_m| < \frac{\epsilon}{3}\) for all \(n, m > K\). Fix \(m > K\) with \(|x_m - y_m| \geq \epsilon\). Then either \(x_m - y_m \geq \epsilon\) or \(y_m - x_m \geq \epsilon\). If \(y_m - x_m \geq \epsilon\), set \(r = x_m + \frac{\epsilon}{3}\) and \(s = y_m - \frac{\epsilon}{3}\). Then \(r < s\), and for any \(n > K\) we have \(x_n < r\) and \(y_n > s\). A similar argument shows that if \(x_m - y_m \geq \epsilon\), and \(r = y_m + \frac{\epsilon}{3}\), \(s = x_m - \frac{\epsilon}{3}\), then \(y_n < r < s < x_n\) for all \(n > K\).

III.5.2.13. **Proposition.** Let \((x_n)\) and \((y_n)\) be sequences in \(\mathbb{Q}\), and \(r, s \in \mathbb{Q}\), \(K \in \mathbb{Q}\) with \(x_n < r < s < y_n\) for all \(n > K\). If \((z_n)\) and \((w_n)\) are sequences in \(\mathbb{Q}\) with \((z_n) \sim (x_n)\) and \((w_n) \sim (y_n)\), and \(r', s' \in \mathbb{Q}\) with \(r < r' < s' < s\), then there is a \(K' \in \mathbb{Q}\) such that \(z_n < r'\) and \(w_n > s'\) for all \(n > K'\).

**Proof:** There is a \(K_1 \in \mathbb{Q}\) such that \(|x_n - z_n| < r' - r\) for all \(n > K_1\), and \(K_2 \in \mathbb{Q}\) such that \(|y_n - w_n| < s - s'\) for all \(n > K_2\). Set \(K' = \max(K_1, K_2, K)\). If \(n > K'\), we have \(z_n = x_n + (z_n - x_n) < r + (r' - r) = r'\), and similarly \(w_n = y_n - (y_n - w_n) > s - (s - s') = s'\).

We can now define the order on \(\mathbb{R}\):
III.5.2.14. Definition. Let \([x_n], [y_n] \in \mathbb{R}\). Then \([x_n]\) < \([y_n]\) if there are \(r, s \in \mathbb{Q}\), \(r < s\), and \(K \in \mathbb{Q}\) such that \(x_n < r\) and \(y_n > s\) for all \(n > K\).

By III.5.2.13, this order is well defined on equivalence classes. It is clearly transitive and antisymmetric. By III.5.2.12, it is a total order, i.e. trichotomy holds. As usual, write \([x_n] \leq [y_n]\) if \([x_n] < [y_n]\) or \([x_n] = [y_n]\), and define > and ≥ accordingly. The induced ordering on \(\mathbb{Q}\) is just the usual ordering on \(\mathbb{Q}\), i.e. if \(r, s \in \mathbb{Q}\), then \([r]\) < \([s]\) if and only if \(r < s\).

III.5.2.15. Proposition. Let \((x_n), (y_n)\) be Cauchy sequences in \(\mathbb{Q}\). If there is a \(K \in \mathbb{Q}\) with \(x_n \leq y_n\) for all \(n > K\), then \([x_n]\) ≤ \([y_n]\).

Proof: Under the hypotheses, \([x_n]\) > \([y_n]\) is impossible!

III.5.2.16. The converse is also true by definition of the order. In fact, if \([x_n]\) < \([y_n]\), then there are Cauchy sequences \((z_n), (w_n)\) in \(\mathbb{Q}\), with \((x_n) \sim (z_n)\) and \((y_n) \sim (w_n)\), such that \(z_n < w_n\) for all \(n\): just take \(z_n = x_n\) and \(w_n = y_n\) if \(x_n < y_n\), and \(z_n = 0, w_n = 1\) if \(x_n \geq y_n\). Then \(z_n = x_n\) and \(w_n = y_n\) for all but finitely many \(n\). The statement also clearly holds with < replaced by ≤ throughout.

We then obtain density of \(\mathbb{Q}\) in \(\mathbb{R}\):

III.5.2.17. Proposition. \(\mathbb{Q}\) is order-dense in \(\mathbb{R}\), i.e. if \([x_n]\) < \([y_n]\), then there is a \(t \in \mathbb{Q}\) with \([x_n]\) < \([t]\) < \([y_n]\).

Proof: Let \(r, s \in \mathbb{Q}\) with \(r < s\), and \(K \in \mathbb{Q}\), such that \(x_n < r\) and \(y_n > s\) for all \(n > K\). Then \([x_n]\) ≤ \([r]\) < \([s]\) ≤ \([y_n]\) by III.5.2.15. If \(t = (r + s)/2\), we have

\[\[x_n]\] ≤ \([r]\) < \([t]\) < \([s]\) ≤ \([y_n]\) .

Algebraic Structure of \(\mathbb{R}\)

We would like to define addition and multiplication of equivalence classes of Cauchy sequences coordinatewise. The next proposition shows that addition is well defined in this way:

III.5.2.18. Proposition. Let \((x_n), (y_n), (z_n), (w_n)\) be sequences in \(\mathbb{Q}\).

(i) If \((x_n)\) and \((y_n)\) are Cauchy sequences, so is \((x_n + y_n)\).

(ii) If \((x_n) \sim (z_n)\) and \((y_n) \sim (w_n)\), then \((x_n + y_n) \sim (z_n + w_n)\).

Proof: The proof is similar to previous ones.
(i): Let $\epsilon > 0$. There is a $K_1 \in \mathbb{Q}$ such that $|x_n - x_m| < \frac{\epsilon}{2}$ for all $n, m > K_1$ and $K_2 \in \mathbb{Q}$ such that $|y_n - y_m| < \frac{\epsilon}{2}$ for all $n, m > K_2$. Set $K = \max(K_1, K_2)$. If $n, m > K$, then
\[|(x_n + y_n) - (x_m + y_m)| = |(x_n - x_m) + (y_n - y_m)| \leq |x_n - x_m| + |y_n - y_m| < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon .\]

(ii): Let $\epsilon > 0$. There is a $K_3 \in \mathbb{Q}$ such that $|x_n - z_n| < \frac{\epsilon}{2}$ for all $n > K_3$ and $K_4 \in \mathbb{Q}$ such that $|y_n - w_n| < \frac{\epsilon}{2}$ for all $n > K_4$. Set $K' = \max(K_3, K_4)$. If $n > K'$, then
\[|(x_n + y_n) - (z_n + w_n)| = |(x_n - z_n) + (y_n - w_n)| \leq |x_n - z_n| + |y_n - w_n| < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon .\]

\[\square\]

Dealing with products is a little harder. We first need a result of general interest. A sequence $(x_n)$ in $\mathbb{Q}$ is bounded if there is an $M \in \mathbb{Q}$ with $|x_n| \leq M$ for all $n \in \mathbb{N}$.

III.5.2.19.  **Proposition.** Every Cauchy sequence in $\mathbb{Q}$ is bounded.

**Proof:** Let $(x_n)$ be a Cauchy sequence. Fix $K \in \mathbb{Q}$ such that $|x_n - x_m| < 1$ for all $n, m > K$, and fix $n > K$. Then, if $m > n$, we have $|x_m| \leq |x_n| + |x_m - x_n| < |x_n| + 1$. The set $\{|x_k|: 1 \leq k < n\}$ is finite, hence has a maximum $M'$. Set $M = \max(M', |x_n| + 1)$. Then $|x_k| \leq M$ for all $k \in \mathbb{N}$.

\[\square\]

III.5.2.20.  **Proposition.** Let $(x_n), (y_n), (z_n), (w_n)$ be sequences in $\mathbb{Q}$.

(i) If $(x_n)$ and $(y_n)$ are Cauchy sequences, so is $(x_n y_n)$.

(ii) If $(x_n) \sim (z_n)$ and $(y_n) \sim (w_n)$, then $(x_n y_n) \sim (z_n w_n)$.

**Proof:** By III.5.2.19, there are $M, M', M'' \in \mathbb{Q}$ such that $|x_n| \leq M$, $|y_n| \leq M'$, $|z_n| \leq M''$ for all $n$. By increasing $M$, $M'$, and $M''$ if necessary, we may assume $M, M', M'' > 0$.

(i): Let $\epsilon > 0$. There is a $K_1 \in \mathbb{Q}$ such that $|x_n - x_m| < \frac{\epsilon}{2M''}$ for all $n, m > K_1$ and $K_2 \in \mathbb{Q}$ such that $|y_n - y_m| < \frac{\epsilon}{2M''}$ for all $n, m > K_2$. Set $K = \max(K_1, K_2)$. If $n, m > K$, then
\[|x_n y_n - x_m y_m| = |x_n y_n - x_m y_n + x_m y_n - x_m y_m| \leq |x_n y_n - x_m y_n| + |x_m y_n - x_m y_m| \]
\[= |y_n||x_n - x_m| + |x_m||y_n - y_m| < M' \frac{\epsilon}{2M''} + M' \frac{\epsilon}{2M''} = \epsilon .\]

(ii): Let $\epsilon > 0$. There is a $K_3 \in \mathbb{Q}$ such that $|x_n - z_n| < \frac{\epsilon}{2M''}$ for all $n > K_3$ and $K_4 \in \mathbb{Q}$ such that $|y_n - w_n| < \frac{\epsilon}{2M''}$ for all $n > K_4$. Set $K' = \max(K_3, K_4)$. If $n > K'$, then
\[|x_n y_n - z_n w_n| = |x_n y_n - z_n y_n + z_n y_n - z_n w_n| \leq |x_n y_n - z_n y_n| + |z_n y_n - z_n w_n| \]
\[= |y_n||x_n - z_n| + |z_n||y_n - w_n| < M' \frac{\epsilon}{2M''} + M'' \frac{\epsilon}{2M''} = \epsilon .\]

\[\square\]

As a result, we may make the following definition:
III.5.2.21. Definition. Define binary operations $+$ and $\cdot$ on $\mathbb{R}$ by $[(x_n)] + [(y_n)] = [(x_n + y_n)]$ and $[(x_n)] \cdot [(y_n)] = [(x_n y_n)]$.

III.5.2.22. Associativity of addition on $\mathbb{R}$ is immediate, since if $(x_n)$, $(y_n)$, and $(z_n)$ are Cauchy sequences in $\mathbb{Q}$, the sequences $(x_n + y_n + z_n)$ and $(x_n + [y_n + z_n])$ are not only equivalent but even identical. A similar observation shows that associativity of multiplication, commutativity of addition and multiplication, and the distributive law hold in $\mathbb{R}$.

We also have that $[(0)]$ is an additive identity and $[(1)]$ is a multiplicative identity. If $(x_n)$ is a Cauchy sequence, then so is $(-x_n)$, and $[(-x_n)]$ is an additive inverse for $[(x_n)]$.

It is obvious that $\mathbb{Q}$ is closed under $+$ and $\cdot$, and the restrictions are the usual operations from $\mathbb{Q}$, i.e. we have $[(r)] + [(s)] = [(r + s)]$ and $[(r)] \cdot [(s)] = [(rs)]$ for $r, s \in \mathbb{Q}$.

There are also multiplicative inverses for nonzero elements of $\mathbb{R}$. First note the next immediate corollary of III.5.2.12:

III.5.2.23. Corollary. Let $(x_n)$ be a Cauchy sequence in $\mathbb{Q}$. If $[(x_n)] \neq [(0)]$, then there are $\alpha \in \mathbb{Q}_+$ and $K \in \mathbb{Q}$ with $|x_n| \geq \alpha$ for all $n > K$.

III.5.2.24. Proposition. Every nonzero element of $\mathbb{R}$ has a multiplicative inverse.

Proof: Let $(x_n)$ be a Cauchy sequence in $\mathbb{Q}$ with $[(x_n)] \neq [(0)]$, and fix $\alpha \in \mathbb{Q}_+$ and $K \in \mathbb{Q}$ such that $|x_n| \geq \alpha$ for all $n \in \mathbb{K}$. Set

$$y_n = \begin{cases} x_n^{-1} & \text{if } x_n \neq 0 \\ 1 & \text{if } x_n = 0 \end{cases}.$$

We show $(y_n)$ is a Cauchy sequence. Let $\epsilon \in \mathbb{Q}_+$. There is a $K_1 \in \mathbb{Q}$ such that $|x_n - x_m| < \alpha^2 \epsilon$ for all $n > K_1$. If $K' = \max(K, K_1)$, and $n, m > K'$, then $|x_n|, |x_m| \geq \alpha$, so $x_n, x_m \neq 0$ and $y_n = \frac{1}{x_n}$, $y_m = \frac{1}{x_m}$, and

$$|y_n - y_m| = \left| \frac{1}{x_n} - \frac{1}{x_m} \right| = \frac{|x_m - x_n|}{|x_m x_n|} \leq \frac{|x_m - x_n|}{\alpha^2} < \epsilon.$$

So $\mathbb{R}$ is a field.

III.5.2.25. We now check that $\mathbb{R}$ is an ordered field. It is easiest to check (Pos). Let $\mathbf{P} = \{(x_n) \in \mathbb{R} : [(x_n)] > [(0)]\}$. We have (P3) and (P4), i.e. that $\mathbb{R}$ is the disjoint union of $\mathbf{P}$, $\{(0)\}$, and $-\mathbf{P}$, so we need only check that $\mathbf{P}$ is closed under addition and multiplication. Let $[(x_n)], [(y_n)] \in \mathbf{P}$, then there are $\alpha, \beta \in \mathbb{Q}_+$ and $K_1, K_2 \in \mathbb{Q}$ such that $x_n \geq \alpha$ for all $n > K_1$ and $y_n \geq \beta$ for all $n > K_2$. Set $K = \max(K_1, K_2)$. If $n > K$, then $x_n + y_n \geq \alpha + \beta \in \mathbb{Q}_+$ and $x_n y_n \geq \alpha \beta \in \mathbb{Q}_+$. So $[(x_n + y_n)]$ and $[(x_n y_n)]$ are in $\mathbf{P}$.

Summarizing, we have

III.5.2.26. Theorem. $\mathbb{R}$ is an ordered field under $+$, $\cdot$, and $<$, with additive identity $[(0)]$ and multiplicative identity $[(1)]$. $\mathbb{Q}$ is an order-dense subfield order-isomorphic to $\mathbb{Q}$.
The Completeness Axiom

Showing that \( \mathbb{R} \) satisfies the Completeness Axiom takes some work. Note that the order-theoretic completeness of the Completeness Axiom is not the same thing as metric completeness, which asserts that every Cauchy sequence converges. For metric completeness of \( \mathbb{R} \), see (a).

III.5.2.27. Theorem. \( (\mathbb{R}, <) \) satisfies the Completeness Axiom, i.e. every nonempty subset of \( \mathbb{R} \) which is bounded above has a supremum.

Proof: Let \( S \) be a nonempty bounded subset of \( \mathbb{R} \). We will construct two equivalent Cauchy sequences in \( \mathbb{Q} \) whose equivalence class is \( \sup(S) \) by a bisection process. First fix \( a, b \in \mathbb{Q} \) such that \( b \) (actually \( [(b)] \)) is an upper bound for \( S \), and \( a \) is not an upper bound. (For \( r \in \mathbb{Q} \) we will write \( r \) for \( \lfloor r \rfloor \) to streamline notation, except when there is possibility of confusion.)

Set \( c_1 = (a + b)/2 \). Either \( c_1 \) is an upper bound for \( S \), or it is not. If \( c_1 \) is an upper bound for \( S \), set \( y_1 = a \) and \( z_1 = c_1 \); otherwise set \( y_1 = c_1 \) and \( z_1 = b \). Then \( y_1 \) is not an upper bound for \( S \), \( z_1 \) is, and \( z_1 - y_1 = 2^{-1}(b - a) \). Repeat the process by setting \( c_2 = (y_1 + z_1)/2 \) and setting \( y_2 = y_1, z_2 = c_2 \) if \( c_2 \) is an upper bound for \( S \) and \( y_2 = c_2, z_2 = z_1 \) otherwise. Iterating the process, we obtain sequences \( (y_n), (z_n) \) in \( \mathbb{Q} \) such that \( y_n \leq y_{n+1} < z_{n+1} \leq z_n \) and \( z_n - y_n = 2^{-n}(b - a) \).

To show that \( (y_n) \) and \( (z_n) \) are Cauchy sequences, and \( (y_n) \sim (z_n) \), let \( \epsilon > 0 \), and fix \( K \in \mathbb{N} \) such that \( 2^{-K}(b - a) \leq \epsilon \). Then, if \( n, m > K, n < m \), we have \( y_K \leq y_n \leq y_m < z_m \leq z_n \leq z_K \), with at least one of the outside inequalities strict. Thus \( |y_n - y_m|, |z_n - z_m|, |y_n - z_n| \) are all less than \( z_K - y_K = 2^{-K}(b - a) \leq \epsilon \).

Thus \( [(y_n)] = [(z_n)] \in \mathbb{R} \). Call this element \( y \). We will show that \( y = \sup(S) \). First suppose \( [(x_n)] \in S \). If \( [(x_n)] > y = [(z_n)] \), then by III.5.2.12. there are \( r, s \in \mathbb{Q} \) with \( r < s \), and \( K_1 \in \mathbb{Q} \), such that \( z_n < r \) and \( x_n > s \) for all \( n > K_1 \). Fix \( m > K_1 \) and set \( u = z_m \). Since the \( z_n \) are decreasing, we have \( z_n \leq u \) for all \( n > m \), and thus \( y \leq [(u)] \). We also have \( x_n > s \) for all \( n > m \) and \( u < s \), so \( [(u)] < [(x_n)] \). But by construction \( u \) (actually \( [(u)] \)) is an upper bound for \( S \), a contradiction. Thus \( [(x_n)] \leq y \), and \( y \) is an upper bound for \( S \).

Now suppose \( [(w_n)] \in \mathbb{R} \) with \( [(w_n)] < y = [(y_n)] \). Then there are \( r, s \in \mathbb{Q}, r < s \), and \( K_2 \in \mathbb{Q} \), such that \( w_n < r \) and \( y_n > s \) for all \( n > K_2 \). Fix \( m > K_2 \), and set \( v = y_m \). By construction, \( v \) (actually \( [(v)] \)) is not an upper bound for \( S \), so there is an \( [(x_n)] \in S \) with \( [(v)] < [(x_n)] \), so there is a \( K_3 \in \mathbb{Q} \) with \( x_n > v \) for all \( n > K_3 \). Since \( v > s \), we have \( w_n < r \) and \( s < x_n \) for all \( n > \max(K_2, K_3) \), so \( [(w_n)] < [(x_n)] \), and \( [(w_n)] \) is not an upper bound for \( S \). Thus \( y \) is the least upper bound of \( S \).

The bottom line is:

III.5.2.28. Theorem. \( \mathbb{R} \), with its addition, multiplication, and order, is a model for \( \mathbb{R} \).

III.5.3. Exercises

III.5.3.1. Let \( \mathbb{R}(X) \) be the field of rational “functions” of Exercise III.4.3.5.(c). If \( 0 \neq f(X) = \frac{p(X)}{q(X)} \in \mathbb{R}(X) \), we say \( f(X) \) is positive if the leading coefficients (coefficients of the highest powers of \( X \)) in \( p(X) \) and \( q(X) \) have the same sign. Let \( P \) be the set of positive elements.

(a) Show that the property of \( f(X) \) being positive is independent of the way \( f(X) \) is represented as a fraction \( \frac{p(X)}{q(X)} \). If \( f \) is regarded as a function from \( \mathbb{R} \setminus \{ x : q(x) = 0 \} \) to \( \mathbb{R} \), show that \( f \) is positive if and only if
f(x) > 0 for all sufficiently large \( x \in \mathbb{R} \).
Show that a sum, product, or quotient of positive elements is positive.

(b) Show that \( \mathbb{R}(X) \) is the disjoint union of \( P, \{0\}, \) and \( -P; \) thus \( (\mathbb{R}(X), P) \) is an ordered field. (This ordering is called the Fréchet ordering on \( \mathbb{R}(X) \).)

(c) If \( \mathbb{R} \) is regarded as the subfield of \( \mathbb{R}(X) \) of constant functions, the order on \( \mathbb{R}(X) \) induces the usual order on \( \mathbb{R} \).

(d) The element \( f(X) = X \) is a positive element which is infinitely large, i.e. \( f > r \) for every \( r \in \mathbb{R} \). The element \( g(X) = \frac{1}{x} \) is a positive element which is infinitesimal, i.e. \( 0 < g < \epsilon \) for all \( \epsilon \in \mathbb{R}, \epsilon > 0 \). Thus \( \mathbb{R}(X) \) is a nonarchimedean ordered field.

III.5.3.2. Formal Power Series. Let \( F \) be a field, e.g. \( F = \mathbb{Q}, \mathbb{R}, \) or \( \mathbb{C} \) (in fact the construction works over any ring).

(a) A formal power series over \( F \) is an expression of the form \( \sum_{k=0}^{\infty} a_k X^k \), where the \( a_k \) are in \( F \) and \( X \) is an indeterminate symbol. Define addition and multiplication of power series by

\[
\left( \sum_{k=0}^{\infty} a_k X^k \right) + \left( \sum_{k=0}^{\infty} b_k X^k \right) = \sum_{k=0}^{\infty} \left( a_k + b_k \right) X^k \\
\left( \sum_{k=0}^{\infty} a_k X^k \right) \cdot \left( \sum_{k=0}^{\infty} b_k X^k \right) = \sum_{k=0}^{\infty} \left( \sum_{j=0}^{k} c_k X^k \right), \text{ where } c_k = \sum_{j=0}^{k} a_j b_{k-j}.
\]

Let \( F[[X]] \) be the set of all formal power series over \( F \). Show that \( F[[X]] \) is a commutative ring under these operations, and that the polynomial ring \( F[X] \) is a subring. In particular, \( F \) can be identified with the set of “constant” power series with \( a_k = 0 \) for \( k > 0 \).

(b) Show that a power series \( \sum_{k=0}^{\infty} a_k X^k \) has a multiplicative inverse in \( F[[X]] \) if and only if \( a_0 \neq 0 \). [Generate the coefficients of the multiplicative inverse series \( \sum_{k=0}^{\infty} b_k X^k \) by successively solving a sequence of linear equations in \( F \).]

The multiplication formula for formal power series can be motivated by writing the series out in informal notation

\[
\sum_{k=0}^{\infty} a_k X^k = a_0 + a_1 X + a_2 X^2 + a_3 X^3 + \cdots
\]

and similarly for \( \sum_{k=0}^{\infty} b_k X^k \), and then formally multiplying out

\[
(a_0 + a_1 X + a_2 X^2 + a_3 X^3 + \cdots)(b_0 + b_1 X + b_2 X^2 + b_3 X^3 + \cdots)
\]

and collecting together like powers of \( X \).

The elements of \( F[[X]] \) are called “formal power series” since there is no notion of convergence implied (in fact, over a general field, the idea of convergence of a power series does not even make sense). So formal power series are just algebraic expressions and should not be thought of as corresponding to “functions”. For example, the series \( \sum_{k=0}^{\infty} k! X^k \) is a perfectly good formal power series over \( \mathbb{Q} \) (or \( \mathbb{R}, \mathbb{C} \)), even though it diverges when any nonzero complex number is substituted for \( X \), and hence cannot be thought of as giving a function on \( \mathbb{C} \) (\( \mathbb{R}, \mathbb{Q} \)). Later, we will consider rings of convergent power series, where ideas from analysis come into the picture in an essential way.
III.5.3.3.  **Formal Laurent Series.** This problem is somewhat of a continuation of Problem III.5.3.2.
Let $F$ be a field. A **formal Laurent series** over $F$ is a sum of the form $\sum_{k=m}^{\infty} a_k X^k$ with the $a_k$ in $F$, where $m \in \mathbb{Z}$ depends on the series, and may be positive, negative, or zero. We will often implicitly assume when writing such an expression that $a_m \neq 0$, although this is not necessary. We will informally write such a series as a formal sum of monomials

$$\sum_{k=m}^{\infty} a_k X^k = a_m X^m + a_{m+1} X^{m+1} + \cdots$$

where only finitely many negative powers of $X$ (perhaps none) occur.

(a) Define addition and multiplication of formal Laurent series as in Problem III.5.3.2. [The formula for multiplication is more complicated, but can be found by considering the informal term-by-term product]

$$(a_m X^m + a_{m+1} X^{m+1} + \ldots)(b_n X^n + b_{n+1} X^{n+1} + \cdots).$$

Show that the set $F((X))$ of formal Laurent series is a commutative ring with this addition and multiplication, and the ring of formal power series $F[[X]]$ is a subring.

(b) Show that every nonzero element of $F((X))$ has a multiplicative inverse. [Use the method of problem III.5.3.2.(b). If the series is $\sum_{k=m}^{\infty} a_k X^k$ with $a_m \neq 0$, generate a series $\sum_{k=-m}^{\infty} b_k X^k$.] Thus $F((X))$ is a field.

(c) Show that $F((X))$ is naturally isomorphic to the quotient field ($()$ of $F[[X]]$. In particular, there is a canonical embedding of the field $F(X)$ of rational functions into $F((X))$, although the formula for the embedding is not obvious: the multiplicative inverse of a polynomial is usually not a polynomial or even a Laurent polynomial (Laurent series with only finitely many nonzero terms).

(d) Suppose $F$ is an ordered field. Declare a nonzero power series $\sum_{k=m}^{\infty} a_k X^k$ with $a_m \neq 0$ to be **positive** if $a_m > 0$. Let $P$ be the set of all positive series. Show that $P$ satisfies (Pos) and hence makes $F((X))$ into an ordered field. Show that $F((X))$ is nonarchimedean: we have $X > 0$, but $nX < 1$ for all $n \in \mathbb{N}$ (identified with a subset of $F$ as in ()), so $X$ is an **infinitesimal** positive element of $F((X))$.

(e) The ordering on $F(X)$ induced by its embedding in $F((X))$ from (c) is not the same as the ordering from Problem III.5.3.1. But show it can be obtained from this ordering by the substitution $X \mapsto \frac{1}{X}$ in $F(X)$.

III.5.3.4.  **Puiseux Series.** This and the next two problems are a continuation of Problem III.5.3.3.; we will define three successively larger fields containing the field $\mathbb{R}((X))$. We will work over $\mathbb{R}$, although the construction can be done over any field.

A **Puiseux Series** is a formal expression of the form $\sum_{k=m}^{\infty} a_k/n X^{k/n}$ for some $m \in \mathbb{Z}$, $n \in \mathbb{N}$, where $a_k/n \in \mathbb{R}$ for all $k$. In other words, a Puiseux series is a formal Laurent series in $X^{1/n}$ for some $n$ (which may vary from series to series). Any formal Laurent series over $\mathbb{R}$ is a Puiseux series with $n = 1$. We identify $X^{k/n}$ and $X^{kr/nr}$ for any $r \in \mathbb{N}$; thus any two (or any finite number of) Puiseux series can be written as formal Laurent series in $X^{1/n}$ for a common $n$.

(a) Define addition and multiplication of Puiseux series in analogy with the definition for formal Laurent series. Show that the set $P$ of Puiseux series is a field containing $\mathbb{R}((X))$ as a subfield. In particular, $P$ contains $\mathbb{R}$ as the subfield of “constant” series, where $a_{k/n} = 0$ for all $k \neq 0$.

(b) Define an ordering on $P$ by defining the positive cone as in Exercise III.5.3.3.(d): If $x = \sum_{k=m}^{\infty} a_k/n X^{k/n}$ is a nonzero element of $P$, with $m/n$ the smallest $k/n$ for which $a_{k/n} \neq 0$ ($m/n$ is called the **degree** of the
series), set \( x > 0 \) if \( a_{m/n} > 0 \). This ordering agrees with the previous one from Exercise III.5.3.3.(d) on \( \mathbb{R}((X)) \).

(c) Show by direct computation that every nonnegative element of \( P \) has a square root. [If \( x \in P \) with degree \( m/n \) with \( m \geq 0 \), write \( x = a_{m/n}X^{m/n}(1 + y) \) where \( a_{m/n} > 0 \) and \( y \) has degree \( > 0 \), and use the binomial series for \((1 + y)^{1/2}\).

In fact, \( P \) is a real-closed field, so is a first-order model for \( \mathbb{R} \) (and is the “smallest” such model containing an infinitesimal). Puiseux series were first formally studied by Puiseux in about 1850, although many of the basic ideas go back to Newton. See [BPR06, Chapter 2] for more information.

III.5.3.5. The Levi-Civita Numbers. This is a continuation of Problem III.5.3.4. We will work over \( \mathbb{R} \), although the construction can be done over any field. A Levi-Civita number is a formal expression of the form \( \sum_{q \in \mathbb{Q}} a_q X^q \), where \( a_q \in \mathbb{R} \) for all \( q \), and for any such sum the set \( S = \{q : a_q \neq 0\} \) is a left-finite set, i.e. for any \( r \in \mathbb{Q} \) the set \( \{q \in S : q < r\} \) is finite. In other words, either \( S \) is finite or the elements of \( S \) can be arranged in a strictly increasing sequence converging to \(+\infty\). (The set \( S \) may vary from series to series.) Any Puiseux series over \( \mathbb{R} \) is a Levi-Civita number.

(a) Define addition and multiplication of Levi-Civita numbers in analogy with the definition for Puiseux series. Show that the set \( \mathcal{R} \) of Levi-Civita numbers is a field containing \( P \) as a subfield.

(b) Define an ordering on \( \mathcal{R} \) by defining the positive cone as in Exercise III.5.3.3.(d): If \( x = \sum_{q \in \mathbb{Q}} a_q X^q \) is a nonzero element of \( \mathcal{R} \), with \( q_0 \) the smallest \( q \) for which \( a_q \neq 0 \) (\( q_0 \) is called the degree of the series), set \( x > 0 \) if \( a_{q_0} > 0 \). This ordering agrees with the previous one from Exercise III.5.3.4. on \( P \).

(c) Show by direct computation that every nonnegative element of \( \mathcal{R} \) has a square root. [The argument is similar to the one in III.5.3.4.(c).]

(d) Show that \( \mathcal{R} \) is complete in the following sense:

In fact, \( \mathcal{R} \) is a real-closed field, so is a first-order model for \( \mathbb{R} \) (and is the “smallest” such model which is complete in the sense of (d) and contains an infinitesimal). The Levi-Civita numbers are important in computational analysis. See [?], [SB10], [Rib92], or [DW96, Theorem 2.15] for more information.

III.5.3.6. Hahn Series. This is a further continuation of Problem III.5.3.5. We will work over \( \mathbb{R} \), although the construction can be done over any field. Let \( G \) be a totally ordered abelian group, e.g. \( \mathbb{Q} \) or \( \mathbb{R} \). A Hahn Series over \( G \) is a formal expression of the form \( \sum_{q \in G} a_q X^q \), where \( a_q \in \mathbb{R} \) for all \( q \), and for any such sum the set \( S = \{q : a_q \neq 0\} \) is a well-ordered set, i.e. every subset of \( S \) has a smallest element (equivalently, \( S \) contains no strictly decreasing sequences). The set \( S \) may vary from series to series. Every Levi-Civita number is a Hahn series over \( \mathbb{Q} \) (but there are Hahn series over \( \mathbb{Q} \) which are not Levi-Civita numbers): a formal Laurent series is a Hahn series over \( \mathbb{Z} \).

(a) Define addition and multiplication of Hahn series in analogy with the definition for Levi-Civita numbers. Show that the set \( \mathcal{S}_G \) of Hahn series over \( G \) is a field.

(b) Define an ordering on \( \mathcal{S}_G \) by defining the positive cone as in Exercise III.5.3.3.(d): If \( x = \sum_{q \in G} a_q X^q \) is a nonzero element of \( \mathcal{S}_G \), with \( q_0 \) the smallest \( q \) for which \( a_q \neq 0 \) (\( q_0 \) is called the degree of the series), set \( x > 0 \) if \( a_{q_0} > 0 \). This ordering agrees with the previous one from Exercise III.5.3.3.(d) on \( \mathbb{R}((X)) \).

(c) Show by direct computation that if \( G \) is 2-divisible, every nonnegative element of \( \mathcal{S}_G \) has a square root. [The argument is similar to the one in III.5.3.4.(c).]

(d) Show that \( \mathcal{S} \) is complete in the sense of III.5.3.5.(d).

In fact, \( \mathcal{S}_G \) is also a real-closed field if \( G \) is divisible. See [DW96] for more information.
This problem is a continuation of III.5.3.2. A formal power series $\sum_{k=0}^{\infty} a_k X^k$ has order $m$ if $a_m \neq 0$ and $a_k = 0$ for $k < m$.

We will suggestively use letters $f, g, h, \ldots$ for elements of $F[[X]]$, or even more suggestively $f(X)$, etc., even though formal power series are not functions in any literal sense.

(a) Let $(f_n)$ be a sequence of formal power series over $F$. Show that if for every $m$ there are only finitely many $f_n$ of order $\leq m$, then the infinite sum $\sum_{n=1}^{\infty} f_n$ is well defined in $F[[X]]$. [Add the coefficients of each power of $X$.]

(b) Give another proof of III.5.3.2. (b) by using the formal infinite series

$$(1 - x)^{-1} = \sum_{n=0}^{\infty} x^n.$$ 

(c) If $f = \sum_{k=0}^{\infty} a_k X^k$ and $g = \sum_{k=0}^{\infty} b_k X^k$ are formal power series over $F$, and $g$ has order $\geq 1$ (i.e. $b_0 = 0$), then the infinite sum

$$\sum_{k=0}^{\infty} a_k g^k = \sum_{k=0}^{\infty} a_k [g(X)]^k$$

is a well-defined element of $F[[X]]$ which can be denoted $f(g(X))$ or $f \circ g$. [The order of $g^n$ is at least $n$.] There is not a well-defined composition if $b_0 \neq 0$.

This can be motivated by regarding formal power series as defining “function germs” around $0 \in F$. It makes sense that composition can only be defined if the inside function sends $0$ to $0$.

(d) Prove that composition, when defined, is associative: if $g$ and $h$ have order $\geq 1$, then $g \circ h$ has order $\geq 1$, and for every $f$ we have $(f \circ g) \circ h = f \circ (g \circ h)$.

(e) Prove the following “Formal Inverse Function Theorem” (where $\iota$ is the “identity function” $X$, i.e. $\iota = \sum_{k=0}^{\infty} a_k X^k$, where $a_1 = 1$ and $a_k = 0$ for $k \neq 1$) by successively solving a sequence of linear equations for the coefficients of $g$:

**Theorem.** Let $f = \sum_{k=0}^{\infty} a_k X^k \in F[[X]]$. Then there exists $g \in F[[X]]$ with $f \circ g = \iota$ if and only if $a_0 = 0$ and $a_1 \neq 0$. If such $g$ exists, it is unique, and also $g \circ f = \iota$.

If $f = \sum_{k=0}^{\infty} a_k X^k \in F[[X]]$, we may write $f(0) = a_0$ and $f'(0) = a_1$ (there is a difficulty carrying this over to higher derivatives unless $F$ has characteristic 0 since a factorial should occur in the formula). Then, if the $g$ exists in the theorem, we have $g(0) = 0$ and $g'(0) = [f'(0)]^{-1}$.

This problem is a continuation of III.5.3.2. and III.5.3.7. A formal power series in two variables $X$ and $Y$ over a field $F$ is a formal sum

$$\sum_{k,j=0}^{\infty} a_{k,j} X^k Y^j$$

where the $a_{k,j}$ are elements of $F$. There is an obvious way of adding and multiplying two such series, making the set $F[[X,Y]]$ of such formal power series into a ring.

(a) Show that there are natural isomorphisms

$$F[[X,Y]] \cong (F[[X]])[[Y]] \cong (F[[Y]])[[X]].$$
In particular, $F[[X]]$ is a subring of $F[[X,Y]]$ consisting of all sums for which $a_{k,j} = 0$ for $j > 0$. Similarly, $F[[Y]]$ is a subring of $F[[X,Y]]$. Write $f$ or $f(X,Y)$, etc., for a general element of $F[[X,Y]]$; elements of the subrings $F[[X]]$ and $F[[Y]]$ can be written $f(X)$, $g(Y)$, etc.

If $f(X,Y) = \sum_{k,j=0}^{\infty} a_{k,j} X^k Y^j$ is an element of $F[[X,Y]]$, we may write $f(0,0) = a_{0,0}$, $f_X(0,0) = \frac{\partial f}{\partial X}(0,0) = a_{1,0}$, and $f_Y(0,0) = \frac{\partial f}{\partial Y}(0,0) = a_{0,1}$.

(b) Describe the invertible elements of $F[[X,Y]]$.

c) If $f, g, h \in F[[X,Y]]$, with $g(0,0) = h(0,0) = 0$, show that there is a well-defined element $f(g(X,Y), h(X,Y)) \in F[[X,Y]]$. If $g, h \in F[[X]]$, then $f(g(X), h(X)) \in F[[X]]$ also.

d) Prove the following “Formal Implicit Function Theorem” (cf. VIII.6.3.10.):

**Theorem.** Let $f(X,Y) \in F[[X,Y]]$ with $f(0,0) = 0$ and $f_Y(0,0) \neq 0$. Then there is a unique $g \in F[[X]]$ such that $f(X, g(X)) = 0$ (where 0 denotes the zero element of $F[[X,Y]]$). We have $g(0) = 0$ and $g'(0) = -\frac{f_X(0,0)}{f_Y(0,0)}$.

e) Discuss Laurent series in two variables and the quotient field of $F[[X,Y]]$.

(f) Generalize to formal power series rings $F[[X_1, \ldots, X_n]]$. Formulate and prove a higher-dimensional version of the Formal Implicit Function Theorem analogous to VIII.6.1.7..

g) To what extent can Puiseux series, Levi-Civita Numbers, and Hahn Series be generalized to several variables?

References: [?, 4.4.7], [Jz75], [Sok11], [KP02a].

**III.5.3.9. The $p$-adic Numbers.** The real numbers are not the only field formed by completing $\mathbb{Q}$. This problem describes the completion of $\mathbb{Q}$ with respect to a different metric. There is actually one of these for each prime number $p$. These fields are important in number theory.

Fix a prime number $p$. If $x \in \mathbb{Q}$, $x \neq 0$, then $x$ can be written $p^n \cdot \frac{a}{b}$, where $n \in \mathbb{Z}$ and $a, b \in \mathbb{Z}$ are not divisible by $p$. The number $n$ is uniquely determined by $x$; write $\nu_p(x) = n$ and $|x|_p = p^{-n} = p^{-\nu_p(x)}$. Set $\nu_p(0) = +\infty$ and $|0|_p = 0$.

(a) Show that if $x, y \in \mathbb{Q}$, $\nu_p(x + y) \geq \min(\nu_p(x), \nu_p(y))$ and $\nu_p(xy) = \nu_p(x) + \nu_p(y)$.

(b) Show that if $x, y \in \mathbb{Q}$, then $|x + y|_p \leq \max(|x|_p, |y|_p) \leq |x|_p + |y|_p$ and $|xy|_p = |x|_p |y|_p$.

(c) Show that $d_p$ defined by $d_p(x, y) = |x - y|_p$ is a metric on $\mathbb{Q}$.

(d) Let $\mathbb{Q}_p$ be the set of equivalence classes of Cauchy sequences of rational numbers with respect to $d_p$, where equivalence is defined as in (). Mimic the proof of () to define addition and multiplication on $\mathbb{Q}_p$, and show that $\mathbb{Q}_p$ is a field. Extend $| \cdot |_p$ and $d_p$ to $\mathbb{Q}_p$, and show that $\mathbb{Q}_p$ is complete with respect to $d_p$. (Note that the topology defined by $d_p$ is quite different from the usual topology on $\mathbb{Q}$: $p^n \to 0$ in the $d_p$-topology, for example.)

(e) Show that if $x \in \mathbb{Z}$, then $|x|_p \leq 1$, and the closure of $\mathbb{Z}$ in $\mathbb{Q}_p$ is

$$\mathbb{Z}_p = \{ x \in \mathbb{Q}_p : |x|_p \leq 1 \}.$$  

This is a subring of $\mathbb{Q}_p$, called the ring of $p$-adic integers. (The notation $\mathbb{Z}_p$ is inconsistent with (); this meaning of the notation $\mathbb{Z}_p$ will be used only in this problem.) Note that $\mathbb{Z}_p \cap \mathbb{Q}$ is larger than $\mathbb{Z}$; it includes all rational numbers $\frac{a}{b}$ where $p$ does not divide $b$. 

299
(f) Show that $\mathbb{Q}_p$ is locally compact with its metric topology, and $\mathbb{Z}_p$ is a compact open subset.

(g) Show that $\mathbb{Q}_p$ is totally disconnected.

(h) Show that the ring $\mathbb{Z}_p$ has only one maximal ideal $J$, the set of multiples of $p$, and $\mathbb{Z}_p/J \cong \mathbb{Z}/p\mathbb{Z}$.
Every nonzero ideal in $\mathbb{Z}_p$ is a principal ideal generated by $p^n$ (the set of all multiples of $p^n$) for some $n \in \mathbb{N}$.

(i) Show that the quotient field (of $\mathbb{Z}_p$) is $\mathbb{Q}_p$.

### III.6. The Complex Numbers

Although they are not as familiar as the real numbers, the complex numbers $\mathbb{C}$ are the natural culmination of the expansion of the number system. Although we will make only very limited use of them in this book, they are also extremely important in analysis, and many parts of analysis, e.g. the theory of analytic functions and Fourier series, are naturally done on $\mathbb{C}$ instead of $\mathbb{R}$. Complex numbers and analysis done on them (complex analysis) are among the most beautiful parts of mathematics, and the most useful in applications.

From a purely algebraic standpoint, the real numbers have almost all the properties one might want in a number system. The only obvious shortcoming is that negative numbers do not have square roots in $\mathbb{R}$. The idea of making the complex numbers is to expand $\mathbb{R}$ to a larger system of numbers in which square roots of negative real numbers (and, as it turns out, square roots of arbitrary numbers in the expanded system) can be taken. The resulting system actually yields a lot more than just square roots.

#### III.6.1. Axiomatization of $\mathbb{C}$

**III.6.1.1.** Axioms for $\mathbb{C}$ are not standardized, but here is a set which can be used:

- (C1) $\mathbb{C}$ has two binary operations making it into a field.
- (C2) $\mathbb{C}$ contains $\mathbb{R}$ as a subfield (more precisely, $\mathbb{C}$ contains a specified subfield $\mathbb{R}$ with a specified isomorphism between $\mathbb{R}$ and $\mathbb{R}$).
- (C3) $\mathbb{C}$ contains an element $i$ with $i^2 = -1$.
- (C4) Every element of $\mathbb{C}$ can be written as $a + bi$ for $a, b \in \mathbb{R}$ (or $\mathbb{R}$).

If $\mathcal{C}$ is any model for $\mathbb{C}$, then since $\mathcal{C}$ is a field, all the standard algebraic operations and identities hold in $\mathcal{C}$, and we are justified in using standard algebraic notation and manipulation in $\mathcal{C}$ without comment.

**III.6.1.2.** **Proposition.** Let $\mathcal{C}$ be a model for $\mathbb{C}$. If $z \in \mathcal{C}$, then $z$ has a unique representation $z = x + yi$ where $x$ and $y$ are in the specified subfield $\mathcal{R}$ which is a model for $\mathbb{R}$.

**Proof:** There is such a representation for $z$ by (C4). To show uniqueness, if $z = x_1 + y_1 i = x_2 + y_2 i$, then $0 = (x_1 - x_2) + (y_1 - y_2) i$, so it suffices to show that if $0 = a + bi$ with $a, b \in \mathcal{R}$, then $a = b = 0$. But

$$0 = 0 \cdot (a - bi) = (a + bi)(a - bi) = a^2 - b^2 i^2 = a^2 + b^2$$

and thus $a = b = 0$.

We can then quickly show that any two models for $\mathbb{C}$ are essentially identical (isomorphic):
III.6.1.3. **Theorem.** Let \((C, \mathcal{R}, i)\) and \((C', \mathcal{R}', i')\) be models for \(\mathbb{C}\), and let \(\psi: \mathcal{R} \to \mathcal{R}'\) be the isomorphism induced by the specified isomorphisms of \(\mathcal{R}\) and \(\mathcal{R}'\) with \(\mathbb{R}\). Define \(\phi: C \to C'\) by

\[
\phi(a + bi) = \psi(a) + \psi(b)i'
\]

(this is well defined by III.6.1.2). Then \(\phi\) is a bijection, and for all \(z, w \in C\),

\[
\phi(z + w) = \phi(z) + \phi(w), \quad \phi(zw) = \phi(z)\phi(w).
\]

Thus the two models are isomorphic.

**Proof:** It is clear that \(\phi\) is a bijection from III.6.1.2, and the fact that \(\psi\) is a bijection. We need check only the algebraic formulas. If \(z = x + yi\) and \(w = u + vi\), we have

\[
zw = (x + yi)(u + vi) = xu + xvi + yui + yvi^2 = (xu - yv) + (xv + yu)i
\]

\[
\phi(z) + \phi(w) = [\psi(x) + \psi(y)i'] + [\psi(u) + \psi(v)i'] = [\psi(x) + \psi(u)] + [\psi(y) + \psi(v)]i' = \phi(x + u) + \phi(y + v)i' = \phi(z + w)
\]

\[
\phi(z)\phi(w) = [\psi(x) + \psi(y)i'][\psi(u) + \psi(v)i']
\]

\[
= \psi(x)\psi(u) + [\psi(x)\psi(v) + \psi(y)\psi(u)]i' + \psi(y)\psi(v)^2 = [\psi(x)\psi(u) - \psi(y)\psi(v)] + [\psi(x)\psi(v) + \psi(y)\psi(u)]i'
\]

\[
= \phi(xu - yv) + \phi(xv + yu)i' = \phi(xu - yv) + [xv + yu]i' = \phi(zw).
\]

Thus, once we have shown that there is a model for \(\mathbb{C}\), as usual we can talk about the complex numbers \(\mathbb{C}\), and regard \(\mathbb{R}\) as a subset of \(\mathbb{C}\).

III.6.1.4. If \((C, \mathcal{R}, i)\) is a model for \(\mathbb{C}\), and \(z = a + bi\) for \(a, b \in \mathcal{R}\), the numbers \(a\) and \(b\) are uniquely determined by \(z\) and are called the real and imaginary parts of \(z\), denoted \(a = \Re(z), b = \Im(z)\) (the notation \(a = \Re(z)\) and \(b = \Im(z)\) is also used). The element \(a - bi\) of \(\mathbb{C}\) is called the complex conjugate of \(z\), denoted \(\overline{z}\), and the real number \(\sqrt{a^2 + b^2}\) is called the absolute value (or modulus, magnitude, length, or norm) of \(z\), denoted \(|z|\). We have \(|i| = 1\), and \(|z|\) on \(\mathcal{R}\) coincides with the usual absolute value on \(\mathbb{R}\) under the specified identification.

The proofs in the next proposition are simple algebraic calculations and are left to the reader.
III.6.1.6. **Proposition.** Let \((C, R, i)\) be a model for \(\mathbb{C}\), and let \(z = x + yi\) and \(w = u + vi\) be elements of \(\mathbb{C}\). Then

(i) \(\bar{z} + \bar{w} = \bar{z + w}\) and \(\bar{z}w = \bar{z}\bar{w}\).

(ii) \(\bar{z} = \bar{z}\).

(iii) \(z\bar{z} = |z|^2\).

(iv) \(|zw| = |z||w|\). In particular, \(|-z| = |z|\) and \(|zi| = |z|\).

(v) \(|Re(z)| \leq |z|\) and \(|Im(z)| \leq |z|\).

It is also true that \(|z + w| \leq |z| + |w|\), but we defer the proof to the next section.

III.6.1.7. It is impossible to make \(\mathbb{C}\) (any model of \(\mathbb{C}\)) into an ordered field. For if \(P\) is a positive cone in \(\mathbb{C}\) satisfying (Pos), then either \(i\) or \(-i\) is in \(P\); in either case \(i^2 = (-i)^2 = -1\) would be in \(P\), a contradiction.

III.6.2. The Standard Model for \(\mathbb{C}\): the Complex Plane

There is a universally-used standard model for \(\mathbb{C}\), the complex plane. In fact, this model for \(\mathbb{C}\) is so standard that \(\mathbb{C}\) is generally defined to be, or at least thought of as, this model. There is no real harm in this, and even some advantage, since the geometric properties of the complex plane are of considerable use in complex analysis. But see III.6.2.24. and I.6.1.11. for some cautionary comments.

III.6.2.1. By considering real and imaginary parts, complex numbers can be naturally identified with ordered pairs of real numbers. So in our standard model, the elements will be ordered pairs of real numbers. Addition of complex numbers just corresponds to addition of the real parts and of the imaginary parts, i.e. coordinatewise addition, which is the usual addition of ordered pairs of numbers. The first calculation in the proof of III.6.1.3. gives a strong clue to how multiplication of ordered pairs should be defined. Thus we are led to the following definition:

III.6.2.2. **Definition.** Let \(\mathbb{C}\) be the set \(\mathbb{R}^2\) of ordered pairs of real numbers. Define addition and multiplication in \(\mathbb{C}\) by

\[
(x, y) + (u, v) = (x + u, y + v)
\]

\[
(x, y)(u, v) = (xu - yv, xv + yu)
\]

III.6.2.3. **Proposition.** The associative, commutative, and distributive laws hold for addition and multiplication in \(\mathbb{C}\).

**Proof:** The commutative laws obviously hold. The associative law for addition is a simple calculation:

\[
[(x, y) + (u, v)] + (s, t) = [(x + u) + s, (y + v) + t] = (x + [u + s], y + [v + t]) = (x, y) + [(u, v) + (s, t)].
\]
The associative law for multiplication and the distributive law are straightforward but tedious calculations which should probably just be left to the interested, skeptical, or masochistic reader, but we give them for completeness:

\[
[(x;y)(u;v)](s;t) = (xu - yv, xv + yu)(s, t) = (xus - yvs - [xv + yu])u + yv + xvs + yus)
= (xus - xvt - [yvs + yvt], xuT + xvs + yus - yv) = (x, y)(us - vt, ut + vs) = (x, y)[(u, v)(s, t)] .
\]

\[
(x, y)[(u, v) + (s, t)] = (x, y)(u + s, v + t) = (xu + xs - [yv + yt], xv + xt + yu + ys)
= ([xu - yv] + [xv + yu], [xv + yu] + [xt + ys]) = (xu - yv, xv + yu) + (xs - yt, xt + ys) = (x, y)(u, v) + (x, y)(s, t) .
\]

**III.6.2.4.** The pair \((0, 0)\) is an additive identity, and \((-x, -y)\) is an additive inverse for \((x, y)\). We also have \((1, 0)(x, y) = (x, y)\) for any \((x, y)\), so \((1, 0)\) is a multiplicative identity. There are also multiplicative inverses:

**III.6.2.5.** Proposition. If \((x, y) \neq (0, 0)\), then \(x^2 + y^2 > 0\) and \(\left(\frac{x}{x^2 + y^2}, -\frac{y}{x^2 + y^2}\right)\) is a multiplicative inverse for \((x, y)\).

**Proof:** The first statement follows from (). We have

\[
(x, y)\left(\frac{x}{x^2 + y^2}, -\frac{y}{x^2 + y^2}\right) = x\left(\frac{x}{x^2 + y^2} - y \left[-\frac{y}{x^2 + y^2}\right]\right) + y\left(\frac{x}{x^2 + y^2} + y \left[-\frac{x}{x^2 + y^2}\right]\right)
= \left(\frac{x^2}{x^2 + y^2} + \frac{y^2}{x^2 + y^2}, -\frac{x}{x^2 + y^2} + \frac{x}{x^2 + y^2}\right) = (1, 0) .
\]

We summarize these results:

**III.6.2.6.** Theorem. \(C\) is a field with respect to the operations + and \(\cdot\) of III.6.2.2., with zero element \((0, 0)\) and multiplicative identity \((1, 0)\).

**III.6.2.7.** Proposition. Let \(a, b, u, v \in \mathbb{R}\). Then in \(C\), \((a, 0)(u, v) = (au, av)\). In particular, \((a, 0)(b, 0) = (ab, 0)\). So, since \((a, 0) + (b, 0) = (a + b, 0)\), the map \(\psi : \mathbb{R} \to C\) with \(\psi(x) = (x, 0)\) is an isomorphism from \(\mathbb{R}\) onto the subfield \(\mathcal{R} = \{(x, 0) : x \in \mathbb{R}\}\) of \(C\).

The proof is a simple calculation left to the reader.

Finally, we need \(i\). The proof of the next proposition is also a simple calculation.

303
III.6.2.8. Proposition. In $C$, $(0, 1)^2 = (-1, 0)$. If $(x, y) \in C$, then $(x, y) = (x, 0) + (y, 0)(0, 1)$.

III.6.2.9. Thus, if we call $(0, 1)$ $i$, we have that every complex number $(x, y)$ can be written $a + bi$ for $a, b \in R$, namely $a = (x, 0), b = (y, 0)$. Under the identification of $R$ with $R$ via $\psi$, we have $i^2 = -1, x = Re((x, y)), y = Im((x, y)), (x, y) = (x, -y)$. We usually write $x + yi$ instead of $(x, y)$ for elements of $C$.

The definition of the complex conjugate, along with III.6.1.6., motivates the calculation in III.6.2.5.: we have $z^{-1} = \frac{\overline{z}}{|z|^2}$ if $z \neq 0$.

Summarizing again, we get our final result:

III.6.2.10. Theorem. $(C, R, (0, 1))$ is a model for $C$. Every model for $C$ is isomorphic to this one.

Geometry of $C$

We thus normally represent $x + yi \in C$ geometrically as $(x, y) \in C = R^2$. The real number $x$ is represented as $(x, 0)$, and $i$ is represented as $(0, 1)$. The $x$-axis in $R^2$ is $R$, called the real axis; the $y$-axis is the set of real multiples of $i$, called the imaginary axis. See Figure ().

III.6.2.11. We also have that $|x + yi| = \sqrt{x^2 + y^2}$. This is the same as $\|(x, y)\|$, where $\| \cdot \|$ is the standard norm in $R^2$ (). Thus $|x + yi|$ can be interpreted as the Euclidean distance between $x + yi = (x, y)$ and $0 = (0, 0)$. The next result then follows immediately from ():

III.6.2.12. Proposition. The triangle inequality holds in $C$: if $z, w \in C$, then $|z + w| \leq |z| + |w|$. In particular, $|z| \leq |Re(z)| + |Im(z)|$.

III.6.2.13. There are nice geometric interpretations of addition and multiplication in $C$ (regarded as $C$). Since addition in $C$ coincides with vector addition in $R^2$, it is given by the parallelogram law (); see Figure ()

Multiplication also has a simple interpretation using polar coordinates. We first describe the polar coordinates of an element of $C$. Some of this discussion must be regarded as informal until the trigonometric functions are properly defined (cf. (); note that no complex numbers are used in the definition of the trigonometric functions or development of their properties).

III.6.2.14. Definition. Let $z = x + yi \in C, z \neq 0$. If $(r, \theta)$ are the polar coordinates () of the point $(x, y) \in R^2$, then $r = \sqrt{x^2 + y^2} = |x + yi|$ is called the modulus, magnitude, length, or norm of $z$, and $\theta$ is called the argument of $z$, denoted $Arg(z)$. We have $x = r \cos \theta$ and $y = r \sin \theta$; if $x \neq 0$, we have $\tan \theta = \frac{y}{x}$. We write $e^{i\theta}$ for the complex number $\cos \theta + i \sin \theta$.

Conversely, if $(r, \theta)$ is a pair of real numbers with $r \neq 0$, then there is a unique $z \in C$ with $r = |z|$ and $\theta = Arg(z)$. We do not define $Arg(0)$. The argument of a positive real number is 0, and the argument of a negative real number is $\pi$.
Note that the argument of a complex number is only determined up to addition of a multiple of $2\pi$. This ambiguity leads to considerable difficulties, but also a certain richness, in complex analysis; cf. III.6.2.21. In particular, the argument cannot be defined continuously for all $z \in \mathbb{C} \setminus \{0\}$, although it can be continuously defined locally (except around 0). Note that even though $\theta$ is not uniquely determined by $z$, the complex number $e^{i\theta}$ is uniquely determined.

We will consider $e^{i\theta}$ to simply be a convenient notational abbreviation for $\cos \theta + i \sin \theta$, but it is actually a special case of the complex exponential function (X.1.1.8 (iii)). This notation retains at least one important property of the usual exponential function:

III.6.2.15. **Proposition.** If $\theta$ and $\phi$ are real numbers, then $e^{i(\theta+\phi)} = e^{i\theta} e^{i\phi}$.

**Proof:** This is just an application of basic trigonometric identities. We have

$$e^{i(\theta+\phi)} = \cos(\theta + \phi) + i \sin(\theta + \phi) = [\cos \theta \cos \phi - \sin \theta \sin \phi] + i[\sin \theta \cos \phi + \cos \theta \sin \phi]$$

$$= (\cos \theta + i \sin \theta)(\cos \phi + i \sin \phi) = e^{i\theta} e^{i\phi}.$$

The next observation is simple, but fundamental:

III.6.2.16. **Proposition.** If $z \in \mathbb{C}$, $z \neq 0$, and $r = |z|$, $\theta = \text{Arg}(z)$, then $z = re^{i\theta}$. So $e^{i\theta} = z/|z|$.

As a corollary of the last two propositions, we get a geometric interpretation of multiplication:

III.6.2.17. **Corollary.** Let $z$ and $w$ be nonzero complex numbers. Then $|zw| = |z||w|$ and $\text{Arg}(zw) = \text{Arg}(z) + \text{Arg}(w)$ (where the last formula is interpreted modulo $2\pi$). Alternatively, if $z = re^{i\theta}$ and $w = se^{i\phi}$ with $r, s, \theta, \phi \in \mathbb{R}$ and $r, s > 0$, then $zw = rse^{i(\theta+\phi)}$.

III.6.2.18. Multiplication by a fixed complex number $z$ can thus be interpreted geometrically as scaling by a factor of $|z|$ and rotating counterclockwise around the origin by an angle $\text{Arg}(z)$. See Figure ( ). This interpretation is in line with the geometric interpretation of multiplication of vectors by real numbers (scalars): multiplication by a positive real number just scales length, and multiplication by a negative real number scales length and reverses direction (rotates by an angle $\pi$).

III.6.2.19. The polar coordinate representation provides an easy way to show that complex numbers have arbitrary roots. Suppose $z \in \mathbb{C}$ and $n \in \mathbb{N}$; we want to show there is an $x \in \mathbb{C}$ with $x^n = z$. If $z = 0$, this is obvious (and the only solution is $x = 0$). Suppose $z \neq 0$. Set $s = |z|^{1/n}$ and $\phi = \text{Arg}(z)/n$. Then $w = se^{i\phi}$ satisfies $w^n = z$. Any multiple of $\frac{2\pi}{n}$ can be added to $\phi$ with the same result; thus there are exactly $n$ distinct solutions in $\mathbb{C}$ to $x^n = z$. Summarizing, we obtain:

III.6.2.20. **Proposition.** Let $z \in \mathbb{C}$ and $n \in \mathbb{N}$. Then the equation $x^n = z$ has a solution in $\mathbb{C}$. If $z = 0$, the unique solution is $x = 0$. If $z \neq 0$, there are exactly $n$ solutions, distributed uniformly on the circle of radius $|z|^{1/n}$ around 0 at angles $\frac{\text{Arg}(z)}{n} + \frac{2k\pi}{n}$, $0 \leq k \leq n - 1$. 

305
III.6.2.21. In particular, every nonzero complex number $z$ has exactly two square roots, which are negatives of each other on the line through the origin of angle $\frac{\text{Arg}(z)}{2}$ with the positive real axis. However, as $z$ varies there is no way to choose one of the two square roots of $z$ continuously on the whole complex plane, although a continuous choice can be made locally (except around 0). Thus there is no continuous square root function from all of $\mathbb{C}$ to $\mathbb{C}$.

There is a considerable generalization of III.6.2.20. which is one of the most important theorems of algebra, as its name suggests.

III.6.2.22. Theorem. [Fundamental Theorem of Algebra] Any nonconstant polynomial with complex coefficients has a root in $\mathbb{C}$. ($\mathbb{C}$ is algebraically closed.)

There are several quite different proofs of this theorem; see X.1.4.2. for a nice one. III.6.2.20. is the special case of the polynomial $x^n - z$ for any $z \in \mathbb{C}$.

III.6.2.23. As a result, there is no algebraic reason to try to expand the number system beyond $\mathbb{C}$, so $\mathbb{C}$ is a natural culmination of the progression from $\mathbb{N}$ through $\mathbb{Z}$, $\mathbb{Q}$, and $\mathbb{R}$.

III.6.2.24. As mentioned earlier, although $\mathbb{C}$ is normally, and profitably, thought of as being the complex plane $\mathbb{C}$, it must be kept in the back of the mind that $\mathbb{C}$ is only a model for $\mathbb{C}$. For example, we want to regard $\mathbb{R}$ as a subfield of $\mathbb{C}$. But $\mathbb{R}$ is not a subset of $\mathbb{C}$: the subfield $\mathbb{R}$ of ordered pairs of real numbers with second coordinate 0 is not the same thing as $\mathbb{R}$, although there is an obvious and natural one-one correspondence between them. And there are other models of $\mathbb{C}$ which are useful in some contexts; see III.6.3.1., III.6.3.2.(e), III.6.3.3. for some examples.

III.6.3. Exercises

III.6.3.1. Consider the following subset of $M_2(\mathbb{R})$:

$$\mathcal{C} = \left\{ \begin{bmatrix} x & -y \\ y & x \end{bmatrix} : x, y \in \mathbb{R} \right\}.$$

(a) Show that $\mathcal{C}$ is a subring of $M_2(\mathbb{R})$.
(b) Show that $\mathcal{C}$ is unital and commutative.
(c) Show that every element $z$ of $\mathcal{C}$ can be written uniquely as $z = x_1 + yi$ for $x, y \in \mathbb{R}$, where

$$1 = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \quad i = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}.$$  

Define $\bar{z} = x_1 - yi$. Show that $zz = (x^2 + y^2)1 = (\text{det } z)1$. If we define $|z| = \sqrt{x^2 + y^2}$, then $|zw| = |z||w|$ for all $z, w \in \mathcal{C}$.
(d) Show that every nonzero element of $\mathcal{C}$ has a multiplicative inverse. Thus $\mathcal{C}$ is a field.
(e) Show that $\mathfrak{R} = \{x_1 : x \in \mathbb{R}\}$ is a subfield of $\mathcal{C}$ isomorphic to $\mathbb{R}$.
(f) Show that $(\mathcal{C}, \mathfrak{R}, i)$ is a model for $\mathbb{C}$.
This model for \( \mathbb{C} \) arises naturally from linear algebra. If \( z = a + bi \) is a fixed element of \( \mathbb{C} \), then multiplication by \( z \) is a real linear transformation \( M_z \) of \( \mathbb{C} = \mathbb{R}^2 \), and the matrix of this linear transformation with respect to the standard basis \( \{1, i\} \) of \( \mathbb{C} = \mathbb{R}^2 \) is \[
abla z = \begin{bmatrix} a & -b \\ b & a \end{bmatrix}.
\]

III.6.3.2. Consider the following subset of \( M_2(\mathbb{C}) \):
\[
\mathbb{H} = \left\{ \begin{bmatrix} z & -\bar{w} \\ w & \bar{z} \end{bmatrix} : z, w \in \mathbb{C} \right\}.
\]

(a) Show that \( \mathbb{H} \) is a subring of \( M_2(\mathbb{C}) \). (By considering \( \mathbb{C} \) as a subring of \( M_2(\mathbb{R}) \) as in (), \( \mathbb{H} \) can be rewritten as the subring
\[
\left\{ \begin{bmatrix} a & -c & -b & -d \\ c & a & d & -b \\ b & -d & a & c \\ d & b & -c & a \end{bmatrix} : a, b, c, d \in \mathbb{R} \right\}
\]

of \( M_4(\mathbb{R}) \).)

(b) Show that \( \mathbb{H} \) is unital and noncommutative. (Consider the following elements:
\[
1 = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \quad i = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}, \quad j = \begin{bmatrix} i & 0 \\ 0 & -i \end{bmatrix}, \quad k = \begin{bmatrix} 0 & i \\ i & 0 \end{bmatrix}.
\]

Compute \( ij, ji, jk, k j, ki, ik \).]

(c) Show that every element \( x \) of \( \mathbb{H} \) can be written uniquely as \( x = a1 + bi + cj + dk \) for \( a, b, c, d \in \mathbb{R} \). Define \( \bar{x} = a1 - bi - cj - dk \). Show that \( x\bar{x} = (a^2 + b^2 + c^2 + d^2)1 \). If we define \( |x| = \sqrt{a^2 + b^2 + c^2 + d^2} \), then \( |x y| = |x||y| \) for all \( x, y \in \mathbb{H} \).

(d) Show that every nonzero element of \( \mathbb{H} \) has a multiplicative inverse. Thus \( \mathbb{H} \) satisfies all the axioms for a field except (M2). Such a ring is called a division ring or skew field.

(e) Show that each of the sets \( \mathbb{R} + \mathbb{R}i, \mathbb{R} + \mathbb{R}j, \) and \( \mathbb{R} + \mathbb{R}k \) is a subring of \( \mathbb{H} \) isomorphic to \( \mathbb{C} \).

(f) If \( x = a1 + bi + cj + dk \in \mathbb{H} \), \( a \) is called the real part or scalar part of \( x \), and \( bi + cj + dk \) the imaginary part of \( x \). If \( i, j, k \) are the standard basis vectors in \( \mathbb{R}^3 \), then \( bi + cj + dk \) can be identified with the vector \( \mathbf{v} = bi + cj + dk \in \mathbb{R}^3 \), called the vector part of \( x \). Thus an element of \( \mathbb{H} \) may be regarded as a pair \( (a, \mathbf{v}) \), where \( a \in \mathbb{R} \) and \( \mathbf{v} \in \mathbb{R}^3 \). Show that the addition is coordinatewise, and the multiplication is given by
\[
(a, \mathbf{v})(b, \mathbf{w}) = (ab - \mathbf{v} \cdot \mathbf{w}, a\mathbf{w} + b\mathbf{v} + \mathbf{v} \times \mathbf{w})
\]
where \( \cdot \) and \( \times \) are the dot and cross product of vectors in \( \mathbb{R}^3 \). (Although \( \times \) is not associative, this multiplication is associative!)

The ring \( \mathbb{H} \) is called the ring of quaternions. The name refers to the fact that it is a four-dimensional vector space (algebra) over \( \mathbb{R} \). The letter \( \mathbb{H} \) is used in honor of the Irish mathematician William Rowan Hamilton, who first defined the quaternions in 1843 and studied their properties. Hamilton became convinced that quaternions were the fundamental structure which could be used to describe and explain most of mathematics and physics. While quaternions have beautiful and useful algebraic and geometric structure, they have not quite lived up to Hamilton’s expectations, although recently they have become an increasingly
important computational tool in such areas as computer graphics and control theory. Quaternions are also of some importance in quantum mechanics; the matrices $i, j, k$ are called the Pauli spin matrices. See (c) for details.

There is a way to make $\mathbb{R}^8$ into a somewhat similar algebraic structure called the Cayley numbers in which every nonzero element has a multiplicative inverse. Multiplication in the Cayley numbers is, however, not associative. It turns out that the only values of $n$ for which $\mathbb{R}^n$ can be made into such a structure are $n = 1, 2, 4,$ and $8$, and the only structures possible are $\mathbb{R}$, $\mathbb{C}$, $\mathbb{H}$, and the Cayley numbers. See (c) for details.

III.6.3.3. Let $\mathbb{R}[X]$ denote the set of all polynomials with real coefficients, i.e.

$$\mathbb{R}[X] = \{a_0 + a_1 X + a_2 X^2 + \cdots + a_n X^n : n \in \mathbb{N}_0, a_0, \ldots, a_n \in \mathbb{R}\}.$$ 

(a) Show that $\mathbb{R}[X]$ is a unital commutative ring with usual addition and multiplication of polynomials.

(b) Let $J$ be the set of all polynomials in $\mathbb{R}[X]$ which are divisible by $X^2 + 1$. Show that $J$ is an ideal (Exercise III.3.7.4.) in $\mathbb{R}[X]$.

(c) Show that the quotient ring $\mathbb{R}[X]/J$ is a field which is a model for $\mathbb{C}$, with the classes of the constant functions playing the role of $\mathbb{R}$, and the class of $X$ playing the role of $i$.

Levi-Civita numbers
III.7. Fundamental Theorems About $\mathbb{R}$

III.7.1. Partitions

In this section, we will discuss partitions and tagged partitions of intervals in $\mathbb{R}$. The primary use of partitions is in Riemann-type integration, but several important basic theorems in analysis can also be proved using tagged partitions.

**Definition.** Let $[a, b]$ be a closed bounded interval in $\mathbb{R}$. A partition of $[a, b]$ is a division of $[a, b]$ into a finite number of subintervals $\{[x_{i-1}, x_i] : 1 \leq i \leq n\}$ with only endpoints in common. A partition $\mathcal{P}$ is usually described by its set of endpoints $\{x_0, x_1, \ldots, x_n\}$, where $a = x_0 < x_1 < \cdots < x_n = b$.

The norm or mesh of a partition $\mathcal{P} = \{x_0, x_1, \ldots, x_n\}$ is
\[ \|\mathcal{P}\| = \max\{x_i - x_{i-1} : 1 \leq i \leq n\}. \]

A tag in an interval $[c, d]$ is a specified number in $[c, d]$. A tagged partition is a partition $\{x_0, x_1, \ldots, x_n\}$ with a specified tag $t_i$ in $[x_{i-1}, x_i]$ for each $i$. A tagged partition is usually denoted by $\mathcal{P} = \{x_0, x_1, \ldots, x_n; t_1, \ldots, t_n\}$.

The norm or mesh of a partition is a measure of how fine the partition is. There is a more sophisticated and flexible notion of fineness of a partition based on gauges:

**Definition.** A gauge on an interval $[a, b]$ is a function $\delta$ from $[a, b]$ to $(0, \infty)$.

If $\delta$ is a gauge on $[a, b]$, a tagged partition $\mathcal{P} = \{x_0, x_1, \ldots, x_n; t_1, \ldots, t_n\}$ of $[a, b]$ is $\delta$-fine if $x_i - x_{i-1} < \delta(t_i)$ for all $1 \leq i \leq n$.

The word “tagged” is frequently omitted in referring to $\delta$-fine partitions, although it must be kept in mind that a $\delta$-fine partition is by definition tagged.

Note that a gauge is just a strictly positive real-valued function on $[a, b]$; no continuity or other restrictions on $\delta$ are assumed. Allowing discontinuous gauges, and ones not bounded below by a positive number, gives the theory of gauges and fine partitions its power.

The smaller a gauge $\delta$ is, the harder it is for a partition to be $\delta$-fine. The most common gauges are constant functions, e.g. $\delta(x) = \epsilon$ for all $x$. For such a $\delta$, a tagged partition $\mathcal{P}$ is $\delta$-fine if and only if $\|\mathcal{P}\| < \epsilon$.

If $\delta$ is a constant gauge, then it follows easily from the Archimedean property of $\mathbb{R}$ that there is a $\delta$-fine partition of any interval $[a, b]$. However, it is not at all obvious that a nonconstant gauge $\delta$ on $[a, b]$ which is not bounded below by a positive number has a $\delta$-fine partition. This turns out to be true, and is the main result of this section; this theorem is actually equivalent to the Completeness Property and easily gives other important equivalent properties of $\mathbb{R}$.

**Theorem.** [Fine Partition Theorem] Let $\delta$ be any gauge on an interval $[a, b]$ in $\mathbb{R}$. Then there is a $\delta$-fine partition of $[a, b]$.

**Proof:** Let $S = \{x \in [a, b] : \text{there is a } \delta\text{-fine partition of } [a, x]\}$. If $a < x < a + \delta(a)$, then $\mathcal{P} = \{a, x; a\}$ is a $\delta$-fine partition of $[a, x]$ (with one subinterval). So $S$ is nonempty. Let $c = \sup S$; then $c \geq a + \delta(a) > a$.

We will show that $c = b$. First note that there is a $\delta$-fine partition of $[a, c]$; if $x \in S$ with $c - \delta(c) < x < c$, and $\{a, x_1, \ldots, x_{n-1}, x; t_1, \ldots, t_n\}$ is a $\delta$-fine partition of $[a, x]$, then $\{a, x_1, \ldots, x_{n-1}, x, c; t_1, \ldots, t_n, c\}$ is a $\delta$-fine partition of $[a, c]$. Now suppose that $c < b$, and let $y \in [a, b]$, $c < y < c + \delta(c)$; then, using the previous notation, $\{a, x_1, \ldots, x_{n-1}, x, c; y; t_1, \ldots, t_n, c, c\}$ is a $\delta$-fine partition of $[a, y]$, contradicting the definition of $c$. Thus $c = b$ and the theorem is proved.
III.7.2. Compactness and Continuity

From the Fine Partition Theorem, we derive several fundamental results about the real numbers. The standard proofs of all these results resemble the proof of the Fine Partition Theorem; our derivation of the results from the Fine Partition Theorem follows R. A. Gordon [?].

A collection $\mathcal{U} = \{U_i : i \in \Omega\}$ of open sets in $\mathbb{R}$ (or in a general topological space) is an open cover of a set $S$ if $S \subseteq \cup U_i$. A subcover of $\mathcal{U}$ for $S$ is a subset of $\mathcal{U}$ which is also a cover of $S$. A subset $F$ of $\mathbb{R}$ is compact if every open cover of $F$ has a finite subcover.

**Theorem.** A closed bounded interval $[a, b]$ in $\mathbb{R}$ is compact.

**Proof:** Let $\mathcal{U} = \{U_i : i \in \Omega\}$ be an open cover of $[a, b]$. For each $x \in [a, b]$, choose an $i_x \in \Omega$ with $x \in U_{i_x}$, and choose $\delta(x) > 0$ such that $(x - \delta(x), x + \delta(x)) \subseteq U_{i_x}$. Then $\delta : [a, b] \to (0, \infty)$ is a gauge on $[a, b]$. Let $\{x_0, x_1, \ldots, x_n, t_1, \ldots, t_m\}$ be a $\delta$-fine partition of $[a, b]$. Then $[x_{k-1}, x_k] \subseteq (t_k - \delta(t_k), t_k + \delta(t_k)) \subseteq U_{i_{t_k}}$ for each $k$, so $\{U_{i_1}, \ldots, U_{i_{t_n}}\}$ is a finite subcover of $\mathcal{U}$.

**Corollary.** Every closed bounded subset of $\mathbb{R}$ is compact.

**Proof:** If $F$ is closed and contained in $[a, b]$, and $\mathcal{U}$ is an open cover of $F$, then $\mathcal{U} \cup \{F^c\}$ is an open cover of $[a, b]$, and this open cover has a finite subcover $\mathcal{V}$ for $[a, b]$. $\mathcal{V} \setminus \{F^c\} \subseteq \mathcal{U}$ is then a finite subcover of $\mathcal{U}$ for $F$.

Virtually the same proof shows that any closed subset of a compact set is compact. The converse is also true:

**Proposition.** A compact subset of $\mathbb{R}$ is closed and bounded.

**Proof:** Let $E$ be a compact subset of $\mathbb{R}$. If $U_m = (-m, m)$, then $\{U_m : m \in \mathbb{N}\}$ is an open cover of $E$, so there is a finite subcover $\{U_{m_1}, \ldots, U_{m_n}\}$. If $M = \max\{m_1, \ldots, m_n\}$, then $E \subseteq (-M, M)$. To see that $E$ is closed, let $c \in E^c$, and for each $\epsilon > 0$ let $U_\epsilon = \{x \in \mathbb{R} : |x - c| > \epsilon\}$. Then $\{U_\epsilon : \epsilon > 0\}$ is an open cover of $E$, so there is a finite subcover $\{U_{\epsilon_1}, \ldots, U_{\epsilon_n}\}$. If $\epsilon = \min\{\epsilon_1, \ldots, \epsilon_n\}$, then $(c - \epsilon, c + \epsilon) \subseteq E^c$, so $E^c$ is open.

Combining these two results, we obtain:

**Corollary.** [Heine-Borel Theorem] A subset of $\mathbb{R}$ is compact if and only if it is closed and bounded.

The Heine-Borel Theorem gives a generalization of the Nested Interval Theorem:

**Theorem.** Let $(F_m)$ be a decreasing sequence of nonempty closed bounded subsets of $\mathbb{R}$. Then $\cap_{m} F_m$ is not empty.

**Proof:** Suppose $F_1 \subseteq [a, b]$. If $\cap F_m = \emptyset$, then $\{F_m^c : m \in \mathbb{N}\}$ is an open cover of $[a, b]$, which has a finite subcover $\{F_{m_1}, \ldots, F_{m_n}\}$. If $M = \max\{m_1, \ldots, m_n\}$, then $F_M = F_{m_1} \cap \cdots \cap F_{m_n} = \emptyset$, a contradiction.

From this, we get the important Bolzano-Weierstrass Theorem:

**Theorem.** [Bolzano-Weierstrass Theorem] Every bounded sequence in $\mathbb{R}$ has a convergent subsequence.
The definition of the formula for the function.

Proof: Suppose \( c \) is not one of the \( b_n \). For \( \epsilon > 0 \), choose \( \delta_1 > 0 \) such that \( c - \delta_1 < x < c \) and \( x \in E \) imply \( |f(x) - f(c)| < \epsilon \) (using the fact that \( f \) is continuous on \( E \)). Since \( c \) is not one of the \( b_n \), there is a

$$
\text{We then get some basic theorems about continuous functions as consequences:}
$$

**Theorem.** Let \( E \) be a compact subset of \( \mathbb{R} \), and let \( f : E \to \mathbb{R} \) be continuous. Then \( f(E) \) is compact.

**Proof:** We first show that \( f(E) \) is bounded. Suppose for each \( n \) there is an \( x_n \in E \) with \( |f(x_n)| \geq n \). Since \( E \) is bounded, \( (x_n) \) has a subsequence \( (x_{k_n}) \) converging to some \( y \in \mathbb{R} \), and \( y \in E \) since \( E \) is closed. Because \( f \) is continuous, the sequence \( (f(x_{k_n})) \) converges to \( f(y) \) by the Sequential Criterion. But this is impossible since \( (f(x_{k_n})) \) is unbounded by construction, a contradiction.

Now suppose that \( c \) is in the closure of \( f(E) \), and choose \( x_n \in E \) such that \( f(x_n) \to c \). Again by the Bolzano-Weierstrass Theorem, \( (x_n) \) has a subsequence \( (x_{k_n}) \) converging to some \( y \in E \). But then \( (f(x_{k_n})) \) converges to \( f(y) \) by the Sequential Criterion: since \( (f(x_{k_n})) \) converges to \( c \), we have \( c = f(y) \in f(E) \) and \( f(E) \) is closed.

**Corollary.** [Max-Min Theorem] Let \( E \) be a closed bounded subset of \( \mathbb{R} \), and \( f : E \to \mathbb{R} \) a continuous function. Then \( f \) is bounded on \( E \) and attains its maximum and minimum on \( E \), i.e. there are \( c, d \in E \) such that \( f(c) \leq f(x) \leq f(d) \) for all \( x \in E \).

For the proof, just note that \( f(E) \) is compact and that a compact subset of \( \mathbb{R} \) has a maximum and a minimum element.

See ( ) for a more complete discussion of compactness.

The next theorem is a variation of the Tietze Extension Theorem of topology ( ). It is certainly not true that a continuous function on a subset \( E \) of \( \mathbb{R} \) can be extended to a continuous function on all of \( \mathbb{R} \); there are many counterexamples, such as \( f(x) = \frac{1}{x} \) on \((0, \infty)\). But if \( E \) is closed, there is always an extension:

**Theorem.** [Tietze Extension Theorem for \( \mathbb{R} \)] Let \( E \) be a closed subset of \( \mathbb{R} \), and \( f : E \to \mathbb{R} \) a continuous function. Then \( f \) can be extended to a continuous function on all of \( \mathbb{R} \), i.e. there is a continuous function \( g : \mathbb{R} \to \mathbb{R} \) which agrees with \( f \) on \( E \).

**Proof:** The definition of \( g \) is very simple. Let \( U = E^c; \) then \( U \) is open, so it consists of a union of countably many disjoint open intervals \( I_n = (a_n, b_n) \) and possibly an unbounded interval of the form \((\infty, a)\) (if \( E \) has a smallest element \( a \)) and/or an unbounded interval \((b, \infty)\) (if \( E \) has a largest element \( b \)). Define \( g \) to be equal to \( f \) on \( E \), linear on \([a_n, b_n] \) for each \( n \), and if necessary constant on \((\infty, a)\) and/or \([b, \infty)\). If \( x \in I_n \), the formula for \( g(x) \) is

$$
g(x) = f(a_n) + \frac{f(b_n) - f(a_n)}{b_n - a_n} (x - a_n).$$

It is geometrically clear that \( g \) is continuous everywhere, but takes a little work to write down a careful proof. Suppose \( c \in \mathbb{R} \); we will show \( g \) is continuous at \( c \). If \( c \notin E \), this is obvious since \( g \) is linear in a neighborhood of \( c \). Suppose \( c \in E \). We will show that \( \lim_{x \to c} f(x) = f(c) \). Let \( \epsilon > 0 \) be given. If \( c = b_n \) for some \( n \), let \( \delta = \min(b_n - a_n, 1/(b_n - f(a_n)) \) (if \( f(a_n) = f(b_n) \), set \( \delta = b_n - a_n \)). Then if \( c - \delta < x < c \), \( g \) is linear on \([x, c]\), so \( |f(x) - f(c)| < \epsilon \).

Now suppose that \( c \) is not one of the \( b_n \). For \( \epsilon > 0 \), choose \( \delta_1 > 0 \) such that \( c - \delta_1 < x < c \) and \( x \in E \) imply \( |f(x) - f(c)| < \epsilon \) (using the fact that \( f \) is continuous on \( E \)). Since \( c \) is not one of the \( b_n \), there is a
Let \( f : [a, b] \to \mathbb{R} \) be bounded, and continuous a.e. Then \( f \) is Riemann integrable on \([a, b] \). 

Theorem. Let \( F \) be a closed bounded set in \( \mathbb{R} \). Then any continuous function from \( F \) to \( \mathbb{R} \) is uniformly continuous.

Apply this theorem to \( F = [a, b] \setminus U \): there is thus a \( \delta > 0 \) such that, whenever \( x, t \in F \) and \( |x - t| < \delta \), \( |f(x) - f(t)| < \epsilon / 2(b - a) \).

Now choose a partition \( \mathcal{P} \) of \([a, b]\), containing the intervals \( I_1, \ldots, I_n \), and such that the other intervals in the partition all have length < \( \delta \). Let \( \phi \) and \( \psi \) be the step functions with values \( \inf_{x \in I} f(x) \) and \( \sup_{x \in I} f(x) \) on \( I \) respectively, for each subinterval \( I \) in \( \mathcal{P} \). (It doesn’t matter how \( \phi \) and \( \psi \) are defined on the endpoints of the subintervals so long as \( \phi \leq f \leq \psi \) there.) Then \( 0 \leq \psi - \phi \leq 2M \), and \( \psi - \phi \leq \epsilon / 2(b - a) \) on \( F \). So

\[
\int_{[a,b]} (\psi - \phi) \, d\lambda = \int_U (\psi - \phi) \, d\lambda + \int_F (\psi - \phi) \, d\lambda \leq 2M \lambda(U) + \frac{\epsilon}{2(b-a)} \lambda(F)
\]

\[
< 2M \frac{\epsilon}{4M} + \frac{\epsilon}{2(b-a)} (b-a) = \epsilon.
\]

Now consider the more difficult case where \( U \) is an infinite disjoint union of open intervals \( I_1, I_2, \ldots \). We may define \( F \) and \( \delta \) as before. We can choose a sequence \( \{\mathcal{P}_n\} \) of partitions of \([a, b]\) such that \( \mathcal{P}_n \) contains \( I_1, \ldots, I_n \) and such that the rest of the subintervals have length < \( \delta \), and define \( \phi_n, \psi_n \) as above. We may with some care arrange for the \( \mathcal{P}_n \) to become successively finer as \( n \) increases (i.e. each interval in \( \mathcal{P}_n \) is a union of intervals in \( \mathcal{P}_{n+1} \)): it is only necessary to insure that every interval \( I_k \) in \( U \) is entirely contained in a single subinterval in \( \mathcal{P}_1 \), which is easily arranged since there are only finitely many of the \( I_k \) with length \( \geq \delta / 2 \). If the \( \mathcal{P}_n \) are successively finer, we have

\[
\phi_1 \leq \phi_2 \leq \cdots \leq \phi \leq \cdots \leq \psi_2 \leq \psi_1.
\]

Let \( \phi = \sup \phi_n, \psi = \inf \psi_n \). Then the \( \phi_n \) and \( \psi_n \) are step functions, but \( \phi \) and \( \psi \) are not step functions in general. However, they are Lebesgue integrable. Also, we have \( \phi \leq f \leq \psi, 0 \leq \psi - \phi \leq 2M \), and \( \psi - \phi \leq \epsilon / 2(b-a) \) on \( F \), so as before we have \( \int_{[a,b]} (\psi - \phi) \, d\lambda < \epsilon \). But by the Monotone Convergence Theorem (or the Dominated Convergence Theorem),

\[
\int_{[a,b]} (\psi - \phi) \, d\lambda = \lim_{n \to \infty} \int_{[a,b]} (\psi_n - \phi_n) \, d\lambda
\]

so \( \int_{[a,b]} (\psi_n - \phi_n) \, d\lambda \leq \epsilon \) for sufficiently large \( n \).
III.7.3. The Creeping Lemma

An alternate approach to many fundamental theorems about \( \mathbb{R} \) was presented in [MR68], based on the following fact which depends crucially on the Completeness Property of \( \mathbb{R} \):

**Theorem. [Creeping Lemma]** Let \( I \) be an interval in \( \mathbb{R} \), and let \( R \) be a transitive relation on \( I \) with the following property: for every \( x \in I \), there is a \( \delta_x > 0 \) (perhaps depending on \( x \)) such that, whenever \( y \in I \), \( x - \delta_x < y \leq x \), then \( yRx \), and whenever \( y \in I \), \( x \leq y < x + \delta_x \), then \( xRy \). Then \( R \) extends \( \leq \) on \( I \), i.e. for every \( a, b \in I \), \( a \leq b \), we have \( aRb \).

**Proof:** \( R \) is automatically reflexive by the assumed condition. Fix \( a, b \in I \), \( a \leq b \). We may suppose \( a < b \). Let
\[
S = \{ x \in [a, b] : aRx \} .
\]
Then \( S \) is a bounded subset of \( \mathbb{R} \) which is nonempty since \( a \in S \). Set \( c = \sup(S) \). Then \( c > a \) since \( [a, a + \delta_a] \subseteq S \) for some \( \delta_a > 0 \), so \( c \geq a + \delta_a \).

There is a \( \delta_c > 0 \) such that if \( c - \delta_c < y \leq c \), then \( yRc \). Since \( c = \sup(S) \), there is an \( x \in S \), \( c - \delta_c < x \leq c \); then \( aRx \) and \( xRc \). Thus \( aRc \) by transitivity.

If \( c < b \), then if \( c < x < \min(c + \delta_c, b) \), we have \( cRx \); since \( aRc \), we have \( aRx \), so \( x \in S \), contradicting that \( c = \sup(S) \). Thus \( c = b \). \( \diamond \)

The next corollary is called the *Weak Creeping Lemma* in [MR68]. For a slick version of the proof, see ().

**Corollary.** Let \( I \) be an interval in \( \mathbb{R} \), and let \( R \) be an equivalence relation on \( I \) with the following property: for every \( x \in I \), there is a \( \delta_x > 0 \) (perhaps depending on \( x \)) such that, whenever \( y \in I \), \( |x - y| < \delta_x \), then \( xRy \). Then \( R \) is the full relation on \( I \), i.e. for every \( a, b \in I \), we have \( aRb \).

Here is a simple sample application. Only the weak version is needed.

**Proposition.** Let \( f \) be a continuous function on a closed bounded interval \([a, b] \). Then \( f \) is bounded on \([a, b]\).

**Proof:** Define an equivalence relation on \( I = [a, b] \) by \( x \sim y \) if \( f \) is bounded on the closed interval between \( x \) and \( y \). Fix \( x \in [a, b] \). There is a \( \delta_x \) such that \( |f(x) - f(y)| < 1 \) if \( y \in [a, b] \) and \( |x - y| < \delta_x \). Thus \( x \sim y \) if \( |x - y| < \delta_x \). By III.7.3.2., \( a \sim b \). \( \diamond \)

**Corollary.** [Extreme Value Theorem] Let \( f \) be a continuous function on a closed bounded interval \([a, b] \). Then \( f \) is bounded on \([a, b]\), and attains a maximum and minimum on \([a, b]\).

**Proof:** By III.7.3.3., \( f \) is bounded. Let \( c = \sup\{ f(x) : x \in [a, b] \} \). If \( f \) never takes the value \( c \) on \([a, b]\), set \( g(x) = \frac{1}{c - f(x)} \); then \( g \) is continuous on \([a, b]\), and positive everywhere. By III.7.3.3., \( g \) is bounded. If \( d = \sup\{ g(x) : x \in [a, b] \} \), then
\[
\frac{1}{c - f(x)} \leq d
\]

313
\[
\frac{1}{d} \leq c - f(x)
\]
\[
f(x) \leq c - \frac{1}{d}
\]
for all \(x \in [a, b]\), contradicting the definition of \(c\). Thus \(f\) takes the value \(c\) on \([a, b]\). The proof that \(f\) attains a minimum is nearly identical.

### III.7.4. Exercises

#### III.7.4.1.
Using the proof of III.7.1. as a model, give a direct proof of III.7.2..

#### III.7.4.2.
The Completeness Property of \(\mathbb{R}\) implies the Fine Partition Theorem, as the proof of III.7.1. shows. Show that the conclusion of the Fine Partition Theorem implies the Completeness Property as follows.

(a) Suppose \(S\) is a nonempty bounded subset of \(\mathbb{R}\) with no supremum. Let \(a \in S\), and \(b\) an upper bound for \(S\).

(b) Define a gauge \(\delta\) on \([a, b]\) as follows. Let \(x \in [a, b]\). If \(x\) is an upper bound for \(S\), let \(y\) be a smaller upper bound for \(S\), and define \(\delta(x) = x - y\). And if \(x\) is not an upper bound for \(S\), let \(y \in S\) with \(x < y\) and set \(\delta(x) = y - x\). (To avoid using the Axiom of Choice, if \(x\) is an upper bound for \(S\) set \(\delta(x) = \frac{1}{n}\), where \(n\) is the smallest natural number for which \(x - \frac{1}{n}\) is an upper bound for \(S\); if \(x\) is not an upper bound for \(S\), let \(\delta(x) = \frac{1}{n}\), where \(n\) is the smallest natural number for which there is a \(y \in S\) with \(x + \frac{1}{n} \leq y\).)

(c) Show that there is no \(\delta\)-fine partition of \([a, b]\).

#### III.7.4.3.
Explain why the name “Creeping Lemma” is appropriate. (See [Pét38].)
III.8. Representation of Real Numbers

III.8.1. Decimal Expansions

“It is India that gave us the ingenious method of expressing all numbers by means of ten symbols, each symbol receiving a value of position as well as an absolute value; a profound and important idea which appears so simple to us now that we ignore its true merit. But its very simplicity and the great ease which it has lent to computations put our arithmetic in the first rank of useful inventions; and we shall appreciate the grandeur of the achievement the more when we remember that it escaped the genius of Archimedes and Apollonius, two of the greatest men produced by antiquity.”

Pierre-Simon Laplace

The most familiar way to represent real numbers is by finite or infinite decimals. In fact, we are accustomed to thinking of real numbers as being decimals. For example, we are used to writing expressions like

\[
\frac{1}{4} = 0.25
\]

\[
\frac{1}{3} = 0.333333333\cdots
\]

\[
\pi = 3.1415926\cdots
\]

even though the precise meaning of the last expression is rather obscure (the first expression, and even the second, has a fairly evident meaning).

It is better from a logical standpoint to regard decimals as merely convenient representations of real numbers. Even natural numbers should not really be thought of as being decimal expressions, since it is sometimes convenient to represent them in other ways. For example, are

\[
2 , \quad 1.999999\cdots , \quad \sqrt{4} , \quad \int_0^\pi \sin x \, dx , \quad \sum_{k=0}^{\infty} \frac{1}{2k}
\]

all natural numbers? Are they the same number? And one runs into immediate logical difficulties in saying that rational numbers are the same thing as their decimal expansions.

In this section, we will carefully develop the theory of decimal expansions, and expansions to other bases, and show that there is a (near) one-to-one correspondence between real numbers and infinite decimals. The arguments are nice illustrations of the Completeness Axiom in various forms, particularly the Nested Intervals Property.

Bases

III.8.1.1. The first ingredient in decimal representations is to fix a base \( b \), which is a natural number greater than 1. The idea is then to write all real numbers in terms of powers of \( b \).
It is pretty universal in modern human societies to use as base the number we call ten. In principle, this base is no better or worse than any other choice of base; it almost certainly came into general use simply because most of us have ten fingers (the basic meaning of the word digit is “finger or toe”). Indeed, the word decimal technically only correctly applies to base ten expansions, although we will, by abuse of language, use it more generally for expansions with different bases.

Other bases have occasionally been used. Besides ten, at least the numbers five, twelve, twenty, forty, and sixty (and reportedly also four, six, fifteen, twenty-four, and twenty-seven) have been used at various times by different societies. There are vestiges of these systems in the names of certain numbers in some modern-day languages (including the word score in English, Russian kopok, Danish halvtreds, and French numbers like quatre-vingt-onze), and in our units of time and measurement of angles. The notorious English system of measurement (and, until recently, money), can also be regarded as a number system with different base (actually more than one!)

I remember as a boy being fascinated by a book advocating use of a base twelve (“duodecimal”) system. The main argument was that arithmetic is simpler in this base since twelve has more divisors than ten; the multiplication table, although somewhat larger, is more systematic and easier to remember, and many more rational numbers have terminating decimals. Although these claims are arguably true, the duodecimal movement never got anywhere.

With the advent of computers, it has become natural in certain settings to use binary (base 2) or hexadecimal (base 16) expansions since they match up nicely with computer architecture and hardware. Binary “decimal” digits are called bits, and groups of binary digits of fixed length (usually 8) are called bytes. Terms such as megabyte and gigabyte are now in common use in the language.

“There are only 10 kinds of people in the world: those who understand binary, and those who don’t.”

Seen on a T-Shirt

In describing decimal expansions, we will generally express everything in the usual base ten. The exposition can easily be adapted to any base b by just replacing 10 by b. We will use the usual base ten digit symbols 0 through 9; for another base b, if b < 10 the digits 0 through b − 1 can be used, and if b > 10 additional symbols must be added. For example, in binary only the digits 0 and 1 are used, and in hexadecimal the letters A through F are customarily used to denote the numbers ten through fifteen, which are single digits in hexadecimal.

It is theoretically possible to vary the base from place to place (e.g. to use base ten for the first decimal digit, base 7 for the second, etc.); it seems almost inconceivable that this would ever be useful in practice, but the English essentially did this for centuries with money, and we still do it with time, and, in the U.S., other measurements. (The theory of continued fractions gives a much more useful version of varying bases; there the “base” varies not only from place to place, but from number to number.) The interested reader can figure out how to adapt the arguments to this case.

There is also a fascinating generalization of decimal expansions where the base b is not required to be a natural number, but can be an arbitrary real or complex number with |b| > 1, and the “digits” are a finite set of real or complex numbers containing 0. Such expansions are intimately connected with the theory of fractal sets in the plane. See [Edg08, §1.6] for details.
Decimal Representations of Integers

Finite Decimals

III.8.1.6. We first review the meaning of a finite decimal. This is an expression of the form

$$\pm m.d_1d_2 \cdots d_n$$

where \(m\) is a nonnegative integer and \(d_1, \ldots, d_n\) are decimal digits between 0 and 9. This expression by definition represents the rational number

$$\pm \left[ m + \frac{d_1d_2 \cdots d_n}{10^n} \right]$$

where \(d_1d_2 \cdots d_n\) denotes a nonnegative integer in the usual way:

$$d_1d_2 \cdots d_n = 10^{n-1}d_1 + 10^{n-2}d_2 + \cdots + 10d_{n-1} + d_n.$$

Alternatively, we have

$$\pm m.d_1d_2 \cdots d_n = \pm \left[ m + \frac{d_1}{10} + \frac{d_2}{10^2} + \cdots + \frac{d_n}{10^n} \right] = \pm \left[ m + \sum_{k=1}^{n} \frac{d_k}{10^k} \right].$$

The \(m\) of course can also be written in decimal form in a similar manner.

III.8.1.7. Conversely, any rational number of the form

$$\frac{p}{10^q}$$

where \(p, q \in \mathbb{Z}\) has a finite decimal representation: suppose \(p > 0\) (the case \(p \leq 0\) is an obvious variation), and \(q > 0\), which can be arranged by multiplying top and bottom by a power of 10. Then we can uniquely write

$$p = 10^qm + r$$

where \(0 \leq r < 10^q\), and we can then expand

$$r = 10^{q-1}d_1 + 10^{q-2}d_2 + \cdots + 10d_{q-1} + d_q$$

for digits \(d_1, \ldots, d_q\). Thus the rational numbers whose denominator is a power of 10 (more precisely, the rational numbers which have such a fractional representation) are precisely the numbers with a finite decimal representation.

III.8.1.8. Definition. A rational number which can be written with a denominator which is a power of 10 is a decadent rational.

Any integer, or any rational number which can be written with a denominator divisible only by 2 and/or 5 is decadent. Every decadent rational is an integer times a power of 10 (and conversely). The set of decadent rational numbers is dense in \(\mathbb{R}\) (in the sense that every interval in \(\mathbb{R}\) contains such a number, in fact infinitely many).
There is one obvious sense in which the finite decimal expression for a decadent rational number is not unique, however: we have

\[ m.d_1d_2\cdots d_n = m.d_1d_2\cdots d_n00\cdots 0 \]

for any (finite) string of zeros. Thus any number of zeros can be appended or deleted at the end of the expression. Except for this, the finite decimal expansion of a decadent rational number is unique. (We can theoretically also add zeros in places to the left of the first digit in the integer part, but it is conventional not to write such zeros.)

The ordering on the decadent rational numbers is obtained easily from the decimal expansion. Working from left to right in the decimal expansions of (nonnegative) \( x \) and \( y \), just find the first place where the expansions differ; the larger digit in this place denotes the larger number. (This is an effective procedure since there are only finitely many nonzero digits in each expansion; the expansions may have to be extended by adding zeros on the left and/or right ends to allow comparison.)

The Decimal Representation of a Real Number

We will show that every real number \( x \) has a decimal expansion of the form

\[ \pm m.d_1d_2\cdots \]

where \( m \) is a nonnegative integer and the \( d_i \) are digits between 0 and 9, that the decimal expansion is unique except for decadent rational numbers which have two such expansions, and that every such decimal expression is the decimal expansion of a unique real number.

We will require that the infinite decimal expansion of a decadent rational number be compatible with the finite expansion, i.e. if

\[ x = \pm m.d_1d_2\cdots d_n \]

we should have that

\[ \pm m.d_1d_2\cdots d_n00\cdots \]

is an infinite decimal expansion for \( x \).

We also want the infinite decimal expansion to reflect the ordering on \( \mathbb{R} \) in the same way as the finite expansions of III.8.1.10. We must be careful, however: although the algorithm described in III.8.1.10 makes sense in this setting (i.e. it is a well-defined finite algorithm), it does not always give the correct answer due to the nonuniqueness of certain infinite decimal expansions (\( c \)). We can, however, say the following: suppose

\[ m.d_1d_2\cdots \]

is an infinite decimal expansion for a real number \( x \). Then, for any \( n \), we have

\[ m + \frac{d_1}{10} + \frac{d_2}{10^2} + \cdots + \frac{d_n}{10^n} \leq x \leq m + \frac{d_1}{10} + \frac{d_2}{10^2} + \cdots + \frac{d_n + 1}{10^n} \]

If \( d_n \neq 9 \), this inequality can be concisely written

\[ m.d_1d_2\cdots d_n \leq x \leq m.d_1d_2\cdots d_n c_n \]

where \( c_n = d_n + 1 \). If \( d_n = 9 \), however, the right-hand inequality does not make sense, and it is notationally very complicated to write a valid version (one must “carry” back past any 9’s at the end of the expression).

As we will see, these two provisions completely determine decimal expansions and give a hint how to find them.
III.8.1.12. The sign in an infinite decimal expression is self-explanatory. From now on, we will only deal with nonnegative real numbers; the decimal expansion of a negative number $x$ will be the decimal expansion of $|x|$ preceded by a minus sign.

III.8.1.13. If $x$ is nonnegative, the $m$ is also clear: it is the unique nonnegative integer such that $m \leq x < m + 1$. This $m$ is called the integer part of $x$, denoted $\lfloor x \rfloor$.

III.8.1.14. By subtracting off the integer part, we may reduce the problem of defining (or computing) the decimal expansion of a number $x$ to the case where $0 \leq x \leq 1$. We will make this restriction from now on.

Generating the Decimal Expansion of a Real Number
Finding a Real Number with a Given Decimal Expansion
Decimal Expansions of Rational and Irrational Numbers
Defining Real Numbers as Decimals

III.8.1.15. Since there is essentially a one-one correspondence between real numbers and decimal expressions, it is possible to define the real numbers via infinite decimals, and this approach is taken in some references. But there are some serious difficulties with this approach.

III.8.1.16. Besides the general problem of defining the real numbers as being one particular model, be it decimal expansions, Dedekind cuts, equivalence classes of Cauchy sequences, or whatever, there are two additional problems in defining the real numbers via decimal expressions:

(i) The correspondence is not quite one-to-one.

(ii) It is not easy or obvious how to define or describe the algebraic operations on $\mathbb{R}$ using the decimal expressions.

III.8.1.17. The first difficulty is easily overcome. One way is just to exclude decimals ending in an infinite string of 9's.

III.8.1.18. The second difficulty is not easily overcome. In school we learn algorithms for adding, subtracting, multiplying, and dividing integers expressed in decimal notation, including memorization of the multiplication table for one-digit natural numbers; later, we also learn the simple modifications needed to use the same algorithms for arithmetic of finite (i.e. terminating) decimals. But there are no finite algorithms for adding or multiplying infinite decimals, since there is no place to “start”. For example, can you even determine the first decimal digit of

$$x = (0.2531486073\cdots) + (0.3468513926\cdots)$$

without further information? Could you even be sure this digit can be determined in a finite length of time with a finite amount of information about the decimal expansions? (The problem is even worse, and more obvious, for multiplication.)
III.8.1.19. The only reasonable way to proceed is to appeal to one of the other approaches, most obviously the Cauchy sequence approach. In the example of the last paragraph, although even the first decimal digit of \( x \) is not clearly determined by the information given, \( x \) itself is determined to a high degree of accuracy (within \( 2 \times 10^{-10} \)) by the ten decimal places of the given expressions. If one has the complete decimal expansions of the summands, or an algorithm for generating them, the number \( x \) can be determined to arbitrary accuracy, i.e. a sequence of rational numbers (terminating decimals) can be generated which converges to \( x \).

III.8.1.20. The problem is that real numbers which are very close together can have different expansions starting early in the expression if they happen to be on opposite sides of a number with a small terminating expansion (i.e. an integer times a small negative power of 10).

Another way of expressing the difficulty is that if we know that real numbers \( x \) and \( y \) satisfy \( |x - y| < 10^{-n} \), we do not necessarily know that \( x \) and \( y \) agree to \( n \), or even \( n - 1 \), decimal places, although they “usually” will; in unusual cases they may not even agree to one decimal place if one expansion has a long string of 0’s after the first place and the other a corresponding long string of 9’s. They will not even necessarily agree when rounded to one decimal place, e.g. if \( x = 0.24999999999999999 \) and \( y = 0.25000000000000001 \). In fact, for any \( n \), the functions which truncate or round a real number to \( n \) decimal places are step functions with jump discontinuities of height \( 10^{-n} \).

III.8.2. Continued Fractions

A somewhat more complicated, but in some ways more efficient, way to represent real numbers by sequences of natural numbers is by continued fractions. The theory of continued fractions is usually, and rightly, considered to be a part of number theory; however, the applications in analysis and probability, along with applications in closely related fields such as dynamical systems, are important enough that the basic theory of continued fractions should be a more integral part of the standard analysis curriculum than is currently the case.

While continued fractions give a much better way of representing real numbers than decimal representations for some purposes (such as finding good rational approximations), they are not nearly as good as decimal representations for the purposes of doing arithmetic, and this shortcoming is the principal reason their use has not become so widespread or popular. But mathematicians need to be familiar with both ways of representing numbers since they are useful for different purposes.

We will cover only a few important basic properties of the theory of continued fractions here which are most relevant in analysis and probability, and omit most of the many fascinating connections with number theory (some of these are described at the end of the section and in the Exercises). Books on number theory such as the classic [HW08] (there are also many others; perhaps my favorite is the little gem [Khi97]) cover continued fractions in more detail; [Sta78] has a thorough and geometrically appealing treatment of the theory.

The fundamental difference between decimal representations and continued fractions is that decimal representations require an initial choice of a base, and all representations are tied to that choice of base; some numbers have nice representations with respect to the chosen base, while others do not. But the continued fraction representation of a number is not tied to any initial choice of base; indeed, one way of thinking of the theory is that at each step in the expansion of a number, the perfect “base” is used for that number at that step.

As a result, the theory of continued fractions concerns the most efficient approximation of real numbers by rational numbers. Of course, the finite parts of the decimal expansion of a real number give rational
approximations, but one can do much better in general by a different approach. Any real number can be approximated arbitrarily closely by rational numbers, but close rational approximations to irrational numbers will necessarily have large denominators. By an “efficient” approximation we will mean an approximation which is close by some measure depending on the size of the denominator of the rational number when expressed in lowest terms. For example, we could ask:

III.8.2.1.  **Question.** For an irrational number \( x \), and a natural number \( n \), what is the rational number with denominator \( \leq n \) which most closely approximates \( x \)?

The theory of continued fractions gives a complete answer to this question.

III.8.2.2.  A **continued fraction** is an expression of the form

\[
x_0 + \cfrac{1}{x_1 + \cfrac{1}{x_2 + \cfrac{1}{x_3 + \cfrac{1}{\ddots + \cfrac{1}{x_n}}}}}.
\]

This is just a formal expression, which may be finite or infinite. In interpreting the meaning of this expression, the \( x_k \) may stand for numbers, functions, indeterminates, \( \ldots \). For example, there has been a large mathematical industry in expanding functions in continued fractions; cf. [Wal48], [JT80], [LW08]. For us, the \( x_k \) will always stand for positive real numbers, usually natural numbers.

More general continued fraction expressions of this type are sometimes considered, where the numerators are not necessarily 1’s; in this case, continued fractions with 1’s in the numerators (the only kind we will consider) are called **simple continued fractions**.

III.8.2.3.  **Definition.** A **finite continued fraction** of depth \( n \in \mathbb{N} \) is an expression of the form

\[
x_0 + \cfrac{1}{x_1 + \cfrac{1}{x_2 + \cfrac{1}{x_3 + \cfrac{1}{\ddots + \cfrac{1}{x_n}}}}}.
\]

The theory of continued fraction expansions of real numbers is based on the following “obvious” fact, which can be easily proved by induction (Exercise (i)).

III.8.2.4.  **Proposition.** (i) Let \( x_1, \ldots, x_n \) be positive real numbers, and \( x_0 \) a real number. Then the expression

\[
x_0 + \cfrac{1}{x_1 + \cfrac{1}{x_2 + \cfrac{1}{x_3 + \cfrac{1}{\ddots + \cfrac{1}{x_n}}}}}.
\]

unambiguously defines a real number by the usual rules of algebra. If \( x_0, \ldots, x_n \) are rational, then the number defined by the expression is rational.
(ii) If \( x_1, \ldots, x_n, x'_n \) are positive real numbers, and \( x_0 \) is a real number, and
\[
\begin{align*}
x_0 + \frac{1}{x_1 + \frac{1}{x_2 + \frac{1}{x_3 + \cdots}}} &= x_0 + \frac{1}{x_1 + \frac{1}{x_2 + \frac{1}{x_3 + \cdots}}} \\
&= x_n \quad \text{for all } n.
\end{align*}
\]
then \( x_n = x'_n \).

Statement (i) can fail if the \( x_k \) \((k \geq 1)\) are not positive, since then a denominator of zero can arise during simplification.

It is notationally clumsy to write these complex fractions; we will use the common notation \([x_0; x_1, \ldots, x_n]\) for the fraction in (i). Variations of this notation, and many other notations for continued fractions, are used in the literature.

We now define a function which will be used repeatedly:

III.8.2.5. Definition. Let \( x \) be a real number. Then the \textit{integer part} of \( x \), denoted \([x]\), is the largest integer which is \( \leq x \). We can now inductively define the continued fraction expansion of a real number:

III.8.2.6. Definition. Let \( x \) be a real number. Define numbers as follows:

Set \( a_0 = x \) and \( r_0 = a_0 = \lfloor a_0 \rfloor \). Let \( p_0 = r_0 \) and \( q_0 = 1 \).

Set \( \beta_1 = a_0 - a_0 = x - r_0 \). Then \( 0 \leq \beta_1 < 1 \).

If \( \beta_1 = 0 \) (i.e. if \( x \in \mathbb{Z} \)), terminate the expansion. Otherwise set \( \alpha_1 = \frac{1}{\beta_1} \) and \( a_1 = \lfloor \alpha_1 \rfloor \). Then \( a_1 \in \mathbb{N} \).

Set \( r_1 = a_0 + \frac{1}{a_1} = \frac{a_0a_1 + 1}{a_1} \). Then \( r_1 \in \mathbb{Q} \), and \( r_0 < x \leq r_1 \). Set \( p_1 = a_0a_1 + 1 \), \( q_1 = a_1 \), so \( r_1 = \frac{p_1}{q_1} \), and define \( \beta_2 \) by \( \beta_2 = a_1 - a_1 \), i.e. \( x = a_0 + \frac{1}{a_1 + \beta_2} \). Then \( 0 \leq \beta_2 < 1 \).

If \( \beta_2 = 0 \) (i.e. if \( x = r_1 \)), terminate the expansion. Otherwise set \( \alpha_2 = \frac{1}{\beta_2} \) and \( a_2 = \lfloor \alpha_2 \rfloor \in \mathbb{N} \).

Set \( r_2 = a_0 + \frac{1}{a_1 + \frac{1}{a_2}} = \frac{p_2}{q_2} \). Then \( r_2 \leq x < r_1 \). Define \( \beta_3 = a_2 - a_2 \) (i.e. \( x = a_0 + \frac{1}{a_1 + \frac{1}{a_2 + \beta_3}} \)). Then \( 0 \leq \beta_3 < 1 \).

Continue inductively defining \( \beta_n, \alpha_n, a_n, r_n = \frac{p_n}{q_n} \) for all \( n \) (or until the process terminates). The finite or infinite sequence \([a_0; a_1, a_2, \ldots]\) is called the \textit{continued fraction} (expression, expansion, decomposition) of \( x \). The \( a_n \) are called the \textit{terms} (or \textit{elements}) of the continued fraction.

The numbers \( a_n, r_n, p_n, q_n, \alpha_n, \beta_n \) depend on \( x \); we will write them \( a_n(x) \), etc., when it is necessary to specify the dependence on \( x \).

The name “continued fraction” for this construction is appropriate, since the idea is to write
\[
x = a_0 + \frac{1}{a_1 + \frac{1}{a_2 + \frac{1}{a_3 + \cdots}}}.
\]

We will discuss later how this expression can be precisely interpreted as the limit of the finite continued fractions \( r_n \).

It is easy to verify the next result (note that we have a recursive formula \( a_n = a_n + \frac{1}{n_{n+1}} \) for all \( n \)):
III.8.2.7. PROPOSITION. Let $x \in \mathbb{R}$, and $n \in \mathbb{N}$. Then
\[
x = [a_0(x); a_1(x), \ldots, a_{n-1}(x), a_n(x)]
\]
\[
r_n(x) = [a_0(x); a_1(x), \ldots, a_n(x)].
\]

We thus get the following “contraction” principle:

III.8.2.8. PROPOSITION. Let $x \in \mathbb{R}$, and $n \in \mathbb{N} \cup \{0\}$. If the continued fraction construction for $x$ lasts at least $n + 1$ steps (i.e. $a_n(x)$ is defined), then $a_n(x) = a_k(a_{n-k}(x))$ for $0 \leq k \leq n$.

We then get a recursive formula for $r_n$:

III.8.2.9. COROLLARY. Let $x \in \mathbb{R}$, and $n \in \mathbb{N} \cup \{0\}$. If the continued fraction construction for $x$ lasts at least $n + 1$ steps, then
\[
r_n(x) = a_0 + \frac{1}{r_{n-1}(\alpha_1(x))} = a_0 + \frac{1}{a_1 + \frac{1}{r_{n-2}(\alpha_2(x))}} = \cdots = a_0 + \frac{1}{a_1 + \frac{1}{a_2 + \frac{1}{r_{n-3}(\alpha_3(x))}}} = \cdots + \frac{1}{r_0(\alpha_n(x))}.
\]

We also have the following uniqueness statement:

III.8.2.10. PROPOSITION. Let $n \in \mathbb{N}$, $b_0 \in \mathbb{Z}$, $b_1, \ldots, b_n \in \mathbb{N}$. If $x \in \mathbb{R}$, and the continued fraction expansion of $x$ lasts at least $n + 2$ steps (i.e. $a_{n+1}(x)$ is defined), then $a_k(x) = b_k$ for $0 \leq k \leq n$ if and only if $x = [b_0; b_1, \ldots, b_n, \alpha]$ for some $\alpha > 1$, i.e. if and only if $x$ is in the open interval between $[b_0; b_1, \ldots, b_n]$ and $[b_0; b_1, \ldots, b_{n-1}, b_n + 1]$.

III.8.2.11. There is one slight ambiguity in continued fraction expansions, however: for any $b_0 \in \mathbb{Z}$, $b_1, \ldots, b_n \in \mathbb{N}$,
\[
[b_0; b_1, \ldots, b_n, 1] = [b_0; b_1, \ldots, b_n + 1]
\]
and the second expression, not the first, is the correct continued fraction expansion of the corresponding rational number. Thus a finite continued fraction expression ending in 1 can be “contracted”, and a terminating continued fraction expansion (of length at least 2) cannot end in 1.

Since the $r_n$ are rational, it is obvious that if $x$ is irrational, then the construction never terminates, so the continued fraction expression for $x$ is an infinite sequence. Conversely, if $x$ is rational, then the construction necessarily terminates, although this is not immediately obvious:
III.8.2.12. **Proposition.** If $r$ is rational, then the continued fraction expansion of $x$ terminates.

**Proof:** Write $x = \frac{p}{q}$. We may suppose $p, q \in \mathbb{N}$ for simplicity (this will happen after one step if $x < 0$, and the result is obvious if $x = 0$). If $p < q$, then $a_0 = 0$ and $\frac{s}{q}$ with $0 \leq s < q \leq p$. If $s = 0$, the process terminates. Otherwise, $a_1 = \frac{q}{s} = a_1 + \frac{1}{\alpha_1}$ with $0 \leq t < s < q$. If $t = 0$, the process terminates. Otherwise, $\alpha_2 = \frac{s}{t}$, and we have $s, t \in \mathbb{N}$, $s < p$, $t < q$, so after 2 steps the remaining procedure computes the continued fraction expansion of a fraction with strictly smaller numerator and denominator. Thus the process must terminate in no more than $2 + 1 \leq 2q + 1$ steps.

In fact, for $x = \frac{p}{q}$ the continued fraction construction is really the same as the Euclidean Algorithm for determining the greatest common divisor of $p$ and $q$. The termination estimate of $1 + 2q$ steps is rather crude: it is known (LAMÉ’s Theorem) that if $p, q > 0$, then the number of steps to termination is bounded by

$$2 + 5 \min(\log_{10}(p), \log_{10}(q))$$

which is roughly 5 times the number of decimal digits in the smaller of $p$ and $q$.

III.8.2.13. If $[b_0, b_1, b_2, \ldots]$ is any sequence with $b_0 \in \mathbb{Z}$ and $b_n \in \mathbb{N}$ for $n \geq 1$, we can define $r_n$ in the analogous manner, i.e.

$$r_n = [b_0, b_1, \ldots, b_n] = b_0 + \frac{1}{b_1 + \frac{1}{b_2 + \frac{1}{\ddots + \frac{1}{b_n}}}}.$$ 

By III.8.2.10., the $b_n$ can be recovered from the continued fraction expansions of the $r_n$.

III.8.2.14. In III.8.2.6., we were not completely precise about the definition of $p_n$ and $q_n$. These are defined by simply converting the compound fraction to a simple fraction and taking numerator and denominator. For example, we have

$$r_2 = a_0 + \frac{1}{a_1 + \frac{1}{a_2}} = a_0 + \frac{a_2}{a_1 a_2 + 1} = \frac{a_0 a_1 a_2 + a_0 + a_2}{a_1 a_2 + 1}$$

so

$$p_2 = a_0 a_1 a_2 + a_0 + a_2 = p_0 + a_2 p_1, \quad q_2 = a_1 a_2 + 1 = q_0 + a_2 q_1.$$ 

In fact, if $[a_0; a_1, a_2, \ldots]$ is any sequence with $a_0 \in \mathbb{Z}$ and $a_n \in \mathbb{N}$ for $n \geq 1$, and

$$r_n = a_0 + \frac{1}{a_1 + \frac{1}{a_2 + \frac{1}{\ddots + \frac{1}{a_n}}}}$$

and $p_n, q_n$ are defined from $r_n$ by clearing complex fractions, the same formulas hold for $n = 2$. 

324
III.8.2.15. Proposition. For any $n \geq 2$,

(i) $p_n = p_{n-2} + a_n p_{n-1}$ and $q_n = q_{n-2} + a_n q_{n-1}$.

(ii) $p_{n-1}q_{n-2} - p_{n-2}q_{n-1} = (-1)^n$.

In particular, $p_n$ and $q_n$ are relatively prime, and $q_n > q_{n-1}$.

In particular, these formulas hold for a sequence arising as the continued fraction of a real number. (We will see later (III.8.2.19.) that every sequence occurs as a continued fraction.)

Proof: We prove (i) by induction, using III.8.2.8. and III.8.2.9. The formula holds for $n = 2$ by the previous calculation. Suppose it holds for $n$ for all $x$. Fix $x$, and let $\alpha_1 = \alpha_1(x)$. Then, from III.8.2.9., $p_{k-1}(\alpha_1) = q_k(x)$ and $q_{k-1}(\alpha_1) = p_k(x) - a_0(x)q_k(x)$ for all $k$. Then

$$p_{n+1}(x) = a_0(x)p_n(\alpha_1) + q_n(\alpha_1).$$

By the inductive hypothesis applied to $\alpha_1$, this equals

$$a_0(x)[p_{n-2}(\alpha_1) + a_n(\alpha_1)p_{n-1}(\alpha_1)] + [q_{n-2}(\alpha_1) + a_n(\alpha_1)q_{n-1}(\alpha_1)]$$

$$= a_0(x)[q_{n-1}(x) + a_{n+1}(x)q_n(x)]$$

$$+ ([p_{n-1}(x) - a_0(x)q_{n-1}(x)] + a_{n+1}(x)[p_n(x) - a_0(x)q_n(x)])$$

$$= p_{n-1}(x) + a_{n+1}(x)p_n(x).$$

A similar calculation shows that

$$q_{n+1}(x) = q_{n-1}(x) + a_{n+1}(x)q_n(x).$$

We now prove (ii) by induction. It holds for $n = 2$ by direct calculation. If it holds for $n$, then by (i)

$$p_nq_{n-1} - p_{n-1}q_n = (p_{n-2} + a_n p_{n-1})q_{n-1} - p_{n-1}(q_{n-2} + a_n q_{n-1})$$

$$= p_{n-2}q_{n-1} - p_{n-2}q_{n-1} + a_n p_{n-1}q_{n-1} - a_n p_{n-1}q_{n-1}$$

$$= -(p_{n-1}q_{n-2} - p_{n-2}q_{n-1}) = -(-1)^n = (-1)^{n+1}$$

so the formula holds for $n + 1$.

It follows from (ii) that $p_n$ and $q_n$ are relatively prime, and it is obvious from (i) that $q_n > q_{n-1}$ since $q_{n-2} \geq 1$ and $a_n \geq 1$. \(\Box\)

III.8.2.16. Corollary. (i) Let \(a_0; a_1, \ldots\) be a sequence with $a_0 \in \mathbb{Z}$ and $a_n \in \mathbb{N}$ for $n \geq 1$, and let $(r_n)$ be the corresponding sequence of finite continued fractions. Then

$$r_0 < r_2 < r_4 < \cdots < r_5 < r_3 < r_1$$

and $|r_n - r_{n-1}| = \frac{1}{q_n q_{n-1}}$ for $n \geq 1$.
(ii) Let \( x \in \mathbb{R} \) with nonterminating continued fraction expansion \([a_0; a_1, \ldots]\), and \((r_n)\) the corresponding sequence of finite continued fractions. Then
\[
\begin{align*}
r_0 < r_2 < r_4 < \cdots < x < \cdots < r_5 < r_3 < r_1
\end{align*}
\]
and \( r_n \to x \). In fact, for \( n \geq 1 \),
\[
|x - r_n| < |r_{n+1} - r_n| = \frac{1}{q_n q_{n+1}} < \frac{1}{a_{n+1} q_n^2} \leq \frac{1}{q_n^2}
\]
(the extreme inequality also obviously holds for \( n = 0 \)).

Because of (ii), \( r_n \) is often called the \( n \)'th continued fraction convergent to \( x \), and we may justifiably write
\[
x = a_0 + \frac{1}{a_1 + \frac{1}{a_2 + \frac{1}{a_3 + \ddots}}}
\]

An alternate way of phrasing the convergence is that the alternating series
\[
a_0 + \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{q_n q_{n-1}}
\]
converges to \( x \). (Note that this series is absolutely convergent since \( q_n \geq n \) for all \( n \).)

III.8.2.17. **Corollary.** If \( x \) and \( y \) are distinct real numbers, their continued fraction expansions are different.

III.8.2.16. almost shows that every sequence as in (i) is the continued fraction expansion of a (necessarily irrational) real number. For under the conditions of (i), by the Nested Intervals Property there is a unique \( x \in \mathbb{R} \) satisfying
\[
r_0 < r_2 < r_4 < \cdots < x < \cdots < r_5 < r_3 < r_1
\]
and we need only show that the continued fraction expansion of this \( x \) is \([a_0; a_1, \ldots]\). This follows from the next proposition, which is essentially a rephrasing of III.8.2.10.: 

III.8.2.18. **Proposition.** Let \([b_0; b_1, \ldots]\) be a sequence with \( b_0 \in \mathbb{Z} \) and \( b_n \in \mathbb{N} \) for \( n \geq 1 \), and let \((r_n)\) be the corresponding sequence of finite continued fractions. If \( x \) is between \( r_n \) and \( r_{n+1} \), then \( a_k(x) = b_k \) for \( 0 \leq k \leq n \).

III.8.2.19. **Corollary.** Let \([a_0; a_1, \ldots]\) be a sequence with \( a_0 \in \mathbb{Z} \) and \( a_n \in \mathbb{N} \) for \( n \geq 1 \), and let \((r_n)\) be the corresponding sequence of finite continued fractions. Let \( x \) be the unique real number satisfying
\[
r_0 < r_2 < r_4 < \cdots < x < \cdots < r_5 < r_3 < r_1
\]
Then the continued fraction expansion of \( x \) is \([a_0; a_1, \ldots]\).

We also have the following useful corollary about the continuity of continued fraction decompositions:
III.8.2.20. Corollary. Let \( x \in \mathbb{R} \) have continued fraction expansion of length at least \( n + 1 \), and \((r_k)\) the corresponding convergents. If \( y \) is between \( r_n \) and \( r_{n+1} \), then \( a_k(y) = a_k(x) \) for \( 0 \leq k \leq n \).

We have the following relations between \( x \) and the \( \alpha_k(x) \), which can be easily proved by induction using III.8.2.15. (i):

III.8.2.21. Proposition. Let \( x \in \mathbb{R} \), and \( n \in \mathbb{N} \). If the continued fraction construction for \( x \) lasts at least \( n + 1 \) steps, we have

\[
x = \frac{\alpha_1 a_0 + 1}{\alpha_1}
\]

and, if \( n \geq 2 \),

\[
x = \frac{\alpha_n p_{n-1} + p_{n-2}}{\alpha_n q_{n-1} + q_{n-2}}.
\]

This gives a refinement of III.8.2.16. (ii) with a lower bound:

III.8.2.22. Corollary. Let \( x \) be an irrational number, and \( r_n = \frac{p_n}{q_n} \) its \( n \)'th continued fraction convergent. Then

\[
\frac{1}{q_n(q_n + q_{n+1})} < |x - r_n| < \frac{1}{q_nq_{n+1}}.
\]

We combine and summarize our main results in a theorem:

III.8.2.23. Theorem. The continued fraction expansion establishes a one-one correspondence between the set \( \mathcal{J} \) of irrational numbers and the set of sequences \([a_0; a_1, a_2, \ldots]\) with \( a_0 \in \mathbb{Z} \) and \( a_n \in \mathbb{N} \) for \( n \geq 1 \). If \((x_m)\) is a sequence of irrational numbers and \( x \) an irrational number, then \( x_m \to x \) if and only if, for each \( n \), there is an \( m_0 \) such that \( a_n(x_m) = a_n(x) \) for all \( m \geq m_0 \).

Approximation by Continued Fractions

We conclude with a survey of some number-theoretic results about continued fractions, mostly stated without proof.

The continued fraction convergents to an irrational number \( x \) are the “best” rational approximants to \( x \) in the sense of Question III.8.2.1. We first make a couple of definitions:
III.8.2.24. Definition. Let \( x \) be an irrational number. A rational number \( \frac{p}{q} \) with \( p \in \mathbb{Z}, q \in \mathbb{N} \) is a good approximation to \( x \) if
\[
\left| x - \frac{p'}{q'} \right| > \left| x - \frac{p}{q} \right|
\]
for all \( p', q' \in \mathbb{Z}, 1 \leq q' \leq q, (p', q') \neq (p, q) \).
A rational number \( \frac{p}{q} \) with \( p \in \mathbb{Z}, q \in \mathbb{N} \) is a best approximation to \( x \) if
\[
|q'x - p'| > |qx - p|
\]
for all \( p', q' \in \mathbb{Z}, 1 \leq q' \leq q, (p', q') \neq (p, q) \).
A best approximation to \( x \) is obviously a good approximation to \( x \). Good approximations and best approximations are sometimes respectively called “best approximations of the first kind” and “best approximations of the second kind.”

III.8.2.25. Theorem. The continued fraction convergents \( \frac{p_n}{q_n} \) to an irrational number \( x \) for \( n \geq 1 \) are precisely the best approximations to \( x \), i.e. every continued fraction convergent is a best approximation, and every best approximation is a continued fraction convergent.

Not every good approximation is a continued fraction convergent, but all good approximations to \( x \) are secondary convergents, numbers of the form \( [a_0; a_1, \ldots, a_{n-1}, c_n] \), where \( [a_0; a_1, \ldots] \) is the continued fraction expansion of \( x \) and \( 1 \leq c_n \leq a_n \). If \( a_n > 1 \) and \( a_n/2 < c_n \leq a_n \), then the secondary convergent is a good approximation; if \( a_n \) is even and \( c_n = a_n/2 \), the secondary convergent is sometimes, but not always, a good approximation, cf. [].

These solve Question III.8.2.1.: since the solution to III.8.2.1. for a given \( n \) is obviously a good approximation, one only needs to find the good approximation with the largest denominator \( \leq n \). One only needs to know the continued fraction expansion to the point where \( q_k \geq n \).

The next theorem is an important result about continued fractions for number theory purposes, and further justifies the statement that the continued fraction convergents to a real number are the “best” rational approximants.

III.8.2.26. Theorem. Let \( x \) be an irrational number, and, for \( n \in \mathbb{N} \), let \( \frac{p_n}{q_n} \) be the \( n \)’th convergent to \( x \).
(i) If \( n \geq 2 \), then at least one of the following inequalities holds:
\[
|x - r_{n-1}| < \frac{1}{2q_n^2} \quad \text{or} \quad |x - r_n| < \frac{1}{2q_n^2}.
\]
(ii) Conversely, if \( r = \frac{p}{q} \ (p, q \in \mathbb{Z}) \) satisfies
\[
|x - r| < \frac{1}{2q^2}
\]
then \( r = r_n \) for some \( n \).

Proof: We prove only (i). Since \( x \) is between \( r_{n-1} \) and \( r_n \), we have
\[
|x - r_{n-1}| + |x - r_n| = |r_n - r_{n-1}| = \frac{1}{q_n q_{n-1} q_{n+1}}.
\]
If the statement is false, i.e.

\[ |x - r_{n-1}| \geq \frac{1}{2q_{n-1}^2} \quad \text{and} \quad |x - r_n| \geq \frac{1}{2q_n^2} \]

we would have

\[ \frac{1}{2q_{n-1}^2} + \frac{1}{q_n^2} \leq \frac{1}{q_{n-1}q_n} \]

and multiplying both sides by \(2q_{n-1}q_n^2\), we have

\[ q_n^2 + q_{n-1}^2 \leq 2q_nq_{n-1} \]

\[ (q_n - q_{n-1})^2 \leq 0 \]

which is a contradiction since \(q_n \neq q_{n-1}\).

Actually, one can do a little better:

**III.8.2.27.** **Theorem.** Let \(x\) be an irrational number, and, for \(n \in \mathbb{N}\), let \(r_n = \frac{p_n}{q_n}\) be the \(n\)’th convergent to \(x\). Then for infinitely many \(n\) (at least one of every three consecutive \(n\)),

\[ |x - r_n| < \frac{1}{\sqrt{5}q_n^2} . \]

The example of the golden ratio (Exercise (\ref{ex:golden_ratio})) shows that \(\sqrt{5}\) is the largest possible constant \(M\) for which

\[ |x - r_n| < \frac{1}{Mq_n} \]

for infinitely many \(n\) in general.

**III.8.2.28.** If the \(a_n(x)\) are unbounded, which is the case for almost all \(x\) (III.8.2.29.), we can do much better, since if \(a_{n+1}(x)\) is large, \(r_n(x)\) is a very good approximation to \(x\) by III.8.2.16.. For example, since \(a_4(\pi) = 292\), we have that \(r_3(\pi) = \frac{355}{113}\) satisfies

\[ \left| \pi - \frac{355}{113} \right| < \frac{1}{292 \cdot 113^2} \approx 2.7 \times 10^{-7} \]

so \(\frac{355}{113}\) agrees with \(\pi\) to (at least, in fact exactly) 6 decimal places. A theorem of **Lochs** (\ref{thm:lochs}) says that for almost all \(x \in \mathbb{J}\) (in the sense of Lebesgue measure), \(r_n(x)\) asymptotically agrees with \(x\) to about \(n\) decimal places.

**Asymptotic Behavior of Continued Fractions**

Here are some asymptotic results about the growth rate of the coefficients \(a_n(x)\) for “typical” irrational numbers:
III.8.2.29. **Theorem.** Let \( \phi : \mathbb{N} \to (1, \infty) \) be a function. Then

(i) If \( \sum_{n=1}^{\infty} \frac{1}{\phi(n)} \) diverges, then the set of \( x \in \mathbb{J} \) for which \( a_n(x) = O(\phi(n)) \) as \( n \to \infty \) has Lebesgue measure 0. In particular, the set of \( x \in \mathbb{J} \) for which \( a_n(x) \) is bounded has Lebesgue measure 0.

(ii) If \( \sum_{n=1}^{\infty} \frac{1}{\phi(n)} \) converges, then \( a_n(x) = o(\phi(n)) \) as \( n \to \infty \) for almost all \( x \in \mathbb{J} \), i.e. the set of \( x \) for which this fails has Lebesgue measure 0.

Thus, almost all irrational numbers have many \( a_n \) which are “large” but which do not grow too rapidly. Theorem III.8.2.29. is roughly a version of the Borel-Cantelli Lemma (it is not exactly the Borel-Cantelli Lemma since the random variables \( (a_n) \) are not quite independent; cf. ().) In contrast, Khinchin [Khi97] proved the following remarkable theorem, which is essentially a version of the Strong Law of Large Numbers ():

III.8.2.30. **Theorem.** For almost all \( x \in \mathbb{J} \), the geometric mean of the \( a_n \) approaches a constant

\[
\kappa = \prod_{k=1}^{\infty} \left[ 1 + \frac{1}{k(k+2)} \right]^{\log_2 k} = \prod_{k=1}^{\infty} k^{\log_2 \left[ 1 + \frac{1}{k(k+2)} \right]} = 2.685452 \cdots
\]

i.e.

\[
\lim_{n \to \infty} \left[ a_1(x)a_2(x) \cdots a_n(x) \right]^{1/n} = \kappa.
\]

So, for almost all irrational numbers \( x \), “most” of the \( a_n(x) \) are small. Note, however, that the arithmetic mean of the \( a_n \)’s almost always diverges: since \( \sum \frac{1}{n \log n} \) diverges, for almost all \( x \) we have \( a_n(x) > n \log n \) for infinitely many \( n \) by III.8.2.29.(i), and thus, for almost all \( x \),

\[
\frac{1}{n} \sum_{k=1}^{n} a_k(x) > \log n
\]

for infinitely many \( n \).

Khinchin’s result is more general:

III.8.2.31. **Theorem.** Let \( f : \mathbb{N} \to [0, \infty) \) be a function for which there exist positive constants \( C \) and \( \delta \) such that

\[
f(k) < Ck^{1/2-\delta}
\]

for all \( k \). Then, for almost all \( x \in \mathbb{J} \),

\[
\lim_{n \to \infty} \frac{1}{n} \sum_{k=1}^{n} f(a_k(x)) = \sum_{k=1}^{\infty} f(k) \log_2 \left[ 1 + \frac{1}{k(k+2)} \right].
\]

III.8.2.30. is the case \( f(k) = \log k \). Another interesting case is to let \( f(k_0) = 1 \) for some \( k_0 \) and \( f(k) = 0 \) for \( k \neq k_0 \). This case shows that the number \( k_0 \) appears with the same asymptotic relative frequency in the continued fraction expansion of almost all numbers, and the frequency is

\[
\log_2 (k_0^2 + 2k_0 + 1) - \log_2 (k_0^2 + 2k_0).
\]

330
For example, for almost all \( x \), the relative frequency of 1 in the continued fraction expansion of \( x \) is
\[
\log_2 4 - \log_2 3 = .4150 \ldots
\]
i.e. asymptotically about 41.5% of the terms in the continued fraction expansion of \( x \) are 1’s. Similarly, about 17% are 2’s, 9.3% are 3’s, etc.

**Approximation of Algebraic and Transcendental Numbers**

**III.8.2.32. Definition.** A real (or complex) number \( x \) is **algebraic** if \( x \) is a root of a polynomial with integer coefficients. A real (or complex) number which is not algebraic is **transcendental**.

A rational number \( \frac{p}{q} \) is a root of the polynomial \( qx - p \), hence is algebraic. It is a standard theorem of abstract algebra that every algebraic number is a root of a unique (up to constant multiple) polynomial with integer coefficients which is irreducible over \( \mathbb{Z} \) (or equivalently over \( \mathbb{Q} \)). The degree of this polynomial is the degree of the algebraic number. Degree 1 algebraic numbers are precisely the rational numbers; degree 2 algebraic numbers are called **quadratic numbers**.

Our first result is a simple argument showing that irrational algebraic numbers cannot be approximated too closely by rational numbers. This result is due to Liouville in 1844.

**III.8.2.33. Theorem.** Let \( x \) be an algebraic number of degree \( n > 1 \). Then there is a constant \( C, 0 < C < 1/2 \), such that
\[
|x - r| > \frac{C}{q^n}
\]
for all rational numbers \( r = \frac{p}{q} \).

**Proof:** Let \( x \) be a root of an irreducible polynomial \( f \) of degree \( n \) with integer coefficients, and let \( M \) be the maximum of \( |f'| \) on the interval \( [x - \frac{1}{2}, x + \frac{1}{2}] \). Then \( M > 0 \) since \( f \) is not constant. By the Mean Value Theorem, if \( r = \frac{p}{q} \) satisfies \( |x - r| < \frac{1}{2} \), there is a \( c \) between \( x \) and \( r \) such that
\[
|q^n f(r)| = |q^n(f(r) - f(x))| = q^n |f'(c)||r - x| \leq Mq^n |x - r|.
\]
Note that \( q^n f(r) \in \mathbb{Z} \), and \( f(r) \neq 0 \) since \( f \) has no rational roots. Thus, if \( C < \frac{1}{M} \), then \( 1 \leq Mq^n |x - r| \), \( |x - r| > \frac{C}{q^n} \) if \( |x - r| < \frac{1}{2} \). Also, \( M > 2 \) since there is an \( s \in \mathbb{Z} \) with \( |x - s| < \frac{1}{2} \), and by the above argument
\[
1 \leq |f(s)| \leq M|x - s|
\]
so \( C < \frac{1}{2} \) and \( \left| x - \frac{p}{q} \right| > \frac{C}{q^n} \) also if \( \left| x - \frac{p}{q} \right| > \frac{1}{2} \).

This result shows that irrational numbers which can be approximated very closely by rational numbers must be transcendental.
III.8.2.34. Definition. An irrational number \( x \) is a Liouville number if, for every \( n \), there are \( p, q \in \mathbb{Z} \) with \( q \geq 2 \) and
\[
\left| x - \frac{p}{q} \right| < \frac{1}{q^n}.
\]

By III.8.2.33., every Liouville number is transcendental.

III.8.2.35. Example. Let \( x = \sum_{k=1}^{\infty} 10^{-k!} \). For each \( n \), we can take \( \frac{p}{q} = \sum_{k=1}^{n} 10^{-k!} \). This was Liouville’s original example, and the first explicit number to be proved transcendental.

The set \( L \) of Liouville numbers is quite an interesting subset of \( \mathbb{R} \). It is very “small” in a measure-theoretic sense, but “large” in a topological (category) sense:

III.8.2.36. Theorem. \( L \) is a dense \( G_\delta \); hence the complement of \( L \) is a meager set.

Proof: For each \( n \), let
\[
U_n = \bigcup_{q \in \mathbb{Q}} \left( \frac{p}{q} - \frac{1}{q^n}, \frac{p}{q} + \frac{1}{q^n} \right).
\]
Then \( U_n \) is an open set containing \( \mathbb{Q} \), hence dense; and \( L = \mathbb{J} \cap \cap_n U_n \). Since \( \mathbb{J} \) and \( \cap_n U_n \) are dense \( G_\delta \)'s, so is \( L \).

III.8.2.37. Theorem. The set \( L \) has \( s \)-dimensional Hausdorff measure 0, for every \( s > 0 \). So \( L \) has Hausdorff dimension 0 and Lebesgue measure 0.

Proof: It suffices to show that if \( 0 < s \leq 1 \) is fixed, the \( s \)-dimensional Hausdorff measure of \( L \cap (-m, m) \) is 0 for every \( m \in \mathbb{N} \), i.e. that for every \( \epsilon > 0 \) there is a sequence \( (I_k) \) of open intervals with \( \sum_k [\ell(I_k)]^s < \epsilon \) and \( L \cap (-m, m) \subseteq \cup I_k \). Fix \( m \in \mathbb{N} \) and \( \epsilon > 0 \). Then, for any \( n \),
\[
L \cap (-m, m) \subseteq U_n \cap (-m, m) = \bigcup_{q=2}^{mq} \bigcup_{p=-mq}^{m} \left( \frac{p}{q} - \frac{1}{q^n}, \frac{p}{q} + \frac{1}{q^n} \right).
\]
We have that
\[
\ell \left( \left( \frac{p}{q} - \frac{1}{q^n}, \frac{p}{q} + \frac{1}{q^n} \right) \right) = \frac{2}{q^n}
\]
so, for sufficiently large \( n \), we have the sum of the \( s \) powers of the lengths of the intervals is
\[
\sum_{q=2}^{\infty} \sum_{p=-mq}^{mq} \left( \frac{2}{q^n} \right)^s = \sum_{q=2}^{\infty} 2^s(2mq + 1) \frac{1}{q^{ns}} \leq \sum_{q=2}^{\infty} 2^s(2mq + q) \frac{1}{q^{ns}}
\]
\[
= 2^s(2m + 1) \sum_{q=2}^{\infty} \frac{1}{q^{ns}} \leq 2^s(2m + 1) \int_{1}^{\infty} \frac{1}{x^{ns}} \, dx = \frac{2^s(2m + 1)}{ns - 2} < \epsilon.
\]
It can be shown (Exercise (i)) that every Liouville number is in the complement of the set of III.8.2.29.(ii) for some φ, giving another proof that L has Lebesgue measure 0.

III.8.2.38. However, it is far from true that all transcendental numbers have rapidly converging continued fraction convergents (or, equivalently, rapidly growing continued fraction coefficients), as III.8.2.29.(ii) shows. In fact, there are transcendental numbers whose continued fraction convergents converge nearly as slowly as those of φ (Exercise III.8.4.2.), namely numbers whose continued fraction expansion is all 1’s except for some (infinitely many!) sparsely distributed 2’s (to see that there are transcendental numbers with such continued fraction expansions, it suffices to note that there are uncountably many such sequences of 1’s and 2’s no matter what your definition of “sparsely distributed” may be. Actually, it is conjectured that every algebraic number of degree > 2 has unbounded continued fraction expansion; if so, all numbers with bounded continued fraction expansion which is not eventually periodic (cf. Exercise III.8.4.4.) would be transcendental.) In fact, there appears to be no foolproof way to distinguish between algebraic and transcendental numbers by a statistical analysis of the pattern of the terms in the continued fraction expansion.

Liouville’s theorem has been improved by various authors, beginning with Thue in 1909. The best result known is due to Roth in 1955:

III.8.2.39. Theorem. Let x be an irrational algebraic number. Then for every ε > 0 there is a C > 0 such that

\[ |x - r| > \frac{C}{q^2 r^\epsilon} \]

for all \( r = \frac{p}{q} \in \mathbb{Q} \).

This can be used to construct other transcendental numbers (cf. Exercise (i)).

III.8.3. Measure Theory of Continued Fractions

In this section, we develop some measure-theoretic properties of continued fraction expansions, and the asymptotic behavior of the terms and convergents.

First, given \( n, k \in \mathbb{N} \), what is the probability that, for a randomly chosen \( x \), we have \( a_n(x) = k \)? To make this precise, let

\[ E_n^{(k)} = \{ x \in (0, 1) : a_n(x) = k \} \]

and let \( P_n^{(k)} \) be the Lebesgue measure of \( E_n^{(k)} \). Then \( P_n^{(k)} \) is a reasonable interpretation of the “probability” that \( a_n(x) = k \) for a randomly chosen \( x \).

III.8.3.40. The case \( n = 1 \) is the easiest to analyze. We have

\[ E_1^{(k)} = \left( \frac{1}{k+1}, \frac{1}{k} \right) \]

and so

\[ P_1^{(k)} = \frac{1}{k(k+1)} = \frac{1}{k^2 + k} \].

333
Similarly, if \(a_1(x)\) is small for a randomly chosen \(x\): in fact, the probability that \(a_1(x) \geq k\) is the Lebesgue measure of \((0, 1/k] = 1/k\).

It is not easy to give such a precise description of \(P_n^{(k)}\) for \(n > 1\). But in general, we have the following estimate:

\[
\frac{1}{3k^2} < P_n^{(k)} < \frac{2}{k^2}.
\]

III.8.3.41. **Theorem.** For any \(n\) and \(k\),

\[
\frac{1}{3k^2} < P_n^{(k)} < \frac{2}{k^2}.
\]

Note that the bounds are independent of \(n\).

**Proof:** The case \(n = 1\) follows from the previous calculation. Let \(n > 1\). Fix \(k_1, \ldots, k_{n-1} \in \mathbb{N}\), and let

\[
J(k_1, \ldots, k_{n-1}) = \{x \in (0, 1] : a_j(x) = k_j \text{ for } 1 \leq j \leq n-1\}.
\]

Then we have \(\lambda\) that \(J(k_1, \ldots, k_{n-1})\) is the interval with endpoints \(\frac{p_{n-1}}{q_{n-1}}\) and \(\frac{p_{n-1} + p_{n-2}}{q_{n-1} + q_{n-2}}\), where \(p_j\) and \(q_j\) are the numerator and denominator of the \(j\)th convergent to the finite continued fraction \([0; k_1, \ldots, k_{n-1}]\). Thus we have that the length of \(J(k_1, \ldots, k_{n-1})\) is

\[
\left| \frac{p_{n-1}}{q_{n-1}} - \frac{p_{n-1} + p_{n-2}}{q_{n-1} + q_{n-2}} \right| = \frac{1}{q_{n-1}(q_{n-1} - q_{n-2})} = \frac{1}{q_{n-1}^2 \left(1 + \frac{q_{n-2}}{q_{n-1}}\right)}.
\]

Similarly, if \(k \in \mathbb{N}\) is fixed, the endpoints of \(J(k_1, \ldots, k_{n-1}, k)\) are \(\frac{p_{n-1}k + p_{n-2}}{q_{n-1}k + q_{n-2}}\) and \(\frac{p_{n-1}k + p_{n-2}}{q_{n-1}k + q_{n-2}}\), and its length is

\[
\left| \frac{p_{n-1}k + p_{n-2}}{q_{n-1}k + q_{n-2}} - \frac{p_{n-1}(k+1) + p_{n-2}}{q_{n-1}(k+1) + q_{n-2}} \right| = \frac{1}{q_{n-1}^2 k^2 \left(1 + \frac{q_{n-2}}{q_{n-1}k}\right)}\left(1 + \frac{q_{n-2}}{q_{n-1}k}\right)
\]

and so

\[
\lambda(J(k_1, \ldots, k_n, k)) = \frac{1}{k^2} \frac{1 + \frac{q_{n-2}}{q_{n-1}}}{1 + \frac{q_{n-2}}{q_{n-1}k}} \lambda(J(k_1, \ldots, k_n))
\]

and we have

\[
1 \leq \frac{1 + \frac{q_{n-2}}{q_{n-1}k}}{1 + \frac{q_{n-2}}{q_{n-1}k}} < 2
\]

\[
1 < \frac{1}{k} + \frac{q_{n-2}}{q_{n-1}k} < 3
\]

so we conclude that

\[
\frac{1}{3k^2} \lambda(J(k_1, \ldots, k_{n-1}, k)) < \lambda(J(k_1, \ldots, k_{n-1}, k)) < \frac{2}{k^2}
\]

\[
\frac{1}{3k^2} \lambda(J(k_1, \ldots, k_{n-1})) < \lambda(J(k_1, \ldots, k_{n-1})) < \frac{2}{k^2} \lambda(J(k_1, \ldots, k_{n-1}))
\]

334
We have that, as \((k_1, \ldots, k_{n-1})\) varies over \(\mathbb{N}^{n-1}\), \(E_n^{(k)}\) is the disjoint union of the \(J(k_1, \ldots, k_{n-1}, k)\) and \((0,1)\) is the disjoint union of the \(J(k_1, \ldots, k_{n-1})\); adding the inequalities over all \((k_1, \ldots, k_{n-1})\), we obtain the desired result.

It is interesting to note the following example. Let \(D\) be the set of real numbers \(x\) such that there exists a strictly increasing sequence \((r_n)\) in \(\mathbb{N}\) for which \(a_{r_n}(x)\) divides \(a_{r_{n+1}}(x)\) for all \(n\). Then \(D\) is a large subset of \(\mathbb{R}\) (it contains all \(x\) which have infinitely many 1's in its continued fraction expansion, and hence \(\mathbb{R} \setminus D\) has Lebesgue measure 0).

**III.8.3.42. Theorem.** \(D\) is not a Borel set in \(\mathbb{R}\).

In fact, \(D\) is an analytic subset of \(\mathbb{R}\). \(\mathbb{R} \setminus D\) is not analytic. These are perhaps the simplest such subsets of \(\mathbb{R}\) to explicitly describe.

**III.8.4. Exercises**

**III.8.4.1.** Prove III.8.2.4. by induction on \(n\). [Hint: apply the inductive hypothesis to the denominator of the fraction.]

**III.8.4.2.** Let \(\varphi\) be the “golden ratio” \(\frac{1 + \sqrt{5}}{2}\). Prove that the continued fraction expansion of \(\varphi\) is \([1; 1, 1, \ldots]\), and relate it to the Fibonacci sequence \((1, 1, 2, 3, 5, 8, \ldots)\), where each term is the sum of the two previous terms. This is the continued fraction expansion which converges most slowly.

The golden ratio is a number which has been of considerable mathematical and cultural significance. See [Liv02] for a cultural history of \(\varphi\).

**III.8.4.3.** (a) Let \(d \in \mathbb{N}\), not a perfect square. Find the continued fraction expansion of \(\sqrt{d}\). Relate the expansion to the integral solutions of Pell’s equation [the name is a misnomer, since Pell made little if any contribution to the theory of this equation; the basic work is due to Fermat]

\[x^2 - dy^2 = \pm 1.\]

(b) Let \(r_n\) be the \(n^{th}\) continued fraction approximation to \(\sqrt{2}\). If Newton’s approximation to the positive root of \(f(x) = x^2 - 2\) is used with initial approximation \(r_n\), i.e.

\[x_{m+1} = \frac{1}{2} \left( x_m + \frac{2}{x_m} \right)\]

with \(x_0 = r_n\), show that the next approximation \(x_1\) is \(r_{2n+1}\). Find the relation between continued fractions and Newton’s method for \(\sqrt{d}, d > 2\) [Duj01], [Mik54], [CMR95], [Ele97].

**III.8.4.4.** (a) Let \(\alpha\) be a quadratic number, i.e. an irrational root of a quadratic polynomial \(ax^2 + bx + c\) with \(a, b, c \in \mathbb{Z}\). Prove that the continued fraction expansion of \(\alpha\) is eventually periodic.

(b) Conversely, suppose \(\beta\) is an irrational number and the continued fraction expansion of \(\beta\) is eventually periodic. Prove that \(\beta\) is a quadratic number.

(Part (a) is an involved problem, and it is unreasonable for the reader to solve it without referring to number theory texts. Part (b) is fairly easy. The two parts were respectively theorems of Lagrange and Euler, two of the most outstanding mathematicians of the 18th century.)
III.8.4.5. Show that the continued fraction expansion of $e$ is
\[ [2; 1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8, 1, \ldots, 1, 2k, 1, \ldots] \,.
\]
[First find the continued fraction expansion of $\frac{e^4}{e^4 - 1}$.] This expansion was found by Euler.
In contrast, the first few terms of the continued fraction expansion of $\pi$ are
\[ [3; 7, 15, 1, 292, 1, 1, 2, 1, 3, 14, 2, 1, 1, 2, 2, 1, 2, 1, 4, 1, 1, 84, 2, 1, 15, 3, 13, 1, 4, 2, 6, 6, 99, 1, 2, 2, 6, 3, 5, 1, 1, 6, 8, 1, 7, 1, 2, 3, 7, 1, 2, 1, 12, 1, 1, 3, 1, 1, 8, 1, 1, 2, 1, 6, 1, 1, 5, 2, 2, 3, 1, 2, 4, 4, 16, 1, 161, 45, 1, 22, 1, 2, 2, 1, 4, 1, 2, \ldots] \]
and no pattern is known (although there are other regular nonsimple continued fraction representations of $\pi$). Millions of terms of this expansion can be found on the internet.

III.8.4.6. (a) Write out the details of the proof that every Liouville number is transcendental. (b) Prove that the number $\sum_{k=1}^{\infty} 10^{-k!}$ is a Liouville number. (c) Prove that the number with continued fraction expansion $[0; 10, 100, \ldots, 10^{n!}, \ldots]$ is a Liouville number.

III.8.4.7. Let $\varphi$ be the golden ratio, and $F_n$ the $n$th Fibonacci number (Exercise (i)). Since $\lim_{n \to \infty} \frac{F_{n+1}}{F_n} = \varphi$, the $F_n$ grow exponentially: if $b$ is any number with $0 < b < \varphi$, then $F_n > b^n$ for all sufficiently large $n$ (and if $c > \varphi$, $F_n < c^n$ for sufficiently large $n$). (a) If $x$ is any irrational number, show that $q_n(x) \geq F_n$ for all $n$. [Prove by induction, using III.8.2.15.(i),] Thus $q_n(x)$ grows at least exponentially. (The inequality $q_n(x) \geq F_n$ also applies for $x$ rational whenever $q_n(x)$ is defined.) (b) Show by induction on $k$ and III.8.2.15.(i) that if $x$ is irrational and $n \geq 2$, then, for all $k$,
\[ \frac{q_{n+k}(x)}{q_n(x)} > F_{k+1} \]
and that $F_{k+1}$ is the largest possible universal constant for the right-hand side. [Note that $q_n(x)$ can be arbitrarily large compared to $q_{n-1}(x)$ if $a_n(x)$ is large.]

III.8.4.8. (a) Prove Proposition III.8.2.21. by induction, using III.8.2.15.(ii) and the relation $a_n(x) = a_n(x) + \frac{1}{a_{n+1}(x)^2}$. (b) Prove the left-hand inequality in III.8.2.22., using $a_n \leq a_n < a_n + 1$.

III.8.4.9. (a) Using III.8.2.22., show that for an irrational number $x$, the following are equivalent:

(i) $x$ is a Liouville number.
(ii) For each $k \in \mathbb{N}$, $q_n(x) \geq q_n(x)^k$ for infinitely many $n$.
(iii) For each $k \in \mathbb{N}$, $a_{n+1}(x) \geq q_n(x)^k$ for infinitely many $n$.

(b) A Liouville number $x$ can have many small $a_n(x)$'s. In fact, we can have the lim inf of the geometric means of the $a_n(x)$ equal to 1 if many 1's are interspersed between the $a_{n+1}$'s of (iii). But (iii) implies that the lim sup of the geometric means of the $a_n(x)$ is infinite. Thus no Liouville numbers are in the set for which the conclusion of III.8.2.30. holds.
III.8.4.10. Champernowne’s constant is obtained by concatenating all positive integers into a single decimal:

\[ c = 0.1234567891011121314 \cdots \]

The continued fraction expansion is

\[ [0; 8, 9, 1, 1, 1] \]

where \( a_{18} \) is a 166 digit number. This is only the beginning: \( a_{40}(c) \) has 2504 digits, and \( a_{34062}(c) \) (the largest one calculated so far) has 7,311,111,092 digits! See http://mathworld.wolfram.com/ChampernowneConstant.html for more information.

Despite the apparent rapid growth of the \( a_n(c) \), \( c \) is not a Liouville number, although it is transcendental [?].

III.8.4.11. This problem gives an analog of (a) for the growth of the \( q_n \). Let \( \psi : \mathbb{N} \to [1, \infty) \) be a function.

(a) Show that if \( \sum_{q=1}^{\infty} \frac{1}{\psi(q)} \) converges, then for almost all \( x \) we have that the inequality

\[ \left| x - \frac{p}{q} \right| < \frac{1}{q \psi(q)} \]

has only finitely many solutions. [We may assume \( 0 < x < 1 \). Fix \( N \). For each \( p \) and \( q, q \geq N, 1 \leq p \leq q \), let \( I_{p,q} \) be an interval of length \( \frac{2}{q \psi(q)} \) centered at \( \frac{p}{q} \). Let \( S_N = \bigcup_{p,q} I_{p,q} \). Then \( \lambda(S_N) \leq \sum_{q=1}^{\infty} \frac{1}{\psi(q)} \). If the inequality has infinitely many solutions for \( x, x \) is in \( \bigcap_N S_N \).

(b) If \( \frac{\psi(q)}{q} \) increases and \( \sum_{q=1}^{\infty} \psi(q) \) diverges, then for almost all \( x \) the inequality

\[ \left| x - \frac{p}{q} \right| < \frac{1}{q \psi(q)} \]

has infinitely many solutions.

III.8.4.12. Consider \( a_n \) as a random variable on the interval \( (0, 1) \).

(a) Find the conditional probability \( P(a_2 = k | a_1 = j) \) [The set

\[ \{ x \in (0, 1) : a_1(x) = j, a_2(x) = k \} \]

is an interval.]

(b) Compute \( P_2^{(k)} = P(a_2 = k) \).

(c) Show that \( a_m \) and \( a_n \) are not independent for any \( m \) and \( n \).

(d) Using III.8.3.41., show that there are independent random variables \( (b_n) \) and positive constants \( \alpha \) and \( \beta \) such that

\[ \alpha < \frac{a_n(x)}{b_n(x)} < \beta \text{ a.e.} \]
III.8.4.13. ([?], [Wag93, p. 75-76]; cf. [?]) For each \( t > 0 \), define
\[
\nu_t = \sum_{n=1}^{\infty} 2^{\left\lfloor nt \right\rfloor} - 2^{n^2}.
\]
The \( \nu_t \) are called the von Neumann numbers.

(a) Show that the series converges for all \( t > 0 \).

(b) Show that each \( \nu_t \) is a Liouville number, and in particular transcendental.

(c) Show that \( \nu_t \) is not algebraic over the subfield \( F_{t} \) of \( \mathbb{R} \) generated by \( \{ \nu_s : s < t \} \), i.e. \( \nu_t \) is not a root of a nonzero polynomial with coefficients in \( F_{t} \). In other words, \( \{ \nu_t : t > 0 \} \) is an algebraically independent set of real numbers of cardinality \( 2^{80} \). [Show that \( \nu_{t} \) can be approximated much more closely by rationals than \( \nu_{s} \) for \( s < t \).] Note that the Axiom of Choice is not needed to construct this set of algebraically independent numbers or to prove its properties.

III.8.4.14. Let \( f \) be a strictly increasing function from \( \mathbb{N} \) to \( \mathbb{N} \), and let \( \mu = \limsup_{n \to \infty} \frac{f(n+1)}{f(n)} \). Let \( d \in \mathbb{N} \), \( d > 1 \), and set \( x = \sum_{n=1}^{\infty} \frac{1}{d^{f(n)}} \).

(a) Show that the equation
\[
|x - r| < \frac{C}{q^{\mu - \epsilon}}
\]
has infinitely many solutions in \( r = \frac{p}{q} \in \mathbb{Q} \) for any fixed \( C > 0 \) and \( \epsilon > 0 \).

(b) Use Roth’s Theorem (III.8.2.39.) to show that \( x \) is transcendental if \( \mu > 2 \).

III.8.4.15. (a) If \( x = \frac{p}{q} \) is a rational number, show that the decimal expansion of \( x \) is eventually periodic, with the length of the period not more than \( q - 1 \). [Divide \( q \) into \( p \) by long division.]

(b) Conversely, if \( x \in \mathbb{R} \) has an eventually periodic decimal expansion, then \( x \) is rational. [If the length of the period of the expansion is \( k \), show that \( 10^{k}x - x \) is a decadent rational.]

If \( 0 \leq x \leq 1 \) and the decimal expansion of \( x \) is exactly periodic, a fractional representation of \( x \) is easy to obtain. For example,
\[
x = .250425042504 \cdots = \frac{2504}{9999},
\]
since \( 10000x - x = 2504 \), and the same pattern works in general, with \( k \) 9’s in the denominator if the period is \( k \). (This representation will not be in lowest terms in general.)

(c) What is the exact relationship between the length of the period of the decimal expansion of \( \frac{p}{q} \) and the denominator \( q \)?

(d) Show that analogous results hold for “decimal” expansions with any base.

III.8.4.16. Show that if \( a \) and \( b \) are positive numbers (e.g. natural numbers), then
\[
\sqrt{a^2 + b} = a + \frac{b}{2a + \frac{b}{2a + \frac{b}{2a + \frac{b}{x + \frac{b}{x + \frac{b}{x + \ddots}}}}}}.
\]
III.9. Irrational and Transcendental Numbers

“It can be of no practical use to know that is irrational, but if we can know, it surely would be intolerable not to know.”

E. C. Titchmarsh

III.9.1. Introduction

III.9.1.1. Analytic methods can be used to prove that specific numbers such as \( e \) and \( \pi \) are irrational and even transcendental. In this section, we give a few proofs not requiring anything beyond basic analysis techniques. More sophisticated results can be obtained by combining such methods with ideas from algebraic number theory; we survey some of these results, mostly without proof.

III.9.1.2. It was known as a result of Euler’s work on continued fractions (III.8.4.5.) that \( e \) (and also \( e^2 \)) is irrational, and in fact, using Lagrange’s Theorem (III.8.4.4.), not algebraic of degree 2. Another proof based on the power series representation was given by Fourier in 1815 (cf. V.5.5.6.; this proof can be easily modified to also give the quadratic result.)

III.9.1.3. The first proof that \( \pi \) is irrational was given by Lambert in 1766, using continued fractions (his proof was not rigorous by modern standards). Legendre gave a rigorous proof along the same lines in 1794 for \( \pi \) and many other numbers. Hermite developed another method in 1873 giving the transcendence of \( e \), which was adapted by Lindemann to give broad transcendence results including transcendence of \( \pi \). Significant advances beginning with the same general method were obtained throughout the twentieth century. See, for example, [Niv56] or the introduction to [Shi89] for a more complete survey.

III.9.2. Irrationality of \( \pi \)

III.9.2.1. We first give a simple proof of the irrationality of \( \pi \) (and \( \pi^2 \)) along the lines of the arguments of Hermite and Lindemann, due to I. Niven [Niv47] and Y. Iwamoto [Iwa49] (cf. [Wac49], [Niv56, 2.6]), which will introduce the techniques used in later proofs of transcendence, even though the result will be subsumed in III.9.3.2. The idea in all these proofs is to assume that a certain rational or polynomial relation exists, and obtain a contradiction by constructing an integral whose value is an integer strictly between 0 and 1. The functions used in the arguments can seem to materialize out of thin air, but actually arise from considerations related to continued fraction expansions; see [Sie49, I, §3], for example, for motivation.

We first make the following simple observation:

III.9.2.2. Lemma. Let \( g(x) \) be a polynomial with integer coefficients, and \( n \in \mathbb{N} \). Set \( f(x) = \frac{x^n g(x)}{n!} \). Then the \( k \)’th derivative \( f^{(k)}(0) \) is an integer for every \( k \).

Proof: Let \( x^n g(x) = \sum_{k=0}^{n+d} c_k x^k \). Then \( c_k \in \mathbb{Z} \) for all \( k \), and \( c_k = 0 \) for \( k < n \). We have, for all \( k \),

\[
  f^{(k)}(0) = \frac{k!c_k}{n!} \in \mathbb{Z}.
\]

III.9.2.3. Theorem. The number $\pi^2$ is irrational. (Hence $\pi$ is also irrational.)

Proof: Let $n$ be a fixed positive integer (which we will choose later), and set

$$f(x) = \frac{x^n(1-x)^n}{n!}.$$ 

Note that if $0 < x < 1$, then $0 < f(x) < \frac{1}{n!}$. By III.9.2.2., $f^{(k)}(0) \in \mathbb{Z}$ for all $k$; and $f^{(k)}(1) \equiv 0$ for $k > 2n$. Since $f(1-x) = f(x)$ for all $x$, we also have $f^{(k)}(1) \in \mathbb{Z}$ for all $k$.

Suppose $\pi^2 = \frac{a}{b}$ for relatively prime $a, b \in \mathbb{N}$. Set

$$F(x) = b^n[\pi^{2n}f(x) - \pi^{2n-2}f^{(2)}(x) + \pi^{2n-4}f^{(4)}(x) - \cdots + (-1)^n f^{(2n)}(x)]$$

and note that $F(0), F(1) \in \mathbb{Z}$. Next,

$$\frac{d}{dx}(F'(x) \sin \pi x - \pi F(x) \cos \pi x) = (F''(x) + \pi^2 F(x)) \sin \pi x$$

$$= b^n \pi^{2n+2} f(x) \sin \pi x = \pi^2 a^n f(x) \sin \pi x$$

so we have

$$\pi a^n \int_0^1 f(x) \sin \pi x \, dx = \left[ \frac{F'(x) \sin \pi x}{\pi} - F(x) \cos \pi x \right]_0^1 = F(1) + F(0) \in \mathbb{Z}.$$ 

On the other hand, since $0 < f(x) \sin \pi x < \frac{1}{n!}$ for $0 < x < 1$,

$$0 < \pi a^n \int_0^1 f(x) \sin \pi x \, dx < \frac{\pi a^n}{n!} < 1$$

for sufficiently large $n$, a contradiction.

A nearly identical proof ([Kok49], [Wac49]) shows that $e^n$ is irrational for all $n$ (see III.9.3.1. for a better result). A modified version of this argument, somewhat more complicated but still elementary (cf. [Niv56, 2.5]), gives:

III.9.2.4. Theorem. If $\alpha$ is any nonzero rational number, then $\cos \alpha$ is irrational.

III.9.2.5. This theorem gives another proof that $\pi$ is irrational, since otherwise $\cos \pi = -1$ would be irrational. It also implies that $\sin^2 \alpha = \frac{1}{2}(1 - \cos 2\alpha)$ and hence $\sin \alpha$ and $\cos^2 \alpha = 1 - \sin^2 \alpha$ are irrational, for nonzero rational $\alpha$. In addition, for $\alpha$ nonzero rational, $\tan^2 \alpha$ is irrational, since otherwise $\cos^2 \alpha = \frac{1}{1 + \tan^2 \alpha}$ would be rational, and hence $\tan \alpha$ is irrational. Thus, if $\alpha$ is nonzero rational, $\arcsin \alpha$ and $\arctan \alpha$ are irrational. These results will be subsumed by the much more general result III.9.3.6.(iii).

340
III.9.3. Transcendence of $e$ and Related Numbers

A proof along the same general lines can be given of the transcendence of $e$, due to A. Hurwitz (1893):

**III.9.3.1. Theorem.** The number $e$ is transcendental.

**Proof:** Suppose $e$ is algebraic. Then there are integers $a_0, a_1, \ldots, a_m$ with $a_0 \neq 0$ and

$$a_0 + a_1 e + a_2 e^2 + \cdots + a_m e^m = 0.$$  

If $n \in \mathbb{N}$ and $f$ is any polynomial of degree $n$ with real coefficients, and we set

$$F(x) = f(x) + f'(x) + f''(x) + \cdots + f^{(n)}(x),$$  

then by repeated integration by parts we obtain, for any $b > 0$,

$$\int_0^b f(t)e^{-t} \, dt = f(0) - f(b)e^{-b} + \int_0^b f'(t)e^{-t} \, dt = \cdots = F(0) - F(b)e^{-b}$$  

called Hermite’s Identity.

We will apply Hermite’s Identity in the case where

$$f(x) = \frac{1}{(p-1)!}x^{p-1}(x-1)^p(x-2)^p\cdots(x-m)^p$$

where $m$ is the degree of the polynomial relation for $e$ given above and $p$ is a large prime number which will be chosen later (recall that there are infinitely many prime numbers, so $p$ can be chosen as large as desired).

Since $f$ is a polynomial of degree $n = p(m+1)-1$, we may apply Hermite’s Identity for $b = 1, \ldots, k, \ldots, m$, we obtain

$$F(0)e^k - F(k) = e^k \int_0^k f(t)e^{-t} \, dt.$$  

The equation also holds when $k = 0$ (both sides are 0). Multiplying by $a_k$ and adding, we get the fundamental relation

$$\sum_{k=0}^m a_k e^k F(0) - \sum_{k=0}^m a_k F(k) = \sum_{k=0}^m a_k e^k \int_0^k f(t)e^{-t} \, dt. \quad (III.1)$$  

The first sum is 0 by the assumed polynomial relation for $e$, so the left side becomes

$$-\sum_{k=0}^m a_k F(k) = -\sum_{k=0}^m \sum_{r=0}^n a_k f^{(r)}(k).$$

If $g$ is a polynomial with integer coefficients, then for any $r$ we have that all coefficients of $g^{(r)}$ are divisible by $r!$ (V.17.7.6.). So, if $r \geq p$, all the coefficients of $f^{(r)}$ are integers divisible by $p$, and hence for $r \geq p$ we have that $f^{(r)}(k)$ is an integer divisible by $p$ for any $k \in \mathbb{Z}$ (and, in particular, for $k = 0, 1, \ldots, m$). Also, for $k = 1, \ldots, m$, $f$ has a zero of order $p$ at $k$, so $f^{(r)}(k) = 0$ for $0 \leq r < p$. Thus $f^{(r)}(k)$ is an integer divisible by $p$ for all $r$. 

341
Since $f$ has a zero of order $p - 1$ at 0, we also have $f^{(r)}(0) = 0$ for $0 \leq r < p - 1$. We can calculate directly from the definition that
\[
f^{(p-1)}(0) = (-1)^p(-2)^p \cdots (-m)^p = (-1)^mp(m!)^p
\]
which is an integer not divisible by $p$ if $p > m$.

So every term on the left is an integer divisible by $p$ except the term $a_0 f^{(p-1)}(0)$, which is an integer not divisible by $p$ if $p > m$ and $p > |a_0|$ (recall that $a_0 \neq 0$). So if $p$ is sufficiently large, the left side of III.1 is a nonzero integer.

Now consider the right side of III.1. For $0 \leq x \leq m$, we have
\[
|f(x)| \leq \frac{m^p-1m^p \cdots m^p}{(p-1)!} = \frac{m^{mp+p-1}}{m(p-1)!} = \frac{(m^{m+1})^p}{m(p-1)!}.
\]
So, if we set
\[
c = e^m \sum_{k=0}^m |a_k| \quad \text{and} \quad d = m^{m+1}
\]
(note that $c$ and $d$ do not depend on $p$), we get for the right side
\[
\left| \sum_{k=0}^m a_k e^k \int_0^k f(t)e^{-t} dt \right| \leq \sum_{k=0}^m |a_k| e^k m \frac{(m^{m+1})^p}{m(p-1)!} \leq c \frac{d^p}{(p-1)!},
\]
which is strictly less than 1 for $p$ sufficiently large, contradicting that the left side is a nonzero integer. ☺

III.9.3.2. A proof that $\pi$ is transcendental can be given along the same lines, but it is slightly more complicated and uses some elementary results from number theory; see, for example, [Bak90, 1.3] or [Shi89, p. 47-50].

Using a refined version of the same argument, plus some facts about algebraic numbers, LINDEMAN in his 1882 paper outlined a proof of a much more general theorem, for which WEIERSTRASS later provided a complete and simplified proof (HERMITE gave a proof of III.9.3.5.):

III.9.3.3. Theorem. Let $\alpha_1, \ldots, \alpha_n$ be distinct algebraic numbers, and $\beta_1, \ldots, \beta_n$ nonzero algebraic numbers. Then
\[
\beta_1 e^{\alpha_1} + \cdots + \beta_n e^{\alpha_n} \neq 0.
\]

This result has the following equivalent formulation, which is often called Lindemann’s Theorem:
III.9.3.4. Theorem. Let $\alpha_1, \ldots, \alpha_n$ be algebraic numbers which are linearly independent over $\mathbb{Q}$. Then $e^{\alpha_1}, \ldots, e^{\alpha_n}$ are algebraically independent over $\mathbb{Q}$, i.e. there does not exist a nonzero polynomial $f(x_1, \ldots, x_n)$ with rational coefficients (or even with algebraic coefficients) with $f(e^{\alpha_1}, \ldots, e^{\alpha_n}) = 0$.

It is a simple standard fact from field theory (cf. Exercise III.9.5.2.) that if $\gamma_1, \ldots, \gamma_n$ are complex numbers which are algebraically independent over $\mathbb{Q}$, then they are algebraically independent over the field of algebraic numbers (the algebraic closure of $\mathbb{Q}$).

To obtain III.9.3.4. from III.9.3.3., let $\alpha_1, \ldots, \alpha_n$ be algebraic numbers which are linearly independent over $\mathbb{Q}$. If $f(x_1, \ldots, x_n)$ is a nonzero polynomial with rational coefficients, then $f$ is a sum of terms of the form $c_{(k_1, \ldots, k_n)} x_1^{k_1} x_2^{k_2} \cdots x_n^{k_n}$, where the $k_i$ are nonnegative integers. So $f(e^{\alpha_1}, \ldots, e^{\alpha_n})$ is a sum of terms of the form $c_{(k_1, \ldots, k_n)} e^{k_1 \alpha_1} e^{k_2 \alpha_2} \cdots e^{k_n \alpha_n} = c_{(k_1, \ldots, k_n)} e^{k_1 \alpha_1 + \cdots + k_n \alpha_n}$ and the exponents are distinct integer linear combinations of $\alpha_1, \ldots, \alpha_n$, hence distinct algebraic numbers by linear independence. Thus by III.9.3.3., $f(e^{\alpha_1}, \ldots, e^{\alpha_n}) \neq 0$.

Conversely, suppose III.9.3.4. holds, and let $\alpha_1, \ldots, \alpha_n$ be distinct algebraic numbers. If the rational span of $\{\alpha_1, \ldots, \alpha_n\}$ has dimension $m$ over $\mathbb{Q}$, then there are algebraic numbers $\gamma_1, \ldots, \gamma_m$ which are linearly independent over $\mathbb{Q}$ such that, for each $k$, $1 \leq k \leq n$,

$$\alpha_k = \sum_{j=1}^{m} a_{jk} \gamma_j$$

with $a_{jk} \in \mathbb{Q}$; we may assume each $a_{jk} \in \mathbb{Z}$ by replacing $\gamma_j$ by $\gamma_j/r_j$ for suitable $r_j \in \mathbb{Z}$. Now let $\beta_1, \ldots, \beta_n$ be nonzero algebraic numbers, and set

$$f(x_1, \ldots, x_n) = \sum_{k=1}^{n} \beta_k x_1^{a_{1k}} x_2^{a_{2k}} \cdots x_m^{a_{mk}}.$$

Then $f$ is a nonzero rational function with algebraic coefficients (the monomials in the terms are all different since the $\alpha_k$ are distinct), hence a quotient of polynomials with algebraic coefficients (the denominator can be taken to be a monomial), so $f(e^{e\gamma_1}, \ldots, e^{e\gamma_m}) \neq 0$ by III.9.3.4. But

$$f(e^{e\gamma_1}, \ldots, e^{e\gamma_m}) = \sum_{k=1}^{n} \beta_k e^{a_{1k} \gamma_1 + \cdots + a_{mk} \gamma_m} = \sum_{k=1}^{n} \beta_k e^{a_k} \neq 0.$$

The special case of III.9.3.4. with $n = 1$ is:

III.9.3.5. Corollary. If $\alpha$ is a nonzero algebraic number, then $e^\alpha$ is transcendental.

In these theorems, the $\alpha_k$ and $\beta_k$ do not have to be real numbers (i.e. they can be complex algebraic numbers).
III.9.3.6. Here are some consequences of III.9.3.5:

(i) This result also implies that $\pi$ is transcendental, since if $\pi$, and hence $\pi i$, were algebraic, then $e^{\pi i} = -1$ would be transcendental.

(ii) If $\alpha$ is a positive algebraic number, $\alpha \neq 1$, then $\log \alpha$ is transcendental, since if it were algebraic we would have $\alpha = e^{\log \alpha}$ transcendental.

(iii) If $\alpha$ is a nonzero algebraic number, then $e^{i\alpha} = \cos \alpha + i \sin \alpha$ is transcendental. If $\cos \alpha$ were algebraic, $\sin \alpha = \pm \sqrt{1 - \cos^2 \alpha}$ would also be algebraic, so $e^{i\alpha}$ would be algebraic. Thus $\cos \alpha$ and $\sin \alpha$ are transcendental. We then also have $\tan \alpha$, $\arcsin \alpha$, $\arctan \alpha$ transcendental by the argument of III.9.2.5.

III.9.4. Twentieth Century Results

III.9.4.1. In his famous 1900 list of problems (#7), HILBERT asked to prove that if $\alpha$ is an algebraic number other than 0 or 1, and $\beta$ is an irrational algebraic number, then $\alpha^\beta$ is transcendental. In a 1920 lecture he expressed the opinion that both the Riemann Hypothesis and Fermat’s Last Theorem would be solved first, and that this problem would not be solved within the lifetime of anyone in the room. Actually, the problem was solved independently in 1934 by GELFOND and SCHNEIDER, well within HILBERT’s own lifetime, using key ideas of GELFOND (1929) and SIEGEL (1929). (Fermat’s Last Theorem was proved in 1994, and the Riemann Hypothesis remains unproved, showing the difficulty in trying to predict the future of mathematics.)

III.9.4.2. Theorem. [Gelfond-Schneider] Let $\alpha$ and $\beta$ be algebraic complex numbers, with $\alpha$ not 0 or 1 and $\beta \notin \mathbb{Q}$. Then $\alpha^\beta$ is transcendental.

Actually, in general $\alpha^\beta$ has many possible values depending on the branch of logarithm chosen; the theorem asserts that all these possible values are transcendental. See [Niv56, Chapter 10] for a proof.

III.9.4.3. For example, numbers such as $2\sqrt{2}$ and $\sqrt[3]{2}$ are transcendental. Also, we obtain that $e^\pi$ is transcendental, since it is one of the values of $i^{-2i}$. Similarly, $e^{\pi \alpha}$ is transcendental for any nonzero real algebraic $\alpha$.

An especially interesting example is the “Ramanujan Constant” (actually discovered by HERMITE in 1859; the name stems from an April Fool joke by MARTIN GARDNER in 1975. See http://en.wikipedia.org/wiki/Ramanujan_constant#Almost_integers_and_Ramanujan.27s_constant or http://mathworld.wolfram.com/RamanujanConstant.html for more information.) Calculation shows that

$$e^{\pi \sqrt{163}} = 262537412640768744.00000000000$$

correct to eleven decimal places; nonetheless, this number is not an integer, and in fact is transcendental. Powers of this number are also remarkably close to integers. The underlying reason is that 163, which is prime, is the largest squarefree integer $d$ such that the ring of integers in the field $\mathbb{Q}(\sqrt{-d})$ has unique factorization.

We also have the following corollary, which was stated but not proved by EULER:
III.9.4.4. Corollary. Let $\alpha$ and $\beta$ be positive algebraic numbers, with $\alpha \neq 1$. If $\beta$ is not a rational power of $\alpha$ (i.e. if $\log_{\alpha} \beta$ is irrational; cf. III.9.5.3.), then $\log_{\alpha} \beta$ is transcendental.

Proof: If $\gamma = \log_{\alpha} \beta$ is irrational but algebraic, then $\beta = \alpha^\gamma$ is transcendental, a contradiction. 

A significant advance arose from the fundamental work of A. Baker in the late 1960’s. One of his theorems was:

III.9.4.5. Theorem. If $\alpha_1, \ldots, \alpha_n$ are nonzero algebraic numbers such that $\log \alpha_1, \ldots, \log \alpha_n$ (any possible values of these are allowed) are linearly independent over $\mathbb{Q}$, then $1, \log \alpha_1, \ldots, \log \alpha_n$ are linearly independent over the algebraic numbers.

III.9.4.6. The case $n = 2$ implies III.9.4.2: if $\alpha$ and $\beta$ are algebraic numbers with $\alpha$ not 0 or 1 (so $\log \alpha$ is defined and nonzero), and $\alpha^\beta$ is algebraic, set $\alpha_1 = \alpha$, $\beta_1 = \beta$, $\alpha_2 = \alpha^\beta$, and $\beta_2 = -1$. Then $\beta_1 \log \alpha_1 + \beta_2 \log \alpha_2 = 0$, so by III.9.4.5. $\{\log \alpha_1, \log \alpha_2\} = \{\log \alpha, \beta \log \alpha\}$ is linearly dependent over $\mathbb{Q}$, i.e. $\beta \in \mathbb{Q}$. (The converse implication is not quite true: III.9.4.2. implies that if $\alpha_1$ and $\alpha_2$ are algebraic numbers with $\{\log \alpha_1, \log \alpha_2\}$ linearly independent over $\mathbb{Q}$, then $\{\log \alpha_1, \log \alpha_2\}$ is linearly independent over the algebraic numbers, but it does not imply that $\{1, \log \alpha_1, \log \alpha_2\}$ is linearly independent over the algebraic numbers.)

III.9.4.7. Corollary. 

(i) If $\alpha_1, \ldots, \alpha_n, \beta_0, \ldots, \beta_n$ are nonzero algebraic numbers, then

$$\beta_0 + \beta_1 \log \alpha_1 + \cdots + \beta_n \log \alpha_n \neq 0.$$ 

(ii) If $\alpha_1, \ldots, \alpha_n, \beta_0, \ldots, \beta_n$ are nonzero algebraic numbers, then

$$e^{\beta_0 \alpha_1^\beta_1 \cdots \alpha_n^\beta_n}$$

is transcendental.

(iii) If $\alpha_1, \ldots, \alpha_n$ are algebraic numbers other than 0 or 1, and $\beta_1, \ldots, \beta_n$ are algebraic numbers with $\{1, \beta_1, \ldots, \beta_n\}$ linearly independent over $\mathbb{Q}$, then

$$\beta_1 \cdots \beta_n$$

is transcendental.

III.9.4.8. These results imply that $\pi + \log \alpha$ is transcendental for any nonzero algebraic number $\alpha$, and that $e^{\pi \log \alpha} = \pi + \log \alpha$ is transcendental for any algebraic $\alpha$ and $\beta$ with $\beta \neq 0$. 

345
III.9.4.9. **Siegell** (1929) began a general study of the values of certain transcendental functions satisfying linear differential equations, and he and subsequent authors obtained far-reaching generalizations of the results of III.9.3.6. See [Shi89] for the full story.

III.9.4.10. We have only scratched the surface of the extensive research done in this subject. Books such as () give a much more complete picture. But despite all the advances, there are still basic questions remaining open. For example, it has been difficult to get algebraic independence results for numbers of the form $\alpha^\beta$, where $\alpha$ and $\beta$ are algebraic, analogous to III.9.3.4. III.9.4.7.(ii)–(iii) are weak analogs, but a better result would be

III.9.4.11. **Conjecture.** Let $\alpha_1, \ldots, \alpha_n$ be algebraic numbers not 0 or 1, let $\beta_1, \ldots, \beta_n$ be algebraic numbers with $\{1, \beta_1, \ldots, \beta_n\}$ linearly independent over $\mathbb{Q}$, and let $\gamma_1, \ldots, \gamma_m$ be algebraic numbers linearly independent over $\mathbb{Q}$. Then $\{\alpha_1^{\beta_1}, \ldots, \alpha_n^{\beta_n}, e^{\gamma_1}, \ldots, e^{\gamma_m}\}$ is algebraically independent over $\mathbb{Q}$.

The $\gamma_j$ and $e^{\gamma_j}$ can be eliminated from this conjecture. See [Rib00a, p. 323-327] for more related conjectures.

III.9.4.12. As an example of the incomplete state of the theory of transcendental numbers, it is not known whether $\pi$ and $e$ are algebraically independent (this is apparently universally believed to be true, but remains unproved). It is not even known whether $\pi + e$ and/or $\pi e$ is irrational! It is known from the following simple proposition that at least one of these numbers is transcendental, but nothing is known about either number individually. It is also not known whether $e^e$, $\pi^\pi$, $\pi^\pi$, or the Euler-Mascheroni constant $\gamma$ are rational or irrational, algebraic or transcendental.

III.9.4.13. **Proposition.** Let $\alpha$ and $\beta$ be numbers.

(i) If $\alpha$ is transcendental, then either $\alpha + \beta$ or $\alpha \beta$ (or both) is transcendental.

(ii) If $\alpha$ is not a quadratic number, then either $\alpha + \beta$ or $\alpha \beta$ (or both) is irrational.

**Proof:** (i) If $\alpha + \beta$ and $\alpha \beta$ are both algebraic, then $\alpha$ is a root of the quadratic polynomial

$$f(x) = (x - \alpha)(x - \beta) = x^2 - (\alpha + \beta)x + \alpha \beta$$

with algebraic coefficients, so $\alpha$ would be algebraic. The proof of (ii) is a slight variation left to the reader. \(\Box\)

III.9.5. **Exercises**

III.9.5.1. (http://math.stackexchange.com/questions/654232/if-cosa-pi-frac13-then-a-is-irrational?noredirect=1&lq=1)

(a) Let $p, q \in \mathbb{N}$. Then $e^{\pm \frac{\pi p}{q}}$ is a root of $X^{2q} - 1$, hence an algebraic integer. Thus $2\cos\left(\frac{\pi p}{q}\right) = e^{\frac{\pi p}{q}} + e^{-\frac{\pi p}{q}}$ is an algebraic integer.
(b) If \( r \in \mathbb{Q} \) and \( \cos \pi r \in \mathbb{Q} \), then \( 2 \cos \pi r \) is an integer (cf. III.9.5.5); hence \( |\cos \pi r| = 0, \frac{1}{2}, \) or 1. Thus if \( 0 < r < \frac{1}{2} \), then \( r = \frac{1}{3} \).

(c) If \( 0 < \alpha < \frac{\pi}{2} \) and \( \cos \alpha \) is rational, then either \( \alpha = \frac{\pi}{3} \) or \( \frac{\pi}{6} \) is irrational.

In light of the fact that \( \pi \) is irrational, even transcendental, this result is almost completely complementary to III.9.2.4. or III.9.3.6 (iii). The proof outlined is quite simple, but uses one nontrivial fact from abstract algebra or number theory: that the sum of two algebraic integers is an algebraic integer. A more elementary proof is given in [HD64] using only III.11.7.33. for \( n = 2 \) and some trigonometric identities; it is also noted there that the result implies that the acute angles in any Pythagorean triangle are irrational multiples of \( \pi \).

**III.9.5.2.** This exercise requires knowledge of the basics of field theory in abstract algebra. See books on abstract algebra such as [DF04] for details, and for an explanation of the standard notation and terminology used in this problem.

Suppose \( K \) is a field, \( F \) a subfield of \( K \), and \( E \) a subfield of \( K \) containing \( F \).

(a) If \( E \) is a finite extension of \( F \) and \( \alpha \in K \), then \( E(\alpha) \) is a finite extension of \( F(\alpha) \) and

\[ |E(\alpha) : F(\alpha)| \leq |E : F| . \]

(b) If \( E \) is an algebraic extension of \( F \) and \( \alpha \in K \), then \( E(\alpha) \) is an algebraic extension of \( F(\alpha) \).

(c) If \( E \) is an algebraic extension of \( F \) and \( \alpha \in K \) is algebraic over \( E \), then \( \alpha \) is algebraic over \( F \).

(d) If \( \gamma_1, \ldots, \gamma_n \in K \), then \( \{\gamma_1, \ldots, \gamma_n\} \) is algebraically independent over \( F \) if and only if \( \gamma_1 \) is transcendental over \( F \) and \( \gamma_{k+1} \) is transcendental over \( F(\gamma_1, \ldots, \gamma_k) \) for \( 1 \leq k < n \).

(e) Show inductively using (b), (c), and (d) that if \( \{\gamma_1, \ldots, \gamma_n\} \subseteq K \) is algebraically independent over \( F \) and \( E \) is algebraic over \( F \), then \( \{\gamma_1, \ldots, \gamma_n\} \) is algebraically independent over \( E \).

**III.9.5.3.**

(a) Prove that \( \log_2 3 \) is irrational. [\( 2^p \) is even and \( 3^q \) is odd for all \( p, q \in \mathbb{N} \).]

(b) Prove that if \( m, n \) are integers \( > 1 \), and \( \log_m n \) is rational, then \( m \) and \( n \) are both integer powers of the same natural number.

(c) Give a similar criterion for rationality of \( \log \alpha \beta \) for positive rational numbers \( \alpha, \beta \) with \( \alpha \neq 1 \).

**III.9.5.4.** This problem shows that if \( n, d \in \mathbb{N} \), then \( \sqrt[d]{n} \) is either a natural number or irrational.

(a) Suppose \( \sqrt[d]{a} = \frac{b}{d} \) for natural numbers \( a, b \). Then \( a^n = b^n d \). Write

\[ a = p_1^{r_1} p_2^{r_2} \cdots p_m^{r_m} \]
\[ b = p_1^{s_1} p_2^{s_2} \cdots p_m^{s_m} \]
\[ d = p_1^{t_1} p_2^{t_2} \cdots p_m^{t_m} \]

where \( p_1, \ldots, p_m \) are distinct prime numbers and the exponents are nonnegative integers (some may be zero).

(b) From \( a^n = b^n d \) obtain that

\[ p_1^{nr_1} p_2^{nr_2} \cdots p_m^{nr_m} = p_1^{ns_1+t_1} p_2^{ns_2+t_2} \cdots p_m^{ns_m+t_m} \]

and conclude that \( t_k \) is divisible by \( n \) for all \( k \), i.e. that \( d = c^n \) for some \( c \in \mathbb{N} \).

This argument uses the unique factorization of natural numbers into products of prime numbers (cf. ()), hence for \( n = 2 \) is not quite as elementary as the one in III.1.12.6. See III.1.13.6.(e) for an argument not requiring unique factorization.

347
III.9.5.5. The purpose of this problem is to give a purely algebraic proof of the following theorem:

**Theorem.** Let \( f(x) = x^n + a_{n-1}x^{n-1} + \cdots + a_1x + a_0 \) be a monic polynomial with integer coefficients. Then any rational number which is a root of \( f \) is an integer (i.e. a rational number which is an algebraic integer is an ordinary integer).

This theorem is a special case of *Gauss’s Lemma*. See books on abstract algebra such as [DF04] for the statement and proof of the general form of Gauss’s Lemma. (This is only one of several results commonly called “Gauss’s Lemma”; he produced a lot of important mathematics.)

If \( n, d \in \mathbb{N} \), applying this theorem to \( f(x) = x^n - d \), we obtain (see Exercise III.9.5.4. for another proof):

**Corollary.** If \( n, d \in \mathbb{N} \), then \( n/d \) is either a natural number or irrational.

These results are special cases of the more general result (also a special case of Gauss’s Lemma):

**Theorem.** If \( f(x) = a_nx^n + a_{n-1}x^{n-1} + \cdots + a_1x + a_0 \) is a polynomial with integer coefficients and \( a_0 \neq 0 \), \( a_n \neq 0 \), and \( \alpha \) is a (nonzero) fraction in lowest terms which is a root, then \( b \) divides \( a_n \), \( c \) divides \( a_0 \), and \( f(x) = (bx - c)k(x) \) for a polynomial \( k \) with coefficients in \( \mathbb{Z} \).

(a) Show that if \( g(x) \) and \( h(x) \) are polynomials with integer coefficients, and \( p \) is a prime number that divides every coefficient of \( g(x)h(x) \), then either \( p \) divides every coefficient of \( g(x) \) or it divides every coefficient of \( h(x) \). [If not, let \( r \) be the largest number for which the coefficient of \( x^r \) in \( g \) is not divisible by \( p \), \( s \) the largest number for which the coefficient of \( x^s \) in \( h \) is not divisible by \( p \), and consider the coefficient of \( x^{r+s} \) in \( gh \).]

(b) If \( q = \frac{\alpha}{\beta} \in \mathbb{Q} \), show that \( f(x) = (x - q)g(x) \) for a polynomial \( g \) with rational coefficients.

(c) Show there is a \( d \in \mathbb{N} \) such that
\[
bd \cdot f(x) = (bx - c)h(x)
\]
where \( h \) is a polynomial with integer coefficients.

(d) If \( p \) is a prime number dividing \( bd \), use (a) to show that \( p \) divides every coefficient of \( h \).

(e) Dividing out prime factors of \( bd \) repeatedly, show that
\[
f(x) = (bx - c)k(x)
\]
for a polynomial \( k \) with integer coefficients. Multiply out to obtain the divisibility conclusion.

(f) In fact, \( \mathbb{Z}[X] \) is a unique factorization domain or *UFD*: any polynomial with integer coefficients can be written as a product of irreducible polynomials with integer coefficients, uniquely up to the order and signs of the factors.

III.9.5.6. Show that there is a unique real number \( a \) such that \( e^a = \frac{1}{a} \), and that this number is transcendental. (We have \( a = W(1) \approx 0.567 \), where \( W \) is the Lambert \( W \) function.)

III.9.5.7. Are the following formulas correct?
\[
\pi^4 + \pi^8 = e^6.
\]
\[
e^\pi - \pi = 20.
\]
III.9.5.8. [Sin13] Use a calculator or computer algebra program to calculate

\[ 12\sqrt{3987^{12} + 4365^{12}}. \]

Does this provide a counterexample to Fermat’s Last Theorem?
III.10. Hyperreal Numbers and Nonstandard Analysis

In the early years, calculus, especially in the Leibniz formulation, was based on the notion of an “infinitesimal” change; indeed, the name “calculus” is a shortened form of “infinitesimal calculus.” The logical foundations of calculus were vigorously, and sometimes rightly, challenged, and appeared to be quite shaky even to some of the developers and defenders of the theory, although no one could deny the apparent accuracy and usefulness of the theory in describing and explaining analytic and physical phenomena. (Leibniz himself regarded infinitesimals as a “fiction, although a well-founded one,” and considered them to be convenient symbolic shorthand for limit arguments, although his pronouncements on the subject were somewhat inconsistent. Newton felt much the same way. See [Jah03, p. 97-98].) When it became more important to mathematicians in the nineteenth century to carefully develop a rigorous theory of calculus and analysis, the intuitive approach via infinitesimals was deemed incapable of direct logical justification (Cantor was particularly firmly convinced that infinitesimals were a logical fiction, calling them the “cholera bacillus of mathematics”⁷), and was bypassed by the familiar $\varepsilon - \delta$ formulations of Cauchy and Weierstrass, which remain the standard approach to this day. See [Gra08, p. 328-346] for a lucid and fascinating discussion of the attitudes about measurement, infinitesimals, and the Archimedean axiom around the turn of the 20th century.

Intuitive arguments involving infinitesimals are far from dead, however, and are quite useful in many instances, particularly to scientists using calculus in their work. The dream among some mathematicians of a rigorous theory of infinitesimals never faded away.

Finally, in 1960, Abraham Robinson (partially anticipated by C. Schmieden and D. Laugwitz [SL58]) found a way to use fairly sophisticated ideas and results from mathematical logic to give a rigorous direct approach to analysis on $\mathbb{R}$ using infinitesimals. The subject growing out of his work is called nonstandard analysis (Robinson’s name).

Nonstandard analysis is one of the most controversial parts of mathematics. There are some “true believers” who think the nonstandard approach is the way to do analysis, and that eventually the mathematical world will see the light; on the other hand, nonstandard methods are definitely unfashionable among most mainstream analysts, although some aspects of probability and mathematical economics seem to have more natural nonstandard formulations (). It should be noted that the controversy has little if anything to do with the correctness or legitimacy of nonstandard analysis as a part of mathematics; no one today except perhaps for a few constructivists (who also reject substantial parts of “classical” analysis) questions the soundness of nonstandard analysis as a mathematical theory.

My own view of nonstandard analysis is that the views on both sides of the controversy are overblown. It is a remarkable theoretical achievement that the infinitesimal approach to analysis can be made completely rigorous. And this is of more than theoretical importance: users of calculus can be assured (if indeed they need such assurance) that arguments involving infinitesimals can be carefully justified logically. While it can be shown that (assuming some form of the Axiom of Choice) exactly the same theorems about analysis on $\mathbb{R}$ can be proved using nonstandard analysis as by traditional methods, it can happen (and in fact has happened) that nonstandard arguments are easier to find in some cases, so nonstandard analysis is a tool which should not be rejected or set aside as merely a curiosity. On the other hand, I think it is unlikely in the foreseeable future that nonstandard analysis will supplant the traditional approach. Proponents of nonstandard analysis often underestimate or underappreciate the degree of sophistication in mathematical logic needed to prove even basic theorems about limits via nonstandard analysis. (For example, the book [Gol98] is one of the most readable and appealing treatments of nonstandard analysis; nevertheless, it should be

⁷cf. [?, p. xiii].
noted that this book does not contain a single complete rigorous nonstandard analysis proof of any theorem of real analysis since the transfer principle is not proved in any form. This is not necessarily a criticism of the book, but does tend to compromise the credibility of the author’s forcefully held belief that nonstandard methods are the future of analysis.

The basic idea of nonstandard analysis is a two-part one. First, the real numbers \( \mathbb{R} \) are embedded in a larger ordered field *\( \mathbb{R} \) called the hyperreal numbers, with particular properties, notably including infinitesimal elements. Second, there is a systematic procedure, called the transfer principle, to convert any appropriately formulated statement *\( P \) about *\( \mathbb{R} \), with the property that *\( P \) is true in *\( \mathbb{R} \) if and only if \( P \) is true in \( \mathbb{R} \). One then proves \( P \) by proving *\( P \). Transfer is used in both directions since the transfer of statements already known to be true in \( \mathbb{R} \) can be used to prove *\( P \). It is also often possible to rephrase *\( P \) as a simpler or more natural statement than \( P \) (e.g. the transfer of some statements can be rephrased as a precise version of a classical statement involving infinitesimals). Stating and proving the validity of the transfer principle is the place where mathematical logic comes into nonstandard analysis. The transfer principle is one of Robinson’s fundamental theoretical contributions. (There is another, somewhat more esoteric, feature of more advanced nonstandard analysis, also introduced by Robinson: concurrence, which is discussed in ().)

To avoid the logical technicalities needed to define the hyperreal numbers and prove the transfer principle, the hyperreals and the transfer principle are sometimes presented axiomatically. It is argued that in many ordinary real analysis courses and texts, the real numbers are also presented axiomatically without a rigorous construction, and this approach to nonstandard analysis is no different. This argument is superficially valid, but on closer examination its persuasiveness begins to evaporate:

1. Rigorous mathematics can in fact be done in both settings, although the statements of the theorems proved are really different from the way they are usually expressed. For example, in an ordinary real analysis class in which \( \mathbb{R} \) is presented axiomatically, the theorems are properly of the form

   “If there is a model for \( \mathbb{R} \), then statement \( P \) is true in this model.”

   (Here \( P \) is a statement about real numbers, sets of real numbers, functions on \( \mathbb{R} \), . . .). One must then be convinced of the existence (and essential uniqueness) of a model for \( \mathbb{R} \) for such a theorem to assume its usual form.

   Similarly, theorems in a nonstandard analysis course in which *\( \mathbb{R} \) (as well as \( \mathbb{R} \)) is presented axiomatically will be of the form

   “If a model for \( \mathbb{R} \) exists, and a model for *\( \mathbb{R} \) with a valid transfer principle exists for this model of \( \mathbb{R} \), then statement \( P \) is true in this model of \( \mathbb{R} \).”

   This is quite a different theorem until one is convinced of the existence of models of the hyperreal numbers.

   I can write down any list of axioms I want and prove theorems from them, but until it is shown that there is a model for the axioms, or preferably that the axioms are satisfied in some natural setting with real applications, the theory is an empty one. (This is one of my principal objections to formalist mathematics, although far from my only one.)

2. By the time they begin calculus, most students are prepared, and even comfortable, to accept on faith the existence of a model for \( \mathbb{R} \) satisfying the usual axioms. But few students, even (one might even say especially) good ones, are prepared to accept on faith the existence of a model for the hyperreals. This point is elucidated at length in the introduction to [Gol98]. I generally agree with Goldblatt on this issue, but I would go farther in that I do not share his expectation that eventually beginning calculus students will be as willing to accept the hyperreals as they are to accept \( \mathbb{R} \) today, primarily because of the next point.

351
3. There are rigorous explicit models for $\mathbb{R}$, e.g. via Dedekind cuts, which are sufficiently simple and concrete that they can be followed and understood by almost any undergraduate mathematics major or even honors calculus student. But all (known) models for the hyperreals are at least an order of magnitude more difficult. Even the construction via ultrapowers, which is probably the simplest and most easily understood of the (known) models, is beyond the ability of most undergraduates to fully understand and appreciate. (To begin with, a free ultrafilter on $\mathbb{N}$ is needed. There is no explicit description of any such ultrafilter; indeed, some form of the Axiom of Choice is needed to even prove existence. And even after the construction of $^*\mathbb{R}$ some nontrivial mathematical logic is needed to justify the transfer principle.)

In this section, we will not take an axiomatic approach. We will first construct (a model for) the hyperreals via ultrapowers, and then discuss and justify the transfer principle.

Every serious mathematician needs to be aware of the basics of nonstandard analysis, and to have a tolerant if not enthusiastic attitude about its place in the world of mathematics.

### III.10.1. Ordered Fields Containing $\mathbb{R}$

The basic object of study in nonstandard analysis is an ordered field $^*\mathbb{R}$ of hyperreal numbers which contains $\mathbb{R}$ as a proper subfield. Let us first examine what such an ordered field must look like.

#### III.10.1.1. Definition.

Let $F$ be an ordered field containing $\mathbb{R}$, and let $x, y \in F$.

- $x$ is **limited** if $|x| < r$ for some $r \in \mathbb{R}$.
- $x$ is **unlimited** if it is not limited.
- $x$ is **infinitesimal** if $|x| < r$ for all $r \in \mathbb{R}, r > 0$.

The terms finite and infinite (or infinitely large) are sometimes used instead of limited and unlimited respectively, but these terms can be confusing in certain contexts. According to our definition, 0 is an infinitesimal; this is not entirely standard.

Every element of $\mathbb{R}$ is clearly limited; the only infinitesimal element of $\mathbb{R}$ is 0.

The field $F$ has the Archimedean property () if and only if $F$ has no unlimited or infinitesimal elements.

#### III.10.1.2. Proposition.

Let $F$ be an ordered field containing $\mathbb{R}$, and let $x, y \in F$.

(i) If $x$ and $y$ are limited, so are $x + y$ and $xy$.

(ii) If $x$ and $y$ are infinitesimal, then $x + y$ is infinitesimal.
(iii) If $x$ is infinitesimal and $y$ is limited, then $xy$ is infinitesimal. In particular, if $x$ is infinitesimal and $r \in \mathbb{R}$, then $rx$ is infinitesimal.

(iv) If $x \neq 0$, then $x$ is infinitesimal if and only if $x^{-1}$ is unlimited.

**III.10.1.4. Proposition.** Let $F$ be an ordered field properly containing $\mathbb{R}$. Then

(i) $F$ contains unlimited elements and nonzero infinitesimals.

(ii) If $x \in F$ is limited, then there is a unique $s \in \mathbb{R}$ such that $x - s$ is infinitesimal. (This $s$ is called the *shadow* of $x$, written $s = sh(x)$.)

**Proof:** (ii) Replacing $x$ by $-x$ if necessary, we may assume $x \geq 0$. Let $A = \{ r \in \mathbb{R} : x < r \}$. By assumption, $A$ is nonempty, and it is bounded below (e.g. by 0). Let $s = \inf(A)$ (infimum in $\mathbb{R}$). If $x = s$, we are done. If $x < s$, then $0 < s - x$. If $s - x > r$ for $r \in \mathbb{R}$, $r > 0$, then $x < s - r$, contradicting the definition of $s$. Thus $s - x$ is infinitesimal. If $x > s$, a similar proof shows that $x - s$ is infinitesimal. Uniqueness is obvious from III.10.1.3.(ii)–(iii) if $x - s$ and $x - t$ are infinitesimal, so is $s - t = (x - t) - (x - s)$.

(i): Let $x \in F \setminus \mathbb{R}$. If $x$ is unlimited, then $x^{-1}$ is infinitesimal. If $x$ is limited, let $s = sh(x)$. Then $x - s$ is a nonzero infinitesimal, and $(x - s)^{-1}$ is unlimited.

The next result is also a corollary of (i), but we give a direct proof.

**III.10.1.5. Corollary.** Let $F$ be an ordered field properly containing $\mathbb{R}$. Then $F$ is not order-complete.

**Proof:** Let $I$ be the set of infinitesimals in $F$. Then $I$ is nonempty and bounded (e.g. by 1). Suppose $I$ has a supremum $x$. Since $F$ contains a positive infinitesimal by III.10.1.4., $x > 0$. Also, every positive $r \in \mathbb{R}$ is an upper bound for $I$, so $x$ is infinitesimal. But then $2x$ is infinitesimal and $2x > x$, a contradiction.

**III.10.1.6.** It is obvious that if $x, y$ are limited, then $sh(x + y) = sh(x) + sh(y)$ and $sh(xy) = sh(x)sh(y)$, and that $x$ is infinitesimal if and only if $sh(x) = 0$; $sh(x) = sh(y)$ if and only if $x - y$ is infinitesimal.

**III.10.1.7. Definition.** If $F$ is an ordered field containing $\mathbb{R}$ and $x, y \in F$, then $x \simeq y$ if $x - y$ is infinitesimal. The *halo* of $x$ is

$$hal(x) = \{ y \in F : y \simeq x \} = \{ x + z : z \text{ infinitesimal} \}.$$ 

**III.10.1.8.** It is immediate from III.10.1.3.(ii)–(iii) that $\simeq$ is an equivalence relation; thus, if $x, y \in F$, then either $hal(x) = hal(y)$ or $hal(x)$ and $hal(y)$ are disjoint. If $x$ and $y$ are limited, then $hal(x) = hal(y)$ if and only if $sh(x) = sh(y)$. Each halo of limited elements contains exactly one real number ($hal(x) = hal(sh(x))$ if $x$ is limited).
III.10.1.9. One can also define a weaker equivalence relation: $x \sim y$ if $x - y$ is limited. The $\sim$-equivalence class of $x$ is called the galaxy of $x$. The galaxy of any limited element is the set of all limited elements.

III.10.2. The Hyperreal Numbers via Ultrafilters

It is not obvious that there exist ordered fields properly containing $\mathbb{R}$. A simple example (the simplest example) is given in Exercise III.5.3.1. In this subsection we describe a somewhat more complicated example with additional properties which will allow us to do nonstandard analysis.

III.10.2.10. Recall () that an ultrafilter on a set $X$ is a collection $\mathcal{U}$ of subsets of $X$ such that

(i) $\mathcal{U}$ is closed under finite intersections.

(ii) If $A \in \mathcal{U}$ and $A \subseteq B$, then $B \in \mathcal{U}$.

(iii) $\emptyset \notin \mathcal{U}$.

(iv) If $A \subseteq X$, then either $A \in \mathcal{U}$ or $A^c \in \mathcal{U}$.

The ultrafilter $\mathcal{U}$ is free if the intersection of the sets in $\mathcal{U}$ is $\emptyset$ (equivalently, if every set with finite complement is in $\mathcal{U}$).

We think of an ultrafilter as giving a coherent way of declaring which subsets of $X$ are “large” (those in the ultrafilter) and which are “negligibly small” (those not in the ultrafilter). Every subset is either large or negligibly small, but never both. If the ultrafilter is free, every finite subset is negligibly small.

III.10.2.11. Using the Axiom of Choice, it can be shown () that every infinite set has a free ultrafilter on it; in fact, there are $2^{2^{\aleph_0}}$ free ultrafilters on an infinite set $X$.

Throughout the rest of this subsection, $\mathcal{U}$ will denote a free ultrafilter on $\mathbb{N}$ which is specified once and for all. It does not matter for nonstandard analysis purposes which of the $2^{2^{\aleph_0}}$ free ultrafilters on $\mathbb{N}$ we choose. While we use $\mathbb{N}$ as an index set to make things a simple and concrete as possible, the construction works identically for any index set; and for some purposes a much larger index set is needed (III.10.8.13.), although not too large (III.10.8.14.).

III.10.2.12. Definition. Let $S$ be the set of all sequences of real numbers. Define an equivalence relation on $S$ as follows. If $x = (x_m)$ and $y = (y_m)$ are in $S$, set $x \sim y$ if

$$\{m \in \mathbb{N} : x_m = y_m\} \in \mathcal{U}.$$ Denote the equivalence class of $x$ by $[[x_m]]$, and let $^*\mathbb{R}$ be the set of equivalence classes. $^*\mathbb{R}$ is called the set of hyperreal numbers (with respect to $\mathcal{U}$).

It is easy to check that $\sim$ is an equivalence relation. We think of two sequences as being equivalent if they agree “almost everywhere” (i.e. except on a “negligibly small” set of indices).

III.10.2.13. In order to specify an element of $^*\mathbb{R}$, it is only necessary to specify a “large” set of coordinates (a set in $\mathcal{U}$). The other coordinates can be chosen arbitrarily and do not affect the element of $^*\mathbb{R}$ specified. This observation will be quite useful in avoiding the annoying and unnecessary step of extending definitions to all of $\mathbb{N}$.

354
III.10.2.14. $S$ has natural algebraic operations of addition, subtraction, and multiplication defined coordinatewise. These drop to well-defined operations on $^*\mathbb{R}$ by the following proposition:

**Proposition.** If $(x_m) \sim (z_m)$ and $(y_m) \sim (w_m)$, then $(x_m + y_m) \sim (z_m + w_m)$, $(x_m - y_m) \sim (z_m - w_m)$, and $(x_my_m) \sim (z_mw_m)$.

**Proof:** We have

$$\{m \in \mathbb{N} : x_m + y_m = z_m + w_m \} \supseteq \{m \in \mathbb{N} : x_m = z_m \} \cap \{m \in \mathbb{N} : y_m = w_m \}.$$  

By assumption, the sets on the right are in $U$, hence so is their intersection by III.10.2.10.(i); therefore the set on the left is also in $U$ by III.10.2.10.(ii). The proof in the other two cases is almost identical. \hspace{1cm} \&

III.10.2.15. **Proposition.** The coordinatewise operations on $S$ give well-defined operations of addition, subtraction, and multiplication on $^*\mathbb{R}$ making it into a unital commutative ring $(,)$. The embedding of $\mathbb{R}$ into $^*\mathbb{R}$ as equivalence classes of constant sequences respects addition, subtraction, and multiplication.

**Proof:** It is immediate from III.10.2.15. that addition, subtraction, and multiplication are well defined on $^*\mathbb{R}$, and then almost a triviality that addition and multiplication are associative and commutative, and that the distributive law holds. The additive identity is the equivalence class of the constant sequence $0$, and the multiplicative unit the equivalence class of the constant sequence $1$. The last statement is also obvious. \hspace{1cm} \&

III.10.2.16. **Proposition.** The coordinatewise operations on $S$ give well-defined operations of addition, subtraction, and multiplication on $^*\mathbb{R}$ making it into a unital commutative ring $(,)$. The embedding of $\mathbb{R}$ into $^*\mathbb{R}$ as equivalence classes of constant sequences respects addition, subtraction, and multiplication.

**Proof:** It is immediate from III.10.2.15. that addition, subtraction, and multiplication are well defined on $^*\mathbb{R}$, and then almost a triviality that addition and multiplication are associative and commutative, and that the distributive law holds. The additive identity is the equivalence class of the constant sequence $0$, and the multiplicative unit the equivalence class of the constant sequence $1$. The last statement is also obvious. \hspace{1cm} \&

If $r \in \mathbb{R}$, we will identify $r$ with the equivalence class of the constant sequence $(r)$, and hence regard $\mathbb{R}$ as a subset of $^*\mathbb{R}$; the operations on $^*\mathbb{R}$ extend the usual ones on $\mathbb{R}$.

III.10.2.17. Reciprocals and division can also be defined with only a slight bit of care. Suppose $x = \langle\langle x_m \rangle\rangle \in ^*\mathbb{R}$, $x \neq 0$. Then $\{m \in \mathbb{N} : x_m \neq 0 \} \in U$, so we can define $x^{-1} \in ^*\mathbb{R}$ as the equivalence class of $(x_m^{-1})$ (this sequence is only defined on a set of indices in $U$, but this is sufficient by the remark in III.10.2.13.). It is clear that $xx^{-1} = 1$, so $x^{-1}$ is a multiplicative inverse for $x$. Thus $^*\mathbb{R}$ is a field, and $\mathbb{R}$ is a subfield.

III.10.2.18. We can also define a total ordering on $^*\mathbb{R}$. If $x \in ^*\mathbb{R}$, $x = \langle\langle x_m \rangle\rangle$, we would like to say that $x > 0$ if $\{m \in \mathbb{N} : x_m > 0 \} \in U$. It is easily seen that this definition is independent of the representing sequence $(x_m)$. It gives a good definition due to the next proposition.

III.10.2.19. **Proposition.** If $(x_m) \in S$, then exactly one of the following sets is in $U$:

$$A = \{m \in \mathbb{N} : x_m > 0 \}, \quad B = \{m \in \mathbb{N} : x_m = 0 \}, \quad C = \{m \in \mathbb{N} : x_m < 0 \}.$$ 

**Proof:** By III.10.2.10.(iv), either $A$ or $A^c = \{m \in \mathbb{N} : x_m \leq 0 \}$ is in $U$, but not both. If $A \in U$, then $A^c \notin U$, so $B \notin U$ and $C \notin U$ by III.10.2.10.(ii) since $B, C \subseteq A^c$. Suppose $A^c \in U$; then $A \notin U$. Either $C \in U$ or $C^c \in U$ but not both. If $C \in U$, then $B \notin U$ as above. If $C^c \in U$, then $B = A^c \cap C^c \in U$ and $A, C \notin U$. \hspace{1cm} \&

We can then define the positive cone in $^*\mathbb{R}$. The construction is a special case of taking the nonstandard extension of a subset of $\mathbb{R}$.
**III.10.2.20.** Corollary. Let \( *P \) be the set of \( x = \lfloor (x_m) \rfloor \in *\mathbb{R} \) such that \( \{m \in \mathbb{N} : x_m > 0\} \in \mathcal{U} \). Then \( *P \) satisfies the positive cone axioms (1) and thus defines a total order on \( *\mathbb{R} \) extending the usual order on \( \mathbb{R} \).

**Proof:** By III.10.2.19., \( *\mathbb{R} \) is the disjoint union of \( *P \), \( \{0\} \), and \(-(*P)\). We only need to check that \( *P \) is closed under addition and multiplication, which follows from an argument almost identical to the proof of III.10.2.15., and that \((*P) \cap \mathbb{R}\) is the usual positive cone of \( \mathbb{R} \), which is obvious.

We summarize the construction in a theorem:

**III.10.2.21.** Theorem. \( *\mathbb{R} \) with the above algebraic operations and ordering is an ordered field containing \( \mathbb{R} \).

One can even extend the algebraic operations on \( \mathbb{R} \) such as exponentiation. This is also a special case of a general procedure for extending functions from \( \mathbb{R} \) to \( *\mathbb{R} \).

**III.10.2.22.** Definition. Let \( x = \lfloor (x_m) \rfloor \) and \( a = \lfloor (a_m) \rfloor \) be elements of \( *\mathbb{R} \), with \( x > 0 \). Define

\[
x^a = \lfloor (x_m^a) \rfloor
\]

(note that \( x_m^a \) is defined for almost all \( m \)).

**III.10.2.23.** Proposition. Exponentiation is well defined, and satisfies the usual rules of exponents: if \( x, y, a, b \in *\mathbb{R} \) with \( x, y \geq 0 \), then \( x^a x^b = x^{a+b} \), \( \frac{x^a}{x^b} = x^{a-b} \), \( (x^a)^b = x^{ab} \), \( (xy)^a = x^a y^a \). If \( x < y \) and \( a > 0 \), then \( x^a < y^a \); if \( a < 0 \), then \( x^a > y^a \). If \( x, a \in \mathbb{R} \), exponentiation in \( *\mathbb{R} \) agrees with usual exponentiation in \( \mathbb{R} \).

The proof is routine along the usual lines. See Exercise (1).

**III.10.2.24.** Corollary. Let \( x \in *\mathbb{R} \), \( x > 0 \), and \( a \in *\mathbb{R} \), \( a \neq 0 \). Then there is a unique \( y \in *\mathbb{R} \), \( y > 0 \), such that \( y^a = x \). In particular, if \( n \in \mathbb{N} \), then \( x \) has a unique nonnegative \( n \)th root in \( *\mathbb{R} \).

**III.10.2.25.** We can similarly define logarithms on \( *\mathbb{R} \). If \( 0 < a = \lfloor (a_m) \rfloor \in *\mathbb{R} \) and \( 0 < x = \lfloor (x_m) \rfloor \in *\mathbb{R} \), define

\[
\log_a x = \lfloor (\log_{a_m} x_m) \rfloor
\]

(this is well defined by the usual argument). We then have \( y = \log_a x \) if and only if \( a^y = x \).

**III.10.2.26.** It may not yet be obvious that \( *\mathbb{R} \) is larger than \( \mathbb{R} \). But it is in fact much larger. We can easily define an unlimited element of \( *\mathbb{R} \): set \( x_m = m \) and \( x = \lfloor (x_m) \rfloor \in *\mathbb{R} \). If \( r \in \mathbb{R} \), then \( \{m \in \mathbb{N} : x_m \leq r\} \) is finite, so \( x > r \). Similarly, if \( y_m = m^{-1} \) and \( y = \lfloor (y_m) \rfloor \in *\mathbb{R} \), then \( y \) is a positive infinitesimal in \( *\mathbb{R} \). Actually, if \( (x_m) \) is any sequence of distinct real numbers, then \( \lfloor (x_m) \rfloor \in *\mathbb{R} \setminus \mathbb{R} \).

Note, however, that \( *\mathbb{R} \) is not larger than \( \mathbb{R} \) in a cardinality sense. We have \( |\mathbb{S}| = (2^{|\mathbb{R}|})^{|\mathbb{R}|} = 2^{|\mathbb{R}|} \), so \( |*\mathbb{R}| \leq 2^{|\mathbb{R}|} \), and the opposite inequality is obvious, so \( |*\mathbb{R}| = 2^{|\mathbb{R}|} = |\mathbb{R}| \). (This is a result of taking an ultralimit on \( \mathbb{N} \) for the construction of \( *\mathbb{R} \). If a free ultrafilter is used on a set of large cardinality, the cardinality of \( *\mathbb{R} \) can be larger than \( 2^{|\mathbb{R}|} \). See Exercise III.10.8.10.)

356
III.10.2.27. Like any totally ordered set, \( *\mathbb{R} \) has an order topology \( (\cdot) \). However, this topology has pathological properties (Exercise III.10.8.9.), and is of little if any use in nonstandard analysis.

III.10.3. Internal and External Sets and Functions

Since \( *\mathbb{R} \) is considerably larger than \( \mathbb{R} \), general subsets of \( *\mathbb{R} \) and general functions from \( *\mathbb{R} \) to \( *\mathbb{R} \) are very complicated (and can depend on the specific construction of \( *\mathbb{R} \) used). Relatively few subsets of \( *\mathbb{R} \) or functions from \( *\mathbb{R} \) to \( *\mathbb{R} \) are sufficiently well describable in standard terms that they can be considered “transferable” from \( \mathbb{R} \) using a transfer principle (in a way independent of the construction used for \( *\mathbb{R} \)). In this subsection we describe the ones which can be used, called internal sets and functions.

The Nonstandard Extension of a Subset of \( \mathbb{R} \)

The simplest subsets of \( *\mathbb{R} \) for transfer purposes are ones directly definable from a subset of \( \mathbb{R} \).

III.10.3.1. Definition. Let \( A \subseteq \mathbb{R} \). Then the nonstandard extension of \( A \) is the set

\[
*A = \{ \llbracket (x_m) \rrbracket \in *\mathbb{R} : x_m \in A \text{ for almost all } m \}
\]

where “\( x_m \in A \) for almost all \( m \)” means “\( \{ m \in \mathbb{N} : x_m \in A \} \in \mathcal{U} \).”

Note that if \( \llbracket (x_m) \rrbracket = \llbracket (y_m) \rrbracket \), i.e. \( x_m = y_m \) for almost all \( m \), then \( x_m \in A \) for almost all \( m \) if and only if \( y_m \in A \) for almost all \( m \) (cf. the proof of III.10.2.15.), so membership in \( *A \) is well defined. \( *A \) could also be defined to be simply the set of equivalence classes of sequences in \( A \).

III.10.3.2. Proposition. Let \( A \subseteq \mathbb{R} \). Then

(i) \( *A \cap \mathbb{R} = A \) (in particular, \( A \subseteq *A \)).

(ii) \( *A = A \) if and only if \( A \) is finite.

(iii) \( (*\mathbb{R} \setminus A) = *\mathbb{R} \setminus *A \).

Proof: (i) is obvious: if \( r \in \mathbb{R} \), then \( \llbracket (r) \rrbracket \in *A \) if and only if \( r \in A \). For (ii), if \( (x_m) \) is a sequence of distinct elements of \( A \), then \( \llbracket (x_m) \rrbracket \in *A \setminus A \), so if \( A \) is infinite we have \( *A \neq A \). On the other hand, if \( A = \{ r^{(1)}, \ldots, r^{(n)} \} \), and \( \llbracket (x_m) \rrbracket \in *A \), set \( N_k = \{ m \in \mathbb{N} : x_m = r^{(k)} \} \) for \( 1 \leq k \leq n \). Then \( N_1 \cup \cdots \cup N_n \in \mathcal{U} \), so \( N_k \in \mathcal{U} \) for some (exactly one) \( k \), i.e. \( \llbracket (x_m) \rrbracket = r^{(k)} \). (Note also that \( *\emptyset = \emptyset \).) For (iii), note that if \( \llbracket (x_m) \rrbracket \in *\mathbb{R} \), then exactly one of the sets \( \{ m \in \mathbb{N} : x_m \in A \} \) and \( \{ m \in \mathbb{N} : x_m \notin A \} \) is in \( \mathcal{U} \).

III.10.3.3. Proposition. Let \( A, B \subseteq \mathbb{R} \). Then \( *(A \cup B) = *A \cup *B \), \( *(A \cap B) = *A \cap *B \), and \( *(A \setminus B) = *A \setminus *B \).

Proof: Note that if \( x = \llbracket (x_m) \rrbracket \in *\mathbb{R} \), then

\[
\{ m \in \mathbb{N} : x_m \in A \} \cap \{ m \in \mathbb{N} : x_m \in B \} = \{ m \in \mathbb{N} : x_m \in A \cap B \}
\]
and the set on the right is in $\mathcal{U}$ if and only if both sets on the left are in $\mathcal{U}$, so $x \in ^* (A \cap B)$ if and only if $x \in ^* A \cap ^* B$. The result for unions and symmetric differences follows from this and III.10.3.2.(iii) by taking complements.

III.10.3.4. Note that this statement is false in general for infinite unions and intersections, even countable ones. (Any infinite set is a union of finite sets; use III.10.3.2.(ii).)

The proof of the next proposition is routine along the same lines:

III.10.3.5. Proposition. Let $a, b \in \mathbb{R}$, $a < b$, and denote by $[a, b]$, $(a, b)$, $(a, b]$, $[a, b)$ the usual intervals in $\mathbb{R}$. Then

\begin{align*}
^*[a, b] &= \{ x \in ^\ast \mathbb{R} : a \leq x \leq b \} \\
^*(a, b) &= \{ x \in ^\ast \mathbb{R} : a < x < b \} \\
^*(a, b] &= \{ x \in ^\ast \mathbb{R} : a < x \leq b \} \\
^*[a, b) &= \{ x \in ^\ast \mathbb{R} : a \leq x < b \} .
\end{align*}

Similar statements hold for $^*(-\infty, a]$, $^*(a, +\infty)$, etc.

III.10.3.6. Proposition. Let $A \subseteq \mathbb{R}$. Then the following are equivalent:

(i) $^*A$ is bounded above in $^\ast \mathbb{R}$.

(ii) Every positive element of $^*A$ is limited.

(iii) $A$ is bounded above in $\mathbb{R}$.

If these conditions hold, any upper bound for $A$ in $\mathbb{R}$ is an upper bound for $^*A$ in $^\ast \mathbb{R}$.

Proof: (ii) $\Rightarrow$ (i) is trivial: any unlimited positive element of $^\ast \mathbb{R}$ would be an upper bound for $^*A$. For (iii) $\Rightarrow$ (ii), and for the last statement, if $b$ is an upper bound for $A$ in $\mathbb{R}$, then $^*A \subseteq ^*(-\infty, b]$, so by III.10.3.5. $b$ is an upper bound for $^*A$ and (ii) holds. To prove (i) $\Rightarrow$ (iii), suppose $A$ is not bounded above in $\mathbb{R}$. Let $x = \lfloor \{x \} \rfloor \in ^\ast \mathbb{R}$. For each $m$ let $y_m \in A$ with $y_m \geq x_m$. Then $y = \lfloor \{y \} \rfloor \in ^*A$ and $x \leq y$.

III.10.3.7. Perhaps the most important nonstandard extension set is $^*\mathbb{N}$, the hypernatural numbers, equivalence classes of sequences of natural numbers. We also have $^*\mathbb{Z}$, the hyperintegers, and $^*\mathbb{Q}$, the hyperrational numbers. We have that $^*\mathbb{N}$ is closed under addition and multiplication, $^*\mathbb{Z}$ is a subring of $^*\mathbb{R}$, and $^*\mathbb{Q}$ is a subfield of $^*\mathbb{R}$. Every element of $^*\mathbb{Z}$ is a difference of two elements of $^*\mathbb{N}$, and every element of $^*\mathbb{Q}$ is a quotient of an element of $^*\mathbb{Z}$ by an element of $^*\mathbb{N}$. All of these sets turn out to be uncountable ( ). See Exercises ( ) for some properties of $^*\mathbb{N}$.
Nonstandard Extensions of Functions

III.10.3.8. Let \( A \subseteq \mathbb{R} \), and let \( f \) be a function from \( A \) to \( \mathbb{R} \). We can extend \( f \) to a function \( *f \) from \( *A \) to \( *\mathbb{R} \) as follows. Let \( x = [((x_m))] \in *A \). Then \( x_m \in A \) for almost all \( m \), so the element \( [((f(x_m)))] \) is well defined as an element of \( *\mathbb{R} \). It is easily seen in the usual way that this element of \( *\mathbb{R} \) is independent of the choice of the representative \( (x_m) \) chosen for \( x \). Write \( *f(x) = [((f(x_m)))] \).

III.10.3.9. If \( f \) is a polynomial or rational function with real coefficients, then \( *f \) defined this way agrees with the usual algebraic extension of \( f \) to a function on \( \mathbb{R} \). More generally, if \( a \in \mathbb{R} \), and \( f(x) = x^a \) on \( [0, +\infty) \), then \( *f \) is the function on \( *[0, +\infty) \) defined by nonstandard exponentiation (III.10.2.22.). Similarly, if \( 0 < a \in \mathbb{R} \), the nonstandard extension of the exponential function \( f(x) = a^x \) is given by nonstandard exponentiation. If \( 0 < a \in \mathbb{R} \), then the nonstandard extension of the function \( f(x) = \log_a x \) is the nonstandard logarithm function of III.10.2.25..

III.10.3.10. Another common instance of nonstandard extension is for trigonometric functions. The functions \( *\sin x \) and \( *\cos x \) are defined for all nonstandard real numbers; the domain of \( *\tan x \) is the set

\[
* \left( \mathbb{R} \setminus \left\{ \frac{\pi}{2} + n\pi : n \in \mathbb{N} \right\} \right) = *\mathbb{R} \setminus \left\{ \frac{\pi}{2} + n\pi : n \in *\mathbb{N} \right\}
\]

and the other extended trig functions have similar domains.

III.10.3.11. It is usual to omit the * on the nonstandard extension of a function except in the relatively rare case (e.g. in III.10.3.14.–III.10.3.15.) where a distinction must be made between the original function and its extension. Thus, for example, we will usually just write \( \sin, \log_a, \) etc., for the extended functions.

The proof of the next result is routine by the usual arguments:

III.10.3.12. Proposition. All standard trigonometric identities hold for the nonstandard extensions. For example:

\[
\begin{align*}
\sin^2 x + \cos^2 x &= 1 \text{ for all } x \in *\mathbb{R}. \\
\sin(x + y) &= \sin x \cos y + \cos x \sin y \text{ for all } x, y \in *\mathbb{R}.
\end{align*}
\]

III.10.3.13. Inequalities valid for standard functions also hold for their extensions. For example:

\[
\begin{align*}
e^x &> 0 \text{ for all } x \in *\mathbb{R}; \ e^x < 1 \text{ for } x < 0 \text{ and } e^x > 1 \text{ for } x > 0. \\
\log x &< 0 \text{ for } x \in *\mathbb{R}, \ 0 < x < 1; \ \log x > 0 \text{ for } x \in *\mathbb{R}, \ x > 1. \\
-1 &\leq \sin x \leq 1 \text{ and } -1 \leq \cos x \leq 1 \text{ for all } x \in *\mathbb{R}.
\end{align*}
\]

If the domain of \( f \) is \( A \), then the domain of \( *f \) is by definition \( *A \). We also have:
III.10.3.14. Proposition. If \( f : A \to \mathbb{R} \) and \( B \subseteq A \), then \( *f(*B) = *[f(B)] \). In particular, the range of \( *f \) is \( *[f(A)] \).

Proof: If \( \mathbf{x} = [[[x_m]]] \in *B \), then \( x_m \in B \) for almost all \( m \), so \( f(x_m) \in f(B) \) for almost all \( m \) and \( [[[f(x_m)]]] \in *[f(B)] \). Conversely, if \( \mathbf{y} = [[[y_m]]] \in *[f(B)] \), then for almost all \( m \) we have \( y_m \in f(B) \), so there is an \( x_m \in B \) with \( y_m = f(x_m) \). The element \( \mathbf{x} = [[[x_m]]] \) is well defined and in \( *B \), and \( *f(\mathbf{x}) = \mathbf{y} \), so \( \mathbf{y} \in *f(*B) \).

III.10.3.15. If \( f : A \to \mathbb{R} \), \( g : B \to \mathbb{R} \), and \( f(A) \subseteq B \), then \( g \circ f : A \to \mathbb{R} \) is defined. It is routine to check that \( *(g \circ f) = *g \circ *f \) as a function from \( *A \) to \( *\mathbb{R} \). In particular, if \( f \) is one-to-one on \( A \), then \( *(f^{-1}) \circ *f \) is the identity on \( *A \) and \( *f \circ *(f^{-1}) \) is the identity on \( *[f(A)] \), so \( *f \) is a bijection from \( *A \) to \( *[f(A)] \) and \( *(f^{-1}) = *(f^{-1}) \).

Nonstandard Euclidean Space

III.10.3.16. For fixed \( n \in \mathbb{N} \), there is a natural one-one correspondence between \( \mathbb{S}^n \), the set of \( n \)-tuples of sequences of real numbers, and the set of sequences of \( n \)-tuples of real numbers:

\[
((x_{m}^{(1)}, x_{m}^{(2)}, \ldots, x_{m}^{(n)})) \leftrightarrow ((x_{m}^{(1)}, x_{m}^{(2)}, \ldots, x_{m}^{(n)}))
\]

and we have that

\[
(x_{m}^{(1)}, x_{m}^{(2)}, \ldots, x_{m}^{(n)}) = (y_{m}^{(1)}, y_{m}^{(2)}, \ldots, y_{m}^{(n)})
\]

for almost all \( m \) if and only if, for each \( k \), \( 1 \leq k \leq n \), we have \( x_{m}^{(k)} = y_{m}^{(k)} \) for almost all \( m \). Thus there is an unambiguous equivalence relation on the set of sequences of \( n \)-tuples of real numbers, and the set \( *(\mathbb{R}^n) \) of equivalence classes can be naturally identified with \( (*\mathbb{R})^n \), the set of \( n \)-tuples of hyperreal numbers. We will denote this set by \( *\mathbb{R}^n \) and freely describe it both ways. Write \( [[[x_{m}^{(1)}, \ldots, x_{m}^{(n)}]]] \) for the equivalence class of the sequence \( ((x_{m}^{(1)}, \ldots, x_{m}^{(n)})) \), thought of as a typical representative of an element of \( *\mathbb{R}^n \).

The Nonstandard Extension of a Relation

The nonstandard extensions of sets and functions can be subsumed in the general notion of the nonstandard extension of an \( n \)-ary relation.

III.10.3.17. Recall that an \( n \)-ary relation on \( \mathbb{R} \) is simply a subset of \( \mathbb{R}^n \). In particular, a usual (binary) relation is a subset of \( \mathbb{R}^2 \); recall that a function is officially a binary relation (its graph). A unary relation is just a subset of \( \mathbb{R} \).

III.10.3.18. Definition. If \( A \) is a subset of \( \mathbb{R}^n \), i.e. an \( n \)-ary relation on \( \mathbb{R} \), we define its nonstandard extension to be

\[
*A = \{ [[[x_{m}^{(1)}, \ldots, x_{m}^{(n)}]]] : (x_{m}^{(1)}, \ldots, x_{m}^{(n)}) \in A \text{ for almost all } m \} \subseteq *\mathbb{R}^n .
\]

If \( n = 1 \), this agrees with the previous definition of the nonstandard extension of a subset of \( \mathbb{R} \). It is also easy to verify that the nonstandard extension of a function on \( \mathbb{R} \) coincides with the nonstandard extension of the corresponding binary relation (the graph of the function).
The binary relation $<$ on $\mathbb{R}$ has a nonstandard extension $^*<$, which coincides with the ordering $<$ on $^*\mathbb{R}$ defined in III.10.2.20.. Even the binary relation $=$ on $\mathbb{R}$ has ordinary equality on $^*\mathbb{R}$ as its nonstandard extension.

A function from $\mathbb{R}^n$ to $\mathbb{R}^k$ can be regarded as an $(n+k)$-ary relation on $\mathbb{R}$, and thus has a nonstandard extension, which can be defined similarly to the nonstandard extension of a function from $\mathbb{R}$ to $\mathbb{R}$. For some simple examples, addition and multiplication may be regarded as functions from $\mathbb{R}^2$ to $\mathbb{R}$; their nonstandard extensions are nothing but addition and multiplication on $^*\mathbb{R}$ as we have defined them. Another example: $f(x, y) = \log_x y$ is a real-valued function defined on $(0, \infty)^2$, and its nonstandard extension is the logarithm function defined in III.10.2.25.

III.10.4. The Transfer Principle

By now we have shown that a great many statements about the real numbers have nonstandard analogs, and the proofs of the nonstandard statements from the standard ones all seem pretty much the same. A few classes of examples (phrased informally) are:

- $\mathbb{R}$ satisfies the ordered field axioms.
- The rules of exponents hold in $\mathbb{R}$.
- Trigonometric identities hold in $\mathbb{R}$.

We might suspect that there is a metaprinciple that every statement about $\mathbb{R}$ has an analog in $^*\mathbb{R}$ and that there is a single scheme for simultaneously deriving proofs of the nonstandard versions of all true standard statements. With due care, there is: this is the transfer principle.

However, we must be careful. Not every true statement about $\mathbb{R}$ can have a nonstandard version. It is easy to find counterexamples: a simple one is “$\mathbb{R}$ contains no nonzero infinitesimals.” A more important example is the Completeness Property of $\mathbb{R}$; for somewhat deeper reasons (III.10.1.5.) this statement cannot be true verbatim about $^*\mathbb{R}$.

So we must instead say that every appropriately formulated statement about $\mathbb{R}$ has a nonstandard analog, which is true if and only if the standard version is true. Precisely describing what “appropriately formulated” means is where mathematical logic comes into the picture.

The transfer principle has two levels: first-order transfer and higher-order transfer. First-order transfer is relatively simple to formulate and even not too hard to prove, and only requires a modest amount of mathematical logic; and first-order transfer is adequate for most elementary applications of nonstandard analysis. Higher-order transfer is more sophisticated logically, but also more powerful. We will concentrate on first-order transfer and only give a brief survey of higher-order transfer.

Simple or First-Order Transfer

The setup for first-order transfer will be to begin with a relational structure $\mathcal{S} = (\Omega, \mathcal{R}, \mathcal{F})$ (II.1.8.1.), which will be called the standard structure. In almost all applications $\mathcal{R}$ and $\mathcal{F}$ will be the sets of all relations and functions on $\Omega$ respectively; in basic nonstandard analysis $\Omega$ will be $\mathbb{R}$ with $\mathcal{R}$ and $\mathcal{F}$ the sets of all relations and functions. At first the reader may want to just assume we are working with this structure.

A subset of $\Omega^n$ can be regarded as an $n$-ary relation on $\Omega$; for technical reasons we will assume that the domain of any function in $\mathcal{F}$ is a relation in $\mathcal{R}$.
In addition, we will fix an index set $I$ and an ultrafilter $\mathcal{U}$ on $I$. For basic nonstandard analysis we take $I = \mathbb{N}$ and $\mathcal{U}$ any free ultrafilter on $\mathbb{N}$.

III.10.4.2. The first step is to define a nonstandard version of $S$. We let $^\ast \Omega$ be the set of equivalence classes of functions from $I$ to $\Omega$, where two functions are equivalent if they agree “almost everywhere” (abbreviated a.e.), or “for almost all $i$,” i.e. on a set in $\mathcal{U}$. In the basic nonstandard analysis case where $\Omega = \mathbb{R}$ and $I = \mathbb{N}$ the set $^\ast \Omega$ is just $^\ast \mathbb{R}$ as defined in (i).

III.10.4.3. If $R$ is an $n$-ary relation in $\mathcal{R}$, we define a nonstandard version $^\ast R$, which will be an $n$-ary relation on $^\ast \Omega$, by letting $^\ast R$ be the set of all $n$-tuples $(\omega_1, \ldots, \omega_n)$ for which there is for each $k$ a representation $\omega_k = [[(\omega_{ki})]]$ such that $$(\omega_{i1}, \ldots, \omega_{in}) \in R$$ for almost all $i \in I$. A routine argument along the lines of () shows that if this condition is satisfied for one $n$-tuple of representatives of $\omega_1, \ldots, \omega_n$, it is satisfied for any other $n$-tuple of representatives. In the basic nonstandard analysis case, $^\ast R$ is just the relation defined in III.10.3.18.. Similarly, if $f \in F$ is a function from a subset of $\Omega^n$ to $\Omega$, we define $^\ast f$ to be the function from a subset of $(^\ast \Omega)^n$ to $^\ast \Omega$ given by $^\ast f(\omega_1, \ldots, \omega_n) = [[(f(\omega_{i1}, \ldots, \omega_{in}))]]$ if $\omega_k = [[(\omega_{ki})]]$ for each $k$ and $(\omega_{i1}, \ldots, \omega_{in})$ is in the domain of $f$ for almost all $i$. It is again routine to check that $^\ast f$ is well defined independent of the choice of representatives, and that the domain of $^\ast f$ is $^\ast (\text{dom } f)$ (recall that $\text{dom } f$ is a relation in $\mathcal{R}$, so $^\ast (\text{dom } f)$ is a defined subset of $(^\ast \Omega)^n$). In the basic nonstandard analysis case, $^\ast f$ is just the function defined in III.10.3.8..

III.10.4.4. Definition. The relational structure $^\ast S = (^\ast \Omega, ^\ast \mathcal{R}, ^\ast \mathcal{F})$, where $^\ast \mathcal{R} = \{^\ast R : R \in \mathcal{R}\}$ and $^\ast \mathcal{F} = \{^\ast f : f \in \mathcal{F}\}$, is called the (first-order) nonstandard structure for $S$ (with respect to $I$ and $\mathcal{U}$).

Although the notation does not reflect it, $^\ast S$ depends on $I$ and $\mathcal{U}$ as well as on $S$. However, for nonstandard analysis purposes the dependence on $I$ and $\mathcal{U}$ is mostly irrelevant and can be largely ignored (but see III.10.8.13. and III.10.8.14.). Note that even if $\mathcal{R}$ is the set of all relations on $\Omega$, $^\ast \mathcal{R}$ will be far from containing all relations on $^\ast \Omega$ in general, and similarly for $^\ast \mathcal{F}$. The relations and functions in $^\ast \mathcal{R}$ and $^\ast \mathcal{F}$ will be the relations and functions on $^\ast \Omega$ which are definable by transfer of definitions in $\Omega$.

III.10.4.5. Next we fix a simple language $\mathcal{L}$ for the relational structure $S$ (), and a language $^\ast \mathcal{L}$ for the relational structure $^\ast S$. We do not require that $^\ast \mathcal{L}$ be a simple language for $^\ast S$, e.g. it could be a simple language for a larger relational structure such as $(^\ast \Omega, ^\ast \mathcal{R}, ^\ast \mathcal{F})$, where $^\ast \mathcal{R}$ and $^\ast \mathcal{F}$ are the sets of all relations and all functions on $^\ast \Omega$. But the only formulas in $^\ast \mathcal{L}$ we will consider are ones from the simple sublanguage for $^\ast S$, so we may restrict to this sublanguage when convenient. We may assume that the variable names in $^\ast \mathcal{L}$ contain all the variable names in $\mathcal{L}$ (in fact, since we only ever use a countable set of variables, we could always use a common set of variable names in all languages).

We then define a “transfer” of each symbol, term, and formula of $\mathcal{L}$ into a corresponding symbol, term, or formula in $^\ast \mathcal{L}$:
III.10.4.6. Definition. (i) If \( c \) is the name of an element \( \omega \in \Omega \), then the transfer \( ^*c \) of \( c \) is a name of the element of \( ^*\Omega \) defined by the constant function \( \omega \) from \( I \) to \( \Omega \). (We will notationally identify the element \( c \in \mathcal{L} \) with \( \ ^*c \in \ ^*\mathcal{L} \), i.e. we will regard \( \Omega \subseteq ^*\Omega \), to simplify notation.)

(ii) If \( R \in \mathcal{R} \), the transfer of \( R \) is \( ^*R \in ^*\mathcal{R} \).

(iii) If \( f \in \mathcal{F} \), the transfer of \( f \) is \( ^*f \in ^*\mathcal{F} \).

(iv) The transfer of any variable or logical symbol \( (\forall, \Rightarrow) \) is itself.

(v) The transfer of any term is defined inductively: the transfer of a constant or variable has already been defined, and the transfer of a term \( f(t_1, \ldots, t_n) \) is \( ^*f(^*t_1, \ldots, ^*t_n) \), where \( ^*t_k \) is the transfer of \( t_k \) for each \( k \).

Transfer of formulas is then defined inductively:

III.10.4.7. Definition. (i) The transfer of the formula \( R(t_1, \ldots, t_n) \) is \( ^*R(^*t_1, \ldots, ^*t_n) \), where \( ^*t_k \) is the transfer of the term \( t_k \) for each \( k \).

(ii) The transfer of the formula \( \forall x_1 \cdots \forall x_n(P) \) is \( \forall x_1 \cdots \forall x_n(^*P) \), where \( ^*P \) is the transfer of \( P \).

(iii) The transfer of the formula \( P_1 \land \cdots \land P_n \) is \( (^*P_1) \land \cdots \land (^*P_n) \), where \( ^*P_k \) is the transfer of \( P_k \) for each \( k \).

(iv) The transfer of the formula \( P_1 \Rightarrow P_2 \) is \( (^*P_1) \Rightarrow (^*P_2) \), where \( ^*P_k \) is the transfer of \( P_k \) for each \( k \).

(v) The transfer of any formula of level \( n + 1 \) is defined by application of the appropriate one of (i)–(iv) to the constituent formulas of level \( n \).

A routine induction argument verifies:

III.10.4.8. Proposition. The transfer of any symbol, term, or formula in \( \mathcal{L} \) is a well-defined symbol, term, or formula in \( ^*\mathcal{L} \). For any formula \( P \), the variables appearing in \( ^*P \) are the same as the ones appearing in \( P \); and a variable is quantified in \( ^*P \) if and only if it is quantified in \( P \). In particular, the transfer of any statement in \( \mathcal{L} \) is a statement in \( ^*\mathcal{L} \).

The Transfer Principle is:

III.10.4.9. Theorem. [Simple or First-Order Transfer Principle] Let \( S \) be a relational structure, \( ^*S \) a first-order nonstandard structure for \( S \), \( \mathcal{L} \) a simple language for \( S \), and \( ^*\mathcal{L} \) a language for \( ^*S \). If \( P \) is any statement of \( \mathcal{L} \), with transfer \( ^*P \) as defined in III.10.4.7., then \( ^*P \) holds in \( ^*S \) if and only if \( P \) holds in \( S \).

III.10.4.10. This result is symmetric in the sense that transfer goes both ways due to the “if and only if.” But it is important to note that transfer is not quite symmetric in \( \mathcal{L} \) and \( ^*\mathcal{L} \): every statement in \( \mathcal{L} \) has a transfer in \( ^*\mathcal{L} \), but not every statement in \( ^*\mathcal{L} \) is the transfer of a statement in \( \mathcal{L} \) in general. If \( ^*\mathcal{L} \) is a simple language for \( ^*S \), then transfer is truly symmetric, since the only formulas of \( ^*\mathcal{L} \) will be transfers of formulas in \( \mathcal{L} \).
We can extend transfer a little to make it more useful. If the relational structure $\mathcal{S}$ is nondegenerate (II.1.8.8.), we can fix a false statement $\Phi$ in $\mathcal{L}$ containing no variables. Then $^*\Phi$ is also false in $^*\mathcal{S}$, and contains no variables. We can extend the simple language $\mathcal{L}$ to an extended simple language $\mathcal{L}'$ by adding the symbols $\neg, \lor, \exists, \iff$ as in II.1.8.10., with a standard translation as in II.1.8.10. using $\Phi$; similarly, if $^*\mathcal{L}$ is simple, or more generally does not contain the extra logical symbols, we can extend $^*\mathcal{L}$ to $^*\mathcal{L}'$ in the same manner, using $^*\Phi$. We then routinely check:

**III.10.4.12.** Proposition. Each formula $P$ of $\mathcal{L}$ has a well-defined transfer to a formula $^*P$ of $^*\mathcal{L}$. If $Q$ is the standard translation of $P$ to $\mathcal{L}$, then the standard translation of $^*P$ to $^*\mathcal{L}$ is $^*Q$. The transfer of a statement is a statement.

Using this, we can extend Transfer:

**III.10.4.13.** Theorem. [Extended Simple or First-Order Transfer Principle] Let $\mathcal{S}$ be a relational structure, $^*\mathcal{S}$ a first-order nonstandard structure for $\mathcal{S}$, $\mathcal{L}$ a simple language for $\mathcal{S}$, $^*\mathcal{L}$ a simple language for $^*\mathcal{S}$, and $^*\mathcal{L}'$ the corresponding extended languages. If $P$ is any statement of $^*\mathcal{L}$, with transfer $^*P$ as defined in III.10.4.12., then $^*P$ holds in $^*\mathcal{S}$ if and only if $P$ holds in $\mathcal{S}$.

Proof: Let $Q$ be the standard translation of $P$ in $\mathcal{L}$. Then

$$
P \text{ holds in } S \iff Q \text{ holds in } S \iff ^*Q \text{ holds in } ^*S \iff ^*P \text{ holds in } ^*S$$

where the first and third equivalences are by definition (III.10.4.12. is needed for the third) and the second equivalence is by III.10.4.9.. ⬅️

**Proof of the Simple Transfer Principle**

The proof of the Simple Transfer Principle, by induction on level, is actually quite straightforward and routine. It is a nearly immediate corollary of the simple version of Loś’s Theorem:

**III.10.4.14.** Theorem. [Loś’s Theorem, Simple or First-Order Version] Let $\mathcal{S}$ be a relational structure, $^*\mathcal{S}$ a first-order nonstandard structure for $\mathcal{S}$, $\mathcal{L}$ a simple language for $\mathcal{S}$, and $^*\mathcal{L}$ a language for $^*\mathcal{S}$. Let $P$ be any formula of $\mathcal{L}$, with transfer $^*P$ as defined in III.10.4.7., with unquantified variables among $x_1, \ldots, x_n$; let $c_1, \ldots, c_n$ be names in $^*\mathcal{L}$ for elements of $^*\Omega$ with $(c_ki)$ a representative for $c_k$ with $c_ki$ the name of an element of $\Omega$ for each $(k, i)$. Then $^*P$ holds for $(c_1, \ldots, c_n)$ in $^*\mathcal{S}$ if and only if, for almost all $i$, $P$ holds for $(c_{1i}, \ldots, c_{ni})$ in $\mathcal{S}$. 364
Superstructures

**III.10.4.15. Definition.** If $X$ is a set, we define

\[
V_0(X) = X \\
V_{n+1}(X) = V_n(X) \cup \mathcal{P}(V_n(X)) \\
V(X) = \bigcup_{n=0}^{\infty} V_n(X)
\]

$V(X)$ is called the *superstructure* of $X$.

Note that if $y \in V(X) \setminus X$, then $y \subseteq V(X)$. The converse is false; however, if $y \subseteq V_n(X)$ for some $n$, then $y \in V_{n+1}(X) \subseteq V(X)$.

**III.10.4.16.** There is a similarity between the construction of superstructures and II.8.7.6. However, $V(X)$ is not a model for set theory (for example, $\mathcal{P}(V(X))$ is not an element of $V(X)$); to get a model for set theory, the construction has to be continued transfinitely for all ordinals (and then the result is a class, not a set). For nonstandard analysis, however, it is adequate to just continue the construction to $\aleph_0$.

**III.10.4.17.** For technical reasons, we will want to assume that $\emptyset \notin X$ and that no element of $V(X)$ belongs to an element of $X$, i.e. that $x \cap V(X) = \emptyset$ for all $x \in X$. This is normally accomplished by assuming that the elements of $X$ are *atoms* (or *urelements*), i.e. if $x \in X$, then $x \neq \emptyset$ but that $x$ has no elements. For a general $X$ we can just replace $X$ by an equipotent set consisting of atoms. For basic nonstandard analysis, we simply assume that real numbers are atoms of set theory, which we can do (III.2.2.9). We will call the elements of $X$ the *elements* of the superstructure $V(X)$, and the elements of $V(X) \setminus X$ the *sets* of the superstructure $V(X)$. If $A$ is a set in $V(X)$, then all the elements of $A$ are either elements or sets in $V(X)$.

**III.10.4.18.** We can define ordered pairs in $V(X)$: if $a, b \in V_k(X)$, then \{a\} and \{a, b\} are in $V_{k+1}(X)$, so $(a, b) = \{\{a\}, \{a, b\}\} \in V_{k+2}(X)$. Similarly, ordered $n$-tuples of elements of $V(X)$ are again elements of $V(X)$. In particular, all ordered $n$-tuples of elements of $X$ are in $V_2(X)$, and thus $X^n \in V_3(X)$. More generally, the cartesian product of any finite number of subsets of $V_k(X)$ is again an element of $V_{k+3}(X) \subseteq V(X)$.

An $n$-ary relation on $V_k(X)$ is a subset of $V_k(X)^n$, hence an element of $V_{k+3}(X)$. Thus $V(X)$ contains all relations on $V_k(X)$ for any $k$. Any such relation is a relation on $V(X)$. But note that not all relations on $V(X)$ are of this form. An $n$-ary relation on $V(X)$ which is contained in $V_k(X)^n$ for some $k$ is called *limited*; these are precisely the relations on $V(X)$ which are elements of $V(X)$.

Similarly, any function from $V_k(X)^n$ to $V_k(X)^m$ is in $V_{k+4}(X)$, hence in $V(X)$. In particular, any function from $X^n$ to $X^m$ is in $V_4(X)$, hence in $V(X)$. As with relations, not every function on $V(X)$ is in $V(X)$, only ones whose domain and range is contained in $V_k(X)$ for some $k$ (called *limited functions*).

**III.10.4.19.** We can thus form a relational structure $(V(X), \mathcal{R}_f, \mathcal{F}_f)$, where $\mathcal{R}_f$ and $\mathcal{F}_f$ are the sets of limited relations and limited functions in $V(X)$. It is convenient to only consider limited relations and functions and not the unwieldy sets of all relations and functions on $V(X)$. However, there are a few basic relations and functions on $V(X)$ which are not limited, which it is convenient to include: $\in, \subseteq, \cup, \cap, \setminus$. These can be avoided at some notational cost: for example, $\in$ can be avoided by only working with the coherent family of limited relations $\in_k$, where $\in_k$ is the membership relation on $V_k(X)$. We will thus include
these five relations in $\mathcal{R}_\ell$ and $\cup$, $\cap$, and \setminus in $\mathcal{F}_\ell$, essentially to ease notation. (Actually any relations or functions on $V(X)$ can be thrown in with no cost by regarding them as coherent families of limited relations or functions in the same manner.)

**III.10.4.20.**  We can then fix a simple language (II.1.8.2.) $\mathcal{L}_X$ for the relational structure $\mathcal{X} = (V(X), \mathcal{R}_\ell, \mathcal{F}_\ell)$, which will be called the **language** of the superstructure of $X$. Since this relational structure is always nondegenerate (even if $X = \emptyset$!), the language $\mathcal{L}_X$ can be extended to an extended simple language $\bar{\mathcal{L}}_X$ adding $\neg$, $\lor$, $\exists \iff$ (II.1.8.10.), which will have their usual meanings. The language $\bar{\mathcal{L}}_X$ is rich enough that we can express any reasonable statement about $X$, subsets of $X$, relations and functions on $X$, etc., in a relatively straightforward way.

**III.10.4.21.**  Some references argue that inclusion of $\mathcal{F}_\ell$ in the relational structure is not necessary: in a relational structure $(\Omega, \mathcal{R}, \mathcal{F})$, the only use of the functions in $\mathcal{F}$ is to define terms; in the case of $(V(X), \mathcal{R}_\ell, \mathcal{F}_\ell)$ this is redundant since the terms defined this way are already constants in $V(X)$. Thus the use of terms, as opposed to constants, is unnecessary. This is technically correct, but terms in a simple language can include variables as well as constants, so inclusion of the functions in $\mathcal{F}_\ell$ serves to expand the simple language of the superstructure in a useful way without causing additional difficulties (sentences in the expanded language can be systematically translated into the simpler language).

**Nonstandard Superstructures**

**III.10.4.22.**  If we now fix and index set $I$ and an ultrafilter $\mathcal{U}$ on $I$, we can form the corresponding nonstandard relational structure $^*\mathcal{X} = (^*V(X), ^*\mathcal{R}_\ell, ^*\mathcal{F}_\ell)$. We would like to regard this relational structure as a (generally proper) substructure of $(V(^*X), \mathcal{R}_\ell^*, \mathcal{F}_\ell^*)$, where $\mathcal{R}_\ell^*$ and $\mathcal{F}_\ell^*$ are the sets of limited relations and functions on $V(^*X)$. However, there is a logical problem: $^*V(X)$ is not a subset of $V(^*X)$ (although $^*X$ is naturally a subset of both). For example, if $A \subseteq X$, then the object $^*A$ of $^*V_1(X)$ is not a subset of $^*X$. Put another way, $A$ may be regarded as a unary relation $R_A$ on $X$, i.e. as an element of $\mathcal{R}_\ell$, but the element $^*A$ of $^*V_1(X)$ is not the unary relation $^*R_A$ on $^*X$ (which is technically a subset of $^*X$, i.e. an element of $V(^*X)$).

This observation leads to the solution: identify $^*V_2(X) = X \cup \mathcal{P}(X)$ with a subset of $V_1(^*X) = X \cup \mathcal{P}(^*X)$ by identifying $^*x \in X$ with itself and $A \subseteq X$ with $^*R_A \in \mathcal{P}(^*X)$. The embedding is well defined since $X \cap \mathcal{P}(X) = \emptyset$ and hence $^*X \cap \mathcal{P}(X) = \emptyset$, and is indeed an embedding (injective) since $^*X \cap \mathcal{P}(^*X) = \emptyset$. Call the embedding $\mu_0$.

This procedure can be continued inductively, although with a slight complication. The embedding $\mu_1$ of $^*V_1(X)$ into $V_2(^*X)$ defines an embedding of $\mathcal{P}(^*V_1(X))$ into $\mathcal{P}(V_1(^*X))$, so we can map $^*V_2(X) = V_1(^*X) \cup \mathcal{P}(V_1(^*X))$ into $V_2(^*X) = V_1(^*X) \cup \mathcal{P}(V_1(^*X))$ as follows. The map $\mu_2$ is defined on $^*V_1(X)$ as $\mu_1$. If $B \subseteq V_1(X)$, so $^*B \in ^*\mathcal{P}(V_1(X))$, regard $B$ as a unary relation $R_B$ on $V_1(X)$; then $^*R_B$ is a unary relation on $^*V_1(X)$, hence defines an element of $\mathcal{P}(^*V_1(X))$ which in turn defines an element $C$ of $\mathcal{P}(V_1(^*X))$. Set $\mu_2(^*B) = C$. It is not entirely obvious that $\mu_2$ is well defined, since $V_1(X) \cap \mathcal{P}(V_1(X)) \neq \emptyset$; but in fact $V_1(X) \cap \mathcal{P}(V_1(X)) = \{\emptyset\}$ and $^*\emptyset = \emptyset$ unambiguously. It is unclear that $\mu_2$ is injective in general.

Iterating this construction, we get a well-defined map $\mu_n$ from $^*V_n(X)$ to $V_n(^*X)$ for each $n$ (the proof that the map is well defined becomes successively more complicated as $n$ increases), and hence a map $\mu : ^*V(X) \to V(^*X)$, called the **Mostowski collapsing map**. We also need to identify relations in $^*\mathcal{R}_\ell$ with relations in $\mathcal{R}_\ell^*$: since every relation in $^*\mathcal{R}_\ell$ is an element of
III.10.5. Other Nonstandard Structures

III.10.6. Proofs and Applications of Nonstandard Analysis

III.10.7. Loeb Measures and a Nonstandard Approach to Measure Theory

III.10.8. Exercises

III.10.8.1. (a) Show that \(*\mathbb{R}\) has no countable cofinal subset: if \((a^{(n)})\) is a sequence in \(*\mathbb{R}\), then there is a \(b \in \ast \mathbb{R}\) with \(a^{(n)} < b\) for all \(n\). [For each \(m \in \mathbb{N}\), set \(b_m = 1 + \max\{a^{(1)}_m, \ldots, a^{(m)}_m\}\).]
(b) Show that if \((a^{(n)})\) and \((b^{(n)})\) are sequences in \(*\mathbb{R}\) with \(a^{(n)} < b^{(r)}\) for all \(n\) and \(r\), there are \(c, d \in \ast \mathbb{R}\) with \(a^{(n)} < c < d < b^{(n)}\) for all \(n\). [For almost all \(m \in \mathbb{N}\), choose \(c_m, d_m \in \mathbb{R}\) with \(a^{(n)}_m < c_m < d_m < b^{(r)}_m\) for all \(n, r \leq m\).]

III.10.8.2. (a) Show that if \(F\) is any ordered field and \(a, b, c, d \in F\) with \(a < b\) and \(c < d\), the open intervals \((a, b)\) and \((c, d)\) are order-isomorphic. [Use a “linear” function.]
(b) Show that any two open intervals in \(*\mathbb{R}\) are order-isomorphic. [Use the extensions \((\cdot)\) of the tangent and arctangent functions to give an order-isomorphism between \(*\mathbb{R}\) and \((-\frac{\pi}{2}, \frac{\pi}{2})\).]

III.10.8.3. Let \(n \in \ast \mathbb{N}\setminus \mathbb{N}\). Show that \(n - 1 \in \ast \mathbb{N}\setminus \mathbb{N}\). Show that the intersection \(\gamma(n)\) of the galaxy of \(n\) with \(\ast \mathbb{N}\) is a copy of \(\mathbb{Z}\) (consisting of \(\{n + k : k \in \mathbb{Z}\}\)). Show that \(\ast \mathbb{N}\) consists of \(\mathbb{N}\) and uncountably many disjoint such \(\gamma(n)\), and between any two such \(\gamma(n)\), or between \(\mathbb{N}\) and any \(\gamma(n)\), there are uncountably many \(\gamma(k)\). In particular, \(\ast \mathbb{N}\) is uncountable. Give similar results for \(\ast \mathbb{Z}\) and \(\ast \mathbb{Q}\). [Argue as in III.10.8.1.]

III.10.8.4. If \(x, a \in \ast \mathbb{N}\), then the nonstandard exponential \(x^a\) is in \(\ast \mathbb{N}\).

III.10.8.5. Let \(n = [[(n_m)]] \in \ast \mathbb{N}\). Either \(\{m \in \mathbb{N} : n_m\text{ is odd}\}\) or \(\{m \in \mathbb{N} : n_m\text{ is even}\}\) is in \(\mathcal{U}\). Say \(n\) is odd or even in the two cases. Show that if \(n \in \ast \mathbb{N}\), then either \(n\) or \(n + 1\) is even, and \(n\) is even if and only if \(n/2 \in \ast \mathbb{N}\).

III.10.8.6. If \(k, n \in \ast \mathbb{N}\), say \(k\) divides \(n\) (written \(k|n\)) if \(n/k \in \ast \mathbb{N}\).
(a) If \(k = [[(k_m)]]\) and \(n = [[(n_m)]]\) with \(k_m, n_m \in \mathbb{N}\) for almost all \(m\), then \(k|n\) if and only if \(k_m|n_m\) for almost all \(m\).
(b) If \(k, n \in \ast \mathbb{N}\), show that \(k\) and \(n\) have a unique greatest common divisor in \(\ast \mathbb{N}\), an element \(d \in \ast \mathbb{N}\) such that \(d|k, d|n\), and for any \(c \in \ast \mathbb{N}\) such that \(c|k\) and \(c|n\), we have that \(c|d\). Similarly show that \(k\) and \(n\) have a least common multiple in \(\ast \mathbb{N}\).

III.10.8.7. Let \(n = [[(n_m)]] \in \ast \mathbb{N}\). Show that \(n\) is divisible by every \(k \in \mathbb{N}\).

III.10.8.8. Let \(p \in \ast \mathbb{N}\). Say \(p\) is prime if whenever \(p = kn\) with \(k, n \in \ast \mathbb{N}\), then either \(k\) or \(n\) is 1.
(a) If \(p = [[(p_m)]]\) with \(p_m \in \mathbb{N}\) for almost all \(m\), then \(p\) is prime in \(\ast \mathbb{N}\) if and only if \(p_m\) is prime in \(\mathbb{N}\) for almost all \(m\).
(b) If \(\Pi\) is the set of primes in \(\mathbb{N}\), then \(\ast \Pi\) is the set of primes in \(\ast \mathbb{N}\).
(c) If \(p\) is prime in \(\ast \mathbb{N}\), and \(k, n \in \ast \mathbb{N}\), then \(p|kn\) if and only if \(p|k\) or \(p|n\).
(d) If \( p \) is prime in \( {}^*\mathbb{N} \), and \( n \in {}^*\mathbb{N} \) with \( p \mid n \), then there is a unique \( r \in {}^*\mathbb{N} \) for which \( n = p^r k \) for some \( k \in {}^*\mathbb{N} \) such that \( p \) does not divide \( k \).

e Let \( n_1, n_2 \in {}^*\mathbb{N} \). Show that \( n_1 = n_2 \) if and only if, for every prime \( p \) in \( {}^*\mathbb{N} \), when we write \( n_1 = p^r k_1 \) and \( n_2 = p^s k_2 \) as in (d), we have \( r = s \).

(f) Can every \( n \in {}^*\mathbb{N} \) be written as a (finite) product of prime powers? [See III.10.8.5..]

**III.10.8.9.** Let \( T \) be the order topology () on \( {}^*\mathbb{R} \), i.e. the topology generated by the open intervals.

(a) Show that the halo and the galaxy of any element are both open and closed in \( {}^*\mathbb{R} \).

(b) Show that the relative topology from \( T \) on \( \mathbb{R} \) is the discrete topology.

(c) Show that \( ({}^*\mathbb{R}, T) \) is totally disconnected. [Use III.10.8.2..]

(d) Show that no point of \( {}^*\mathbb{R} \) has a countable local base for \( T \). [Use III.10.8.1..]

**III.10.8.10.** Let \( X \) be an uncountable set. Mimic the construction of \( {}^*\mathbb{R} \) using an ultrafilter on \( X \) containing all subsets of \( X \) with cardinality less than \( |X| \). Show that ordered fields containing \( \mathbb{R} \) of arbitrarily large cardinality can be constructed. (See [GJ76, 12E].) Are such fields a satisfactory model for the hyperreal numbers for the purpose of nonstandard analysis? See Exercise III.10.8.14.

**III.10.8.11.** (a) Repeat the construction of the hyperreal numbers using \( {}^*\mathbb{R} \) in place of \( \mathbb{R} \): let \( U \) be a free ultrafilter on \( \mathbb{N} \), and \( {}^*\mathbb{S} \) the set of sequences of elements of \( {}^*\mathbb{R} \). Define an equivalence relation on \( {}^*\mathbb{S} \) via \( \mathcal{F} \) as before, and let \( **\mathbb{R} \) be the set of equivalence classes. Show that \( **\mathbb{R} \) is an ordered field containing \( {}^*\mathbb{R} \). Is it essentially larger? Is it isomorphic to \( {}^*\mathbb{R} \)?

(b) Repeat the construction transfinitely, taking a “union” (direct limit) at limit ordinals, to construct ordered fields of arbitrary cardinality containing \( \mathbb{R} \). Is there a transfer principle for these fields?

**III.10.8.12.** [Dav77] A Nonstandard Construction of \( \mathbb{R} \). Construct the nonstandard rational numbers \( {}^*\mathbb{Q} \). Let \( L \) be the set of all limited elements of \( {}^*\mathbb{Q} \), and \( I \) the set of infinitesimals in \( {}^*\mathbb{Q} \).

(a) Show that \( L \) is a commutative unital ring, and that \( I \) is a maximal ideal in \( L \). Thus \( R = L/I \) is a field.

(b) Show that the ordering on \( {}^*\mathbb{Q} \) induces an ordering on \( R \) making it an ordered field. If \( \mathbb{Q} \) is regarded as a subring of \( L \) in the usual way, then the image of \( \mathbb{Q} \) in \( R \) is order-dense.

(c) If \( A \) and \( B \) are nonempty subsets of \( {}^*\mathbb{Q} \) with \( a < b \) for all \( a \in A \), \( b \in B \), then there is a \( c \in {}^*\mathbb{Q} \) with \( a < c < b \) for all \( a \in A \), \( b \in B \). [Use the argument of III.10.8.1.(b).]

(d) Conclude that \( R \) is a complete ordered field. [If \( A \) is a nonempty subset of \( R \) with no largest element which is bounded above, let \( B \) be the set of upper bounds for \( A \). Consider the inverse images in \( L \), and apply (c).]

This is a very efficient construction of \( \mathbb{R} \), but unlike the Dedekind cut or Cauchy sequence constructions it requires some form of AC (existence of a free ultrafilter on \( \mathbb{N} \)).

**III.10.8.13.** (a) Show that (assuming AC) using a countable index set (e.g. \( \mathbb{N} \)) in the construction of \( {}^*\mathbb{R} \) is not sufficient to obtain concurrence (); an index set \( I \) of cardinality at least \( 2^\aleph_0 \) is needed. [Consider a well ordering of \( \mathbb{R} \) according to the smallest ordinal of cardinality \( 2^\aleph_0 \), which is a concurrent relation on \( \mathbb{R} \). Every element of \( {}^*\mathbb{R} \) is determined by a function from \( I \) to \( \mathbb{R} \), hence by at most \( |I| \) elements of \( \mathbb{R} \).]
(b) Show similarly that (under AC) to obtain concurrence in a nonstandard model for a structure of cardinality \( \kappa \), an index set of cardinality at least \( \kappa \) is necessary. (Even then the ultrafilter needs to be carefully chosen.)

**III.10.8.14.**  
(a) Show that if an ultrafilter on some index set \( I \) is used for the construction of \( *\mathbb{R} \) which is not closed under countable intersections (such an ultrafilter is necessarily free), we obtain \( *\mathbb{R} \neq \mathbb{R} \) so that \( *\mathbb{R} \) is a true nonstandard model for \( \mathbb{R} \). [Show there is a sequence \( (V_n) \) of subsets of \( I \) with \( \cup_{n=1}^{\infty} V_n = I \) and \( V_n \notin \mathcal{U} \) for every \( n \). Use this sequence to construct an element of \( *\mathbb{N} \setminus \mathbb{N} \).]  
(b) Conversely, if an ultrafilter is used which is closed under countable intersections (this can only happen if the ultrafilter is fixed or if \( I \) is huge, of cardinality at least as large as a measurable cardinal), then \( *\mathbb{R} = \mathbb{R} \) so the construction is degenerate and not suitable for nonstandard analysis. [First show that if \( U_1, U_2, \ldots \) is a sequence of subsets of \( I \) and \( \cup_{n=1}^{\infty} U_n \in \mathcal{U} \), then some \( U_n \in \mathcal{U} \). Then show that \( *\mathbb{N} = \mathbb{N} \) and that \( *\mathbb{R} \) has no unlimited elements, and apply III.10.1.4.]

**III.10.8.15. Theorem.** The following theorems are logically equivalent:

(i) Tikhonov’s Theorem for Hausdorff spaces.

(ii) Tikhonov’s Theorem for copies of \([0,1]\).

**Proof:** (i) \( \Rightarrow \) (ii) and (iv) \( \Rightarrow \) (iii) are trivial. (ii) \( \Rightarrow \) (iv) is the standard construction of the Stone-Čech compactification \( \beta X \). So we need only prove (iii) \( \Rightarrow \) (i).

Let \( \{X_i : i \in I\} \) be an indexed collection of compact Hausdorff spaces, and let \( X = \prod_i X_i \) with the product topology. Let \( Y \) be the set \( X \) with the discrete topology, and \( \beta Y \) its Stone-Čech compactification. For each \( i \), the coordinate map \( \pi_i : X \to X_i \), regarded as a map from \( Y \) to \( X_i \), extends uniquely to a continuous function \( f_i \) from \( \beta Y \) to \( X_i \), by the universal property of \( \beta Y \). The \( f_i \) define a continuous function from \( \beta Y \) to \( X \) \( \), which is surjective since its restriction to \( Y \) is the identity map from \( Y \) to \( X \). Thus \( X \) is a continuous image of the compact space \( \beta Y \), hence compact by \( \beta \).

Note that (ii) \( \Rightarrow \) (i) is a simple consequence of the fact that every compact Hausdorff space can be embedded in a product of intervals, but we did not need to use this argument.

It is a direct consequence of (iii) that every filter on a set \( X \) is contained in an ultrafilter. Thus this statement, along with the ones from the theorem, is logically strictly weaker than the Axiom of Choice.

369
III.11. Linear Algebra

Linear algebra is one of the most important and fundamental parts of elementary (university-level) mathematics. Although linear algebra is not directly part of the subject of this book, it is an indispensable tool in analysis, particularly vector analysis and functional analysis, as well as throughout mathematics in general. We will not give a full treatment of the subject here (there are any number of good texts available, as well as some that are not so good), but simply review the parts of the subject most relevant to analysis, often from the point of view of the analysis applications.

The linear algebra done in most texts is finite-dimensional linear algebra. While finite-dimensional linear algebra is important in analysis, especially vector analysis, much of advanced analysis uses infinite-dimensional vector spaces, so we will place more emphasis than is usual in linear algebra on aspects of the subject relevant in the infinite-dimensional case.

Abstract linear algebra is done over an arbitrary (but fixed) field $\mathbb{F}$. In 75% of the analysis applications (at least in this book), $\mathbb{F}$ will be the real numbers $\mathbb{R}$, and in 99% of the applications in which $\mathbb{F}$ is not $\mathbb{R}$ it is the complex numbers $\mathbb{C}$. The reader may just take the symbol $\mathbb{F}$ to stand for either $\mathbb{R}$ or $\mathbb{C}$ without essential loss of generality for analysis purposes. (In the remaining applications, $\mathbb{F}$ could be the rational numbers $\mathbb{Q}$, the hyperreal numbers $^*\mathbb{R}$ (III.10.2.21.), a field of rational functions (III.4.3.5.(c)) or Laurent series (III.5.3.3.), the $p$-adic numbers (III.5.3.9.), or occasionally something else.)

III.11.1. Matrix Algebra

Matrices can be regarded simply as an extremely useful shorthand notation for certain complicated algebraic systems. They are so useful, however, that they are really more than just a shorthand, becoming important mathematical objects in their own right.

III.11.1.1. Definition. Let $m, n \in \mathbb{N}$. An $m$-by-$n$ ($m \times n$) matrix over $\mathbb{F}$ is an array

$$A = \begin{bmatrix}
a_{11} & a_{12} & \cdots & a_{1n} \\
a_{21} & a_{22} & \cdots & a_{2n} \\
\vdots & \vdots & \ddots & \vdots \\
a_{m1} & a_{m2} & \cdots & a_{mn}
\end{bmatrix}$$

of elements $\{a_{ij}\} \in \mathbb{F}$, with $m$ rows and $n$ columns. The element $a_{ij}$ in the $i$'th row and $j$'th column is called the $(i, j)$ entry of the matrix $A$, sometimes written $A_{ij}$. $A$ is sometimes denoted $[a_{ij}]$ or $[a_{ij}]_{mn}$.

Actually, most of the theory of matrices works equally well over any ring $R$, i.e. the $a_{ij}$ are all elements of $R$. For some of the theory it is necessary to restrict to a commutative ring (we will note these instances).

Addition of Matrices

III.11.1.2. Only matrices of the same size can be added. Addition is done entrywise:

$$\begin{bmatrix}
a_{11} & a_{12} & \cdots & a_{1n} \\
a_{21} & a_{22} & \cdots & a_{2n} \\
\vdots & \vdots & \ddots & \vdots \\
a_{m1} & a_{m2} & \cdots & a_{mn}
\end{bmatrix} + \begin{bmatrix}
b_{11} & b_{12} & \cdots & b_{1n} \\
b_{21} & b_{22} & \cdots & b_{2n} \\
\vdots & \vdots & \ddots & \vdots \\
b_{m1} & b_{m2} & \cdots & b_{mn}
\end{bmatrix} = \begin{bmatrix}
a_{11} + b_{11} & a_{12} + b_{12} & \cdots & a_{1n} + b_{1n} \\
a_{21} + b_{21} & a_{22} + b_{22} & \cdots & a_{2n} + b_{2n} \\
\vdots & \vdots & \ddots & \vdots \\
a_{m1} + b_{m1} & a_{m2} + b_{m2} & \cdots & a_{mn} + b_{mn}
\end{bmatrix}$$

The sum is another matrix of the same size.
III.11.1.3. Example. Let
\[ A = \begin{bmatrix} 1 & -2 & 4 \\ 0 & 1 & -2 \end{bmatrix}, B = \begin{bmatrix} -2 & 1 & 0 \\ 5 & -3 & 3 \end{bmatrix}, C = \begin{bmatrix} 2 & 3 \\ -1 & 2 \end{bmatrix}. \]

Then
\[ A + B = \begin{bmatrix} -1 & -1 & 4 \\ 5 & -2 & 1 \end{bmatrix} \]

and \( A + C \) and \( B + C \) are not defined since \( A \) and \( B \) are \( 2 \times 3 \) and \( C \) is \( 2 \times 2 \).

The next result is obvious:

III.11.1.4. Proposition. Let \( m, n \in \mathbb{N} \). Addition of \( m \times n \) matrices over \( \mathbb{F} \) is associative and commutative. There is an \( m \times n \) zero matrix \( 0 = 0_{m \times n} \) such that \( 0 + A = A + 0 = A \) for every \( m \times n \) matrix \( A \). For every such \( A \) there is a unique \( m \times n \) matrix \( -A \) such that \( A + (-A) = 0 \).

In fact, \( 0_{m \times n} \) is the \( m \times n \) matrix whose entries are all 0, and if \( A = [a_{ij}] \), then \( -A = [-a_{ij}] \).

III.11.1.5. We can also define scalar multiplication of matrices. If \( A = [a_{ij}] \) is an \( m \times n \) matrix over \( \mathbb{F} \) and \( r \in \mathbb{F} \), then define \( rA = [ra_{ij}] \). Scalar multiplication can be regarded as a special case of matrix multiplication (), and thus satisfies all the usual algebraic rules () (this is easily verified directly). We have \( -A = (-1)A \) for any \( A \).

Row and Column Vectors

III.11.1.6. A \( 1 \times n \) matrix over \( \mathbb{F} \) is of the form
\[ \begin{bmatrix} a_1 & a_2 & \cdots & a_n \end{bmatrix} \]
and is usually called a row \( n \)-vector. The set of row \( n \)-vectors can be naturally identified with \( \mathbb{F}^n \).

An \( m \times 1 \) matrix over \( \mathbb{F} \) is of the form
\[ \begin{bmatrix} a_1 \\ a_2 \\ \vdots \\ a_m \end{bmatrix} \]
and is usually called a column \( m \)-vector. The set of column \( m \)-vectors can be naturally identified with \( \mathbb{F}^m \).

Under both identifications, matrix addition and scalar multiplication corresponds with usual vector addition and scalar multiplication.
Matrix Multiplication

III.11.1.7. The normal way to multiply matrices is more complicated and less obvious. Coordinatewise multiplication of matrices of the same size turns out not to be the useful product for most purposes (although this multiplication, called Schur product, does have some limited applications). The most useful product is hard to motivate until some further linear algebra is developed, so we will just give the definition and then see why it is important and has nice properties.

Multiplication of matrices is not necessarily defined for matrices of the same size. Instead, if $A$ is an $m \times n$ matrix and $B$ is a $q \times p$ matrix, then $AB$ is defined if and only if $n = q$, and the product is then an $m \times p$ matrix. Here is the formal definition:

III.11.1.8. Definition. Let $A = [a_{ij}]$ be an $m \times n$ matrix and $B = [b_{ij}]$ a $q \times p$ matrix. Then the matrix product $AB$ is defined to be the $m \times p$ matrix $C = [c_{ij}]$, where

$$c_{ij} = \sum_{k=1}^{n} a_{ik} b_{kj}$$

if $n = q$, and $AB$ is undefined if $n \neq q$.

The idea is that to get the $(i,j)$ entry of $AB$, the $i$'th row of $A$ is “multiplied” times the $j$'th column of $B$ (in a manner strongly reminiscent of the dot product in $\mathbb{R}^n$; in fact, this “multiplication” is exactly the dot product of the $i$’th row vector of $A$ and the $j$’th column vector of $B$ if $F = \mathbb{R}$.) The product of the matrices is then defined if and only if the row vectors of $A$ and the column vectors of $B$ have the same length.

If $A$ and $B$ are square matrices of the same size (i.e. $n \times n$ for some $n$), then $AB$ is defined and is again an $n \times n$ matrix.

III.11.1.9. Examples. Let

$$A = \begin{bmatrix} 1 & -2 & 4 \\ 0 & 1 & -2 \end{bmatrix}, B = \begin{bmatrix} -2 & 1 \\ 0 & 5 \\ -3 & 3 \end{bmatrix}, C = \begin{bmatrix} 2 & 3 \\ -1 & 2 \end{bmatrix}.$$  

Then

$$AB = \begin{bmatrix} -14 & 3 \\ 6 & -1 \end{bmatrix}, BA = \begin{bmatrix} -2 & 5 & -10 \\ 0 & 5 & -10 \\ -3 & 9 & -6 \end{bmatrix}$$

$$CA = \begin{bmatrix} 2 & -1 & 2 \\ -1 & 4 & 0 \end{bmatrix}, BC = \begin{bmatrix} -5 & -4 \\ -5 & 10 \\ -9 & -3 \end{bmatrix}, C^2 = CC = \begin{bmatrix} 1 & 12 \\ -4 & 1 \end{bmatrix}$$

and $AC$, $CB$, $A^2$, and $B^2$ are undefined.

III.11.1.10. It is obvious from this example that $AB$ and $BA$ are usually not the same. In fact, one of these products can be defined and the other undefined, and even if both are defined they need not even be the same size. Even if $A$ and $B$ are square matrices of the same size, so $AB$ and $BA$ are both defined and the same size, they need not be equal (in almost any example one tries randomly they will be different). Thus matrix multiplication is noncommutative in a very fundamental sense.

It may then be surprising that the other usual rules of algebra hold for matrix multiplication:

372
III.11.1.11. **Proposition.** Matrix multiplication, when defined, is associative: if $A, B, C$ are matrices and $(AB)C$ is defined, then $A(BC)$ is also defined and $A(BC) = (AB)C$.

**Proof:** This is a straightforward calculation. The products are defined if and only if $A$ is $m \times n$, $B$ is $n \times p$, and $C$ is $p \times q$ for some $m, n, p, q \in \mathbb{N}$. In this case, for $1 \leq i \leq m$, $1 \leq j \leq q$ we have

$$[(AB)C]_{ij} = \sum_{r=1}^{p} (AB)_{ir}C_{rj} = \sum_{r=1}^{p} \left( \sum_{k=1}^{n} A_{ik}B_{kr} \right)C_{rj} = \sum_{r=1}^{p} \sum_{k=1}^{n} A_{ik}B_{kr}C_{rj}$$

$$= \sum_{k=1}^{n} \sum_{r=1}^{p} A_{ik}B_{kr}C_{rj} = \sum_{k=1}^{n} A_{ik} \left( \sum_{r=1}^{p} B_{kr}C_{rj} \right) = \sum_{k=1}^{n} A_{ik}(BC)_{kj} = [A(BC)]_{ij}.$$

III.11.1.12. **Proposition.** The distributive laws hold for matrix addition and multiplication:

(i) If $A, B, C$ are matrices with $B$ and $C$ the same size, and $AB$ (and hence also $AC$) is defined, then $A(B+C)$ is defined and $A(B+C) = AB + AC$.

(ii) If $A, B, C$ are matrices with $A$ and $B$ the same size, and $AC$ (and hence also $BC$) is defined, then $(A+B)C$ is defined and $(A+B)C = AC + BC$.

The proof is a straightforward calculation. Note that both distributive laws must be stated and proved because of the noncommutativity of matrix multiplication.

**The Identity Matrix**

III.11.1.13. For $n \in \mathbb{N}$, define the *identity matrix of size $n$* to be the (square) $n \times n$ matrix

$$I_n = \begin{bmatrix} 1 & 0 & \cdots & 0 \\ 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 \end{bmatrix}$$

i.e. the $(i, j)$ entry is 1 if $i = j$ and 0 if $i \neq j$.

A simple calculation shows that the identity matrices are “multiplicative identities”:

III.11.1.14. **Proposition.** Let $A$ be an $m \times n$ matrix. Then $I_mA = AI_n = A$.

**Rings of Square Matrices**

III.11.1.15. If $n \in \mathbb{N}$, the set $M_n(\mathbb{F})$ of $n \times n$ matrices over $\mathbb{F}$ is closed under addition and multiplication, and the ring axioms () are satisfied. Since $I_n \in M_n(\mathbb{F})$, $M_n(\mathbb{F})$ is a unital ring under this addition and multiplication; this ring is noncommutative if $n > 1$. More generally, if $R$ is any ring, then the set $M_n(R)$ of $n \times n$ matrices over $R$ is a ring, which is unital if $R$ is unital, and noncommutative if $R$ is unital and $n > 1$.
**Invertible Matrices**

**III.11.1.16.** If $A$ is an $m \times n$ matrix and $B$ is $n \times m$, and $AB = I_m$, then $A$ is a left inverse for $B$ and $B$ is a right inverse for $A$, and $A$ and $B$ are right and left invertible respectively. It turns out that this is possible only if $n \geq m$. If $n = m$, left and right inverses, if they exist, are unique and are actually two-sided inverses, i.e. if $A$ and $B$ are $n \times n$ matrices and $AB = I_n$, then automatically $BA = I_n$ also. (These results are valid only for matrices over commutative rings.) A square matrix $A$ with a (necessarily two-sided) inverse is called invertible, or nonsingular, and its inverse is denoted $A^{-1}$.

**III.11.1.17.** **Examples.** The identity matrix $I_n$ is invertible, with $I_n^{-1} = I_n$. The zero matrix is obviously not invertible.

Not every nonzero square matrix is invertible: a simple calculation shows, for example, that

\[
\begin{bmatrix}
1 & 0 \\
0 & 0
\end{bmatrix}
\]

is not invertible.

We will later give criteria for when a square matrix is invertible.

**Transpose**

**III.11.1.18.** If $A$ is an $m \times n$ matrix, the transpose of $A$, denoted $A^t$, is the $n \times m$ matrix obtained by interchanging the rows and columns of $A$, i.e. if $A = [a_{ij}]_{mn}$, then $A^t = [a_{ji}]_{nm}$. The transpose of a row vector is a column vector, and conversely. If $A$ is any matrix, then $[A^t]^t = A$. If $A$ and $B$ are matrices of the same size, then $(A + B)^t = A^t + B^t$.

Transpose reverses multiplication:

**III.11.1.19.** **Proposition.** Let $A$ be $m \times n$ and $B$ $n \times p$. Then $(AB)^t = B^t A^t$.

The proof is a simple calculation left to the reader. (This result is only valid over a commutative ring.)

Since $I_n^t = I_n$, we have:

**III.11.1.20.** **Corollary.** If $A$ is an $n \times n$ matrix, then $A^t$ is invertible if and only if $A$ is invertible, and $(A^t)^{-1} = (A^{-1})^t$.

**Multiplication by Blocks**

**III.11.1.21.** A very useful symbolic procedure for multiplying matrices, frequently overlooked in linear algebra texts, is by decomposition into blocks.

Let $m, n, m_1, m_2, n_1, n_2 \in \mathbb{N}$ with $m = m_1 + m_2, n = n_1 + n_2$. If $A$ is an $m \times n$ matrix over $\mathbb{F}$, then $A$ can be decomposed or partitioned symbolically as

\[
A = \begin{bmatrix}
A_{11} & A_{12} \\
A_{21} & A_{22}
\end{bmatrix}
\]
where $A_{ij}$ is an $m_i \times n_j$ matrix ($A_{11}$ and $A_{12}$ comprise the first $m_1$ rows of $A$, etc.) Sometimes we draw dotted lines in an array to denote a partition of the matrix. (We have described this in the case where the rows and columns are each partitioned into two blocks, but any finite numbers of blocks, including one, can be used independently for the rows and columns.)

The proof of the next key proposition is a straightforward but ugly calculation along the lines of the proof of III.11.1.11.

**III.11.1.22. Proposition.** Let $m, n, p, m_1, m_2, n_1, n_2, p_1, p_2 \in \mathbb{N}$ with $m = m_1 + m_2$, $n = n_1 + n_2$, $p = p_1 + p_2$. Let $A$ be an $m \times n$ matrix and $B$ an $n \times p$ matrix, and set $C = AB$. Partition $A, B, C$ according to the $m_i, n_i, p_i$. Then for any $i$ and $j$,

$$C_{ij} = A_{i1}B_{1j} + A_{i2}B_{2j}$$

($C_{ij}$ is an $m_i \times p_j$ matrix, and so are the two terms on the right). A similar result holds for partitions into other numbers of blocks (provided only that the columns of $A$ and the rows of $B$ are partitioned in the same way).

Symbolically, $AB$ can be computed by multiplying

$$\begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} \begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix}$$

according to the usual rule for multiplying two $2 \times 2$ matrices, i.e. the matrix product can be “computed by blocks.”

If the matrices are square and all blocks are the same size, as a special case we obtain:

**III.11.1.23. Corollary.** If $m, n \in \mathbb{N}$, then $M_m(M_n(\mathbb{F}))$ is naturally isomorphic to $M_{mn}(\mathbb{F})$.

This result holds over any ring. For fields (or commutative rings), it can also be proved by tensor products.

The technique of multiplication by blocks is especially useful if one of the matrices has a rectangular block of zeroes. Here is a sample application, which will be used in the proof of the Implicit Function Theorem of vector calculus:

**III.11.1.24. Proposition.** Let $n, n_1, n_2 \in \mathbb{N}$ with $n = n_1 + n_2$, $A$ an $n_1 \times n_1$ matrix, and $B$ an $n_1 \times n_2$ matrix. Then the $n \times n$ matrix

$$C = \begin{bmatrix} A & B \\ 0 & I \end{bmatrix}$$

(where the 0 is an $n_2 \times n_1$ block and $I$ is $n_2 \times n_2$ identity matrix) is invertible if and only if $A$ is invertible, and in this case

$$C^{-1} = \begin{bmatrix} A^{-1} & -A^{-1}B \\ 0 & I \end{bmatrix}.$$
Proof: It is easily checked by multiplication by blocks that if \( A \) is invertible, then the formula gives an
inverse for \( C \). Conversely, suppose \( C \) is invertible and
\[
C^{-1} = \begin{bmatrix} X & Y \\ Z & W \end{bmatrix}
\]
with blocks of the same size as in \( C \). We then have
\[
\begin{bmatrix} A & B \\ 0 & I \end{bmatrix} \begin{bmatrix} X & Y \\ Z & W \end{bmatrix} = \begin{bmatrix} AX + BZ & AY + BW \\ Z & W \end{bmatrix} = \begin{bmatrix} I & 0 \\ 0 & I \end{bmatrix}
\]
and comparing entries, we get \( Z = 0, W = I, X = A^{-1}, Y = -A^{-1}B \).

Systems of Linear Equations

As an example of the utility of using matrix notation, we briefly review the theory of systems of linear
equations.

III.11.1.25. A system of \( m \) linear equations in \( n \) unknowns over \( F \) is of the form
\[
a_{11}x_1 + a_{12}x_2 + \cdots + a_{1n}x_n = b_1 \\
a_{21}x_1 + a_{22}x_2 + \cdots + a_{2n}x_n = b_2 \\
\vdots \\
a_{m1}x_1 + a_{m2}x_2 + \cdots + a_{mn}x_n = b_m
\]
where the \( a_{ij} \) and the \( b_j \) are given elements of \( F \), and \( x_1, \ldots, x_n \) are unknowns. The system is homogeneous
if all the \( b_j \) are 0. A solution is, of course, a set of values for the \( x_i \) in \( F \) satisfying the equations.

III.11.1.26. This system can be conveniently abbreviated in matrix form. If
\[
A = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{bmatrix}, \quad x = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix}, \quad b = \begin{bmatrix} b_1 \\ b_2 \\ \vdots \\ b_m \end{bmatrix}
\]
we can then compactly represent the system as the matrix equation
\[
Ax = b
\]
where \( A \) is a given \( m \times n \) matrix, \( b \) a given column \( m \)-vector, and \( x \) an unknown column \( n \)-vector. This
clean formulation alone gives some justification for why matrix multiplication as we have defined it is useful.
But this is only the beginning of the utility.
III.11.1.27. We would expect to have a unique solution to the system if and only if \( m = n \); if \( m < n \) the system is “underdetermined” and we would expect many solutions, and if \( m > n \) we would expect that the system is “overdetermined” and that there is no solution in general. These answers are “usually” correct, but can fail if there are degeneracies in the system.

In the case \( m = n \), if the matrix \( A \) is invertible, the matrix form gives a way to find a solution (which turns out to be the unique solution for any \( b \)):

\[
x = A^{-1}b.
\]

We will examine the general theory after developing some linear algebra machinery ().

III.11.2. Vector Spaces
A vector space is simply an abstraction of Euclidean space \( \mathbb{R}^n \) with its essential algebraic structure. The two basic algebraic operations in \( \mathbb{R}^n \) are vector addition and scalar multiplication. Other algebraic operations such as the dot product will not be used at this point, but will be incorporated later.

Let \( \mathbb{F} \) be a field (usually \( \mathbb{R} \) or \( \mathbb{C} \) in analysis applications), called the field of scalars, which is fixed throughout the discussion. A vector space over \( \mathbb{F} \) will be a set equipped with an addition and a scalar multiplication satisfying a list of natural algebraic properties. Specifically:

III.11.2.1. Definition. A vector space over \( \mathbb{F} \) is a set \( V \) with two binary operations \( + : V \times V \to V \) (written \( (x, y) = x + y \)) and \( \cdot : \mathbb{F} \times V \to V \) (written \( (\alpha, x) = \alpha \cdot x \) or usually just \( \alpha x \)) satisfying:

- **(A1)** The binary operation \( + \) is associative: \( x + (y + z) = (x + y) + z \) for all \( x, y, z \in V \).
- **(A2)** The binary operation \( + \) is commutative: \( x + y = y + x \) for all \( x, y \in V \).
- **(A3)** There is an element \( 0 \in V \) such that \( 0 + x = x \) for all \( x \in V \).
- **(A4)** For every \( x \in V \) there is an element \( -x \in V \) with \( x + (-x) = 0 \).
- **(M1)** The binary operation \( \cdot \) is associative: \( \alpha (\beta x) = (\alpha \beta) x \) for all \( \alpha, \beta \in \mathbb{F}, x \in V \).
- **(M2)** The binary operation \( \cdot \) is distributive: \( \alpha (x + y) = \alpha x + \alpha y \) and \( (\alpha + \beta) x = \alpha x + \beta x \) for all \( \alpha, \beta \in \mathbb{F}, x, y \in V \).
- **(M3)** \( 1 \cdot x = x \) for all \( x \in V \).

If \( R \) is a ring, a set with two operations satisfying these axioms is called a left \( R \)-module. Thus a vector space is just a left module over a field.

III.11.2.2. Examples. (i) If \( n \in \mathbb{N} \), then the set \( \mathbb{F}^n \) of \( n \)-tuples of elements of \( \mathbb{F} \), with coordinatewise addition and scalar multiplication, is a vector space over \( \mathbb{F} \). This is the prototype example. It will turn out that any finite-dimensional vector space over \( \mathbb{F} \) is essentially identical to this example for a unique \( n \).

(ii) Let \( m, n \in \mathbb{N} \). The set \( M_{m,n}(\mathbb{F}) \) of \( m \times n \) matrices over \( \mathbb{F} \), with matrix addition and scalar multiplication, is a vector space over \( \mathbb{F} \). This vector space has a natural identification with \( \mathbb{F}^{mn} \) by writing the entries of the matrix in a single string in a fixed order.
(iii) Here is a general example including (i) and (ii) as a special case: let $X$ be a set and $V$ the set of all functions from $X$ to $\mathbb{F}$. Define addition and scalar multiplication pointwise: if $f, g \in V$ and $\alpha \in \mathbb{F}$, set $(f+g)(x) = f(x)+g(x)$ and $(\alpha f)(x) = \alpha f(x)$ (where the operations on the right-hand sides are the operations in $\mathbb{F}$). Example (i) is the case where $X = \{1, \ldots, n\}$ and example (ii) is the case $X = \{1, \ldots, m\} \times \{1, \ldots, n\}$.

(iv) Let $P$ be the set of all polynomials with coefficients in $\mathbb{F}$, expressions of the form

$$f(x) = a_0 + a_1 x + a_2 x^2 + \cdots + a_n x^n$$

where the $a_k \in \mathbb{F}$ and the $n$ may vary from polynomial to polynomial. Add polynomials formally in the usual way by collecting together terms with the same power of $x$, and multiply by scalars termwise. Then $P$ is a vector space over $\mathbb{F}$.

(v) Let $[a, b]$ be an interval in $\mathbb{R}$, and $C([a, b])$ the set of continuous functions from $[a, b]$ to $\mathbb{R}$. Add functions and multiply by scalars pointwise in the usual way, as in (iii) (a theorem is needed to show that $C([a, b])$ is closed under these operations). Then $C([a, b])$ is a vector space over $\mathbb{R}$.

Example (v) has many variations which are important in analysis.

III.11.2.3. In some of these examples, there is a natural multiplication defined on pairs of elements of the vector space which is compatible (bilinear) with scalar multiplication. This multiplication is not part of the vector space structure. A vector space over $\mathbb{F}$ with a compatible multiplication is called an algebra over $\mathbb{F}$. $M_n(\mathbb{F})$ and $P$ are typical examples of algebras over $\mathbb{F}$. $C([a, b])$ is an algebra over $\mathbb{R}$.

III.11.2.4. There are two important points which must be emphasized about the definition of a vector space. First, the operations of addition and scalar multiplication are part of the definition and must be specified; thus it is technically incorrect to make a statement such as “Let $V$ be a vector space over $\mathbb{F}$.” But we do this all the time when the operations in $V$ are understood, such as in these examples or variations of them.

Secondly, the field of scalars must be specified; it is incorrect to say “Let $V$ be a vector space.” (We often do this too, but the field of scalars must be understood.) There is a variation of this point which must be kept in mind: if $V$ is a vector space over $\mathbb{C}$, then since $\mathbb{R} \subseteq \mathbb{C}$ we can restrict scalar multiplication to $\mathbb{R}$ and obtain a real vector space (vector space over $\mathbb{R}$). Some references thus state:

“A complex vector space is a real vector space.”

From a logical standpoint, however, this statement is meaningless: real vector spaces and complex vector spaces are distinct mathematical structures and it does not make sense to mix them. A more careful and logically correct way of phrasing this statement is:

“A complex vector space has a unique underlying structure as a real vector space.”

The situation is similar to the corresponding relation between metric spaces and topological spaces (I). The same considerations apply to any other field and subfield (e.g. $\mathbb{Q} \subseteq \mathbb{R}$).
Elements of a vector space are typically called points or vectors. This terminology does not carry with it any necessary geometric interpretation. In fact, general vector spaces do not have any natural geometric interpretation. But the quasi-geometric language used is well established, and can be useful in motivating results, although care must be exercised in proofs not to use anything beyond what simply follows from the axioms.

The standard algebraic properties similar to those of \( \mathbb{R} \) are consequences of the axioms. Here are some of the most important ones:

**Proposition.** Let \( V \) be a vector space over \( F \). Then

(i) \( 0x = 0 \) for all \( x \in V \).

(ii) If \( \alpha \in F \) and \( x \in V \), then \( \alpha x = 0 \) if and only if \( \alpha = 0 \) or \( x = 0 \).

(iii) If \( x, y, z \in V \) and \( x + z = y + z \), then \( x = y \).

(iv) If \( \alpha \in F, \alpha \neq 0, \) and \( x, y \in V, \) and \( \alpha x = \alpha y, \) then \( x = y \).

(v) \( (-1)x = -x \) for all \( x \in V \).

**Isomorphism of Vector Spaces**

As is usual in mathematics, we need a precise specification of when two vector spaces are abstractly the “same.” The obvious criterion is:

**Definition.** Let \( V \) and \( W \) be vector spaces over \( F \). A function \( T : V \to W \) is an isomorphism (of vector spaces over \( F \)) if \( T \) is a bijection which is linear, i.e. respects addition and scalar multiplication:

\[
T(x + y) = T(x) + T(y)
\]

\[
T(\alpha x) = \alpha T(x)
\]

for all \( x, y \in V, \alpha \in F \). \( V \) and \( W \) are isomorphic (as vector spaces over \( F \)) if there is an isomorphism from \( V \) to \( W \).

**Definition.** Let \( V \) and \( W \) be vector spaces over \( F \). A subset \( W \) of \( V \) is a vector subspace or linear subspace (often just called a subspace) if \( W \) is itself a vector space under the same operations of \( V \).

If \( W \) is a vector subspace of \( V \), the definition entails that \( W \) is closed under addition and scalar multiplication, i.e. if \( x, y \in W \) and \( \alpha \in F \), then \( x + y \) and \( \alpha x \) are in \( W \). \( W \) is also nonempty since \( 0 \in W \). These are sufficient:
III.11.2.10. Proposition. Let $\mathcal{V}$ be a vector space over $\mathbb{F}$, and $\mathcal{W} \subseteq \mathcal{V}$. Then $\mathcal{W}$ is a vector subspace of $\mathcal{V}$ if and only if $\mathcal{W}$ is nonempty and closed under addition and scalar multiplication.

Proof: Necessity has been observed. Conversely, suppose $\mathcal{W}$ is nonempty and closed under addition and scalar multiplication. Axioms (A1), (A2), and (M1)–(M3) are automatic in $\mathcal{W}$ since they hold in $\mathcal{V}$. If $x \in \mathcal{W}$, then $0x = 0 \in \mathcal{W}$, so (A3) holds. And if $x \in \mathcal{W}$, then $-x = (-1)x \in \mathcal{W}$, so (A4) holds.

III.11.2.11. Examples. (i) If $\mathcal{V}$ is any vector space, then $\mathcal{V}$ and $\{0\}$ are vector subspaces of $\mathcal{V}$. These are called the trivial subspaces.

(ii) Let $\mathcal{V}$ be a vector space over $\mathbb{F}$, and $x \in \mathcal{V}$. Then

$$\{\alpha x : \alpha \in \mathbb{F}\}$$

is a vector subspace of $\mathcal{V}$. If $x \neq 0$, this is called the one-dimensional subspace of $\mathcal{V}$ spanned by $x$. This example will be generalized in III.11.2.14.

(iii) Let $\mathcal{V}$ be the set of all functions from $[a,b]$ to $\mathbb{R}$. Then $\mathcal{V}$ is a real vector space as in III.11.2.2 (iii). Then $C([a,b])$ (III.11.2.2.(v)) is a vector subspace of $\mathcal{V}$.

Span of a Subset, Linear Combinations

III.11.2.12. It is obvious that an arbitrary intersection of vector subspaces of a vector space $\mathcal{V}$ over $\mathbb{F}$ is a vector subspace (the intersection is nonempty since every subspace contains $0$). Thus, if $S$ is any subset of $\mathcal{V}$, the intersection of all subspaces of $\mathcal{V}$ containing $S$ is a subspace of $\mathcal{V}$ which is the smallest subspace of $\mathcal{V}$ containing $S$. (Note that there is at least one subspace of $\mathcal{V}$ containing $S$, $\mathcal{V}$ itself.) This smallest subspace is called the span of $S$, denoted $span(S)$. We say $S$ spans $\mathcal{V}$ if $span(S) = \mathcal{V}$.

There is a concrete description of $span(S)$ using the notion of linear combination:

III.11.2.13. Definition. Let $\mathcal{V}$ be a vector space over $\mathbb{F}$, and $x_1, \ldots, x_n \in \mathcal{V}$. A linear combination ($\mathbb{F}$-linear combination) of $\{x_1, \ldots, x_n\}$ is a vector of the form

$$\alpha_1 x_1 + \alpha_2 x_2 + \cdots + \alpha_n x_n$$

where the $\alpha_k$ are in $\mathbb{F}$.

If $S$ is an arbitrary nonempty subset of $\mathcal{V}$, then a linear combination of $S$ is a vector which is a linear combination of a set of vectors in $S$. The set of linear combinations of $\emptyset$ is defined to be $\{0\}$.

Note that even if $S$ is infinite, a linear combination of $S$ is a linear combination of a finite subset of $S$, i.e. an individual linear combination involves only finitely many elements of $S$.

III.11.2.14. Proposition. Let $\mathcal{V}$ be a vector space over $\mathbb{F}$, and $S \subseteq \mathcal{V}$. Then $span(S)$ is precisely the set $Lin(S)$ of linear combinations of $S$.

Proof: Any vector in $S$ is trivially in $Lin(S)$, and every linear combination of $S$ is in any vector subspace containing $S$. Thus $S \subseteq Lin(S) \subseteq span(S)$. So it suffices to note that $Lin(S)$ is a vector subspace of $\mathcal{V}$. It is obvious that $0 \in Lin(S)$, and that a sum or scalar multiple of linear combinations of $S$ is again a linear combination of $S$. 

$\Box$
III.11.2.15. Proposition. Let $V$ be a vector space over $F$, and $S \subseteq V$. If $x_0 \in S$ and $x_0$ can be written as a linear combination of other vectors in $S$, then $\text{span}(S \setminus \{x_0\}) = \text{span}(S)$.

Proof: Suppose $x_0 = \alpha_1 x_1 + \cdots + \alpha_n x_n$ with $\alpha_1, \ldots, \alpha_n \in F$ and $x_1, \ldots, x_n \in S \setminus \{x_0\}$. Let $x \in \text{span}(S)$. Then $x = \beta_1 y_1 + \cdots + \beta_m y_m$ for some $y_1, \ldots, y_m \in S$ and $\beta_1, \ldots, \beta_m \in F$. By collecting together terms, we may assume all the $y_i$ are distinct. If none of the $y_i$ are equal to $x_0$, then $x$ is already written as a linear combination of $S \setminus \{x_0\}$. If $y_i = x_0$ for some $i$, by reordering we may assume $i = 1$. Then

$$x = \beta_1 (\alpha_1 x_1 + \cdots + \alpha_n x_n) + \beta_2 y_2 + \cdots + \beta_m y_m$$

and $x$ is again in $\text{span}(S \setminus \{x_0\})$.

III.11.2.16. Definition. Let $V$ be a vector space over $F$. $V$ is finite-dimensional if there is a finite subset of $V$ which spans $V$.

III.11.2.17. Examples. (i) $F^n$ is spanned by $\{e_1, \ldots, e_n\}$, where $e_k = (0, \ldots, 0, 1, 0, \ldots, 0)$, with the 1 in the $k$’th place. (This set of vectors is called the standard basis of $F^n$). Thus $F^n$ is finite-dimensional.

(ii) The vector space $\mathcal{P}$ of all polynomials over $F$ (III.11.2.2.(iv)) is not finite-dimensional, since a finite set of polynomials has a maximal degree and no linear combination of the finite set of polynomials can have greater degree. The countable set $\{1, x, x^2, \ldots\}$ does span $\mathcal{P}$.

It is a little harder to show that Example III.11.2.2.(v), and III.11.2.2.(iii) for infinite $X$, are not finite-dimensional (this follows from III.11.2.30.(iv) in both cases; cf. III.11.2.21.(iv)).

Linear Independence

III.11.2.18. Definition. Let $V$ be a vector space over $F$, and $S$ a subset of $V$. Then $S$ is linearly independent (over $F$) if no vector in $S$ is a linear combination of the other vectors in $S$.

In other words, $S$ is linearly independent if it has no “redundancy,” i.e. no proper subset of $S$ has the same span as $S$: every vector in $S$ makes an essential contribution to the span. Since the zero vector is in the span of $\emptyset$, no linearly independent set can contain the zero vector.

The empty set is vacuously linearly independent.

A convenient rephrasing is:

III.11.2.19. Proposition. Let $V$ be a vector space over $F$, and $S \subseteq V$. The following are equivalent:

(i) $S$ is linearly independent.

(ii) Whenever $x_1, \ldots, x_n \in S$ and $\alpha_1, \ldots, \alpha_n \in F$, and

$$\alpha_1 x_1 + \cdots + \alpha_n x_n = 0$$

then $\alpha_1 = \cdots = \alpha_n = 0$. 381
(iii) Every nonzero vector in \( \text{span}(S) \) can be written as a linear combination of vectors in \( S \) with nonzero coefficients in a unique way.

The uniqueness in (iii) must be expressed carefully; additional terms with coefficients 0 may be added to the sum without changing the vector represented.

**Proof:** (i) \( \Rightarrow \) (ii): Suppose \( x_1, \ldots, x_n \in S \), \( \alpha_1, \ldots, \alpha_n \in \mathbb{F} \), and \( \alpha_1 x_1 + \cdots + \alpha_n x_n = 0 \) with not all \( \alpha_k = 0 \). By reordering, we may assume \( \alpha_1 \neq 0 \). Then we have

\[
x_1 = -\frac{\alpha_2}{\alpha_1} x_2 - \cdots - \frac{\alpha_n}{\alpha_1} x_n
\]

so \( S \) is not linearly independent.

(ii) \( \Rightarrow \) (iii): Suppose, for some \( x \in \text{span}(S) \),

\[
x = \alpha_1 x_1 + \cdots + \alpha_n x_n = \beta_1 x_1 + \cdots + \beta_n x_n
\]

with \( \alpha_k \neq \beta_k \) for some \( k \). Then

\[
(\alpha_1 - \beta_1) x_1 + \cdots + (\alpha_n - \beta_n) x_n = 0
\]

with \( \alpha_k - \beta_k \neq 0 \), so (ii) does not hold.

(iii) \( \Rightarrow \) (i): If \( x \in S \) were a linear combination \( x = 1x = \alpha_1 x_1 + \cdots + \alpha_n x_n \) with \( x_k \neq x \) for all \( k \), then \( x \) would be a linear combination of vectors in \( S \) in a nonunique way.

\( \blacklozenge \)

**III.11.2.20.** A sum \( \alpha_1 x_1 + \cdots + \alpha_n x_n = 0 \) as in (ii) with \( x_1, \ldots, x_n \in S \) and \( \alpha_1, \ldots, \alpha_n \in \mathbb{F} \) not all zero is called a linear dependence (or linear relation) in \( S \) (over \( \mathbb{F} \)), and a set with a linear dependence (i.e. a set which is not linearly independent) is called linearly dependent.

**III.11.2.21.** Examples. (i) A set \( \{x\} \) of one vector in a vector space \( V \) is linearly independent if and only if \( x \neq 0 \).

(ii) If \( \{x, y\} \) is a subset of \( V \) with \( x \neq y \), then \( \{x, y\} \) is linearly independent in \( V \) if and only if \( x \) is nonzero and \( y \) is not a scalar multiple of \( x \). (The condition is symmetric in \( x \) and \( y \).)

(iii) It is harder to tell by inspection whether a set of three or more vectors is linearly independent, since the set can be linearly dependent even if no vector in the set is a scalar multiple of another. For example, it is easily seen that

\[
\{(1,0), (0,1), (1,1)\}
\]

is linearly dependent in \( \mathbb{R}^2 \) since the third vector is the sum of the first two.

(iv) In Example III.11.2.2, (iv) or (v), let \( f_n(x) = x^n \). It is easy to verify that \( \{f_n : n \in \mathbb{N}\} \) is linearly independent in each case. In case (iv) this set spans the vector space, and in (v) it does not.
Bases

III.11.2.22. **DEFINITION.** Let $V$ be a vector space over $F$. A *basis* for $V$ (over $F$) is a linearly independent set of vectors in $V$ which spans $V$.

A basis is a set of vectors which is “just large enough” to span $V$ yet small enough to contain no redundancies. If $B$ is a basis for $V$, then no smaller subset of $V$ spans $V$ and no larger subset of $V$ is linearly independent, i.e. $B$ is a maximal linearly independent subset of $V$.

The plural of *basis* is *bases*. The plural of *base* is spelled the same way but pronounced differently.

III.11.2.23. Bases are especially important in finite-dimensional vector spaces, where they can be regarded as giving a “coordinate system.” They are of less crucial importance in infinite-dimensional vector spaces. Certain infinite-dimensional topological vector spaces have other basis-like sets (where “linear combinations” involve infinite series) which are a more useful substitute. In infinite-dimensional vector spaces a basis in the linear algebra sense (i.e. in the sense of III.11.2.22.) is often called a *Hamel basis* to distinguish the concept from the other one.

III.11.2.24. **PROPOSITION.** Let $V$ be a vector space over $F$. A subset $B$ of $V$ is a basis for $V$ if and only if $B$ is a maximal linearly independent subset.

**Proof:** It has already been observed that a basis is a maximal linearly independent subset. On the other hand, suppose $B$ is a maximal linearly independent set in $V$, and $x \in V$. If $x \notin \text{span}(B)$, then $S \cup \{x\}$ is linearly independent, contradicting maximality of $S$. Thus $\text{span}(B) = V$ and $B$ is a basis for $V$.

III.11.2.25. **EXAMPLES.** (i) Let $V = F^n$ as a vector space over $F$. Then the set of standard basis vectors $\{e_1, \ldots, e_n\}$ is a basis for $F^n$: if $x = (\alpha_1, \ldots, \alpha_n) \in F^n$, then

$$(\alpha_1, \ldots, \alpha_n) = \alpha_1 e_1 + \cdots + \alpha_n e_n$$

is the unique expression of $x$ as a linear combination of $\{e_1, \ldots, e_n\}$.

(ii) One can give completely different bases for $F^n$. For example, a simple calculation shows that

$$\begin{align*}
x_1 &= (1, -1, 0, \ldots, 0) \\
x_2 &= (0, 1, -1, \ldots, 0) \\
&\vdots \\
x_{n-1} &= (0, 0, \ldots, 1, -1) \\
x_n &= (-1, 0, 0, \ldots, 0, 1)
\end{align*}$$

forms a basis for $F^n$. (There are also *many* other bases, especially if $F$ is $\mathbb{R}$ or $\mathbb{C}$.)

(iii) The set $\{f_n : n \in \mathbb{N}\}$ (III.11.2.21.(iv)) is a basis for the vector space $P$ over $\mathbb{R}$ (III.11.2.2.(iv)).

383
\textbf{III.11.2.26.} Examples (i) and (ii) show that there is nothing unique about bases for a vector space; two bases may have no vectors in common. But it turns out (III.11.2.28.(iv)) that the number of vectors in any two bases for a vector space $V$ is always the same; this number is called the \textit{dimension} of $V$.

\textbf{III.11.2.27.} Elaborating further on Example III.11.2.25., if $V$ is a vector space over $\mathbb{F}$ with basis $B = \{x_1, \ldots, x_n\}$, then the (ordered) basis $B$ induces a natural one-one correspondence with $\mathbb{F}^n$:

$$(\alpha_1, \ldots, \alpha_n) \leftrightarrow \alpha_1 x_1 + \cdots + \alpha_n x_n$$

which respects vector addition and scalar multiplication (a \textit{vector space isomorphism}). Thus an ordered basis for $V$ can be regarded as a “coordinate system” in $V$. Indeed, a finite-dimensional abstract vector space over $\mathbb{F}$ can just be regarded as a copy of $\mathbb{F}^n$ for some $n$ with the “natural” coordinate system stripped away; choice of a basis specifies a coordinate system, with any such coordinate system as good as any other for most linear algebra purposes (if a linear operator is being considered, some coordinate systems may be more compatible with the operator than others; this will be discussed later).

\textbf{Fundamental Theorems of Linear Algebra}

It is not obvious that every vector space has a basis (in fact, in general, the Axiom of Choice is needed to prove this). The following blockbuster theorem shows that the situation is as nice as could be hoped for:

\textbf{III.11.2.28. \textsc{Theorem.}} Let $V$ be a vector space over $\mathbb{F}$. Then

(i) $V$ has a basis.

(ii) Every linearly independent subset of $V$ can be expanded to a basis for $V$.

(iii) Every spanning subset of $V$ contains a basis for $V$.

(iv) Any two bases for $V$ have the same cardinality (if $V$ is finite-dimensional, any two bases for $V$ have the same finite number of elements).

This theorem is elementary to prove if $V$ is finite-dimensional, but more delicate (requiring the AC) in the general case. We give the finite-dimensional proof here and defer the general proof until III.11.2.32. \textsc{Proof:} (Finite-dimensional case.) Clearly (ii) $\Rightarrow$ (i) (begin with $\emptyset$). To (partly) prove (ii), let $\{y_1, \ldots, y_m\}$ be a finite set which spans $V$, and let $\{x_1, \ldots, x_r\}$ be a finite linearly independent set in $V$. Set

$$S_1 = \{x_1, \ldots, x_r, y_1, \ldots, y_m\}$$

regarded as an ordered set. $S_1$ spans $V$, and is linearly dependent since each $x_i$ can be written as a linear combination of the $y_j$. Working from left to right, let $z_1$ be the first vector which can be written as a linear combination of the preceding ones. There must be such a $z_1$, and it must be one of the $y_j$ since the $x_i$ are linearly independent. Set $S_2 = S_1 \setminus \{z_1\}$. Then $\text{span}(S_2) = \text{span}(S_1) = V$ by III.11.2.15.. If $S_2$ is linearly independent, it is a basis containing $\{x_1, \ldots, x_r\}$; otherwise, repeat the process, letting $z_2$ be the first vector in the ordered set $S_2$ which can be written as a linear combination of the preceding vectors, and $S_3 = S_2 \setminus \{z_2\}$. Since $S_1$ is finite, we must reach a linearly independent set in a finite number of steps; this
set will be a basis for $V$ consisting of $x_1, \ldots, x_r$ and (in general) some, but not all, of the $y_j$. This argument proves (ii) for a finite linearly independent set, and thus the special case (i).

The argument for (iv) is similar. We will show a stronger statement: if $\{x_1, \ldots, y_n\}$ is a basis for $V$, and $\{x_1, \ldots, x_r\}$ is a linearly independent set in $V$, then $r \leq n$. This will show (iv) by symmetry, and also complete the proof of (ii) since it implies that any linearly independent set in $V$ is finite. Suppose $r > n$.

Set $S_1 = \{x_1, y_1, \ldots, y_n\}$, regarded as an ordered set. This set spans $V$ and is linearly dependent. Let $z_1$ be the first vector which can be written as a linear combination of the previous ones; then $z_1$ must be one of the $y_j$. Set

$$S_2 = \{x_2, x_1, y_1, \ldots, y_n\}$$

with $z_1 = y_j$ removed. Then $\text{span}(S_2) = \text{span}(S_1) = V$, and $S_2$ is linearly dependent since $x_2 \in \text{span}(S_1 \setminus \{z_1\}) = V$. Repeat the process. At each stage another $x_k$ is added and a $y_j$ is removed; thus after $n$ steps we have $S_n \setminus \{z_n\} = \{x_n, \ldots, x_1\}$, and this set spans $V$, contradicting that $x_{n+1}$ is not a linear combination of $\{x_1, \ldots, x_n\}$. Thus $r \leq n$.

Finally, we show (iii). Let $S$ be a set which spans $V$, and $\{y_1, \ldots, y_n\}$ a basis for $V$. Each $y_j$ can be written as a linear combination of a finite number of vectors in $S$; hence there is a finite subset of $S$ whose span includes all the $y_j$, hence is $V$. Thus we may assume $S$ is finite. List the elements of $S$ and successively eliminate any vector which can be written as a linear combination of the preceding ones. Each reduced set will still span $V$ by III.11.2.15. In a finite number of steps a linearly independent set will be reached, which is a basis for $V$.

\[\square\]

III.11.2.29. Definition. Let $V$ be a vector space over $F$. The (linear) dimension of $V$, denoted $\text{dim}(V)$, is the cardinality of a basis of $V$.

The dimension of $V$ is well defined by III.11.2.28.(iv), and is finite (a natural number) if and only if $V$ is finite-dimensional in the sense of III.11.2.16. We sometimes write $\text{dim}_F(V)$ to emphasize the field we are working over (cf. III.11.2.33).

We note the following corollary of the finite-dimensional version of III.11.2.28.

III.11.2.30. Corollary. Let $V$ be a finite-dimensional vector space over $F$, with $\text{dim}(V) = n$. Then

(i) If $\{x_1, \ldots, x_r\}$ is a linearly independent set of vectors in $V$, then $r \leq n$.

(ii) If $S = \{x_1, \ldots, x_n\}$ is a linearly independent set of vectors in $V$, then $S$ spans $V$ (i.e. is a basis for $V$).

(iii) If $\{x_1, \ldots, x_r\}$ spans $V$, then $r \geq n$.

(iv) If $S = \{x_1, \ldots, x_n\}$ is a set of vectors in $V$ which spans $V$, then $S$ is linearly independent (i.e. is a basis for $V$).

(v) If $W$ is a vector subspace of $V$, then $\text{dim}(W) \leq \text{dim}(V)$; $\text{dim}(W) = \text{dim}(V)$ if and only if $W = V$. In particular, any subspace of $V$ is finite-dimensional.

Proof: (i)–(iv) are obvious from III.11.2.28. For (v), suppose $\text{dim}(W) > n$ (or $W$ is not finite-dimensional). Then (without any form of AC) we can choose a set $S = \{x_1, \ldots, x_{n+1}\}$ in $W$ which is linearly independent [let
$x_1$ be any nonzero vector in $W$, and successively choose $x_{k+1}$ to be a vector not in the span of $\{x_1, \ldots, x_k\}$. Then $S$ is a linearly independent subset of $V$, contradicting (i). If $\dim(W) = n$, apply (ii) to a basis for $W$. 

**III.11.2.31. Theorem.** Two vector spaces over $\mathbb{F}$ are isomorphic if and only if they have the same dimension. In particular, any $n$-dimensional vector space over $\mathbb{F}$ is isomorphic to $\mathbb{F}^n$.

**Proof:** Let $V$ and $W$ be vector spaces over $\mathbb{F}$ of the same dimension, and let $B$ and $C$ be bases for $V$ and $W$ respectively. Let $\psi : B \to C$ be a bijection. Extend $\psi$ to a bijection $\phi : V \to W$ as follows. If $x \in V$, then $x$ can be written uniquely as

$$x = \alpha_1 x_1 + \cdots + \alpha_n x_n$$

with $\alpha_1, \ldots, \alpha_n \in \mathbb{F}$, all nonzero, and $x_1, \ldots, x_n \in B$. Define

$$\phi(x) = \alpha_1 \psi(x_1) + \cdots + \alpha_n \psi(x_n).$$

Then $\phi$ is well defined and one-to-one since $C$ is linearly independent. If $y \in W$, then

$$y = \alpha_1 y_1 + \cdots + \alpha_m y_m$$

for some $\alpha_1, \ldots, \alpha_m \in \mathbb{F}$ and $y_1, \ldots, y_m \in C$; if $y_j = \psi(x_j)$ for each $j$, then $y = \phi(x)$, where

$$x = \alpha_1 x_1 + \cdots + \alpha_m x_m.$$ 

So $\phi$ is surjective. It is routine to check that $\phi$ is linear.

**III.11.2.32.** We now prove the general version of Theorem III.11.2.28. This proof requires the Axiom of Choice (in fact, (i)–(iii) may each be equivalent to AC; (iv) only needs a weaker version of Choice).

**Proof:** We again begin by proving (ii), which clearly implies (i) as before. Let $S$ be a linearly independent subset of $V$. Let $\mathcal{X}$ be the collection of all linearly independent subsets of $V$ containing $S$, ordered by inclusion. If $\{X_i : i \in I\}$ is a chain in $\mathcal{X}$, then $X = \cup_i X_i$ is a linearly independent subset of $V$, since a linear dependence involves only finitely many vectors and any finite subset of $X$ is contained in some $X_i$. Thus $X \in \mathcal{X}$, and $X$ is an upper bound for $\{X_i : i \in I\}$. By Zorn’s Lemma, $\mathcal{X}$ contains a maximal element $B$. As in III.11.2.24., $B$ is a basis for $V$ containing $S$.

The proof of (iii) is similar. Let $S$ be a set which spans $V$. Let $\mathcal{X}$ be the collection of all linearly independent subsets of $S$, ordered by inclusion. As before, Zorn’s Lemma applies to give a maximal element $B$ of $\mathcal{X}$. As in the proof of III.11.2.24., if $\text{span}(B)$ is not all of $V$, it cannot contain all of $S$ since $S$ spans $V$; if $x \in S \setminus \text{span}(B)$, then $B \cup \{x\}$ is linearly independent, contradicting maximality of $B$. Thus $B$ is a basis for $V$.

The proof of (iv) is more complicated. Suppose $\{x_i : i \in I\}$ and $\{y_j : j \in J\}$ are bases for $V$. We may assume $I$ and $J$ are infinite since the finite case has already been proved. Let $\kappa = \text{card}(I)$ and $\lambda = \text{card}(J)$. Each $x_i$ is a linear combination of finitely many $y_j$, and every $y_j$ occurs in one of these finite sets, or otherwise all the $x_i$ would be contained in the proper subspace of $V$ spanned by a proper subset of the $y_j$. Thus $\{y_j : j \in J\}$ is a union of $\kappa$ finite subsets, so $\lambda \leq 8^n \kappa = \kappa$ since $\kappa$ is infinite (II.9.7.4.). Symmetrically, $\kappa \leq \lambda$. Thus $\kappa = \lambda$ by the Schröder-Bernstein Theorem.
III.11.2.33. When the same set is regarded as a vector space over more than one field, the notions of span, linear independence, basis, and dimension are dependent on the choice of base field. For example, \( \mathbb{C}^n \) may be regarded as an \((n\text{-dimensional})\) vector space over \( \mathbb{C} \), or as a vector space over \( \mathbb{R} \) by restriction of scalar multiplication. The standard basis \( \{e_1, \ldots, e_n\} \) is indeed a basis for \( \mathbb{C}^n \) over \( \mathbb{C} \). This set is linearly independent over \( \mathbb{R} \), but not a basis for \( \mathbb{C}^n \) over \( \mathbb{R} \); in fact, its real span is the real vector subspace \( \mathbb{R}^n \) of \( \mathbb{C}^n \). On the other hand, the set 
\[
\{e_1, \ldots, e_n, i e_1, \ldots, i e_n\}
\]
is linearly independent over \( \mathbb{R} \) but not over \( \mathbb{C} \). It is easily checked that this set is a basis for \( \mathbb{C}^n \) over \( \mathbb{R} \), and thus \( \dim_{\mathbb{R}}(\mathbb{C}^n) = 2n \).

Complementary Subspaces

III.11.2.34. Definition. Let \( \mathcal{V} \) be a vector space over \( \mathbb{F} \). Two subspaces \( \mathcal{W}_1 \) and \( \mathcal{W}_2 \) of \( \mathcal{V} \) are complementary if \( \mathcal{W}_1 \cap \mathcal{W}_2 = \{0\} \) and \( \text{span}(\mathcal{W}_1 \cup \mathcal{W}_2) = \mathcal{V} \). \( \mathcal{W}_2 \) is complementary to \( \mathcal{W}_1 \) and vice versa.

This definition is symmetric in \( \mathcal{W}_1 \) and \( \mathcal{W}_2 \). But we often talk about subspaces complementary to a given subspace.

III.11.2.35. There is nothing remotely unique about complementary subspaces to a given subspace. For example, if \( \mathcal{W} \) is any one-dimensional subspace of \( \mathbb{R}^2 \), then any one-dimensional subspace of \( \mathbb{R}^2 \) not equal to \( \mathcal{W} \) is complementary to \( \mathcal{W} \).

III.11.2.36. Proposition. Let \( \mathcal{V} \) be a vector space over \( \mathbb{F} \), and \( \mathcal{W}_1 \) and \( \mathcal{W}_2 \) subspaces of \( \mathcal{V} \). Then \( \mathcal{W}_1 \) and \( \mathcal{W}_2 \) are complementary subspaces of \( \mathcal{V} \) if and only if every vector \( x \in \mathcal{V} \) can be uniquely written as \( x = x_1 + x_2 \), with \( x_j \in \mathcal{W}_j \).

Proof: If \( x \in \text{span}(\mathcal{W}_1 \cup \mathcal{W}_2) \), then \( x \) can be written as
\[
x = \alpha_1 y_1 + \cdots + \alpha_n y_n + \beta_1 z_1 + \cdots + \beta_m z_m
\]
with \( y_1, \ldots, y_n \in \mathcal{W}_1 \) and \( z_1, \ldots, z_m \in \mathcal{W}_2 \). If \( x_1 = \alpha_1 y_1 + \cdots + \alpha_n y_n \) and \( x_2 = \beta_1 z_1 + \cdots + \beta_m z_m \), then \( x_j \in \mathcal{W}_j \) and \( x = x_1 + x_2 \). Thus every vector in \( \mathcal{V} \) can be so written if and only if \( \text{span}(\mathcal{W}_1 \cup \mathcal{W}_2) = \mathcal{V} \). Suppose \( \mathcal{W}_1 \cap \mathcal{W}_2 = \{0\} \), and \( x = x_1 + x_2 = y_1 + y_2 \) with \( x_j, y_j \in \mathcal{W}_j \). Then \( x_1 - y_1 = x_2 - y_2 \); the left side is in \( \mathcal{W}_1 \) and the right side is in \( \mathcal{W}_2 \), so both sides are in \( \mathcal{W}_1 \cap \mathcal{W}_2 \). Hence both sides are zero and the representation of \( x \) is unique. Conversely, if \( x \in \mathcal{W}_1 \cap \mathcal{W}_2 \), then \( x = x + 0 = 0 + x \) gives a nonunique decomposition unless \( x = 0 \).

III.11.2.37. Corollary. Let \( \mathcal{V} \) be a vector space over \( \mathbb{F} \), and \( \mathcal{W}_1 \) and \( \mathcal{W}_2 \) be subspaces of \( \mathcal{V} \), \( B_j \) a basis for \( \mathcal{W}_j \), and \( B = B_1 \cup B_2 \). Then

(i) \( \mathcal{W}_1 \cap \mathcal{W}_2 = \{0\} \) if and only if \( B \) is linearly independent.

(ii) \( \mathcal{W}_1 \cup \mathcal{W}_2 \) spans \( \mathcal{V} \) if and only if \( B \) spans \( \mathcal{V} \).

(iii) \( \mathcal{W}_1 \) and \( \mathcal{W}_2 \) are complementary if and only if \( B \) is a basis for \( \mathcal{V} \).

387
In particular, if $W_1$ and $W_2$ are complementary, then $\dim(W_1) + \dim(W_2) = \dim(V)$.

This suggests a method of proof of the following theorem, which is the main result on this topic:

**III.11.2.38. Theorem.** Let $V$ be a vector space over $F$, and $W$ a subspace of $V$. Then there is a subspace of $V$ complementary to $W$.

**Proof:** This is an easy consequence of Theorem III.11.2.28. (thus it is elementary if $V$ is finite-dimensional, and requires AC in general). Let $S$ be a basis for $W$, and $B$ a basis for $V$ containing $S$. Then the span of $B \setminus S$ is a subspace of $V$ complementary to $W$, as is easily checked.

There is an alternate direct proof of this theorem using Zorn's Lemma (Exercise ()).

**III.11.2.39.** From a theoretical point of view, this theorem is a fundamental fact; it is the essential feature distinguishing the theory of vector spaces from the theory of modules over rings. In fact, it is precisely the failure of this result for modules over a ring which is not a field that makes module theory considerably more complicated (and more interesting!) than the theory of vector spaces.

Two ways to rephrase this result are:

- Every subspace of a vector space is a direct summand.
- Every short exact sequence of vector spaces splits.

See books on abstract algebra such as [DF04] for details.

**Quotient Spaces**

There is one remaining topic about vector spaces, which is somewhat more complicated conceptually than the results so far, and which is not usually treated in linear algebra texts: quotient spaces. This construction is used frequently in functional analysis.

**III.11.2.40.** Let $V$ be a vector space over $F$, and $W$ a subspace of $V$. Define a relation $\sim$ on $V$ by $x \sim y$ if $x - y \in W$.

**III.11.2.41. Proposition.**

(i) If $x, y, z \in V$, $x \sim y$, and $y \sim z$, then $x \sim z$ ($\sim$ is transitive).

(ii) If $x_1, x_2, y_1, y_2 \in V$, $x_1 \sim y_1$, and $x_2 \sim y_2$, then $x_1 + x_2 \sim y_1 + y_2$.

(iii) If $x, y \in V$, $\alpha \in F$, and $x \sim y$, then $\alpha x \sim \alpha y$. 

388
Proof: (i): we have $x - y \in W$ and $y - z \in W$, so
\[ x - z = (x - y) + (y - z) \in W. \]
(ii) is similar: $x_1 - y_1 \in W$ and $x_2 - y_2 \in W$, so
\[ (x_1 + x_2) - (y_1 + y_2) = (x_1 - y_1) + (x_2 - y_2) \in W. \]
The proof of (iii) is almost identical.

III.11.2.42. By (i), $\sim$ is an equivalence relation () since it is obviously reflexive and symmetric. Thus $V$ partitions into a disjoint union of equivalence classes (called cosets of $W$ in $V$). Denote by $V/W$ the set of equivalence classes, and for $x \in V$ let $[x]$ denote the equivalence class $\{y \in V : y \sim x\}$ of $X$.

By (ii), addition of equivalence classes by $[x] + [y] = [x + y]$ is well defined, and by (iii) scalar multiplication by $\alpha [x] = [\alpha x]$ is also well defined.

III.11.2.43. Proposition. With this addition and scalar multiplication, $V/W$ is a vector space over $F$.

Proof: To prove associativity of addition, if $x, y, z \in V$, we have
\[ ([x] + [y]) + [z] = [x + y] + [z] = [(x + y) + z] = [x + (y + z)] = [x] + [y + z] = [x] + ( [y] + [z]) . \]
The proofs of the other properties are similar.

III.11.2.44. Definition. The vector space $V/W$ is called the quotient vector space of $V$ by $W$. The dimension of $V/W$ is called the codimension of $W$ in $V$.

III.11.2.45. Examples. (i) Let $\mathbb{F} = \mathbb{R}, V = \mathbb{R}^2$, and $W$ the one-dimensional space spanned by $e_2 = (0, 1)$. If $x = (\alpha_1, \alpha_2) \in \mathbb{R}^2$, then the equivalence class of $x$ is
\[ [x] = \{(\alpha_1, \beta) : \beta \in \mathbb{R}\} . \]
Thus the equivalence classes are parametrized by their first coordinates, and there is a natural one-one correspondence of $\mathbb{R}^2/W$ with $\mathbb{R}^1$; this correspondence respects addition and scalar multiplication, so $\mathbb{R}^2/W \cong \mathbb{R}^1$.

(ii) Here is a more typical example of how quotient spaces are used in analysis. Let $X$ be an infinite set, and $V$ the vector space of all functions from $X$ to $\mathbb{F}$ (III.11.2.2. (iii)). Let $W$ be the subspace of all functions which are 0 except on a finite subset of $X$ (which may vary from function to function). It is easy to check that $W$ is a subspace of $V$. If $f, g \in V$, then $f \sim g$ if and only if the functions $f$ and $g$ agree “almost everywhere” (except on a finite subset of $X$), i.e.
\[ \{x \in X : f(x) \neq g(x)\} \]
is a finite subset of $X$. We can form the quotient vector space $V/W$, whose elements are equivalence classes of functions which agree “almost everywhere”; we often by slight abuse of terminology regard elements of $V/W$ as functions from $X$ to $\mathbb{F}$, with functions agreeing almost everywhere identified together.
III.11.2.46. There is a systematization of the identification in (i) using complementary subspaces which is sometimes useful. Let $V$ be a vector space and $W$ a subspace of $V$. Let $W'$ be a complementary subspace to $W$. For $x \in W'$, define $\phi(x) = [x] \in V/W$.

III.11.2.47. **Proposition.** The map $\phi: W' \to V/W$ is an isomorphism.

**Proof:** If $x \in V$, then $x$ can be written as $y + z$, with $y \in W$ and $z \in W'$. Then $x - z = y \in W$, so $[x] = [z] = \phi(z)$ and $\phi$ is surjective. If $x, y \in W'$ and $\phi(x) = [x] = [y] = \phi(y)$, then $x - y \in W$; since $x - y \in W'$, we have $x - y \in W \cap W' = \{0\}$, so $x = y$ and $\phi$ is injective. The fact that $\phi$ is linear follows immediately from the way addition and scalar multiplication in $V/W$ are defined. 

III.11.2.48. **Corollary.** If $V$ is finite-dimensional and $W$ is a subspace of $V$, then $V/W$ is finite-dimensional and $\dim(V/W) = \dim(V) - \dim(W)$. Thus the dimension of $W$ plus the codimension of $W$ in $V$ equals the dimension of $V$.

III.11.2.49. Even if $V$ and $W$ are infinite-dimensional, the codimension of $W$ in $V$ is well defined. Thus the last statement of III.11.2.48. is true in general, and we obtain the nonobvious general fact that any two subspaces of $V$ complementary to $W$ have the same dimension.

III.11.2.50. The identification in III.11.2.47. is important in principle, but it does not help much in understanding an example like III.11.2.45.(ii), since in this case there is no obvious explicitly describable subspace of $V$ which is complementary to $W$ (in fact, in general the AC must be employed to obtain a complement in this example).

**Summary**

III.11.3. **Linear Transformations**

It follows from the results of the last section that the theory of vector spaces over a field $F$ (especially finite-dimensional ones) is quite simple and not very interesting: the only isomorphism invariant is the dimension, and there are simple standard examples of vector spaces of each dimension.

The primary subject matter of linear algebra is not vector spaces themselves, but linear transformations between them. These form a much more complicated, and interesting, theory, which we outline in this section.

III.11.3.1. **Definition.** Let $V$ and $W$ be vector spaces over $F$. A function $T : V \to W$ is a **linear transformation** (linear function, linear operator) if $T$ respects addition and scalar multiplication:

$$T(x + y) = T(x) + T(y)$$
$$T(\alpha x) = \alpha T(x)$$

for all $x, y \in V, \alpha \in F$. 

390
III.11.3.2. The terms *linear transformation*, *linear function*, and *linear operator* are synonymous and interchangeable. We will usually use the term *linear transformation*, but often the term *(linear) operator* when $V = W$. The “linear” is often left out and understood when the term operator is used; nonlinear operators are also sometimes considered, but we will always qualify such operators explicitly as “nonlinear.”

Note that the field $\mathbb{F}$ must be specified in the definition of linearity. If there is any potential ambiguity about the field we are working over, we use the more precise term $\mathbb{F}$-linear in place of linear. For example, if $V$ and $W$ are vector spaces over $\mathbb{C}$, we distinguish between real-linear and complex-linear transformations (any complex-linear transformation is real-linear, but not conversely); in this setting, “linear” will normally mean “complex-linear”.

It is often customary to eliminate the parentheses around the argument of a linear transformation, i.e. to write $Tx$ in place of $T(x)$. We will try to avoid doing this, at least at first, in the interest of clarity, to emphasize that a linear transformation is a function.

The first simple observation is:

III.11.3.3. Proposition. Let $V$ and $W$ be vector spaces over $\mathbb{F}$, and $T : V \to W$ a linear transformation. Then $T(0) = 0$.

Proof: By linearity, we have $T(0) = T(0 \cdot 0) = 0 \cdot T(0) = 0$.

This is generalized in III.11.3.6.

III.11.3.4. Examples. (i) An isomorphism of vector spaces (III.11.2.7.) is a linear transformation.
(ii) If $V$ and $W$ are any vector spaces over $\mathbb{F}$, the constant function $0$ from $V$ to $W$ is linear.
(iii) Regard $\mathbb{F}$ as a one-dimensional vector space over $\mathbb{F}$. Let $T : \mathbb{F} \to \mathbb{F}$ be linear, and set $m = T(1)$. Then, for any $x \in \mathbb{F}$, we have $T(x) = T(x \cdot 1) = x \cdot T(1) = x \cdot m = mx$. Thus $T(x) = mx$ for some fixed $m \in \mathbb{F}$. Conversely, by the associative, commutative, and distributive laws in $\mathbb{F}$, any such function is linear.
(iv) Let $\mathcal{P}$ be the real vector space of polynomials with real coefficients. Define $D : \mathcal{P} \to \mathcal{P}$ by $D(f) = f'$. Elementary theorems of calculus (),(,) show that $D$ is a linear transformation.

III.11.3.5. Example (iii) for $\mathbb{F} = \mathbb{R}$ reveals an ambiguity in standard mathematical terminology. It is customary in calculus and precalculus to call a function $f : \mathbb{R} \to \mathbb{R}$ a “linear function” if it is of the form

$$f(x) = mx + b$$

for constants $m$ and $b$. But such a function is a linear function in the linear algebra sense if and only if $b = 0$. To resolve this ambiguity, we will usually call a function of the form $f(x) = mx + b$ an affine function rather than a linear function if $b \neq 0$, reserving the term “linear” for functions which are actually linear in the sense of III.11.3.1.

Null Space and Range

Linear transformations map subspaces to subspaces in the following sense:
III.11.3.6. **Proposition.** Let $V$ and $W$ be vector spaces over $F$, and let $T : V \to W$ be a linear transformation.

(i) Let $X$ be a subspace of $V$. Set 

$$T(X) = \{ T(x) : x \in X \} .$$

Then $T(X)$ is a subspace of $W$.

(ii) Let $Y$ be a subspace of $W$. Set 

$$T^{-1}(Y) = \{ x \in V : T(x) \in Y \} .$$

Then $T^{-1}(Y)$ is a subspace of $V$.

**Proof:**

(i) $T(X)$ is nonempty since $X$ is nonempty. Let $y_1, y_2 \in T(X)$. Then $y_1 = T(x_1)$ and $y_2 = T(x_2)$ for some $x_1, x_2 \in X$. Then $x_1 + x_2 \in X$, and 

$$T(x_1 + x_2) = T(x_1) + T(x_2) = y_1 + y_2 \in T(X)$$

since $T$ is linear. A similar argument shows that $T(X)$ is closed under scalar multiplication.

(ii): Since $T(0_V) = 0_W$ and $0_W \in Y$, $0_V \in T^{-1}(Y)$ and $T^{-1}(Y) \neq \emptyset$. If $x_1, x_2 \in T^{-1}(Y)$, then $T(x_1), T(x_2) \in Y$ and thus 

$$T(x_1 + x_2) = T(x_1) + T(x_2) \in Y$$

so $x_1 + x_2 \in T^{-1}(Y)$. Similarly, $T^{-1}(Y)$ is closed under scalar multiplication.

There are two especially important subspaces associated with any linear transformation:

III.11.3.7. **Definition.** Let $V$ and $W$ be vector spaces over $F$, and let $T : V \to W$ be a linear transformation. The **range** of $T$ is 

$$\mathcal{R}(T) = T(V) = \{ T(x) : x \in V \} \subseteq W .$$

The **null space** of $T$ is 

$$\mathcal{N}(T) = T^{-1}(\{ 0 \}) = \{ x \in V : T(x) = 0 \} \subseteq V .$$

By III.11.3.6., $\mathcal{R}(T)$ and $\mathcal{N}(T)$ are subspaces of $W$ and $V$ respectively.

III.11.3.8. **Proposition.** Let $V$ and $W$ be vector spaces over $F$, and let $T : V \to W$ be a linear transformation. Then $T$ is one-to-one if and only if $\mathcal{N}(T) = \{ 0 \}$.

**Proof:** If $T$ is one-to-one, if $x \in \mathcal{N}(T)$, then $T(x) = 0 = T(0)$, so $x = 0$. Conversely, suppose $\mathcal{N}(T) = \{ 0 \}$. If $x_1, x_2 \in V$ and $T(x_1) = T(x_2)$, then $T(x_1 - x_2) = T(x_1) - T(x_2) = 0$ and $x_1 - x_2 \in \mathcal{N}(T)$, so $x_1 = x_2$ and $T$ is one-to-one.

The next result, a generalization of III.11.3.8., is one of the fundamental facts from linear algebra:
III.11.3.9. Theorem. [First Isomorphism Theorem] Let $V$ and $W$ be vector spaces over $F$, and let $T : V \rightarrow W$ be a linear transformation. Then $T$ induces a well-defined linear isomorphism $\tilde{T}$ from $V/N(T)$ onto $R(T)$ by $\tilde{T}( [x] ) = T(x)$. Proof: We have to show that $\tilde{T}$ is well-defined and one-to-one; then it is automatic that $\tilde{T}$ is linear and $R(\tilde{T}) = R(T)$. So suppose $x_1, x_2 \in V$ and $[x_1] = [x_2]$ in $V/N(T)$. Then $x_1 - x_2 \in N(T)$, so we have

$$T(x_1) = T(x_2 + (x_1 - x_2)) = T(x_2) + T(x_1 - x_2) = T(x_2) + 0 = T(x_2)$$

and $\tilde{T}$ is well defined. The argument is reversible: if $\tilde{T}( [x_1] ) = \tilde{T}( [x_2] )$, then $T(x_1) = T(x_2)$, $T(x_1 - x_2) = 0$, $x_1 - x_2 \in N(T)$, so $[x_1] = [x_2]$. Thus $\tilde{T}$ is one-to-one.

III.11.3.10. Here is an alternate argument. Let $X$ be a subspace of $V$ complementary to $N(T)$ (III.11.2.38.). Then $\tilde{T} := T|_X$ is a linear transformation from $X$ to $W$. It is easily checked that $\tilde{T}$ is one-to-one (since $X \cap N(T) = \{0\}$), and that $R(\tilde{T}) = R(T)$. $T$ is then obtained by composing $\tilde{T}$ with the natural isomorphism from $V/N(T)$ onto $X$ (III.11.2.47.).

Using III.11.2.48., we obtain:

III.11.3.11. Corollary. Let $V$ and $W$ be vector spaces over $F$, and let $T : V \rightarrow W$ be a linear transformation. Then $\dim(\text{R}(T)) = \text{codim}(\text{N}(T))$. In particular,

$$\dim(\text{N}(T)) + \dim(\text{R}(T)) = \dim(V)$$

This corollary is often called the “dimension-counting theorem” for linear transformations. It has an important consequence for finite-dimensional vector spaces (using III.11.3.8):

III.11.3.12. Corollary. Let $V$ be a finite-dimensional vector space over $F$, and let $T : V \rightarrow V$ be a linear transformation. Then $T$ is injective if and only if it is surjective.

This can be false if $V$ is infinite-dimensional ()

III.11.4. More on Matrices and Linear Equations

III.11.5. Affine Subspaces and Affine Functions

General Position

A useful variation of linear independence is general position.

III.11.5.1. Definition. Let $V$ be a vector space over $F$, and $S$ a subset of $V$. Then $S$ is in general position, or the points in $S$ are in general position, if, whenever $\{x_0, x_1, \ldots, x_m\}$ is a set of $m + 1$ points in $S$ with $m \leq \dim(V)$, then $\{x_1 - x_0, \ldots, x_m - x_0\}$ is linearly independent.

This definition is applied most often when $S$ is a finite subset of $V$, but makes sense in general. It is most interesting when the size of $S$ is at least the dimension of $V$.

The proof of the next proposition is nearly trivial, and is left to the reader.
III.11.5.2. **Proposition.** Let \( \mathcal{V} \) be an \( n \)-dimensional vector space over \( F \), and \( S \) a subset of \( \mathcal{V} \) with \( r \) elements (\( r = \infty \) is allowed). Set \( m = \min(r, n + 1) \). Then the following are equivalent:

(i) \( S \) is in general position.

(ii) Whenever \( \{x_0, \ldots, x_{m-1}\} \) is a subset of \( S \) with \( m \) distinct elements, \( \{x_1 - x_0, \ldots, x_{m-1} - x_0\} \) is linearly independent.

(iii) Whenever \( \{x_0, \ldots, x_{m-1}\} \) is a subset of \( S \) with \( m \) distinct elements, the smallest affine subspace of \( \mathcal{V} \) containing \( \{x_0, \ldots, x_{m-1}\} \) has dimension \( m - 1 \).

(iv) Whenever \( \{x_0, \ldots, x_k\} \) is a subset of \( S \) with \( k \) distinct elements (\( k \leq m - 1 \)), the smallest affine subspace of \( \mathcal{V} \) containing \( \{x_0, \ldots, x_k\} \) has dimension \( k \).

III.11.5.3. If \( F \) is a finite field and \( \mathcal{V} \) is an \( n \)-dimensional vector space over \( F \), then there is a limit to the size of a set in general position. But if \( F \) is infinite, there can be infinite sets in general position. For example, if \( \mathcal{V} \) is 1-dimensional, any set of vectors is in general position.

III.11.5.4. **Example.** For a set \( S \) to be in general position, it is not enough that there be an \( x_0 \in S \) such that, whenever \( \{x_1, \ldots, x_{m-1}\} \) is a subset of \( S \) with \( m - 1 \) distinct elements all distinct from \( x_0 \), then \( \{x_1 - x_0, \ldots, x_{m-1} - x_0\} \) is linearly independent: consider the set \( \{(0,0), (2,0), (0,2), (1,1)\} \subset \mathbb{R}^2 \).

III.11.5.5. Any subset of a set in general position is in general position. A set of at most \( n + 1 \) vectors in an \( n \)-dimensional vector space which is in general position is called **affinely independent**. If \( \{x_0, \ldots, x_n\} \) is affinely independent, then any subset of size \( k + 1 \) generates a \( k \)-dimensional affine subspace.

III.11.6. **The Dot Product on \( \mathbb{R}^n \) and Adjoints**

We now discuss a piece of algebraic structure unique to \( \mathbb{R}^n \) (there is a similar structure on \( \mathbb{C}^n \)).

One of the big algebraic things distinguishing \( \mathbb{R}^n, n > 1 \), from \( \mathbb{R} \) is that there is no way to multiply (or divide) vectors. (There is a nonobvious way to define vector multiplication in \( \mathbb{R}^n \) for \( n = 2, 4, \) or \( 8 \), cf. **III.6.2.2.** and **III.6.3.2.**, but for no other \( n > 1 \).) However, there is a simple and very important way to “multiply” two vectors and obtain a scalar, called the dot product or inner product.

III.11.6.1. **Definition.** Let \( \mathbf{x} = (x_1, \ldots, x_n) \) and \( \mathbf{y} = (y_1, \ldots, y_n) \) be vectors in \( \mathbb{R}^n \). The **dot product** of \( \mathbf{x} \) and \( \mathbf{y} \) is

\[
\mathbf{x} \cdot \mathbf{y} = (x_1, \ldots, x_n) \cdot (y_1, \ldots, y_n) = x_1y_1 + x_2y_2 + \cdots + x_ny_n = \sum_{k=1}^{n} x_ky_k.
\]

Note that \( \mathbf{x} \cdot \mathbf{y} \in \mathbb{R} \), i.e. the dot product defines a function from \( \mathbb{R}^n \times \mathbb{R}^n \) to \( \mathbb{R} \).
The dot product \( \mathbf{x} \cdot \mathbf{y} \) is sometimes written \( \langle \mathbf{x}, \mathbf{y} \rangle \) (other notations are also occasionally used). The dot product is an example of an inner product, discussed in XV.9.1.

The next proposition lists the important algebraic properties of the dot product. The results are either obvious or proved by straightforward calculations, and the proofs are left to the reader.

**Proposition.** Let \( \mathbf{x}, \mathbf{y}, \mathbf{z} \) be vectors in \( \mathbb{R}^n \). Then:

(i) \( \mathbf{x} \cdot \mathbf{y} = \mathbf{y} \cdot \mathbf{x} \).

(ii) \( \mathbf{x} \cdot (\mathbf{y} + \mathbf{z}) = \mathbf{x} \cdot \mathbf{y} + \mathbf{x} \cdot \mathbf{z} \).

(ii') \( (\mathbf{x} + \mathbf{y}) \cdot \mathbf{z} = \mathbf{x} \cdot \mathbf{z} + \mathbf{y} \cdot \mathbf{z} \).

(iii) \( (\alpha \mathbf{x}) \cdot \mathbf{y} = \alpha (\mathbf{x} \cdot \mathbf{y}) \) for any \( \alpha \in \mathbb{R} \). In particular, \( 0 \cdot \mathbf{y} = 0 \).

(iii') \( \mathbf{x} \cdot (\alpha \mathbf{y}) = \alpha (\mathbf{x} \cdot \mathbf{y}) \) for any \( \alpha \in \mathbb{R} \). In particular, \( \mathbf{x} \cdot 0 = 0 \).

(iv) \( \mathbf{x} \cdot \mathbf{x} = ||\mathbf{x}||^2 \). In particular, \( \mathbf{x} \cdot \mathbf{x} \geq 0 \), and \( \mathbf{x} \cdot \mathbf{x} = 0 \) implies \( \mathbf{x} = 0 \).

(v) \( \mathbf{x} \cdot \mathbf{y} = \frac{1}{4}[||\mathbf{x} + \mathbf{y}||^2 - ||\mathbf{x} - \mathbf{y}||^2] \).

Property (i) is called *symmetry*; properties (ii)-(ii')-(iii)-(iii') are together called *bilinearity* (note that because of (i), (ii') and (iii') follow from (ii) and (iii) respectively). The last part of (iv) is called *positive definiteness*, and (v) is the *polarization identity*.

**Corollary.** Let \( T \) be a linear isometry of \( \mathbb{R}^n \) into \( \mathbb{R}^m \). If \( \mathbf{x}, \mathbf{y} \in \mathbb{R}^n \), then

\[
(T\mathbf{x}) \cdot (T\mathbf{y}) = \mathbf{x} \cdot \mathbf{y}.
\]

**Proof:** Apply polarization (III.11.6.3.(v)).

There is a nice geometric interpretation of the dot product. If \( \mathbf{x} \) and \( \mathbf{y} \) are nonzero vectors in \( \mathbb{R}^n \), there is a well-defined angle \( \theta \) between them if we take \( 0 \leq \theta \leq \pi \), measured in the two-dimensional subspace spanned by \( \mathbf{x} \) and \( \mathbf{y} \).

**Proposition.** Let \( \mathbf{x} \) and \( \mathbf{y} \) be nonzero vectors in \( \mathbb{R}^n \), and \( \theta \) the angle between them. Then

\[
\mathbf{x} \cdot \mathbf{y} = ||\mathbf{x}|| ||\mathbf{y}|| \cos \theta.
\]

**Proof:** Since there is a linear isometry from \( \mathbb{R}^2 \) onto the two-dimensional subspace of \( \mathbb{R}^n \) spanned by \( \mathbf{x} \) and \( \mathbf{y} \), by III.11.6.4. we may assume \( n = 2 \). And by III.11.6.3.(iii)-(iii') we may assume \( \mathbf{x} \) and \( \mathbf{y} \) are unit vectors.

There is a rotation (isometry) \( T \) of \( \mathbb{R}^2 \) sending \( \mathbf{x} \) to \( (1,0) \). We then have \( T\mathbf{y} = (\cos \theta, \pm \sin \theta) \), so

\[
\mathbf{x} \cdot \mathbf{y} = (T\mathbf{x}) \cdot (T\mathbf{y}) = (1,0) \cdot (\cos \theta, \pm \sin \theta) = \cos \theta.
\]
III.11.6.6. **Corollary. [Cauchy's Inequality or CBS Inequality]** Let \( \mathbf{x} \) and \( \mathbf{y} \) be vectors in \( \mathbb{R}^n \). Then

\[
|\mathbf{x} \cdot \mathbf{y}| \leq \|\mathbf{x}\| \|\mathbf{y}\|
\]

**Proof:** If \( \mathbf{x} \) and \( \mathbf{y} \) are nonzero, let \( \theta \) be the angle between them. Then

\[
|\mathbf{x} \cdot \mathbf{y}| = \|\mathbf{x}\| \|\mathbf{y}\| |\cos \theta| \leq \|\mathbf{x}\| \|\mathbf{y}\|
\]

since \( |\cos \theta| \leq 1 \). And if \( \mathbf{x} \) or \( \mathbf{y} \) is \( 0 \), both sides are 0.

III.11.6.7. This inequality is commonly called the Cauchy-Schwarz inequality or even the Schwarz inequality. But it was first stated and proved in this form by Cauchy in 1821, sixty years before Schwarz. For a more direct proof and extensions to general inner products, and a discussion of the history of the inequality and its names, see XV.9.2.

III.11.6.8. **Proposition.** The dot product on \( \mathbb{R}^n \) is jointly continuous: if \( \mathbf{x}_k \to \mathbf{x} \) and \( \mathbf{y}_k \to \mathbf{y} \), then \( \mathbf{x}_k \cdot \mathbf{y}_k \to \mathbf{x} \cdot \mathbf{y} \).

**Proof:** This follows easily from the CBS inequality, or just the fact that the formula is a polynomial function in the entries.

III.11.7. **Determinants**

There is a number (scalar) called the determinant associated with any square matrix, which is of both theoretical and practical significance. In particular, a (square) matrix is invertible if and only if its determinant is nonzero.

Determinants have gotten somewhat of a bad rap. It is widely fashionable in linear algebra (cf. [Axl95]) to try to banish determinants from the subject. Indeed, elementary linear algebra can be efficiently and elegantly developed without reference to determinants (e.g. [Axl97]). Determinants are mostly excluded from numerical linear algebra. There is one good overriding reason for avoiding determinants wherever possible, especially in numerical work: determinants are hard to compute!

However, determinants cannot be entirely avoided, especially in applications to analysis. The reason is that the determinant has a natural and crucial geometric or measure-theoretic interpretation, and hence appears naturally in such analysis formulas as the change-of-variables formula for integrals \( (\cdot) \). (And modern numerical analysis techniques make determinants somewhat more efficient to compute than by the straightforward brute-force method.)

We will therefore review the basics of the theory of determinants from the analysis point of view. Note that the determinant (as we do it here) is strictly a finite-dimensional notion.

**The Determinant of a Matrix**

There are two approaches to defining the determinant of a matrix. From an abstract point of view, the “best” way is to prove the existence and uniqueness theorem \( (\text{III.11.7.27.}) \) from scratch and then derive a formula for the determinant from it. We will take a lower-tech approach, defining the determinant by a (fairly complicated) algebraic formula, and deriving its properties from the formula.
III.11.7.1. **Definition.** Let $A = [a_{ij}]$ be an $n \times n$ matrix over $\mathbb{F}$. The *determinant* of $A$ is the scalar

$$\text{det}(A) = \sum_{\sigma \in S_n} \text{sgn}(\sigma)a_{1\sigma(1)}a_{2\sigma(2)} \cdots a_{n\sigma(n)}$$

where $S_n$ is the set of permutations (i) of $\{1, \ldots, n\}$ and $\text{sgn}(\sigma) = \pm 1$ is the sign (i) of the permutation $\sigma$.

There are $n!$ terms, each of which is a product of $n$ entries of $A$, exactly one from each row and column, with all possible such products represented.

To see how this works, we write out the determinant explicitly for small $n$:

III.11.7.2. **Examples.**

(i) $n = 1$: if $A = [a]$ is a $1 \times 1$ matrix (scalar), then $\text{det}(A) = a$ since there is only one permutation of $\{1\}$.

(ii) $n = 2$: Let $A = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}$. There are two permutations of $\{1, 2\}$, the identity $\iota$ and the permutation $\sigma$, where $\sigma(1) = 2$ and $\sigma(2) = 1$, and $\text{sgn}(\iota) = 1$, $\text{sgn}(\sigma) = -1$. Thus we have

$$\text{det}(A) = \text{sgn}(\iota)a_{1\iota(1)}a_{2\iota(2)} + \text{sgn}(\sigma)a_{1\sigma(1)}a_{2\sigma(2)} = a_{11}a_{22} - a_{12}a_{21}.$$

This formula is usually remembered as:

$$\text{det}\left( \begin{bmatrix} a & b \\ c & d \end{bmatrix} \right) = ad - bc.$$

(iii) $n = 3$: We write this case out explicitly, but the formula more serves as a warning of how rapidly the determinant formula becomes complicated as $n$ increases than as a useful formula. There are 6 permutations of $\{1, 2, 3\}$. Rather than working through all the details, we simply give the end result:

$$\text{det}\left( \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \right) = a_{11}a_{22}a_{33} - a_{11}a_{23}a_{32} + a_{12}a_{23}a_{31} - a_{12}a_{21}a_{33} + a_{13}a_{21}a_{32} - a_{13}a_{22}a_{31}.$$

(iv) $n = 4$: This formula has 24 terms and exceeds the patience of the author to write.

We will obtain a somewhat simpler inductive method of computing determinants in (i); but computing the determinant of even a general $10 \times 10$ matrix is a computational challenge on a computer (there are $10! = 3,628,800$ terms).

III.11.7.3. The notation $|A|$ is also frequently used for $\text{det}(A)$, especially when the matrix $A$ is written out in an array. This notation can be somewhat confusing, since the determinant has nothing to do with absolute value (e.g. the determinant of a matrix with real entries can be negative). Besides, in analysis we often need to work with the absolute value of the determinant, possibly adding to the confusion. We will stick with the notation $\text{det}(A)$.

**Elementary Properties of Determinants**

The first observation is immediate from the definition of determinant:
III.11.7.4. Proposition. For any \( n \), the determinant of the identity matrix \( I_n \) is 1. More generally, the determinant of any diagonal matrix is the product of the diagonal elements.

In fact, it is only slightly harder to show that the determinant of any triangular matrix is the product of the diagonal elements.

Another immediate consequence of the definition is:

III.11.7.5. Proposition. Let \( A \) be an \( n \times n \) matrix over \( \mathbb{F} \). If \( A \) has a zero row or zero column, then \( \det(A) = 0 \).

This result has a generalization ( ).

The next result is also a simple consequence of the definition.

III.11.7.6. Proposition. Let \( A \) be an \( n \times n \) matrix over \( \mathbb{F} \), and \( r \in \mathbb{F} \). Let \( B \) be the matrix obtained from \( A \) by multiplying one row of \( A \) by \( r \) and leaving all other rows unchanged. Then

\[
\det(B) = r \cdot \det(A)
\]

Note that the \( B \) in the proposition is not a scalar multiple of \( A \). In fact, by applying the proposition successively to each row, we obtain that \( \det(rA) = r^n \cdot \det(A) \).

Proof: Comparing the formulas for \( \det(B) \) and \( \det(A) \), each term in the sum for \( \det(B) \) is obtained from the corresponding term for \( \det(A) \) by multiplying one of the factors by \( r \) and leaving the rest unchanged. Thus a factor of \( r \) can be taken out of the sum by the distributive property.

The next result is more esoteric to state, but has a similarly simple proof:

III.11.7.7. Proposition. Let \( B = [b_{ij}] \) and \( C = [c_{ij}] \) be \( n \times n \) matrices which are identical except for some row, i.e. for which there is an \( i_0 \) such that \( b_{ij} = c_{ij} \) for all \( i \neq i_0 \) and all \( j \). Let \( A = [a_{ij}] \) be the matrix with \( a_{ij} = b_{ij} = c_{ij} \) for \( i \neq i_0 \) and all \( j \), and \( a_{i_0j} = b_{i_0j} + c_{i_0j} \) for all \( j \) (i.e. the \( i_0 \)'th row of \( A \) is the sum of the \( i_0 \)'th rows of \( B \) and \( C \) and the other rows of \( A \) are identical to the other rows of \( B \) and \( C \)). Then

\[
\det(A) = \det(B) + \det(C)
\]

Proof: We have

\[
\det(A) = \sum_{\sigma \in S_n} \text{sgn}(\sigma) a_{1\sigma(1)} a_{2\sigma(2)} \cdots a_{n\sigma(n)} = \sum_{\sigma \in S_n} \text{sgn}(\sigma) a_{1\sigma(1)} a_{2\sigma(2)} \cdots (b_{i_0\sigma(i_0)} + c_{i_0\sigma(i_0)}) \cdots a_{n\sigma(n)}
\]

\[
= \sum_{\sigma \in S_n} \text{sgn}(\sigma) b_{1\sigma(1)} b_{2\sigma(2)} \cdots b_{n\sigma(n)} + \sum_{\sigma \in S_n} \text{sgn}(\sigma) c_{1\sigma(1)} c_{2\sigma(2)} \cdots c_{n\sigma(n)} = \det(B) + \det(C)
\]
The previous two results are abbreviated by saying that the determinant is *multilinear* (or, more specifically, *n-linear*) in the rows of the matrix. See () for the general theory of multilinear functions.

Next we obtain a property which is simpler to state but a little trickier to prove:

**III.11.7.9.** **Proposition.** Let $A$ be an $n \times n$ matrix over $F$, and $B$ a matrix obtained by interchanging two rows of $A$. Then

$$
\det(B) = -\det(A).
$$

**Proof:** Suppose the $i_1$’th and $i_2$’th rows of $A$ are interchanged. Let $\tau$ be the permutation of $\{1, \ldots, n\}$ which interchanges $i_1$ and $i_2$ and leaves everything else fixed. Then $\tau$ is a transposition, so $sgn(\tau) = -1$ and, more generally, $sgn(\sigma \tau) = -sgn(\sigma)$ for every $\sigma \in S_n$. By rearranging the order of factors in each term, we have

$$
\det(B) = \sum_{\sigma \in S_n} sgn(\sigma)a_{1\sigma(1)} \cdots a_{n\sigma(n)} = -\sum_{\sigma \in S_n} sgn(\sigma \tau)a_{1\sigma(1)} \cdots a_{n\sigma(n)}.
$$

But as $\sigma$ ranges over $S_n$, so does $\sigma \tau$; so the last sum is exactly $\det(A)$.

This property of the determinant is called the *alternating* property. It implies:

**III.11.7.10.** **Corollary.** Let $A$ be an $n \times n$ matrix. If $A$ has two identical rows, then $\det(A) = 0$.

(This is actually not a corollary of III.11.7.7. if $F$ has characteristic 2. But this result has a direct proof which works also in the characteristic 2 case; see Exercise III.11.11.1.)

Combining this with III.11.7.6., we obtain an extension:

**III.11.7.12.** **Corollary.** Let $A$ be an $n \times n$ matrix over $F$. If one row of $A$ is a scalar multiple of another row, then $\det(A) = 0$.

**Proof:** If the $i_2$’th row of $A$ is $r$ times the $i_1$’th row, then by III.11.7.6., $\det(A) = r \cdot \det(B)$ for a matrix $B$ with two identical rows.

This will be further extended in ().

Now combining this with III.11.7.7., we obtain:
III.11.7.13. Corollary. Let $A$ be an $n \times n$ matrix over $\mathbb{F}$, and let $B$ be the matrix obtained from $A$ by replacing one row by that row plus a scalar multiple of another row. Then $\det(B) = \det(A)$.

Proof: Let $C$ be the matrix obtained from $A$ by replacing the $i_1$'th row by $r$ times the $i_2$'th row for some $r \in R$. If $b_{i_1,j} = a_{i_1,j} + ra_{i_2,j}$ and $b_{i_2,j} = a_{i_2,j}$ for $i \neq i_1$, then by III.11.7.7, we have $\det(B) = \det(A) + \det(C)$. But $\det(C) = 0$ by III.11.7.12.

Another important property of determinants has a proof similar to the proof of III.11.7.9.

III.11.7.14. Proposition. Let $A$ be an $n \times n$ matrix over $\mathbb{F}$. Then $\det(A^t) = \det(A)$.

Proof: We have

$$\det(A^t) = \sum_{\sigma \in S_n} \text{sgn}(\sigma)a_{\sigma(1)1}a_{\sigma(2)2}\cdots a_{\sigma(n)n}.$$ 

Since $\text{sgn}(\sigma^{-1}) = \text{sgn}(\sigma)$ for any $\sigma$, by rearranging the order of the factors in each term we get

$$\det(A^t) = \sum_{\sigma \in S_n} \text{sgn}(\sigma^{-1})a_{1\sigma^{-1}(1)}a_{2\sigma^{-1}(2)}\cdots a_{n\sigma^{-1}(n)}.$$ 

But as $\sigma$ ranges over $S_n$, so does $\sigma^{-1}$, hence the last sum is just $\det(A)$.

As a result, the previous results on rows apply also to columns:

III.11.7.15. Corollary. Let $A$ be an $n \times n$ matrix over $\mathbb{F}$.

(i) The determinant is multilinear in the columns of $A$. In particular, if $B$ is obtained from $A$ by multiplying a column of $A$ by a scalar $r$, then $\det(B) = r \cdot \det(A)$.

(ii) If $B$ is obtained from $A$ by interchanging two columns, then $\det(B) = -\det(A)$.

(iii) If $A$ has two identical columns, or if one column of $A$ is a scalar multiple of another column, then $\det(A) = 0$.

(iv) If $B$ is obtained from $A$ by replacing one column of $A$ by that column plus a scalar times another column, then $\det(B) = \det(A)$.

There are many other properties of determinants discussed in abstract algebra books. We mention only a couple which are relevant for analysis. The proofs are quite obvious from the definition.

III.11.7.16. Proposition. (i) Let $A$ be an $n \times n$ matrix with entries in $\mathbb{Z}$. Then $\det(A) \in \mathbb{Z}$.

(ii) Let $A = [a_{ij}]$ be an $n \times n$ matrix with entries in $\mathbb{C}$, and $\bar{A} = [\bar{a}_{ij}]$ be the complex conjugate matrix. Then $\det(\bar{A}) = \det(A)$.

Combining (ii) with III.11.7.14, we obtain:
III.11.7.17. **Corollary.** Let $A$ be an $n \times n$ matrix over $\mathbb{C}$, and $A^*$ its adjoint matrix ($\cdots$). Then $\det(A^*) = \det(A)$.

III.11.7.18. In fact, the theory of determinants works equally well over any commutative ring (some aspects require the ring to be unital): if $R$ is a commutative ring, for any $n$ there is a determinant function from $M_n(R)$ to $R$ which is $n$-linear and alternating, defined by the same formula as in III.11.7.1. If $R$ and $S$ are commutative rings and $\phi : R \to S$ is a ring-homomorphism, then there is an induced coordinatewise ring homomorphism $\phi_n$ from $M_n(R)$ to $M_n(S)$ for any $n$, and the determinant is natural, i.e. $\det(\phi_n(A)) = \phi(\det(A))$ for any $A \in M_n(R)$. See also III.11.7.53.

However, determinants simply do not work for matrices over noncommutative rings; there is no determinant-like function with reasonable properties on $M_n(R)$ for noncommutative $R$.

**Expansion by Minors**

The multilinear and alternating properties of the determinant lead to an inductive procedure for computing the determinant of an $n \times n$ matrix in terms of determinants of smaller submatrices. This procedure, called expansion by minors or expansion by cofactors, is the way most determinants (at least ones of modest size) are computed in practice.

We first define a set of submatrices of an $n \times n$ matrix:

III.11.7.19. **Definition.** Let $A$ be an $n \times n$ matrix over $F$, and $1 \leq i, j \leq n$. The $(i,j)$ minor of $A$ is the $(n-1) \times (n-1)$ matrix $A^m_{ij}$ obtained from $A$ by deleting the $i$th row and $j$th column. The $(i,j)$ cofactor of $A$ is $d_{ij}(A) = (-1)^{i+j} \det(A^m_{ij})$.

The $(-1)^{i+j}$ in the definition of cofactor is conventional, and simplifies later formulas.

III.11.7.20. **Theorem.** Let $A$ be an $n \times n$ matrix over $F$. For any fixed $i_0$, $1 \leq i_0 \leq n$, we have

$$\det(A) = \sum_{j=1}^{n} a_{i_0j} \cdot d_{i_0j}(A) = \sum_{j=1}^{n} (-1)^{i_0+j} a_{i_0j} \cdot \det(A^m_{i_0j}).$$

For any fixed $j_0$, $1 \leq j_0 \leq n$, we have

$$\det(A) = \sum_{i=1}^{n} a_{ij_0} \cdot d_{ij_0}(A) = \sum_{i=1}^{n} (-1)^{i+j_0} a_{ij_0} \cdot \det(A^m_{ij_0}).$$

Thus the computation of an $n \times n$ determinant can be reduced to the computation of $n$ determinants, each $(n-1) \times (n-1)$. Each of these can be calculated by computing $n-1$ determinants, each $(n-2) \times (n-2)$, etc. It does not matter which row or column is used at each stage; as a practical matter, if the matrix has some zero entries it usually saves work to choose the row or column with the most zeroes at each stage.
III.11.7.21. Example. Expanding along the first row \((i_0 = 1)\), we have

\[
\det \begin{bmatrix}
1 & 2 & -1 \\
3 & -2 & 1 \\
1 & 0 & -4
\end{bmatrix} = (-1)^2(1)\det \begin{bmatrix}
-2 & 1 \\
0 & -4
\end{bmatrix} + (-1)^3(2)\det \begin{bmatrix}
3 & 1 \\
1 & -4
\end{bmatrix} + (-1)^4(-1)\det \begin{bmatrix}
3 & -2 \\
1 & 0
\end{bmatrix}
\]

\[
= 8 - 2(-13) - 2 = 32.
\]

Expanding along the second column \((j_0 = 2)\), we have

\[
\det \begin{bmatrix}
1 & 2 & -1 \\
3 & -2 & 1 \\
1 & 0 & -4
\end{bmatrix} = (-1)^1(2)\det \begin{bmatrix}
3 & 1 \\
1 & -4
\end{bmatrix} + (-1)^2(-1)\det \begin{bmatrix}
1 & -1 \\
1 & 1
\end{bmatrix} + (-1)^3(0)\det \begin{bmatrix}
1 & -1 \\
3 & 1
\end{bmatrix}
\]

\[
= -2(-13) - 2(-3) + 0 = 32.
\]

The second way is slightly simpler since one term is zero and only two \(2 \times 2\) determinants must be computed.

Determinants and Elementary Matrices

There is another way to view the multilinear and alternating properties of the determinant. Each describes the behavior of the determinant under an elementary row operation. Each elementary row operation on a matrix \(A\) can be performed by multiplying on the left by an elementary matrix. We can easily compute the determinant of elementary matrices:

III.11.7.22. Proposition. Determinants of elementary matrices are as follows:

(i) If \(\Pi_{ij}\) is the matrix that interchanges \(i\) and \(j\), then \(\det(\Pi_{ij}) = -1\).

(ii) If \(M_i(r)\) is the diagonal matrix with \((i, i)\) entry \(r\) and the rest of the diagonal entries 1, then \(\det(M_i(r)) = r\).

(iii) If \(E_{ij}(r)\) \((i \neq j)\) is the matrix obtained from \(I_n\) by replacing the \((i, j)\) element by \(r\), then \(\det(E_{ij}(r)) = 1\).

This can be proved by applying III.11.7.9. for (i), III.11.7.6. (or just III.11.7.4.) for (ii), and III.11.7.13. for (iii) (or readily proved directly from the definition of determinant).

Comparing the effect of row operations on the determinant with III.11.7.22., we obtain:

III.11.7.23. Corollary. Let \(A\) be an \(n \times n\) matrix over \(F\), and let \(E\) be an elementary \(n \times n\) matrix over \(F\). Then \(\det(EA) = \det(E) \cdot \det(A)\).

Multiplicative Property of Determinants

The two most important properties of determinants for most applications are simple consequences of III.11.7.23. and (i).
III.11.7.24. Theorem. Let $A$ be an $n \times n$ matrix over $F$. Then $A$ is invertible if and only if $\det(A) \neq 0$.

Proof: By (), there are finitely many elementary matrices $E_1, \ldots, E_m$ such that either $E_1 E_2 \cdots E_m A = I_n$ (if $A$ is invertible) or $E_1 E_2 \cdots E_m A$ has a zero row (if $A$ is singular). In the first case we have

$$A = E_m^{-1} E_{m-1}^{-1} \cdots E_1^{-1}$$

so $A$ is a product of elementary matrices. By repeated applications of III.11.7.23., we obtain

$$\det(A) = \det(E_m^{-1}) \cdot \det(E_{m-1}^{-1}) \cdots \det(E_1^{-1}) \neq 0.$$ 

In the second case, we have from III.11.7.23. that $\det(E_1 \cdots E_m A)$ is a nonzero multiple of $\det(A)$. But $E_1 \cdots E_m A$ has a zero row, so $\det(E_1 \cdots E_m A) = 0$ and hence $\det(A) = 0$. ☝

III.11.7.25. Theorem. Let $A$ and $B$ be $n \times n$ matrices over $F$. Then $\det(AB) = \det(A) \cdot \det(B)$.

Proof: If $A$ is not invertible, then $AB$ is not invertible () and $\det(AB) = 0 = \det(A) \cdot \det(B)$. And if $A$ is invertible, then $A$ is a product of elementary matrices, so by repeated applications of III.11.7.23., we obtain that $\det(AB) = \det(A) \cdot \det(B)$. ☃

Proving this result by direct computation from the definition of determinant is a mess even for $n = 2$, and becomes impossibly complicated for larger $n$. The result holds for matrices over general commutative rings, although it needs a different proof there (cf. III.11.7.28.).

III.11.7.26. In the case of $F = \mathbb{R}$, the result follows immediately from the measure-scaling property of the determinant (). Note, however, that in establishing the properties of the determinant it is important to avoid circularity in arguments; our proof of the measure-scaling property () uses the multiplicativity of the determinant, so while the measure-scaling property is a good geometric explanation of multiplicativity, it is not a good way to prove it.

The Uniqueness Theorem

It turns out that the properties we have obtained uniquely characterize the determinant function:

III.11.7.27. Theorem. Let $F$ be a field.

(i) For any $n \in \mathbb{N}$ there is a unique function $\phi : M_n(F) \to F$ which is $n$-linear in the rows, alternating, and such that $\phi(I_n) = 1$. We have $\phi(A) = \det(A)$ for all $A \in M_n(F)$.

(ii) If $\phi : M_n(F) \to F$ is $n$-linear in the rows, alternating, and $\phi(I_n) = 0$, then $\phi$ is identically zero.

Proof: (i): The existence of such a $\phi$, namely $\det$, has already been established. We prove uniqueness by induction on $n$. For $n = 1$, $\phi$ must be a linear function from $F$ to $F$, hence $\phi(a) = ma$ for some constant $m$; since $\phi(1) = 1$, $m = 1$, so $\phi([a]) = a = \det([a])$. Now suppose the statement has been proved for $n$. ***** ☃

403
III.11.7.28. An alternate proof of III.11.7.25. can be based on the Uniqueness Theorem:

PROOF: Fix $B \in M_n(F)$. It is routine to check that the function $\phi : M_n(F) \to F$ given by $\phi(A) = det(AB)$ is $n$-linear and alternating. We have $\phi(I) = det(B)$. If $det(B) = 0$, then $\phi$ is identically zero by III.11.7.27.(ii); thus $det(AB) = 0 = det(A) \cdot det(B)$ for any $A$. And if $det(B) \neq 0$, set $\psi(A) = \frac{1}{det(B)} \phi(A) = \frac{1}{det(B)} det(AB)$.

By III.11.7.27.(i), $\psi(A) = det(A)$ for all $A$, and thus $\phi(A) = det(AB) = det(A) \cdot det(B)$ for any $A$. ✅

Continuity and Differentiability of the Determinant

The Determinant of a Linear Transformation

III.11.7.29. If $V$ is a finite-dimensional vector space over $F$, and $T$ is a linear transformation from $V$ to $V$, then $T$ does not have a canonical matrix representation; to represent $T$ by a matrix, a basis for $V$ must be chosen (). Although the matrix of $T$ depends on the choice of basis, there is not too much flexibility: if $B$ and $B'$ are bases, then the matrices of $T$ with respect to $B$ and $B'$ are similar:

$$[T]_{B'} = P_{B,B'}^{-1} [T]_B P_{B,B'}$$

where $P_{B,B'}$ is the change-of-basis matrix (), and so we have

$$det([T]_{B'}) = det(P_{B,B'})^{-1} det([T]_B) det(P_{B,B'}) = det([T]_B)$$

(using commutativity of multiplication in $F$), i.e. the determinant of $[T]_B$ does not depend on the choice of basis $B$. Thus the linear transformation $T$ has a well-defined associated scalar, the determinant of the matrix representation of $T$ with respect to any basis.

III.11.7.30. Definition. Let $T$ be a linear transformation from a finite-dimensional vector space $V$ over $F$ to itself. Set

$$det(T) = det([T]_B)$$

where $B$ is any basis for $V$ over $F$.

III.11.7.31. Note that if $S,T$ are linear transformations from $V$ to $V$, then

$$det(S \circ T) = det(S)det(T) .$$

III.11.7.32. The determinant of a linear transformation does depend on the choice of base field $F$, however. If $V$ is a vector space over $\mathbb{C}$ and $T : V \to V$ a linear transformation, then $det(T)$ is not the same if $V$ is regarded as a vector space over $\mathbb{R}$ as it is over $\mathbb{C}$ in general. (See Exercise () for the relationship.)

Geometric Interpretation of the Determinant

Although the theory of determinants is purely algebraic and works equally well over any field (in fact, over any commutative ring), there is a geometric interpretation of the determinant which is exclusive to the case where the field $F$ is $\mathbb{R}$ (and, to a limited extent, to the case $F = \mathbb{C}$). This interpretation underlies the importance of the determinant in analysis.
III.11.7.33. **Volume Principle of Determinants:** Let $A$ be an $n \times n$ matrix with real entries. Regard $A$ as giving a linear transformation $T : \mathbb{R}^n \to \mathbb{R}^n$ (with respect to the standard basis). Then $T$ multiplies $n$-dimensional “volume” by a constant factor $|\text{det}(A)|$, i.e. if $E$ is a subset of $\mathbb{R}^n$ with a well-defined $n$-dimensional “volume” $V(E)$ (technically a Jordan region () or, more generally, a Lebesgue measurable subset), then $T(E)$ also has a well-defined $n$-dimensional volume and $V(T(E)) = |\text{det}(A)| \cdot V(E)$.

III.11.7.34. Actually, we should first define what we mean by $n$-dimensional “volume” of a subset of $\mathbb{R}^n$. This is not as easy as it sounds: the general problem is essentially the basic subject matter of measure theory. It would take us too far afield to try to treat this question here, so we will just assume that “volume” is defined for sufficiently well-behaved subsets of $\mathbb{R}^n$, and satisfies

(i) If $R$ is a “rectangle” $[a_1, b_1] \times \cdots \times [a_n, b_n]$, then $V(R) = (b_1 - a_1) \cdots (b_n - a_n)$.

(ii) If $E \subseteq F$, then $V(E) \leq V(F)$.

(iii) If $E_1, \ldots, E_m$ are nonoverlapping regions (“nonoverlapping” means the intersection of any two is contained in the boundary of both), then

$$V(E_1 \cup \cdots \cup E_m) = V(E_1) + \cdots + V(E_m).$$

(iv) Congruent regions (including allowing reflections) have the same volume.

(There is actually a subtle technical problem with (iii), since the boundary of a region can have positive measure, but this will not cause difficulty if we consider only regions bounded by finitely many smooth hypersurfaces. Actually we will only need to work with regions bounded by finitely many hyperplanes.)

III.11.7.35. We first look at the case $n = 2$, which is the only one we will examine in detail. Here 2-dimensional “volume” is “area.” Suppose

$$A = \begin{bmatrix} a & c \\ b & d \end{bmatrix}$$

is a $2 \times 2$ matrix. The $T(1,0) = (a,b)$ and $T(0,1) = (c,d)$. The image of the unit square $[0,1] \times [0,1]$ is the parallelogram with vertices $(0,0)$, $(a,b)$, $(c,d)$, and $(a+c, b+d)$. We claim the area of this parallelogram is $|\text{det}(A)| = |ad - bc|$.

The argument reduces to several special cases. First consider the case where $a > 0, b \geq 0, d > 0, c \geq 0$, and either $c = 0$ or $\frac{d}{c} \leq \frac{b}{a}$ (Figure III.1).

The area of the total rectangle is $(a+c)(b+d)$. The blue triangles fit together into a rectangle of length $a$ and height $b$, so the blue area is $ab$. Similarly, the green area is $cd$. The two red rectangles each have area $bc$. Thus the area of the parallelogram is

$$(a + c)(b + d) - ab - cd - 2bc = ab + ad + bc + cd - ab - cd - 2bc = ad - bc.$$  

The case where $\frac{d}{c} < \frac{b}{a}$ can be handled by interchanging columns of $A$, which multiplies the determinant by $-1$.

III.11.7.36. Now look at the case $c < 0$, but $a, b, d \geq 0$ (Figure III.2).

The area of the large rectangle is $(a-c)(b+d)$. The blue triangles fit together into a rectangle of area $ab$, and the green triangles have total area $-cd$. So the area of the parallelogram is

$$(a - c)(b + d) - ab + cd = ab + ad - bc - cd - ab + cd = ad - bc.$$
III.11.7.37. The other cases can be handled similarly, or by reducing to these cases by interchanging rows or columns and/or multiplying one or both rows and/or columns by \(-1\), none of which change the absolute value of the determinant.

III.11.7.38. If instead of the unit square, we begin with the rectangle with vertices \((0, 0)\), \((r, 0)\), \((0, s)\), and \((r, s)\), a virtually identical argument shows that the image parallelogram has area \(|\det(A)|rs\). The image of any other coordinate rectangle (rectangle with sides parallel to the axes) of length \(rs\) is congruent to this parallelogram, hence has the same area by property (iv). Thus \(T\) multiplies areas of all coordinate rectangles by the constant factor \(|\det(A)|\).

III.11.7.39. For the case \(n = 3\), the image of the unit cube under the transformation \(T\) is the parallelepiped with vertices at the origin, the column vectors of \(A\), and their sums. A more complicated argument along the same lines as the dimension 2 case shows that the volume of this parallelepiped is exactly \(|\det(A)|\). The argument generalizes to the images of rectangular solids with edges parallel to the axes (coordinate rectangles).

III.11.7.40. The case \(n \geq 4\) is difficult to visualize and quite complicated to give a geometric argument for. But some special cases can be easily shown for any \(n\):
(i) If $A$ is a diagonal matrix, the image of any coordinate rectangle $R$ is another coordinate rectangle, whose $n$-dimensional volume is $V(R)$ times the absolute value of the product of the diagonal elements of $A$, which is $|\det(A)|$.

(ii) If $A$ is a permutation matrix ($\cdot$), and $R$ is a coordinate rectangle, then $T(R)$ is a coordinate rectangle congruent to $R$, so $V(T(R)) = V(R)$; and $\det(A) = \pm 1$, so $|\det(A)| = 1$ and the measure-scaling property holds.

(iii) If $A$ is the elementary matrix with $r$ in the $(i,j)$ place ($\cdot$), then the image of the unit cube is a prism whose base is a rhombus of side 1; thus $V(T(R)) = V(R)$, and $\det(A) = 1$ ($\cdot$).

By the multiplicative property of determinants and the fact that any invertible square matrix is a product of elementary matrices, the measure-scaling property holds for coordinate rectangles for general invertible $A$. For singular $A$, see ($\cdot$).

**III.11.7.41.** To handle a general (Jordan) region $E$, cover $E$ by a fine grid so that the inside and outside estimates for $V(E)$ ($\cdot$) from this grid are close together. The image $T(E)$ is then trapped between finite unions of paralleloptopes, both of which have volume close to $|\det(A)| \cdot V(E)$ by property (iii) of volume. The approximations can be made as closely as desired. By property (ii), $V(T(E)) = |\det(A)| \cdot V(E)$. A similar argument ($\cdot$) gives the result for Lebesgue measurable $E$. 407
III.11.7.42. If $A$ is an $n \times n$ matrix over $\mathbb{C}$, then $A$ can be thought of as giving a linear transformation $T$ from $\mathbb{C}^n \cong \mathbb{R}^{2n}$ to itself, and it can be shown that the factor that $T$ multiplies $2n$-dimensional “volume” by is the square of $|\det(A)|$.

The Inverse of a Matrix

There is actually an explicit algebraic formula for the inverse of a (square) matrix, which we develop here.

III.11.7.43. Definition. Let $A$ be an $n \times n$ matrix over $\mathbb{F}$. The classical adjoint of $A$ is the matrix

$$\text{adj}(A) = [d_{ji}(A)] = [d_{ij}(A)]^t$$

where $d_{ij}(A)$ is the $(i,j)$ cofactor of $A$ (III.11.7.19).

The classical adjoint has nothing to do with the (ordinary) adjoint of a matrix over $\mathbb{C}$ as defined in (). Note the transpose in the definition of $\text{adj}(A)$.

The importance of the classical adjoint is:

III.11.7.44. Theorem. Let $A$ be an $n \times n$ matrix over $\mathbb{F}$. Then

$$A \cdot \text{adj}(A) = \text{adj}(A) \cdot A = (\det(A))I_n .$$

As a corollary, we get an algebraic formula for the inverse of a matrix:

III.11.7.45. Corollary. Let $A$ be an $n \times n$ matrix over $\mathbb{F}$. If $A$ is invertible (i.e. $\det(A) \neq 0$), then

$$A^{-1} = \frac{1}{\det(A)} \text{adj}(A) .$$

III.11.7.46. The algebraic formula for the inverse via the classical adjoint is not computationally efficient to use; it is pretty cumbersome even for $n = 4$. It is much more computationally efficient to compute the inverse by row reduction (Gaussian elimination) (). But the formula at least gives a very simple way to write down the inverse of a $2 \times 2$ matrix:

III.11.7.47. Corollary. Let $\begin{bmatrix} a & b \\ c & d \end{bmatrix}$ be a $2 \times 2$ matrix over $\mathbb{F}$. Then $A$ is invertible if and only if $ad - bc \neq 0$, and in this case

$$A^{-1} = \frac{1}{ad - bc} \begin{bmatrix} d & -b \\ -c & a \end{bmatrix} = \begin{bmatrix} \frac{d}{ad - bc} & \frac{-b}{ad - bc} \\ \frac{-c}{ad - bc} & \frac{a}{ad - bc} \end{bmatrix} .$$

This formula may be easily checked by direct computation.

The algebraic formula for the inverse does have an important theoretical consequence:
III.11.7.48. Corollary. The entries of the inverse of an invertible (square) matrix $A$ over $\mathbb{F}$ are rational functions of the entries in $A$.

If $\mathbb{F}$ is $\mathbb{R}$ or $\mathbb{C}$, this can be nicely rephrased.

III.11.7.49. Definition. Let $\mathbb{F}$ be a field. Write $GL_n(\mathbb{F})$ for the set of invertible $n \times n$ matrices over $\mathbb{F}$. $GL_n(\mathbb{F})$ is called the general linear group of size $n$ over $\mathbb{F}$.

If $A, B \in GL_n(\mathbb{F})$, then $AB$ and $A^{-1}$ are also in $GL_n(\mathbb{F})$; thus $GL_n(\mathbb{F})$ is a group under matrix multiplication. By III.11.7.24, $GL_n(\mathbb{F}) = \{ A \in M_n(\mathbb{F}) : \det(A) \neq 0 \}$.

III.11.7.50. Theorem. Let $\mathbb{F}$ be $\mathbb{R}$ or $\mathbb{C}$. Then $GL_n(\mathbb{F})$ is an open set in $M_n(\mathbb{F}) \cong \mathbb{F}^{n^2}$, and $A \mapsto A^{-1}$ is an analytic (hence $C^\infty$) function from $GL_n(\mathbb{F})$ to $GL_n(\mathbb{F}) \subseteq M_n(\mathbb{F})$.

Proof: Since $\det : M_n(\mathbb{F}) \to \mathbb{F}$ is continuous, $GL_n(\mathbb{F})$ is the inverse image of the open set $\mathbb{F} \setminus \{0\}$ under a continuous map, hence open. The other statement follows from III.11.7.48, since rational functions are analytic on their domains.

III.11.7.51. Corollary. Let $A = [a_{ij}]$ be an invertible $n \times n$ matrix over $\mathbb{R}$ or $\mathbb{C}$. Then there is an $\epsilon > 0$ (depending on $A$) such that, whenever $B = [b_{ij}]$ is an $n \times n$ matrix over $\mathbb{R}$ or $\mathbb{C}$ with $|a_{ij} - b_{ij}| < \epsilon$ for all $i$ and $j$, then $B$ is also invertible.

The formula for the inverse of a matrix has other consequences, for example:

III.11.7.52. Corollary. Let $A$ be an $n \times n$ matrix with integer entries. Then $A$ has an inverse with integer entries (i.e. $A$ is invertible in $M_n(\mathbb{Z})$) if and only if $\det(A) = \pm 1$.

Proof: If $A$ has an inverse $A^{-1}$ with integer entries, then $\det(A)$ and $\det(A^{-1}) = \frac{1}{\det(A)}$ are integers, hence $\det(A) = \pm 1$. Conversely, if $\det(A) = \pm 1$, III.11.7.45. (applied with $\mathbb{F} = \mathbb{R}$) shows that $A$ is invertible and that $A^{-1}$ has integer entries.

This result generalizes to unital commutative rings:

III.11.7.53. Theorem. Let $R$ be a commutative unital ring. If $A \in M_n(R)$, then $A$ is invertible in $M_n(R)$ if and only if $\det(A)$ is a unit (invertible element) of $R$.

Here is another consequence. If $R$ is a unital subring of a larger unital ring $R'$, an element of $R$ can in general be invertible in the larger ring $R'$ without being invertible in $R$ (e.g. $R = \mathbb{Z}$, $R' = \mathbb{R}$). But if $\mathbb{F}$ is a field contained in a larger field $\mathbb{F}'$, and we regard $M_n(\mathbb{F})$ as a subring of $M_n(\mathbb{F}')$, this cannot happen:
**III.11.7.54. Corollary.** Let $F \subseteq F'$ be fields. If $A \in M_n(F)$, then $A$ is invertible in $M_n(F')$ if and only if $A$ is invertible in $M_n(F)$, i.e. if $A$ is invertible in $M_n(F')$, then the entries of $A^{-1}$ are in $F$.

This applies for example if $F = \mathbb{R}$ and $F' = \mathbb{C}$, or if $F = \mathbb{Q}$ and $F' = \mathbb{R}$.

Cramer’s Rule

**III.11.8. Eigenvalues and Eigenvectors**

**III.11.9. Tensor Products and Multilinear Algebra**

**III.11.10. Differential Algebra**

**III.11.11. Exercises**

**III.11.11.1.** Let $A$ be an $n \times n$ matrix over $F$. Show directly from the definition that if $A$ has two identical rows, then the terms in the expansion of $\det(A)$ cancel in pairs, and hence $\det(A) = 0$. [If $\tau$ is the transposition interchanging the two rows, for any $\sigma$ consider the terms for $\sigma$ and $\sigma \tau$.]

**III.11.11.2.** Say that a $2m \times 2n$ matrix $A$ over $\mathbb{R}$ is complex if, when $A$ is partitioned into $2 \times 2$ blocks, each subblock is of the form

$$\begin{bmatrix} a & -b \\ b & a \end{bmatrix}$$

where the $a$ and $b$ are real numbers which vary from block to block (cf. III.6.3.1.).

(a) Show that a sum or product of complex matrices, if defined, is complex. [Use III.11.1.22.]

(b) If a $2n \times 2n$ matrix over $\mathbb{R}$ is complex and invertible (in $M_{2n}(\mathbb{R})$), show that its inverse is also complex.

(c) If $A$ is the complex matrix

$$\begin{bmatrix} a_{11} & -b_{11} & a_{12} & -b_{12} & \cdots & a_{1n} & -b_{1n} \\ b_{11} & a_{11} & b_{12} & a_{12} & \cdots & b_{1n} & a_{1n} \\ a_{21} & -b_{21} & a_{22} & -b_{22} & \cdots & a_{2n} & -b_{2n} \\ b_{21} & a_{21} & b_{22} & a_{22} & \cdots & b_{2n} & a_{2n} \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ a_{m1} & -b_{m1} & a_{m2} & -b_{m2} & \cdots & a_{mn} & -b_{mn} \\ b_{m1} & a_{m1} & b_{m2} & a_{m2} & \cdots & b_{mn} & a_{mn} \end{bmatrix}$$

identify $A$ with the $m \times n$ matrix

$$\begin{bmatrix} c_{11} & c_{12} & \cdots & c_{1n} \\ c_{11} & c_{12} & \cdots & c_{1n} \\ \vdots & \vdots & \ddots & \vdots \\ c_{m1} & c_{m2} & \cdots & c_{mn} \end{bmatrix}$$

with complex entries, where $c_{jk} = a_{jk} + ib_{jk}$ for $1 \leq j \leq m$, $1 \leq k \leq n$. Show that this correspondence preserves addition, multiplication, and inversion.

(d) Interpret this correspondence as follows. Let $S = \{e_1, \ldots, e_n\}$ be the standard (ordered) basis for $\mathbb{C}^n$ as a vector space over $\mathbb{C}$. Then the set $B = \{e_1, ie_1, \ldots, e_n, ie_n\}$ is an ordered basis for $\mathbb{C}^n$ as a real vector
space. If $T$ is a real-linear transformation from $\mathbb{C}^n$ to $\mathbb{C}^m$, then the matrix for $T$ with respect to the $B$-bases is complex if and only if $T$ is complex-linear, in which case its matrix (over $\mathbb{C}$) with respect to the standard bases is the corresponding matrix in $M_{mn}(\mathbb{C})$.

(e) More generally, show that if $R$ is a ring, and $R'$ is a subring of $M_k(R)$, then the $m \times n$ matrices over $R'$ can be identified with the set of $km \times kn$ matrices over $R$ whose $k \times k$ block entries are in $R'$, and the identification preserves matrix addition, multiplication, and (if $R'$ is closed under inverses in $M_k(R)$) inversion. In particular, if $\mathbb{F}$ is a field and $\mathbb{F}'$ is a finite extension field of degree $k$, then $\mathbb{F}'$ can be embedded as a (unital) subring of $M_k(\mathbb{F})$, so this construction applies.

(f) Interpret this problem as a special case of the tensor product construction ().
Chapter IV

Sequences and Series

Infinite sequences and infinite series can be regarded as the beginning of analysis. The idea that a sequence of numbers can approach a limiting value, or that an infinite set of numbers can be “added”, is the principal concept that underlies the whole development of the subject. The notion of limit of a sequence is a subtle one which takes some getting used to, but which must be mastered before calculus and analysis of any type can be understood.

Sequences and their limits appear in various contexts throughout mathematics. The most basic situation is sequences of real (or complex) numbers, which is where we begin. The subject then moves on to sequences of points in a metric space, and then to sequences in topological spaces; in fact, the entire subject of topology can be regarded as a way of giving a general setting for studying limits of sequences. Another (intertwined) direction of development is the theory of limits of sequences of functions. The study of infinite series of numbers or functions may be regarded as a special case of the theory of sequences, or really the same theory from a different point of view, although much of this theory predated the advent of a careful theory of sequences and developed in parallel.

In this chapter, we will develop the theory of sequences and their limits, first for numbers and then in more general settings, and the theory of infinite series of numbers. Infinite sequences and series of functions will be postponed until the calculus chapter.

IV.1. Sequences

Recall () that a sequence in a set $X$ is a function from $\mathbb{N}$ to $X$. The usual notation uses a subscript for the argument of the function, which is called the index of the sequence. Thus the value of the function (sequence) $a$ at the number $n$ is normally written $a_n$ instead of $a(n)$; $a_n$ is called the $n$'th term of the sequence. Occasionally the index of a sequence takes values in a set of the form $\{n \in \mathbb{Z} : n \geq n_0\}$ instead of in $\mathbb{N}$.

The notation $(x_n)$ is commonly used to denote a sequence; the notation $(x_n)_{n \in \mathbb{N}}$ is a more precise variation. Some authors use the notation $(x_n)$, or something similar. Note the difference between $(x_n)$ and $x_n$: $(x_n)$ refers to the entire sequence, while $x_n$ denotes the $n$'th term of the sequence for a specific single $n$. We sometimes write a formula for the $n$'th term, surrounded by parentheses, to define a sequence; thus, for example, $(\frac{1}{n})$ or, more precisely, $(\frac{1}{n})_{n \in \mathbb{N}}$, denotes the sequence $(x_n)$ with $x_n = \frac{1}{n}$ for each $n$. 

412
IV.1.1. Sequences of Numbers

In this section and the subsequent subsections, we will concentrate on sequences of numbers, real or (occasionally) complex. The structure of the real numbers makes possible some definitions and operations which do not make sense for sequences in general sets.

Terms and Range of Sequences

IV.1.1.1. If \((x_n)\) is a sequence of numbers (or a sequence in a general set \(X\)), a careful distinction must be made between the terms of the sequence and the set \(\{x_n : n \in \mathbb{N}\}\). This set is the range of the function from \(\mathbb{N}\) to \(\mathbb{R}\) (or \(X\)). For example, consider the sequence \((-1)^n = (-1, 1, -1, 1, \ldots)\). There are infinitely many terms in this sequence, as there are in any sequence, but the range of the sequence is the two-point set \(\{1, -1\}\). The terms \(x_2\) and \(x_4\) are different terms of the sequence, even though these terms have the same numerical value. The most extreme example is a constant sequence, where all the terms of the sequence have the same numerical value; they are nonetheless distinct terms.

This distinction causes complications when we try to depict sequences on the number line. Fortunately, sequences which arise naturally in applications tend to have terms with distinct values, i.e. as a function the sequence is injective, and for such sequences the distinction largely disappears, but not entirely: for example, if the order of the terms is rearranged a different sequence is obtained, even though it has the same range.

Bounded and Unbounded Sequences

IV.1.1.2. **Definition.** A sequence \((x_n)\) of real numbers is bounded above if there is an \(M \in \mathbb{R}\) such that \(x_n \leq M\) for all \(n\). The sequence \((x_n)\) is bounded below if there is an \(M \in \mathbb{R}\) such that \(M \leq x_n\) for all \(n\). The sequence \((x_n)\) is bounded if it is both bounded above and bounded below, i.e. if there is an \(M \in \mathbb{R}\) such that \(|x_n| \leq M\) for all \(n\). A sequence which is not bounded is unbounded.

In other words, the sequence \((x_n)\) is bounded [bounded above, bounded below] if and only if the range \(\{x_n : n \in \mathbb{N}\}\) is bounded [bounded above, bounded below] as a subset of \(\mathbb{R}\).

Algebraic Operations on Sequences

IV.1.2. Subsequences and Tails

IV.1.3. Limits of Sequences

IV.1.3.1. Now we turn to the fundamental concept of analysis, the notion of what it means for a sequence to converge to a limit. The idea is that the sequence \((x_n)\) approaches the limit (limiting value) \(a\) if eventually, i.e. from some point on, the terms of the sequence are approximately equal to \(a\) to within any given tolerance. Pictorially, for sequences of numbers, on the number line the number \(x_n\) should become almost indistinguishable from the limiting value \(a\) for all sufficiently large \(n\):

The terms of the sequence, however, do not ever have to be exactly equal to the limit, and “usually” are not. Indeed, the notion of limit is most interesting for sequences which are not eventually constant.

It is important to note that “most” sequences of numbers do not approach a limiting value, i.e. do not converge. In fact, it is quite special for a sequence to have a limit.
IV.1.3.2. A way of making this notion precise is to say that the sequence \((x_n)\) approaches the limit \(a\) if, no matter how tiny an interval \(I\) around \(a\) we specify, all the terms of the sequence eventually lie within the interval \(I\). The smaller the interval \(I\), the longer we might have to wait before the terms of the sequence settle down into \(I\), but eventually they must for any \(I\):

We are thus led to the following formal definition.

IV.1.3.3. Definition. [Limit of a Sequence, Version 1] Let \((x_n)\) be a sequence in \(\mathbb{R}\), and \(a \in \mathbb{R}\). The sequence \((x_n)\) converges to \(a\), or \(a\) is the limit of the sequence \((x_n)\), if for every interval \(I\) in \(\mathbb{R}\) containing \(a\) in its interior, there is an \(N \in \mathbb{N}\) such that \(x_n \in I\) for all \(n \geq N\).

IV.1.3.4. It turns out to usually be more useful in practice to rephrase the definition slightly. It is only necessary to consider open intervals which are centered at \(a\), since any interval containing \(a\) in its interior contains a smaller open interval centered at \(a\). It is customary in analysis to use the Greek letter epsilon (\(\epsilon\)), or the Greek letter delta (\(\delta\)), to denote the length of the interval to the left or right of \(a\); thus any (bounded) interval centered at \(a\) is of the form

\[(a-\epsilon, a+\epsilon)\]

for some positive real number \(\epsilon\), and conversely any \(\epsilon > 0\) defines such an interval:

Thus we can rephrase the definition in an equivalent way:

IV.1.3.5. Definition. [Limit of a Sequence, Version 2] Let \((x_n)\) be a sequence in \(\mathbb{R}\), and \(a \in \mathbb{R}\). The sequence \((x_n)\) converges to \(a\), or \(a\) is the limit of the sequence \((x_n)\), if for every \(\epsilon > 0\), there is an \(N \in \mathbb{N}\) such that

\[a - \epsilon < x_n < a + \epsilon\]

for all \(n \geq N\).

There is one last slight notational variation. Note that \(|x_n - a| < \epsilon\) if and only if \(a - \epsilon < x_n < a + \epsilon\). Thus we can restate the definition in its usual form:

IV.1.3.6. Definition. [Limit of a Sequence, Final Version] Let \((x_n)\) be a sequence in \(\mathbb{R}\), and \(a \in \mathbb{R}\). The sequence \((x_n)\) converges to \(a\), or \(a\) is the limit of the sequence \((x_n)\), if for every \(\epsilon > 0\), there is an \(N \in \mathbb{N}\) such that

\[|x_n - a| < \epsilon\]

for all \(n \geq N\).

The sequence \((x_n)\) diverges if there is a real number \(a\) such that \(a\) is the limit of the sequence \((x_n)\). If there is no such \(a\), the sequence \((x_n)\) diverges.

IV.1.3.7. It is unimportant in this definition whether or not we use strict inequality in the \(|x_n - a| < \epsilon\) and/or the \(n \geq N\), or whether we require that \(N \in \mathbb{N}\); see Exercise IV.1.11.1.
IV.1.3.8. **NOTATION:** There are two standard notations for the limit of a sequence. If \((x_n)\) converges to \(a\), we write

\[ x_n \to a \]

or

\[ \lim_{n \to \infty} x_n = a. \]

The last expression is read “the limit of \(x_n\) as \(n\) goes to infinity is \(a\).”

Note that we write \(\lim_{n \to \infty} x_n = a\), not \(\lim_{n \to \infty} x_n \to a\).

IV.1.3.9. **The definition of limit is often described as a game or bet.** If I claim that \(x_n \to a\) and you challenge me, we play a game. You give me a positive number \(\epsilon\), and I must produce an \(N\) that works in the definition for the \(\epsilon\) you give me. If I can, I win; if I can’t, you win. The smaller the \(\epsilon\) you give me, the harder it will be for me to find an \(N\) that works, and the larger it will have to be in general. But I don’t have to find the \(N\) until you give me your \(\epsilon\); my \(N\) can (and in general will) depend on what your \(\epsilon\) is.

A proof that \(x_n \to a\) really consists of a demonstration that I can always win the game; I must convince you that no matter what \(\epsilon\) you give me, I can always find an \(N\) that works, so that you realize it would be pointless for you to challenge me with any specific \(\epsilon\). On the other hand, a disproof that \(x_n \to a\) normally consists of demonstrating a specific positive \(\epsilon\) which is small enough that there is no \(N\) that works for it.

Note that for a given \(\epsilon\), there is more than one possible \(N\) that works: the \(N\) can always be increased with no penalty. If there is any \(N\) that works, there is always a smallest \(N\), but it may be difficult to find the smallest \(N\) in specific situations, and it is usually not necessary; a larger \(N\) which is easier to find works just as well. (There are instances, e.g. in some numerical work, where it is important to find the smallest, or at least very nearly the smallest, \(N\) that works in a given setting, but such situations are rather unusual in analysis.)

In the same way, if a certain \(N\) works for one \(\epsilon\) for a particular limit, the same \(N\) works for any larger \(\epsilon\), so there is no penalty in first making the \(\epsilon\) smaller before finding an \(N\) that works. It may be hard to believe that it can sometimes be useful to do this, but it is; see, for example, ()

IV.1.3.10. **EXAMPLES.** (i) Let \(x_n = \frac{1}{n}\) for all \(n\). This is one of the most important limits, and will appear constantly. It seems intuitively clear that \(x_n \to 0\). To prove this, we must show that for any \(\epsilon > 0\), there is an \(N\) such that

\[ |x_n - 0| = \left| \frac{1}{n} - 0 \right| = \frac{1}{n} < \epsilon \]

for all \(n \geq N\). So suppose \(\epsilon > 0\) is given. In order to have \(\frac{1}{n} < \epsilon\), it is sufficient (and also necessary) that \(n > \frac{1}{\epsilon}\). Thus we can choose \(N\) to be any natural number greater than \(\frac{1}{\epsilon}\). There is such an \(N\) by the Archimedean property of \(\mathbb{R}\) (). Then if \(n \geq N\), we have

\[ |x_n - 0| = \frac{1}{n} \leq \frac{1}{N} < \epsilon \]

so this \(N\) works for the given \(\epsilon\).

Note that if \(\epsilon\) is very small, then \(\frac{1}{\epsilon}\) is very large, so \(N\) will have to be large; the smaller the \(\epsilon\), the larger the \(N\) will have to be. For example, if \(\epsilon = 10^{-9}\), we will have to take \(N = 1,000,000,001\) (or any larger integer).

Note that none of the terms of this sequence are exactly equal to the limit 0.
(ii) Similarly, suppose \( x_n = 1 + \frac{1}{n} \). We guess that \( x_n \to 1 \). To prove this, we must show that, if \( \epsilon > 0 \), there is an \( N \) such that
\[
|x_n - 1| = \left| \left(1 + \frac{1}{n}\right) - 1\right| = \frac{1}{n} < \epsilon
\]
for all \( n \geq N \). Thus, by an identical argument to the one in (i), we can choose \( N \) to be any integer greater than \( \frac{1}{\epsilon} \).

(iii) Here is an example which is so simple that it is hard. Suppose \((x_n)\) is a constant sequence with \( x_n = a \) for all \( n \). We certainly expect that \( x_n \not\to a \). If \( \epsilon > 0 \), we have
\[
|x_n - a| = |a - a| = 0 < \epsilon
\]
for any \( n \). Thus we can take \( N = 1 \) no matter what \( \epsilon \) is, so \( x_n \to a \). This is practically the only example where the \( N \) does not depend on \( \epsilon \).

(iv) Suppose \( x_n = (-1)^n \) for all \( n \). Since this sequence alternates \( \pm 1 \), we might expect that the sequence has two limits, 1 and \(-1\). However, this is incorrect; in fact, this sequence diverges, i.e. has no limit, since to have a limit \( a \) all the terms of the sequence from some point on must be close to \( a \). (We will later define cluster points for sequences; this sequence has cluster points 1 and \(-1\).)

For example, let us show that \((x_n)\) does not converge to 1. We have \( |x_n - 1| = 0 \) if \( n \) is even, but \( |x_n - 1| = 2 \) for \( n \) odd. If we are given an \( \epsilon > 0 \), we may or may not be able to find an \( N \) that works. If the person challenging us is stupid enough to give us \( \epsilon = 3 \) (or any \( \epsilon > 2 \)), we can find an \( N \) that works: in fact, \( N = 1 \) works for such an \( \epsilon \). But if our challenger is smart enough to give us an \( \epsilon \) which is \( \leq 2 \), we cannot find an \( N \) that works, since no matter what \( N \) we take there will be an odd \( n \) which is greater than \( N \), and for this \( n \) we have
\[
|x_n - 1| = 2 \geq \epsilon .
\]
Thus we have shown that \((x_n)\) does not converge to 1. An almost identical argument shows that \((x_n)\) does not converge to \(-1\).

However, this does not yet show that the sequence \((x_n)\) diverges, i.e. that \( \lim_{n \to \infty} x_n \) does not exist. To do this, we must show that for any \( a \in \mathbb{R} \), the sequence does not converge to \( a \). Fix an \( a \in \mathbb{R} \). It suffices to exhibit an \( \epsilon > 0 \) for which there is no \( N \) that works for this \( \epsilon \) and \( a \). Take \( \epsilon = 1 \) (any smaller positive number also works). Suppose there is an \( N \) that works, i.e.
\[
|x_n - a| < 1
\]
for all \( n \geq N \). If we take \( n \) to be an odd number greater than \( N \), we have that
\[
|x_n - a| = |1 - a| = |1 + a| < 1
\]
and similarly if \( n \geq N \) is even, we have that
\[
|x_n - a| = |1 - a| < 1 .
\]
Thus we necessarily have the inequalities \( |1 + a| < 1 \) and \( |1 - a| < 1 \), so using the triangle inequality we have
\[
2 = |(1 + a) + (1 - a)| \leq |1 + a| + |1 - a| < 1 + 1
\]
which is a contradiction. Thus the sequence cannot converge to any \( a \in \mathbb{R} \), and hence diverges.
IV.1.3.11. In many books and references, the phrase “closer and closer” is used to informally describe the limiting process, i.e. \( x_n \to a \) if \( x_n \) gets “closer and closer” to \( a \) as \( n \to \infty \). But this phrasing is too imprecise to be an adequate definition, and is even not entirely correct. For example, as SAUNDERS MACLANE was fond of pointing out, the sequence \((1 + \frac{1}{n})\) gets closer and closer to 0 as \( n \to \infty \). The missing idea is the notion of eventually becoming \textit{arbitrarily} close. We might add that if, for example, \( x_n = 1 \) for all \( n \), then \( x_n \to 1 \), but \( x_n \) does not get “closer and closer” to 1 as \( n \) increases since one cannot get any closer to 1 than 1 itself. And, anyway, if \( x_n \to a \) the distance between \( x_n \) and \( a \) need not monotonically decrease as \( n \) increases, e.g. if \( x_n = \frac{1}{n^2} \) for \( n \) odd and \( x_n = \frac{1}{n} \) for \( n \) even (with \( a = 0 \)), so \( x_n \) does not really get “closer and closer” to \( a \). Thus it is best not to use this phrase at all even though it has some conceptual legitimacy.

IV.1.3.12. Indeed, the primary intellectual step forward (primarily due to CAUCHY, although reaching full fruition only with WEIERSTRASS) which made a satisfactory definition of limit possible was abandonment of the “dynamic” idea of approach, which previously dominated thought and discourse on the subject and was an apparently insurmountable obstacle to making a careful and rigorous definition, replacing it with a “static” one of simply being approximately equal within an arbitrarily specified tolerance. The dynamic point of view still has considerable intuitive value, however.

**Uniqueness of Limits**

We have used some suggestive language in Definition IV.1.3.6: we have referred to “the limit of a (convergent) sequence.” To justify this language, we must show that a sequence cannot have more than one limit:

IV.1.3.13. **Theorem.** The limit of a convergent sequence is unique: if \((x_n)\) is a sequence in \( \mathbb{R} \), \( a, b \in \mathbb{R} \), and \( x_n \to a \) and \( x_n \to b \), then \( a = b \).

The idea of the proof is simple: if \( I \) and \( J \) are intervals around \( a \) and \( b \) respectively, and both \( x_n \to a \) and \( x_n \to b \) are true, then for all sufficiently large \( n \) we must have \( x_n \in I \), and similarly for all sufficiently large \( n \) we have \( x_n \in J \). But if \( a \neq b \), then if \( I \) and \( J \) are short enough they are disjoint, so we cannot simultaneously have \( x_n \in I \) and \( x_n \in J \) for any \( n \).

The details of the proof give a good example of how the definition of limit is used, and also of some of the common basic techniques used in analysis proofs. A reader unfamiliar with analysis proofs should be sure to examine the proof carefully to understand how it works logically and how it reflects the informal outline of the previous paragraph.

**Proof:** We will prove the statement by contradiction. Suppose \( a \neq b \), i.e. \(|a - b| > 0\). Set \( \epsilon = \frac{1}{2}|a - b| \); then \( \epsilon > 0 \). Since \( x_n \to a \), there is an \( N_1 \) such that \( |x_n - a| < \epsilon \) for all \( n \geq N_1 \). Similarly, there is an \( N_2 \) such that \( |x_n - b| < \epsilon \) for all \( n \geq N_2 \). Set \( n = \max(N_1, N_2) \). Then \( |x_n - a| < \epsilon \) and \( |x_n - b| < \epsilon \) for this \( n \), so using the triangle inequality () we have

\[
|a - b| = |(a - x_n) + (x_n - b)| \leq |a - x_n| + |x_n - b| < \epsilon + \epsilon = 2\epsilon = \frac{2}{3}|a - b|
\]

and dividing both ends by \(|a - b|\), we obtain \( 1 < \frac{2}{3} \), which is a contradiction. ☞
IV.1.3.14. The “trick” of adding and subtracting the same thing within an absolute value and using the triangle inequality is one of the most important techniques in analysis, and will be seen in a great many arguments. (It is said that the difference between a “trick” and a “technique” is that a trick is a procedure which is used once, or a few times, and a technique a procedure which is used multiple times. This is definitely a technique under this distinction.)

IV.1.3.15. There is a subtle point connected with the proof of IV.1.3.13., which can be confusing to beginners. If I am trying to prove that $x_n \to a$, I am not allowed to choose the $\epsilon$; I must show that there is an $N$ that works for any $\epsilon$ someone else may decide to give me. But if I am assuming that $x_n \to a$ and want to use this to prove something else, as in the proof of IV.1.3.13., I am free to choose any $\epsilon$ I please, as long as it is positive, and I am assured (by my assumption) that there is an $N$ that works for this $\epsilon$.

**Boundedness and Convergence**

A convergent sequence is bounded:

IV.1.3.16. **Proposition.** Let $(x_n)$ be a convergent sequence in $\mathbb{R}$. Then $(x_n)$ is bounded: there is an $M \in \mathbb{R}$ such that $|x_n| \leq M$ for all $n$.

**Proof:** Suppose $x_n \to a$. Let $N$ be a natural number that works in the definition of limit for $\epsilon = 1$, i.e. $|x_n - a| < 1$ for all $n \geq N$. Then $a - 1 < x_n < a + 1$ for all $n \geq N$, so $|x_n| \leq |a| + 1$ for all $n \geq N$. Set

$$M = \max(|x_1|, |x_2|, \ldots, |x_{N-1}|, |a| + 1)$$

(this is a finite set of numbers, so the maximum exists). Then $|x_n| \leq M$ for all $n$. 

IV.1.3.17. The converse is false: a bounded sequence does not converge in general. A simple example is $((-1)^n)$. But a bounded sequence always has a convergent subsequence ( ).

A companion result, showing that the limit of a convergent sequence lies within any closed interval containing the sequence, is very important:

IV.1.3.18. **Theorem.** Let $(x_n)$ be a convergent sequence in $\mathbb{R}$, with $x_n \to c$. Then

(i) If $a \in \mathbb{R}$, $a < c$, then there is an $N \in \mathbb{N}$ such that $a < x_n$ for all $n \geq N$.

(ii) If $b \in \mathbb{R}$, $c < b$, then there is an $N \in \mathbb{N}$ such that $x_n < b$ for all $n \geq N$.

(iii) If $a \in \mathbb{R}$, $a \leq x_n$ for all $n$ or more generally if there is an $N$ such that $a \leq x_n$ for all $n \geq N$, then $a \leq c$.

(iv) If $b \in \mathbb{R}$, $x_n \leq b$ for all $n$ or more generally if there is an $N$ such that $x_n \leq b$ for all $n \geq N$, then $c \leq b$.

(v) If $a, b \in \mathbb{R}$, $a \leq x_n \leq b$ for all $n$ or more generally if there is an $N$ such that $a \leq x_n \leq b$ for all $n \geq N$, then $a \leq c \leq b$. 

418
Proof: (i): Set $\epsilon = c - a > 0$. Then there is an $N$ such that

$$a = c - \epsilon < x_n$$

for all $n \geq N$.

(ii): Nearly identical to (i), setting $\epsilon = b - c$.

(iii) and (iv) are the contrapositives of (ii) and (i) respectively, and (v) is a combination of (iii) and (iv).

**Caution:** The forms of the inequalities in this result are very important. In (i) and (ii) strict inequality in the hypothesis is essential. In (iii)-(v), if we have strict inequality in the hypothesis, the result applies, but we do not necessarily get strict inequality in the conclusion. For example, if $x_n = \frac{1}{n}$, then $0 < x_n$ for all $n$, but the limit is not positive.

Here is a simple corollary of (i) and (ii) which is useful:

**Corollary.** Let $(x_n)$ be a sequence of real numbers, and $c \in \mathbb{R}$. If $x_n \to c$ and $c \neq 0$, then there is an $N \in \mathbb{N}$ such that $x_n \neq 0$ for all $n \geq N$.

Proof: Apply IV.1.3.18. (i) with $a = 0$ if $c > 0$, and IV.1.3.18. (ii) with $b = 0$ if $c < 0$.

This corollary also has a simple direct proof which works in $\mathbb{C}$ as well as in $\mathbb{R}$: Set $\epsilon = \frac{|c|}{2}$ and choose $N$ as in the definition of limit for this $\epsilon$.

**Limits and Subsequences**

**Algebraic Operations and Limits**

The algebraic operations (addition, multiplication, division) behave nicely with respect to limits.

**Theorem.** Let $(x_n)$ and $(y_n)$ be sequences in $\mathbb{R}$. Suppose $x_n \to a$ and $y_n \to b$. Then

(i) $x_n + y_n \to a + b$.

(ii) $x_n y_n \to ab$.

(iii) If $y_n \neq 0$ for all $n$ and $b \neq 0$, then $\frac{x_n}{y_n} \to \frac{a}{b}$. 

419
IV.1.3.22. The theorem is often informally stated as “the limit of a sum [product, quotient] is the sum [product, quotient] of the limits,” and written

\[
\lim_{n \to \infty} (x_n + y_n) = \left( \lim_{n \to \infty} x_n \right) + \left( \lim_{n \to \infty} y_n \right)
\]

\[
\lim_{n \to \infty} (x_n y_n) = \left( \lim_{n \to \infty} x_n \right) \left( \lim_{n \to \infty} y_n \right)
\]

\[
\lim_{n \to \infty} \left( \frac{x_n}{y_n} \right) = \frac{\lim_{n \to \infty} x_n}{\lim_{n \to \infty} y_n}
\]

(provided \(\lim_{n \to \infty} y_n \neq 0\)).

However, stating the result this way can be misleading if one is not careful. The results only hold under the assumption that the sequences \((x_n)\) and \((y_n)\) converge, i.e. the limits on the right side exist; existence of the limits on the left in these expressions does not mean the limits on the right exist and that the limits on the left can be calculated in the indicated way. So care must be exercised not to try to apply the converse of the statements of IV.1.3.21.

The following special case of IV.1.3.21. (ii) (with \((y_n)\) a constant sequence) is used very frequently:

IV.1.3.23. Corollary. Let \((x_n)\) be a sequence of real numbers, and \(a \in \mathbb{R}\). If \(x_n \to a\), then for any \(c \in \mathbb{R}\) the sequence \((cx_n)\) converges to \(ca\). In other words, if \((x_n)\) converges, then \((cx_n)\) converges and

\[
\lim_{n \to \infty} (cx_n) = c \cdot \left( \lim_{n \to \infty} x_n \right)
\]

IV.1.3.24. We first give the proof of IV.1.3.21.(i). We will give the reasoning steps in great detail since the technique is a very common one which can be confusing to beginners; note the comments in IV.1.3.15.

Let \(\epsilon > 0\) be given. We must find an \(N\) (i.e. show that one exists) such that

\[
| (x_n + y_n) - (a + b) | < \epsilon
\]

for all \(n \geq N\). We assume that \(x_n \to a\), so for any \(\epsilon_1 > 0\) (not necessarily the given \(\epsilon\)) there is an \(N_1\) such that \(|x_n - a| < \epsilon_1\) for all \(n \geq N_1\). Similarly, since \(y_n \to b\), for any \(\epsilon_2 > 0\) (not necessarily the same as either \(\epsilon\) or \(\epsilon_1\)) there is an \(N_2\) such that \(|y_n - b| < \epsilon_2\) for all \(n \geq N_2\). Thus, if we fix an \(\epsilon_1\) and an \(\epsilon_2\) and take the corresponding \(N_1\) and \(N_2\), and set \(N = \max(N_1, N_2)\), we have

\[
| (x_n + y_n) - (a + b) | = | (x_n - a) + (y_n - b) | \leq |x_n - a| + |y_n - b| < \epsilon_1 + \epsilon_2
\]

for all \(n \geq N\). We are given \(\epsilon\), but we are free to choose \(\epsilon_1\) and \(\epsilon_2\) however we please, and there are automatically corresponding \(N_1\) and \(N_2\), hence an \(N\) that works for the limit of the sum for \(\epsilon_1 + \epsilon_2\). All we need to do is choose \(\epsilon_1\) and \(\epsilon_2\) so that \(\epsilon_1 + \epsilon_2 \leq \epsilon\), and the process gives us an \(N\) that works for the limit of the sum for the given \(\epsilon\). The simplest thing is just to choose

\[
\epsilon_1 = \epsilon_2 = \frac{\epsilon}{2}
\]

420
All of this could be regarded as preliminary “scratch work” giving us the idea of the proof. The way we would write the proof formally is:

**Proof:** Let $\epsilon > 0$. Since $x_n \to a$, there is an $N_1$ such that $|x_n - a| < \frac{\epsilon}{2}$ for all $n \geq N_1$. Since $y_n \to b$, there is an $N_2$ such that $|y_n - b| < \frac{\epsilon}{2}$ for all $n \geq N_2$. Set $N = \max(N_1, N_2)$. Then, for all $n \geq N$,

$$|(x_n + y_n) - (a + b)| = |(x_n - a) + (y_n - b)| \leq |x_n - a| + |y_n - b| < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon$$

and so, since $\epsilon > 0$ is arbitrary, $x_n + y_n \to a + b$.

**IV.1.3.25.** Now we turn to the proof of **IV.1.3.21.(ii).** The argument is somewhat similar, but more complicated. We go through the reasoning more quickly.

As before, for any $\epsilon_1$ and $\epsilon_2$ we have an $N$ such that $|x_n - a| < \epsilon_1$ and $|y_n - b| < \epsilon_2$ for all $n \geq N$. Then, by the adding and subtracting technique, we have

$$|x_ny_n - ab| = |(x_ny_n - ay_n) + (ay_n - ab)| \leq |x_ny_n - ay_n| + |ay_n - ab| = |y_n||x_n - a| + |a||y_n - b| < |y_n|\epsilon_1 + |a|\epsilon_2$$

for all $n \geq N$. Thus, if we are given an $\epsilon > 0$, we want to choose $\epsilon_1$ and $\epsilon_2$ so that

$$|y_n|\epsilon_1 + |a|\epsilon_2 \leq \epsilon$$

for all $n$. We might try

$$\epsilon_1 = \frac{\epsilon}{2|y_n|} \quad \text{and} \quad \epsilon_2 = \frac{\epsilon}{2|a|}$$

but there is a serious problem with the first of these since $\epsilon_1$ cannot depend on $n$. (There is a slight problem with the other one too since we could have $a = 0$.)

Fortunately, there is an easy way past the difficulty. Since $(y_n)$ converges, it is bounded (**IV.1.3.16.**); hence there is an $M$ such that $|y_n| \leq M$ for all $n$. We might as well choose $M$ so that $|a| \leq M$ to ease notation; and we can assume $M > 0$ since there is no penalty in increasing $M$ (and the case where we can take $M = 0$ is pretty trivial anyway). Then we can take

$$\epsilon_1 = \epsilon_2 = \frac{\epsilon}{2M}$$

for this $M$. Thus the formal proof is:

**Proof:** Let $\epsilon > 0$. Since $(y_n)$ converges, there is an $M$ such that $|y_n| \leq M$ for all $n$ by **IV.1.3.16.**; we may also assume $M > 0$ and $|a| \leq M$ by increasing $M$ if necessary. Since $x_n \to a$, there is an $N_1$ such that $|x_n - a| < \frac{\epsilon}{2M}$ for all $n \geq N_1$, and since $y_n \to b$ there is an $N_2$ such that $|y_n - b| < \frac{\epsilon}{2M}$ for all $n \geq N_2$. Set $N = \max(N_1, N_2)$. If $n \geq N$, then

$$|x_ny_n - ab| = |(x_ny_n - ay_n) + (ay_n - ab)| \leq |x_ny_n - ay_n| + |ay_n - ab| = |y_n||x_n - a| + |a||y_n - b|$$

$$\leq M|x_n - a| + M|y_n - b| < M\frac{\epsilon}{2M} + M\frac{\epsilon}{2M} = \epsilon$$

and so, since $\epsilon > 0$ is arbitrary, $x_ny_n \to ab$. $\diamondsuit$
Finally, we prove (iii). It will actually suffice to prove the following special case:

**Lemma.** Let \((y_n)\) be a convergent sequence of real numbers, \(y_n \to b\), with all \(y_n \neq 0\) and \(b \neq 0\). Then \(\frac{1}{y_n} \to \frac{1}{b}\).

Then (iii) follows by combining the lemma with (ii). (Note also that the hypothesis in (iii) that \(y_n \neq 0\) for all \(n\) is almost automatic: by IV.1.3.20., \(y_n \neq 0\) for all sufficiently large \(n\) if \(b \neq 0\).)

To prove the lemma, note that

\[
\frac{1}{y_n} - \frac{1}{b} = \frac{b - y_n}{by_n}
\]

for all \(n\). Thus we have

\[
\frac{1}{|y_n - b|} = \frac{1}{|by_n|} |y_n - b|
\]

for all \(n\). If we can show that the sequence \(\left(\frac{1}{|y_n|}\right)\) is bounded, we can easily proceed. Note that since \(b \neq 0\), there is an \(N_1\) such that \(|y_n - b| < \frac{|b|}{2}\) for all \(n \geq N_1\), and thus \(|y_n| > \frac{|b|}{2}\) for \(n \geq N_1\). Set

\[
M = \max\left(\frac{1}{|by_1|}, \ldots, \frac{1}{|by_{N_1-1}|}, \frac{2}{|b|^2}\right)
\]

and note that \(\frac{1}{|y_n|} \leq M\) for all \(n\) (and that \(M > 0\)).

Now suppose \(\epsilon > 0\) is given. There is an \(N\) such that

\[
|y_n - b| < \frac{\epsilon}{M}
\]

for all \(n \geq N\). Then, for \(n \geq N\),

\[
\frac{1}{|y_n - b|} = \frac{1}{|by_n|} |y_n - b| \leq M \frac{\epsilon}{M} = \epsilon
\]

**IV.1.3.27.** Note that IV.1.3.21.(iii) does not apply if \(b = 0\), even if \(y_n \neq 0\) for all \(n\). It turns out that if \(b = 0\) and \(a \neq 0\), then \(\lim \limits_{n \to \infty} \left(\frac{x_n}{y_n}\right)\) cannot exist (since if it did, and equaled \(c\), we would have

\[
a = \lim \limits_{n \to \infty} \left(\frac{x_n}{y_n}\right) = \left(\lim \limits_{n \to \infty} y_n\right) \left(\lim \limits_{n \to \infty} \left(\frac{x_n}{y_n}\right)\right) = bc
\]

by (ii), which is impossible). But if \(a = b = 0\), the limit of the quotient sequence can exist, but cannot be computed simply in general. This is a type of indeterminate form. One of the important parts of calculus and analysis is the resolution of indeterminate forms of various types; see (), (), . . .

**Limits in \(\mathbb{C}\)**

Limits in \(\mathbb{C}\) behave essentially identically to those in \(\mathbb{R}\), although the geometric interpretation is a little different (it is essentially like the interpretation in \(\mathbb{R}^n\) described in ()). The definition of convergence in \(\mathbb{C}\) is identical to the final version (IV.1.3.6.) with \(\mathbb{R}\) replaced by \(\mathbb{C}\) throughout and no other changes:
IV.1.3.28. **Definition.** [Limit of a Complex Sequence] Let \((z_n)\) be a sequence in \(\mathbb{C}\), and \(c \in \mathbb{C}\). The sequence \((z_n)\) *converges* to \(c\), or \(c\) is the *limit* of the sequence \((z_n)\), if for every \(\epsilon > 0\), there is an \(N \in \mathbb{N}\) such that

\[ |z_n - c| < \epsilon \]

for all \(n \geq N\).

The sequence \((z_n)\) *converges* if there is a complex number \(c\) such that \(c\) is the limit of the sequence \((z_n)\). If there is no such \(c\), the sequence \((z_n)\) *diverges*.

IV.1.3.29. All the results about real sequences except those depending on the ordering of \(\mathbb{R}\) (e.g. IV.1.3.18. and the results on monotone sequences) hold for sequences in \(\mathbb{C}\), with identical proofs. As an alternate approach, we may reduce the theory of sequences in \(\mathbb{C}\) to the theory for \(\mathbb{R}\) by considering real and imaginary parts.

IV.1.3.30. **Proposition.** Let \((z_n)\) be a sequence in \(\mathbb{C}\). For each \(n\), write \(z_n = x_n + iy_n\) with \(x_n, y_n \in \mathbb{R}\). Then \((x_n)\) and \((y_n)\) are real sequences. If \(c = a + ib \in \mathbb{C}\) with \(a, b \in \mathbb{R}\), then \(z_n \to c\) if and only if \(x_n \to a\) and \(y_n \to b\).

**Proof:** Suppose \(z_n \to c\). Let \(\epsilon > 0\). There is an \(N\) such that \(|z_n - c| < \epsilon\) for all \(n \geq N\). Since the real and imaginary parts of a complex number are not larger than the absolute value,

\[ |x_n - a| \leq |x_n - a + i(y_n - b)| = |z_n - c| < \epsilon \]

for all \(n \geq N\), so \(x_n \to a\). Similarly, \(y_n \to b\).

Conversely, suppose \(x_n \to a\) and \(y_n \to b\). Let \(\epsilon > 0\). Then there is an \(N_1\) such that

\[ |x_n - a| < \frac{\epsilon}{2} \]

for all \(n \geq N_1\), and there is an \(N_2\) such that

\[ |y_n - b| < \frac{\epsilon}{2} \]

for all \(n \geq N_2\). Set \(N = \max(N_1, N_2)\). Then, if \(n \geq N\),

\[ |z_n - c| = |(x_n - a) + i(y_n - b)| \leq |x_n - a| + |y_n - b| < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon \]

and thus \(z_n \to c\).

IV.1.4. **Infinite Limits**

IV.1.5. **Monotone Sequences**

IV.1.6. **Subsequences and Cluster Points of Sequences**

“Most” sequences, even most bounded sequences, do not converge.
The Bolzano-Weierstrass Theorem

IV.1.7. Limit Superior and Limit Inferior

In this subsection, we define two generalizations of limit for sequences of real numbers, limit superior and limit inferior. Every real sequence has a limit superior and a limit inferior, even sequences which do not converge; in fact, these notions are most interesting for nonconvergent sequences (they both just reduce to the usual limit for convergent sequences).

These notions make essential use of the ordering on \(\mathbb{R}\), and thus do not generalize to \(\mathbb{C}\), \(\mathbb{R}^n\), or general metric spaces.

Limit Superior and Limit Inferior for Bounded Sequences

We first consider only bounded sequences for simplicity. We give the formal definitions, then explain them.

IV.1.7.1. Definition. Let \((x_n)\) be a bounded sequence in \(\mathbb{R}\). Define

\[
\limsup_{n \to \infty} x_n = \lim_{n \to \infty} \left[ \sup_{k \geq n} x_k \right] = \inf_n \left[ \sup_{k \geq n} x_k \right]
\]

\[
\liminf_{n \to \infty} x_n = \lim_{n \to \infty} \left[ \inf_{k \geq n} x_k \right] = \sup_n \left[ \inf_{k \geq n} x_k \right]
\]

called the limit superior and limit inferior of \((x_n)\) respectively.

IV.1.7.2. To explain these definitions, first note that the set \(\{x_k : k \geq n\}\) is a bounded nonempty set of numbers for any \(n\), hence has a supremum \(s_n\) and infimum \(t_n\). As \(n\) increases, \(s_n\) decreases and \(t_n\) increases since the set \(\{x_k : k \geq n\}\) decreases. Thus \((s_n)\) is a bounded decreasing (nonincreasing) sequence, hence converges to its infimum; similarly, \((t_n)\) increases and converges to its supremum. These limits are \(\limsup_{n \to \infty} x_n\) and \(\liminf_{n \to \infty} x_n\) respectively.

The \(\limsup_{n \to \infty} x_n\) and \(\liminf_{n \to \infty} x_n\) are often written \(\limsup_{n \to \infty} x_n\) and \(\liminf_{n \to \infty} x_n\) respectively. In all notations the “\(n \to \infty\)” is frequently omitted whenever there is no possibility of confusion.

IV.1.7.3. Examples. (i) Let \(x_n = (-1)^n\). For each \(n\) we have \(\sup_{k \geq n} x_k = 1\) and \(\inf_{k \geq n} x_k = -1\), so \(\limsup_{n \to \infty} x_n = 1\) and \(\liminf_{n \to \infty} x_n = -1\).

(ii) Let \(x_n = (-1)^n \left(1 + \frac{1}{n}\right)\). Then for \(n\) odd we have \(\sup_{k \geq n} x_k = 1 + \frac{1}{n+1}\) and \(\inf_{k \geq n} x_k = -1 - \frac{1}{n+1}\), and for \(n\) even we have \(\sup_{k \geq n} x_k = 1 + \frac{1}{n}\) and \(\inf_{k \geq n} x_k = -1 - \frac{1}{n+1}\), so \(\limsup_{n \to \infty} x_n = 1\) and \(\liminf_{n \to \infty} x_n = -1\).

(iii) Let \(x_n = \sin n\). Then \(-1 < x_n < 1\) for all \(n\). There is a sequence \((n_j)\) in \(\mathbb{N}\) with \(\sin n_j \to 1\) (), so for any \(n\) we have \(\sup_{k \geq n} x_k = 1\) and \(\limsup_{n \to \infty} x_n = 1\). Similarly, there is a sequence \((m_j)\) in \(\mathbb{N}\) with \(\sin m_j \to -1\), so for any \(n\) we have \(\inf_{k \geq n} x_k = -1\) and \(\liminf_{n \to \infty} x_n = -1\).
IV.1.7.4. We obviously have $\lim\inf x_n \leq \lim\sup x_n$ since $t_n \leq s_n$ for each $n$. We will show (IV.1.7.9.) that $\lim\sup x_n$ and $\lim\inf x_n$ are just the largest and smallest cluster points () of the sequence $(x_n)$, which is usually the best way to think of them. To begin with, we make the following observation:

IV.1.7.5. **Proposition.** Let $(x_n)$ be a bounded sequence in $\mathbb{R}$, and let $a \in \mathbb{R}$.

(i) If for every $\epsilon > 0$ there are only finitely many $x_n$ satisfying $x_n > a + \epsilon$, then $\lim\sup x_n \leq a$.

(ii) If for every $\epsilon > 0$ there are infinitely many $x_n$ satisfying $x_n > a - \epsilon$, then $\lim\sup x_n \geq a$.

(iii) If for every $\epsilon > 0$ there are only finitely many $x_n$ satisfying $x_n < a - \epsilon$, then $\lim\inf x_n \geq a$.

(iv) If for every $\epsilon > 0$ there are infinitely many $x_n$ satisfying $x_n < a + \epsilon$, then $\lim\inf x_n \leq a$.

**Proof:**

(i): Let $\epsilon > 0$, and fix $N$ so that $x_k \leq a + \epsilon$ for all $k \geq N$. Then, for all $n \geq N$, $s_n = \sup_{k \geq n} x_k \leq a + \epsilon$, so $\lim\sup x_n = \lim_{n \to \infty} s_n \leq a + \epsilon$. Since this is true for every $\epsilon > 0$, $\lim\sup x_n \leq a$.

(ii) For any $\epsilon > 0$, we have $s_n > a - \epsilon$ for every $n$, so each $s_n$ satisfies $s_n \geq a$ and thus $\inf_n s_n \geq a$.

(iii) and (iv) are essentially identical with inequalities reversed.

A simple rephrasing is often useful:

IV.1.7.6. **Corollary.** Let $(x_n)$ be a bounded sequence. Then

(i) $\lim\sup x_n = \inf \{b \in \mathbb{R} : x_n < b \text{ for all sufficiently large } n\}$.

(ii) $\lim\inf x_n = \sup \{a \in \mathbb{R} : x_n > a \text{ for all sufficiently large } n\}$.

**Proof:** For (i), let $B = \inf \{b \in \mathbb{R} : x_n < b \text{ for all sufficiently large } n\}$ and $L = \lim\sup x_n$. Then we have $L \leq B$ by IV.1.7.5.(i) and $L \geq B$ by IV.1.7.5.(ii). The proof of (ii) is analogous.

The next result gives a useful way of thinking of $\lim\sup$ and $\lim\inf$.

IV.1.7.7. **Theorem.** Let $(x_n)$ be a bounded sequence.

(i) Let $L = \lim\sup x_n$. Then $L$ satisfies

(a) For any $\epsilon > 0$ there are infinitely many $n$ such that $x_n > L - \epsilon$

(b) For any $\epsilon > 0$ there are only finitely many $n$ such that $x_n > L + \epsilon$

and $L$ is the unique real number with these two properties.

(ii) Let $l = \lim\inf x_n$. Then $l$ satisfies

(a) For any $\epsilon > 0$ there are infinitely many $n$ such that $x_n < l + \epsilon$
(b) For any \( \epsilon > 0 \) there are are only finitely many \( n \) such that \( x_n < l - \epsilon \) and \( l \) is the unique real number with these two properties.

**Proof:** (i): By IV.1.7.5. (i)–(ii), any number satisfying (ia)–(ib) must be equal to \( L \). On the other hand, if \( \epsilon > 0 \), then \( s_n = \sup_{k \geq n} x_k \) satisfies \( s_n \geq L \) for all \( n \), so for each \( n \) there must be a \( k \geq n \) with \( x_k > L - \epsilon \), i.e. \( x_k > L - \epsilon \) for infinitely many \( k \). But if \( x_k > L + \epsilon \) for infinitely many \( k \), then \( s_n > L + \epsilon \) for all \( n \), and thus \( L = \inf_n s_n \geq L + \epsilon \), a contradiction.

(ii): Almost identical with inequalities reversed. 🍊

**IV.1.7.8. Corollary.** Let \((x_n)\) be a bounded sequence in \( \mathbb{R} \). Then \( \lim \inf_{n \to \infty} x_n = \lim \sup_{n \to \infty} x_n \) if and only if \( \lim_{n \to \infty} x_n \) exists, in which case

\[
\lim \inf_{n \to \infty} x_n = \lim \sup_{n \to \infty} x_n = \lim_{n \to \infty} x_n.
\]

**Proof:** If \( \lim_{n \to \infty} x_n \) exists and equals \( L \), then \( L \) satisfies all four conditions, so

\[
L = \lim \inf_{n \to \infty} x_n = \lim \sup_{n \to \infty} x_n.
\]

Conversely, if \( \lim \inf_{n \to \infty} x_n = \lim \sup_{n \to \infty} x_n = L \), then \( L \) satisfies (ib) and (iib), hence \( \lim_{n \to \infty} x_n \) exists and equals \( L \). 🍊

Finally, we obtain the characterization of \( \lim \sup \) and \( \lim \inf \) in terms of cluster points:

**IV.1.7.9. Theorem.** Let \((x_n)\) be a bounded sequence. Then \( \lim \sup_{n \to \infty} x_n \) is the largest cluster point of \((x_n)\) and \( \lim \inf_{n \to \infty} x_n \) is the smallest cluster point of \((x_n)\).

**Proof:** Let \( L = \lim \sup_{n \to \infty} x_n \). If \( c \) is a cluster point of \((x_n)\), then for any \( \epsilon > 0 \) there are infinitely many \( x_n \) satisfying \( x_n > c - \epsilon \), so \( c \leq L \) by IV.1.7.5.(ii). On the other hand, for any \( \epsilon > 0 \) there are infinitely many \( x_n \) satisfying \( x_n > L - \epsilon \) by IV.1.7.7.(ia), and all but finitely many of these also satisfy \( x_n < L + \epsilon \) by IV.1.7.7.(ib), so \( L \) is a cluster point of \((x_n)\). The proof for \( \lim \inf \) is analogous. 🍊

**Tail Dependence**

If \((x_n)\) is a bounded sequence, then \( \lim \sup_{n \to \infty} x_n \) and \( \lim \inf_{n \to \infty} x_n \), like \( \lim_{n \to \infty} x_n \) if it exists, depend only on the tails of the sequence. We state two precise versions of this, whose simple proofs are left to the reader ()().

**IV.1.7.10. Proposition.** Let \((x_n)\) be a bounded sequence, and \((y_n)\) any tail sequence of \((x_n)\). Then \( \lim \sup_{n \to \infty} x_n = \lim \sup_{n \to \infty} y_n \) and \( \lim \inf_{n \to \infty} x_n = \lim \inf_{n \to \infty} y_n \).
**IV.1.7.11.** Proposition. Let \((x_n)\) and \((y_n)\) be bounded sequences, with \(x_n = y_n\) for all sufficiently large \(n\). Then \(\limsup_{n \to \infty} x_n = \limsup_{n \to \infty} y_n\) and \(\liminf_{n \to \infty} x_n = \liminf_{n \to \infty} y_n\).

We can improve the last result:

**IV.1.7.12.** Proposition. Let \((x_n)\) and \((y_n)\) be bounded sequences, with \(\lim_{n \to \infty} (x_n - y_n) = 0\). Then \(\limsup_{n \to \infty} x_n = \limsup_{n \to \infty} y_n\) and \(\liminf_{n \to \infty} x_n = \liminf_{n \to \infty} y_n\).

A direct proof can be given, but the result is an immediate corollary of **IV.1.7.17.**

**Algebraic and Order Properties**

We begin with two simple observations, whose proofs are left to the reader. The first generalizes **IV.1.7.13.**:

**IV.1.7.13.** Proposition. Let \((x_n)\) and \((y_n)\) be bounded sequences, with \(x_n \leq y_n\) for all sufficiently large \(n\). Then \(\limsup_{n \to \infty} x_n \leq \limsup_{n \to \infty} y_n\) and \(\liminf_{n \to \infty} x_n \leq \liminf_{n \to \infty} y_n\).

The next observation gives a symmetry between \(\limsup\) and \(\liminf\):

**IV.1.7.14.** Proposition. Let \((x_n)\) be a bounded sequence. Then \(\limsup_{n \to \infty} (-x_n) = -\liminf_{n \to \infty} x_n\) and \(\liminf_{n \to \infty} (-x_n) = -\limsup_{n \to \infty} x_n\).

**IV.1.7.15.** The limit of a sum of two convergent sequences is the sum of the limits (). However, the analogous statement does not hold for \(\limsup\) and \(\liminf\). For example, let \(x_n = (-1)^n\) and \(y_n = (-1)^{n+1}\) for all \(n\). Then \(\limsup_{n \to \infty} x_n = \limsup_{n \to \infty} y_n = 1\) and \(\liminf_{n \to \infty} x_n = \liminf_{n \to \infty} y_n = -1\). But \(x_n + y_n = 0\) for all \(n\), so
\[
\limsup_{n \to \infty} (x_n + y_n) = 0 \neq 2 = \limsup_{n \to \infty} x_n + \limsup_{n \to \infty} y_n
\]
\[
\liminf_{n \to \infty} (x_n + y_n) = 0 \neq -2 = \liminf_{n \to \infty} x_n + \liminf_{n \to \infty} y_n.
\]

However, we do have inequalities:

**IV.1.7.16.** Theorem. Let \((x_n)\) and \((y_n)\) be bounded sequences. Then
\[
\liminf_{n \to \infty} x_n + \liminf_{n \to \infty} y_n \leq \liminf_{n \to \infty} (x_n + y_n) \leq \limsup_{n \to \infty} x_n + \limsup_{n \to \infty} y_n \leq \limsup_{n \to \infty} (x_n + y_n) \leq \limsup_{n \to \infty} x_n + \limsup_{n \to \infty} y_n.
\]

Of course, the \(x_n\) and \(y_n\) may be interchanged in the middle, i.e. the middle expression can be replaced by \(\liminf_{n \to \infty} x_n + \limsup_{n \to \infty} y_n\).
Proof: For the first inequality, let \( l = \liminf_{n \to \infty} x_n \) and \( l' = \liminf_{n \to \infty} y_n \). Let \( \epsilon > 0 \). Then there is an \( N \) such that \( x_n > l - \frac{\epsilon}{2} \) and \( y_n > l' - \frac{\epsilon}{2} \) for all \( n \geq N \). Then \( x_n + y_n > l + l' - \epsilon \) for all \( n \geq N \), so \( \liminf_{n \to \infty} (x_n + y_n) \geq l + l' \) by IV.1.7.5.(iii).

For the second inequality, let \( L = \limsup_{n \to \infty} x_n \) and \( l' = \liminf_{n \to \infty} y_n \). Let \( \epsilon > 0 \). Then there is an \( N \) such that \( x_n < L + \frac{\epsilon}{2} \) for all \( n \geq N \). For infinitely many such \( n \), \( y_n < l' + \frac{\epsilon}{2} \). Thus for infinitely many \( n \), \( x_n + y_n < L + l' + \epsilon \), and thus \( \liminf_{n \to \infty} (x_n + y_n) \leq L + l' \) by IV.1.7.5.(iv).

The proofs of the other two inequalities are analogous.

We do get equalities if one of the sequences converges:

IV.1.7.17. Corollary. Let \( (x_n) \) be a bounded sequence and \( (y_n) \) a convergent sequence. Then

\[
\begin{align*}
\limsup_{n \to \infty} (x_n + y_n) &= \limsup_{n \to \infty} x_n + \lim_{n \to \infty} y_n \\
\liminf_{n \to \infty} (x_n + y_n) &= \liminf_{n \to \infty} x_n + \lim_{n \to \infty} y_n.
\end{align*}
\]

Proof: For the first equality, we have

\[
\limsup_{n \to \infty} x_n + \lim_{n \to \infty} y_n = \limsup_{n \to \infty} x_n + \limsup_{n \to \infty} y_n \leq \limsup_{n \to \infty} (x_n + y_n) \leq \limsup_{n \to \infty} x_n + \limsup_{n \to \infty} y_n = \limsup_{n \to \infty} x_n + \lim_{n \to \infty} y_n.
\]

The second is analogous, using the remark at the end of Theorem IV.1.7.16.

Unbounded Sequences

IV.1.7.18. The same definition of \( \limsup \) and \( \liminf \) makes sense, properly interpreted, for unbounded sequences of real numbers and even extended real numbers; in this case the \( \limsup \) and/or the \( \liminf \) may take the values \( +\infty \), as well as real-number values. It is simplest to just note the following criteria for when they take infinite values:

IV.1.7.19. Proposition. Let \( (x_n) \) be a sequence of real numbers. Then

(i) \( \limsup_{n \to \infty} x_n = +\infty \) if and only \( (x_n) \) is not bounded above.

(ii) \( \liminf_{n \to \infty} x_n = -\infty \) if and only \( (x_n) \) is not bounded below.

Proof: (i): \( \limsup_{n \to \infty} x_n < +\infty \) if and only if \( s_n = \sup_{k \geq n} x_k \) is finite for some \( n \), i.e. a tail of \( (x_n) \) is bounded above. But this implies that the entire sequence is bounded above. Conversely, if \( x_n \leq M \) for all \( n \), then \( s_n \leq M \) for all \( n \) and \( \limsup_{n \to \infty} x_n \leq M \).

The proof of (ii) is analogous.

428
IV.1.7.20. Proposition. Let \((x_n)\) be a sequence of real numbers. Then

(i) \(\lim_{n \to \infty} \sup x_n = -\infty\) if and only if \(\lim_{n \to \infty} x_n = -\infty\) (in the sense of ()).

(ii) \(\lim_{n \to \infty} \inf x_n = +\infty\) if and only if \(\lim_{n \to \infty} x_n = +\infty\).

The simple proof is left to the reader.

IV.1.7.21. All the results about \(\lim \sup\) and \(\lim \inf\) for bounded sequences, suitably interpreted, hold also for unbounded sequences, although some of the proofs need to be modified. Details are left to the reader.

IV.1.8. Cauchy Sequences

IV.1.9. Sequences in \(\mathbb{R}^n\)

IV.1.10. Sequences in Metric Spaces

IV.1.11. Exercises

IV.1.11.1. Show that in the definition of limit (IV.1.3.6., ??) it is unimportant whether strict inequality is used in two places: if \((x_n)\) is a sequence in \(\mathbb{R}\), then the following conditions are equivalent to the condition in IV.1.3.6.

(i) For every \(\epsilon > 0\), there is an \(N \in \mathbb{N}\) such that

\[|x_n - a| \leq \epsilon\]

for all \(n \geq N\). [For one direction, decrease \(\epsilon\) before finding \(N\).]

(ii) For every \(\epsilon > 0\), there is an \(N \in \mathbb{N}\) such that

\[|x_n - a| < \epsilon\]

for all \(n > N\). [For one direction, replace \(N\) by \(N + 1\).]

(iii) For every \(\epsilon > 0\), there is an \(N \in \mathbb{N}\) such that

\[|x_n - a| \leq \epsilon\]

for all \(n > N\).

(iv) Show that the condition \(N \in \mathbb{N}\) can be replaced by \(N \in \mathbb{R}\) without changing the definition of limit, i.e. that the following condition is equivalent to the condition in IV.1.3.6.: For every \(\epsilon > 0\), there is an \(N \in \mathbb{R}\) such that

\[|x_n - a| < \epsilon\]

for all \(n \in \mathbb{N}\), \(n \geq N\). [For one direction, use the Archimedean property of \(\mathbb{R}\) ().]

Do the same for the conditions in (i)–(iii). Show analogous results for limits of sequences in metric spaces.

IV.1.11.2. Let \((x_n)\) and \((y_n)\) be sequences converging to the same limit \(a\). Alternate or shuffle the \(x_n\) and \(y_n\) into a single sequence \((z_n)\) by taking \(z_n = x_m\) if \(n = 2m - 1\) is odd, and \(z_n = y_m\) if \(n = 2m\) is even. Give two proofs that \(z_n \to a\), one directly from the definition of limit and one from ()

429
IV.1.11.3. Prove the following theorem ([?]; cf. []):

**Theorem.**

(i) Let \((\alpha_n)\) be a sequence of positive numbers satisfying \(\alpha_{n+m} \leq \alpha_n \alpha_m\) for all \(n\) and \(m\). Set \(\beta_n = \alpha_n^{1/n}\). Then \(\lim_{n \to \infty} \beta_n\) exists (as a real number) and

\[
\lim_{n \to \infty} \beta_n = \inf_n \beta_n.
\]

(ii) Let \((a_n)\) be a sequence of real numbers satisfying \(a_{n+m} \leq a_n + a_m\) for all \(n\) and \(m\). Set \(b_n = \frac{a_n}{n}\). Then \(\lim_{n \to \infty} b_n\) exists as a real number or \(-\infty\), and

\[
\lim_{n \to \infty} b_n = \inf_n b_n.
\]

(iii) Let \((a_n)\) be a sequence of real numbers satisfying \(a_{n+m} \geq a_n + a_m\) for all \(n\) and \(m\). Set \(b_n = \frac{a_n}{n}\). Then \(\lim_{n \to \infty} b_n\) exists as a real number or \(+\infty\), and

\[
\lim_{n \to \infty} b_n = \sup_n b_n.
\]

(a) Show that (i), (ii), and (iii) are equivalent. So it suffices to prove (iii).

(b) In (iii), replacing \(a_n\) by \(a_n - na_1\) for all \(n\), it suffices to assume \(a_1 = 0\).

(c) For any \(k, m \in \mathbb{N}\), \(a_{km} \geq ka_m\), and hence \(b_{km} \geq b_m\). In particular, \(a_n \geq na_1 = 0\) for all \(n\), and hence \(b_n \geq 0\) for all \(n\).

(d) Fix \(m \in \mathbb{N}\). For \(k \in \mathbb{N}\) and \(1 \leq r \leq m\),

\[a_{km+r} \geq a_{km} + a_r \geq a_{km}\]

and thus

\[
b_{km+r} = \frac{a_{km+r}}{km+r} \geq \frac{a_{km}}{(k+1)m} = \frac{k}{k+1} \cdot b_{km} \geq \frac{k}{k+1} \cdot b_m.
\]

(e) Conclude that

\[
\lim_{n \to \infty} \inf b_n \geq \sup_n b_n.
\]

IV.1.11.4. Let \((a_n)\) and \((b_n)\) be sequences of real numbers, with \((b_n)\) a strictly increasing sequence of nonzero numbers with \(\lim_{n \to \infty} b_n = +\infty\). Suppose

\[
\lim_{n \to \infty} \frac{a_{n+1} - a_n}{b_{n+1} - b_n}
\]

exists (in either the ordinary or extended sense) and equals \(L\). Show that

\[
\lim_{n \to \infty} \frac{a_n}{b_n}
\]

also exists (in the same sense) and equals \(L\). [Show that for every \(\epsilon > 0\) there is an \(m\) such that

\[(L - \epsilon)(b_n - b_m) < a_n - a_m < (L + \epsilon)(b_n - b_m)\]

for all \(n > m\) by adding a telescoping sum.]

This result can be regarded as a discrete version of l’Hôpital’s Rule Version 2d’ (V.9.2.11.).

430
IV.2. Infinite Series

Infinite series (first of numbers, then of functions) form one of the most important and useful topics in analysis.

An infinite series is an expression of the form

$$\sum_{k=1}^{\infty} a_k$$

(or slight variations of this general form, e.g. we may start the summation at 0 or another integer), where the \(a_k\), called the terms of the series, are numbers or (later) functions.

The summation notation of infinite series suggests that the series represents a sum of numbers (or functions), hence has a numerical value. But an infinite series is, at least at first, just a formal expression and we do not necessarily associate to it a numerical value. We can associate a numerical “sum” to many series, but not all (the ones which have an associated sum are called convergent, and the ones which do not are called divergent). These “sums,” however, do not always behave like finite sums. The following principle must be kept in mind at all times in this subject:

First Fundamental Principle of Infinite Series: An infinite series is NOT a finite sum and cannot be treated like one!

The following chart lists the main differences between infinite series and finite sums:

<table>
<thead>
<tr>
<th>Finite Sum</th>
<th>Infinite Series</th>
</tr>
</thead>
<tbody>
<tr>
<td>Always represents a number</td>
<td>May or may not converge</td>
</tr>
<tr>
<td>Purely algebraic expression</td>
<td>Requires limits and analysis to define sum</td>
</tr>
<tr>
<td>Associative and commutative laws hold</td>
<td>Laws of arithmetic do not hold in general</td>
</tr>
</tbody>
</table>

A lot of the theory of infinite series is devoted to establishing that under certain conditions, infinite series can be manipulated and evaluated roughly like finite sums. But operations on infinite series which would be routine or trivial for finite sums must always be carefully justified using the results of the theory. In finding results or formulas, it can be very useful to manipulate infinite series formally as though they were finite sums, but formulas obtained in this way cannot be considered valid unless justified by careful applications of theorems about infinite series; some such formulas turn out to be correct and others don’t.

IV.2.1. Partial Sums and Convergence

IV.2.1.1. Suppose \(\sum_{k=1}^{\infty} a_k\) is an infinite series. We can associate to this series two sequences. One obvious sequence is the sequence \((a_k)\) of terms. The other, much more important, is the sequence \((s_n)\) of partial sums:

IV.2.1.2. Definition. Let \(\sum_{k=1}^{\infty} a_k\) be an infinite series, and \(n \in \mathbb{N}\). The \(n^{th}\) partial sum of the series is the finite sum

$$s_n = \sum_{k=1}^{n} a_k .$$
IV.2.1.3. Conversely, if \((s_n)\) is any sequence of real numbers, there is a unique infinite series \(\sum_{k=1}^{\infty} a_k\) such that \((s_n)\) is the sequence of partial sums: set \(a_1 = s_1\) and \(a_k = s_k - s_{k-1}\) for \(k > 1\). Thus in a sense the theory of infinite series is identical to the theory of sequences, although we usually take a somewhat different point of view. (This correspondence can be regarded as a discrete version of the Fundamental Theorem of Calculus.)

Since the partial sums of an infinite series are finite sums, the usual rules of arithmetic and algebra can be used with them. We can also use facts and results about sequences, applied to the sequence of partial sums, to analyze series. In particular, we can define convergence for an infinite series:

IV.2.1.4. Definition. The infinite series \(\sum_{k=1}^{\infty} a_k\) converges, with sum \(s \in \mathbb{R}\), if the sequence \((s_n)\) of partial sums converges to \(s\). If the sequence \((s_n)\) does not converge, the series is said to diverge.

If the series \(\sum_{k=1}^{\infty} a_k\) converges with sum \(s\), we will often write

\[
\sum_{k=1}^{\infty} a_k = s
\]

and regard the infinite series as representing the number \(s\). Of course, by the uniqueness of limits for convergent sequences (IV.1.3.13.), the sum of a convergent infinite series is uniquely determined.

We reiterate the First Fundamental Principle: use of the word “sum” for a convergent infinite series does not mean that the “sum” is an actual sum in the algebraic sense.

IV.2.1.5. It is sometimes useful, if imprecise, to write an infinite series \(\sum_{k=1}^{\infty} a_k\), especially a convergent series, as

\[
\sum_{k=1}^{\infty} a_k = a_1 + a_2 + a_3 + \cdots
\]

We will mostly avoid this notation since it is imprecise and can be misleading, although with due care it can be helpful in working with the series. When writing an infinite series this way one must be especially careful not to treat it like a finite sum; even great mathematicians have occasionally been misled into errors by confusing such an expression with a finite sum and applying unjustifiable algebraic operations.

A sequence converges if and only if all “tail” sequences converge (). A similar statement holds for series:

IV.2.1.6. Proposition. Let \(\sum_{k=1}^{\infty} a_k\) be an infinite series. The following are equivalent:
(i) The series \( \sum_{k=1}^{\infty} a_k \) converges.

(ii) For some \( n \in \mathbb{N} \), the tail series \( \sum_{k=n+1}^{\infty} a_k \) converges.

(iii) For every \( n \in \mathbb{N} \), the tail series \( \sum_{k=n+1}^{\infty} a_k \) converges.

**Proof:** (i) \( \Rightarrow \) (iii): Suppose the series converges, with sum \( s \), and fix \( n \in \mathbb{N} \). Let \( s_m \) be the \( m \)'th partial sum of the original series, and \( t_m \) the \( m \)'th partial sum of the series \( \sum_{k=n+1}^{\infty} a_k \).

The relationship is that \( t_m = s_{n+m} - s_n \) for any \( m \). We have that

\[
\lim_{m \to \infty} t_m = \left[ \lim_{m \to \infty} s_{n+m} \right] - s_n = s - s_n
\]

so the series \( \sum_{k=n+1}^{\infty} a_k \) converges with sum \( s - s_n \).

(iii) \( \Rightarrow \) (ii) is trivial.

(ii) \( \Rightarrow \) (i): If the tail series converges for some \( n \in \mathbb{N} \), with sum \( t \), we have

\[
\lim_{m \to \infty} s_{n+m} = \left[ \lim_{m \to \infty} t_m \right] + s_n = t + s_n
\]

so the original series converges with sum \( t + s_n \).

**IV.2.1.7.** Note, however, that there is a difference between sequences and series: the limit of a tail of a sequence is the same as the limit of the whole sequence (i.e. the limit of a sequence depends only on the tail terms). But the sum of a tail of a convergent infinite series is not generally the same as the sum of the whole series, i.e. although the convergence of an infinite series depends only on tail behavior, the sum of the series depends on all the terms.

A useful first observation is that for an infinite series to converge, it is necessary for the terms to approach zero (the key observation is that \( s_{n+1} - s_n = a_{n+1} \) for any \( n \)):  

433
IV.2.1.8. **Proposition.** Let $\sum_{k=1}^{\infty} a_k$ be an infinite series. If the series converges, then

$$\lim_{k \to \infty} a_k = 0.$$ 

**Proof:** Let $\epsilon > 0$. Since $\lim_{n \to \infty} s_n$ exists and equals, say, $s$, there is an $N$ such that for all $n \geq N$,

$$|s_n - s| < \frac{\epsilon}{2}.$$ 

If $n \geq N$, we also have $|s_{n+1} - s| < \frac{\epsilon}{2}$. So for all $n \geq N$ we have

$$|a_{n+1}| = |s_{n+1} - s_n| = |(s_{n+1} - s) + (s - s_n)| \leq |s_{n+1} - s| + |s - s_n| < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon$$

and thus $\lim_{n \to \infty} a_n = 0$. 

IV.2.1.9. It is important to note that this result goes only one way: if the terms of an infinite series approach zero, the series may or may not converge. A simple example is $\sum_{n=1}^{\infty} \frac{1}{n}$: we have $s_n \geq n \cdot \frac{1}{\sqrt{n}} = \sqrt{n}$ for each $n$, so the partial sums are unbounded and cannot converge. We will see many other examples later.

The result IV.2.1.8. is commonly used in its contrapositive form:

IV.2.1.10. **Corollary. [Divergence Criterion]** Let $\sum_{k=1}^{\infty} a_k$ be an infinite series. If the sequence $(a_k)$ of terms does not converge to zero, then the infinite series diverges.

We can give an important refinement of IV.2.1.8., using the Cauchy Criterion (). The key observation here is that if $n < m$, then

$$s_m - s_n = \sum_{k=n+1}^{m} a_k.$$ 

IV.2.1.11. **Theorem. [Cauchy Criterion for Series]** Let $\sum_{k=1}^{\infty} a_k$ be an infinite series. Then the series converges if and only if, for every $\epsilon > 0$, there is an $N \in \mathbb{N}$ such that

$$\left| \sum_{k=n+1}^{m} a_k \right| < \epsilon$$

whenever $N \leq n < m$. 

434
In other words, an infinite series converges if and only if the sum of arbitrarily many consecutive terms is small, provided only that the sum starts sufficiently far out in the sequence of terms. This result includes IV.2.1.8., which is the special case where \( m = n + 1 \).

As a variation, we have a version involving sums of “tails” of the series which refines part of IV.2.1.6.: 

**IV.2.1.12. Corollary.** Let \( \sum_{k=1}^{\infty} a_k \) be an infinite series. If the series converges, then for every \( \epsilon > 0 \) there is an \( N \in \mathbb{N} \) such that
\[
\sum_{k=n+1}^{\infty} a_k
\]
(which converges for all \( n \in \mathbb{N} \) by IV.2.1.6.) satisfies
\[
\left| \sum_{k=n+1}^{\infty} a_k \right| < \epsilon
\]
whenever \( n \geq N \).

**Proof:** Suppose the series converges. Let \( \epsilon > 0 \), and fix \( N \in \mathbb{N} \) such that
\[
\left| \sum_{k=n+1}^{m} a_k \right| < \frac{\epsilon}{2}
\]
whenever \( N \leq n < m \). We have, for \( n \geq N \),
\[
\left| \sum_{k=n+1}^{\infty} a_k \right| = \lim_{m \to \infty} \left| \sum_{k=n+1}^{m} a_k \right| \leq \frac{\epsilon}{2} < \epsilon.
\]

This corollary can also be proved directly with a slight extension of the proof of IV.2.1.6.

**Geometric Series**

One of the most basic examples of an infinite series is the geometric series.

**IV.2.1.13. Definition.** Let \( x \in \mathbb{R} \). The geometric series with ratio \( x \) is the infinite series
\[
\sum_{k=1}^{\infty} x^k.
\]

Eventually, we will want to regard \( x \) as a variable to obtain a function (power series), but for now \( x \) will be just regarded as a fixed number.
**IV.2.1.14. PROPOSITION.** The geometric series with ratio $x$ converges if and only if $|x| < 1$. In this case, we have

$$\sum_{k=1}^{\infty} x^k = \frac{x}{1-x}.$$ 

**Proof:** If $|x| \geq 1$, the series diverges by the Divergence Criterion since the terms do not go to zero. For any $x$, we have, for any $n \in \mathbb{N},$

$$(1 - x)(x + x^2 + \cdots + x^n) = x - x^{n+1}$$

by a simple calculation (or, more precisely, a simple proof by induction), so if $s_n$ is the $n$’th partial sum of the geometric series with ratio $x$, we have

$$(1 - x)s_n = x - x^{n+1}$$

and thus, for $x \neq 1$, we have

$$s_n = \frac{x}{1-x} - \frac{x^{n+1}}{1-x}$$

so, if $|x| < 1$, we have

$$\lim_{n \to \infty} s_n = \frac{x}{1-x} - \lim_{n \to \infty} \frac{x^{n+1}}{1-x} = \frac{x}{1-x}$$

and thus the series converges with sum $\frac{x}{1-x}$. 

**IV.2.1.15. REMARKS.**

(i) This is one of the few infinite series where it is possible to find a simple formula for the exact sum. In many cases, it can be shown easily from one of the convergence tests that the series converges, but the exact sum is not easy (and often even impossible) to find.

(ii) The closely related series

$$\sum_{k=0}^{\infty} x^k$$

is often called the geometric series instead. This series just has one more term at the beginning, equal to 1; thus it also converges if and only if $|x| < 1$, and the sum is

$$1 + \frac{x}{1-x} = \frac{(1-x) + x}{1-x} = \frac{1}{1-x}.$$ 

**Linear Combinations of Convergent Series**

There is some nice algebraic behavior for convergent infinite series: 

436
IV.2.1.16. **Proposition.** Let \( \sum_{k=1}^{\infty} a_k \) and \( \sum_{k=1}^{\infty} b_k \) be convergent infinite series. Then the series \( \sum_{k=1}^{\infty} (a_k + b_k) \) converges, and
\[
\sum_{k=1}^{\infty} (a_k + b_k) = \sum_{k=1}^{\infty} a_k + \sum_{k=1}^{\infty} b_k .
\]

**Proof:** Let \( s_n \) and \( t_n \) be the \( n \)’th partial sum of the series \( \sum_{k=1}^{\infty} a_k \) and \( \sum_{k=1}^{\infty} b_k \) respectively. Then
\[
\sum_{k=1}^{n} (a_k + b_k) = \sum_{k=1}^{n} a_k + \sum_{k=1}^{n} b_k = s_n + t_n
\]
for any \( n \) by usual rules of algebra for finite sums. Then, using \( () \), we obtain
\[
\lim_{n \to \infty} \left[\sum_{k=1}^{n} (a_k + b_k)\right] = \lim_{n \to \infty} (s_n + t_n) = \lim_{n \to \infty} s_n + \lim_{n \to \infty} t_n = \sum_{k=1}^{\infty} a_k + \sum_{k=1}^{\infty} b_k
\]
and thus the series \( \sum_{k=1}^{\infty} (a_k + b_k) \) converges and has the desired sum. \( \triangle \)

IV.2.1.17. Note that this result also goes only one way: \( \sum_{k=1}^{\infty} (a_k + b_k) \) can converge even if the two individual series diverge. A rather trivial example is to take \( a_k = 1 \) and \( b_k = -1 \) for all \( k \).

Similarly, we have a “distributive law” for infinite series:

IV.2.1.18. **Proposition.** Let \( \sum_{k=1}^{\infty} a_k \) be an infinite series and \( c \in \mathbb{R} \). If the series \( \sum_{k=1}^{\infty} a_k \) converges, then the series \( \sum_{k=1}^{\infty} ca_k \) converges, and
\[
\sum_{k=1}^{\infty} ca_k = c \left[ \sum_{k=1}^{\infty} a_k \right] .
\]
Proof: If $s_n$ is the $n$’th partial sum of $\sum_{k=1}^{\infty} a_k$, then for each $n$ we have

$$\sum_{k=1}^{n} c a_k = c \left[ \sum_{k=1}^{n} a_k \right] = c s_n$$

by the distributive law for finite sums. Thus, by (), we have

$$\lim_{n \to \infty} \left[ \sum_{k=1}^{n} c a_k \right] = \lim_{n \to \infty} c s_n = c \left[ \lim_{n \to \infty} s_n \right] = c \sum_{k=1}^{\infty} a_k$$

and the result follows.

IV.2.1.19. Note that there is no corresponding result for term-by-term products; there is no simple relationship between the partial sums of $\sum_{k=1}^{\infty} a_k b_k$ and those of $\sum_{k=1}^{\infty} a_k$ and $\sum_{k=1}^{\infty} b_k$. In fact, if $\sum_{k=1}^{\infty} a_k$ and $\sum_{k=1}^{\infty} b_k$ converge, the series $\sum_{k=1}^{\infty} a_k b_k$ may or may not converge (). (However, see Exercise (); see Exercise () for a somewhat related result.)

Grouping and Contraction of Series

There is a limited sense in which the associative law applies in a convergent series.

IV.2.1.20. Definition. Let $\sum_{k=1}^{\infty} a_k$ be an infinite series. A grouping or contraction of the series is an infinite series $\sum_{k=1}^{\infty} b_k$, where

$$b_k = \sum_{j=m_{k-1}+1}^{m_k} a_j$$

for some strictly increasing sequence $0 = m_0 < m_1 < m_2 < \cdots$ in $\mathbb{N} \cup \{0\}$.

Informally, the series $\sum_{k=1}^{\infty} b_k$ is obtained by inserting parentheses

$$(a_1 + \cdots + a_{m_1}) + (a_{m_1+1} + \cdots + a_{m_2}) + \cdots + (a_{m_k+1} + \cdots + a_{m_{k+1}}) + \cdots$$

Note that all the terms in the original series appear exactly once, and in the same order; they are simply grouped together.
IV.2.1.21. **Proposition.** Let $\sum_{k=1}^{\infty} a_k$ be a convergent infinite series. Then any grouping or contraction of the series also converges, and has the same sum.

**Proof:** Let $\sum_{k=1}^{\infty} b_k$ be a contraction of the series. Then every partial sum of the contraction is also a partial sum of the original series; hence the sequence of partial sums of $\sum_{k=1}^{\infty} b_k$ is a subsequence of the sequence of partial sums of $\sum_{k=1}^{\infty} a_k$, and thus converges to the same limit. 

IV.2.1.22. This result does not apply to divergent series. A famous example concerns the series $\sum_{k=1}^{\infty} \frac{1}{k}$. We can contract this divergent series to $(1 - 1) + (1 - 1) + (1 - 1) + \cdots$ to obtain a convergent series with sum 0, or to $1 + (-1 + 1) + (-1 + 1) + (-1 + 1) + \cdots$ to obtain a convergent series with sum 1.

Before convergence of infinite series was well understood, several great mathematicians argued over what should be the correct sum of this series; some, including Leibniz and Euler, claimed that the true sum should be $\frac{1}{2}$, since among other things this is the average of the two “equally reasonable” groupings above (they had better reasons too; cf. ()). The Cesaro sum $\sum$ of this series is $\frac{1}{2}$.

IV.2.1.23. Applying IV.2.1.21, repeatedly, we may insert parentheses at will in a convergent series (not changing the order of terms) without affecting convergence or changing the sum, so long as any two pairs of inserted parentheses are either nested or disjoint, i.e. only the patterns (]), [)], (][), or []() are allowed, not (][) or ([) (which do not make sense anyway).

If the order of the terms in a convergent series is changed, however, or if some (infinitely many) terms are deleted, the new series may not converge; see (), (), .

IV.2.2. **Nonnegative Series**

IV.2.2.1. A **nonnegative series** is an infinite series in which all the terms are nonnegative. Nonnegative series behave somewhat more nicely than general infinite series, and criteria for convergence are considerably simpler to state. In this subsection and the next two, we examine convergence of nonnegative series and develop the standard tests for convergence.
Of course, as for any infinite series, the terms of a convergent nonnegative infinite series must converge to zero. But a nonnegative series whose terms go to zero does not necessarily converge (IV.2.1.9.). In fact, we will develop a set of results that make precise the following informal principle:

**Fundamental Principle of Nonnegative Series:** A nonnegative series converges if and only if the terms of the series approach zero sufficiently rapidly.

The important fact about the sequence of partial sums of a nonnegative series is that it is nondecreasing. Since a nondecreasing sequence converges if and only if it is bounded (), we obtain:

**Proposition.** Let \( \sum_{k=1}^{\infty} a_k \) be a nonnegative infinite series. Then the series converges if and only if the sequence of partial sums is bounded.

This result can fail for series which are not nonnegative. For example, in the geometric series \( \sum_{k=1}^{\infty} (-1)^k \) the partial sum \( s_n \) is \(-1\) for \( n \) odd and \( 0 \) for \( n \) even, hence the sequence of partial sums is bounded. But the series does not converge by the Divergence Criterion.

Indeed, some authors distinguish between infinite series which are “divergent” (or “definitely divergent”) in the sense that the limit of the partial sums is \(+\infty\) or \(-\infty\), and series which are “indeinitely divergent,” or “oscillatory,” in the sense that the sequence of partial sums has no limit in the extended real line.

**The Comparison Test**

The first test we develop for convergence of nonnegative series, which makes the Fundamental Principle more precise, is the Comparison Test. This test will, however, only have teeth once we develop a reasonable supply of “test series” to compare new series to. (So far the only examples we have are geometric series.)

**Theorem. [Comparison Test]** Let \( \sum_{k=1}^{\infty} a_k \) and \( \sum_{k=1}^{\infty} b_k \) be nonnegative infinite series. Suppose \( a_k \leq b_k \) for all \( k \). Then

(i) If \( \sum_{k=1}^{\infty} b_k \) converges, then \( \sum_{k=1}^{\infty} a_k \) converges.

(ii) If \( \sum_{k=1}^{\infty} a_k \) diverges, then \( \sum_{k=1}^{\infty} b_k \) diverges.
Proof: Statement (ii) is just the contrapositive of statement (i), so we need only prove (i). For $n \in \mathbb{N}$, let $s_n$ and $t_n$ be the $n$'th partial sum of $\sum_{k=1}^{\infty} a_k$ and $\sum_{k=1}^{\infty} b_k$ respectively. Then $s_n \leq t_n$ for all $n$. Since the sequence $(t_n)$ converges, it is bounded (); any bound for $(t_n)$ is also a bound for $(s_n)$, hence $(s_n)$ is also bounded. Thus $\sum_{k=1}^{\infty} a_k$ converges by IV.2.2.4.

We can give a slight extension in which finitely many terms can be ignored in each sequence:

**IV.2.2.7.** Corollary. [Extended Comparison Test] Let $\sum_{k=1}^{\infty} a_k$ and $\sum_{k=1}^{\infty} b_k$ be nonnegative infinite series. Suppose there are $p, q \in \mathbb{N}$ such that $a_{p+k} \leq b_{q+k}$ for all $k$ (this will be satisfied, for example, if there is an $N \in \mathbb{N}$ for which $a_k \leq b_k$ for all $k > N$, by taking $p = q = N$). Then

(i) If $\sum_{k=1}^{\infty} b_k$ converges, then $\sum_{k=1}^{\infty} a_k$ converges.

(ii) If $\sum_{k=1}^{\infty} a_k$ diverges, then $\sum_{k=1}^{\infty} b_k$ diverges.

Proof: Apply the Comparison Test to the tail series $\sum_{k=p+1}^{\infty} a_k$ and $\sum_{k=q+1}^{\infty} b_k$, and apply IV.2.1.6.

**IV.2.2.8.** The substance of these results is that a nonnegative series whose terms go to zero “more rapidly” than those of a convergent nonnegative series also converges, and a nonnegative series whose terms go to zero “more slowly” than those of a divergent nonnegative series also diverges.

The Harmonic Series

**IV.2.2.9.** Perhaps the most important single infinite series is the harmonic series

$$\sum_{k=1}^{\infty} \frac{1}{k}.$$

**IV.2.2.10.** It is not obvious whether the harmonic series converges. Its terms do go to zero, so the Divergence Criterion does not rule out convergence but does not guarantee it either. If we do some numerical experiments calculating some partial sums we obtain

$$s_{10} = 1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{10} = 2.9289\cdots$$
\( s_{50} = 1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{50} = 4.499 \ldots \)
\( s_{100} = 1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{100} = 5.187 \ldots \)

and the partial sums might appear to be approaching a limit. If we go on and compute
\( s_{1000} = 1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{1000} = 7.485 \ldots \)
\( s_{10000} = 1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{10000} = 9.787 \ldots \)

this conclusion seems less obvious. Are the partial sums bounded?

**IV.2.2.11. Theorem.** The harmonic series diverges, i.e. the partial sums are unbounded.

**Proof:** We will give a quick proof later using the Integral Test, but here we give an alternate elementary proof based on the Comparison Test. Define a new series \( \sum_{k=1}^{\infty} a_k \) by setting \( a_1 = 1 \) and \( a_k = 2^{-r} \) for \( 2^{r-1} + 1 \leq k \leq 2^r, \, r \in \mathbb{N} \). Note that \( a_k \leq \frac{1}{k} \) for all \( k \). If \( s_n \) is the \( n \)'th partial sum of the series \( \sum_{k=1}^{\infty} a_k \), then for \( m \in \mathbb{N} \) and \( n = 2^m \) we have

\[
s_n = s_{2^m} = \sum_{k=1}^{2^m} a_k = 1 + \sum_{r=1}^{m} \sum_{k=2^{r-1}+1}^{2^r} a_k = 1 + \sum_{r=1}^{m} [2^{r-1} \cdot 2^{-r}] = 1 + \sum_{r=1}^{m} \frac{1}{2} = 1 + \frac{m}{2}.
\]

These are unbounded as \( m \to \infty \), so \( \sum_{k=1}^{\infty} a_k \) diverges, and hence the harmonic series also diverges by the Comparison Test.

**IV.2.2.12.** The argument of this proof was discovered by the French mathematician NICOLE ORESME in the fourteenth century, and is one of the most significant pieces of mathematics surviving from medieval Europe. (Oresme also developed the theory of exponents, and was the first to draw graphs of functions.) Despite this argument, convergence of infinite series and its importance were not widely understood by mathematicians until the nineteenth century.

**IV.2.2.13.** The argument indicates that the partial sums of the harmonic series grow only logarithmically in \( n \), and thus go to +\( \infty \) very slowly. This conclusion will follow more carefully from an application of the Integral Test. In fact, it takes \( 15,092,688,622,113,788,323,693,563,264,538,101,449,859,497 \approx 1.5 \times 10^{43} \) terms to make the partial sum exceed 100, for example \([?]\). For more information about the partial sums of the harmonic series, see the website [http://mathworld.wolfram.com/HarmonicNumber.html](http://mathworld.wolfram.com/HarmonicNumber.html).

The divergence of the harmonic series leads to some apparent paradoxes. For example, a stable stack of identical books, or bricks, etc., can be made (in principle) in which the top book overhangs the bottom one by an arbitrary amount: overhang the \((k-1)\)'th book from the \(k\)'th (counting down from the top) by \( \frac{1}{k} \) times the width of the book. For other “paradoxes” involving the harmonic series, see [\(\)].
The \( p \)-Series

The harmonic series is a member of an important class of infinite series to which a similar argument applies, the \( p \)-series:

**IV.2.2.14.** Definition. Let \( p \in \mathbb{R} \). The \( p \)-series with exponent \( p \) is the infinite series

\[
\sum_{k=1}^{\infty} k^{-p} = \sum_{k=1}^{\infty} \frac{1}{k^p}.
\]

The \( p \)-series with exponent \( p \) is a nonnegative series. The only interesting case is when \( p > 0 \), since for \( p \leq 0 \) the terms of the series do not approach zero, so the series automatically diverges.

**IV.2.2.15.** The harmonic series is the \( p \)-series with exponent 1. We know this series diverges (IV.2.2.11.), and by comparison we have that a \( p \)-series for \( p < 1 \) also diverges. We now show that a \( p \)-series with \( p > 1 \) converges. We will give another proof of these facts using the Integral Test (IV.2.3.5.).

**IV.2.2.16.** Theorem. The \( p \)-series with exponent \( p \) converges if and only if \( p > 1 \).

**Proof:** We have already done the cases \( p \leq 1 \), so assume \( p > 1 \). Define a new series \( \sum_{k=1}^{\infty} a_k \) by setting \( a_1 = 1 \) and \( a_k = 2^{-pr} = [2^{-r}]^p \) for \( 2^r \leq k \leq 2^{r+1} - 1 \), \( r \in \mathbb{N} \). Note that \( a_k \geq \frac{1}{2^r} \) for all \( k \). If \( s_n \) is the \( n \)’th partial sum of the series \( \sum_{k=1}^{\infty} a_k \), then for \( m \in \mathbb{N} \) and \( n = 2^{m+1} - 1 \) we have

\[
s_n = s_{2^{m+1} - 1} = \sum_{k=1}^{2^{m+1} - 1} a_k = 1 + \sum_{r=1}^{m} \sum_{k=2^r}^{2^{r+1} - 1} a_k = 1 + \sum_{r=1}^{m} [2^r \cdot 2^{-pr}] = 1 + \sum_{r=1}^{m} [2^{1-p}]^r.
\]

These are partial sums of a geometric series with ratio \( 2^{1-p} < 1 \), so the \( s_n \) converge, and hence the \( p \)-series converges by the Comparison Test.

The Limit Comparison Test

There is a variation of the Comparison Test which is often simpler to use:

**IV.2.2.17.** Theorem. [Limit Comparison Test] Let \( \sum_{k=1}^{\infty} a_k \) and \( \sum_{k=1}^{\infty} b_k \) be infinite series with positive terms. Suppose

\[
L = \lim_{k \to \infty} \frac{a_k}{b_k}
\]

exists as a (nonnegative) extended real number. Then:

443
(i) If $0 \leq L < +\infty$ and $\sum_{k=1}^{\infty} b_k$ converges, then $\sum_{k=1}^{\infty} a_k$ converges.

(ii) If $0 < L \leq +\infty$ and $\sum_{k=1}^{\infty} b_k$ diverges, then $\sum_{k=1}^{\infty} a_k$ diverges.

**Proof:** For (i), if $0 < L < +\infty$, then we have $a_k < cb_k$ for all sufficiently large $k$. We have that $\sum_{k=1}^{\infty} cb_k$ converges, so $\sum_{k=1}^{\infty} a_k$ converges by the **Extended Comparison Test**. The proof of (ii) is almost identical: if $0 < d < L$, then $\sum_{k=1}^{\infty} db_k$ diverges, so $\sum_{k=1}^{\infty} a_k$ diverges.

A refined version using $\limsup$ and $\liminf$ holds with the same proof:

**IV.2.2.18. Theorem.** [Limit Comparison Test, General Version] Let $\sum_{k=1}^{\infty} a_k$ and $\sum_{k=1}^{\infty} b_k$ be infinite series with positive terms.

(i) If $\limsup_{k \to \infty} \frac{a_k}{b_k} < +\infty$ and $\sum_{k=1}^{\infty} b_k$ converges, then $\sum_{k=1}^{\infty} a_k$ converges.

(ii) If $\liminf_{k \to \infty} \frac{a_k}{b_k} > 0$ and $\sum_{k=1}^{\infty} b_k$ diverges, then $\sum_{k=1}^{\infty} a_k$ diverges.

The next class of examples gives one of the most important applications of the Limit Comparison Test:

**IV.2.2.19. Example.** Let $f(k)$ and $g(k)$ be functions which are finite sums of terms of the form $c_r k^r$ for $r \in \mathbb{R}$. ($f$ and $g$ need not be polynomials, i.e. the powers need not be nonnegative integers.) Suppose $g(k) \neq 0$ for all $k$. Let $c_p k^p$ be the term in $f$ with largest power, and $d_q k^q$ the term in $g$ with largest power ($c_p$ and $d_q$ are nonzero). Then:

(i) If $q - p > 1$, the series $\sum_{k=1}^{\infty} \frac{f(k)}{g(k)}$ converges.

(ii) If $q - p \leq 1$, the series $\sum_{k=1}^{\infty} \frac{f(k)}{g(k)}$ diverges.
For we can do a limit comparison test with the $p$-series $\sum_{k=1}^{\infty} \frac{1}{k^{q-p}}$ since
\[
\lim_{k \to \infty} \frac{k^{q-p} f(k)}{g(k)} = \frac{c_p}{d_q}
\]
which is a nonzero finite number. (If $\frac{c_p}{d_q}$ is negative, first multiply the series by $-1$. The terms of the series will then eventually be strictly positive.)

The Border Between Convergence and Divergence

IV.2.2.20. The set of nonnegative sequences $(a_n)$ converging to zero splits into two disjoint sets, those for which $\sum_{k=1}^{\infty} a_k$ converges and those for which it diverges. Any sequence dominated by a sequence in the first group is in the first group, and any sequence which dominates one in the second is in the second. Is there some identifiable border between the sets? Specifically, we can ask:

(i) Is there a sequence $(a_n)$ such that $a_n \to 0$ most slowly among terms of convergent series, i.e. a nonnegative series $\sum_{k=1}^{\infty} b_k$ converges if and only if $\frac{a_k}{b_k}$ is bounded?

(ii) Is there a sequence $(a_n)$ such that $a_n \to 0$ most rapidly among terms of divergent series, i.e. a nonnegative series $\sum_{k=1}^{\infty} b_k$ diverges if and only if $\frac{a_k}{b_k}$ is bounded?

(We could restrict to nonincreasing sequences to sharpen the questions and eliminate some obvious pathologies; the terms of a nonnegative series can be reordered without affecting convergence – see IV.2.8.4.)

Both questions have negative answers: for any convergent nonnegative series there is another convergent nonnegative series whose terms approach zero more slowly (Exercise IV.2.16.5.), and for every divergent nonnegative series there is a divergent nonnegative series whose terms go to zero more rapidly (Exercise IV.2.16.6.). The border cannot even be countably described: for any countable collection of convergent nonnegative series there is a convergent nonnegative series whose terms go to zero more slowly than all of them, and for any countable collection of divergent nonnegative series there is a divergent nonnegative series whose terms go to zero more rapidly than all of them (Exercise IV.2.16.17.). Thus, although a sequence like $(\frac{1}{k})$ can be regarded as “close to the border between series convergence and divergence” (i.e. “just barely divergent”), there is no precise countable description of an exact border between convergence and divergence, and thus no foolproof countably describable test for convergence of nonnegative series.

Nonetheless, there are many useful tests which together work for most series arising in practice, as described in the next two sections.

IV.2.3. Tests for Convergence of Nonnegative Series

Besides the Comparison Tests of the previous section, which primarily illustrate the Fundamental Principle of Nonnegative Series, there are several standard tests for convergence of such series, along with a large number of specialized tests. In this subsection, we describe the three standard tests, the Integral Test, the Root Test, and the Ratio Test, and give a sampling of some of the more important specialized tests.
The Integral Test

Infinite series bear a close resemblance to improper integrals; in fact, infinite series can be regarded as a discrete analog of improper integrals. At least in the case of nonnegative series, this close relationship can be exploited to give a test for convergence of certain nonnegative series using improper integrals.

IV.2.3.1. Suppose $f$ is a function on the interval $[1, \infty)$ which is (Riemann-)integrable on each finite subinterval (e.g. continuous or at least piecewise-continuous, or monotone). Recall (IV.2.2.2.) that the improper integral of $f$ from 1 to $\infty$ is defined to be

$$\int_1^{\infty} f(t) \, dt = \lim_{b \to \infty} \left[ \int_1^{b} f(t) \, dt \right]$$

if the limit exists (the improper integral is then said to converge). The finite integrals may be regarded as “partial integrals” and some sort of continuous analog of the partial sums of an infinite series.

If $f$ is nonnegative on $[1, \infty)$, the “partial integral” from 1 to $b$ is nondecreasing as $b$ increases, so the improper integral converges if and only if the partial integrals are bounded; and

$$\int_1^{\infty} f(t) \, dt = \sup_{b>1} \left[ \int_1^{b} f(t) \, dt \right]$$

if the supremum is finite. This will be the case if and only if $f(t) \to 0$ “sufficiently rapidly” as $t \to \infty$, in complete analogy with the Fundamental Principle of Nonnegative Series (IV.2.2.2.).

IV.2.3.2. If the function $f$ is nonnegative and nonincreasing, we have that

$$f(k + 1) \cdot 1 \leq \int_k^{k+1} f(t) \, dt \leq f(k) \cdot 1$$

for all $k$ (see Figure (IV.2.3.2.)). It follows that for any $n$, we have

$$\sum_{k=2}^{n+1} f(k) \leq \int_1^{n+1} f(t) \, dt \leq \sum_{k=1}^{n} f(k) .$$

Thus, if the nonnegative infinite series $\sum_{k=1}^{\infty} f(k)$ converges, we obtain that the supremum of the partial integrals from 1 to $n$ is finite, and hence the improper integral $\int_1^{\infty} f(t) \, dt$ also converges. Conversely, we have

$$\sum_{k=1}^{n} f(k) \leq f(1) + \int_1^{n} f(t) \, dt$$

for every $n$, so if the improper integral converges, the partial sums of the series $\sum_{k=1}^{\infty} f(k)$ are bounded and so the series converges. Thus we obtain:
IV.2.3.3. Theorem. [Integral Test] Let \( f \) be a function which is nonnegative and nonincreasing on the interval \([1, \infty)\). Then the infinite series \( \sum_{k=1}^{\infty} f(k) \) converges if and only if the improper integral \( \int_{1}^{\infty} f(t) \, dt \) converges, and we have
\[
\int_{1}^{\infty} f(t) \, dt - f(1) \leq \sum_{k=1}^{\infty} f(k) \leq \int_{1}^{\infty} f(t) \, dt.
\]

IV.2.3.4. Note that this test, when it applies, gives a complete necessary and sufficient condition for convergence of the series \( \sum_{k=1}^{\infty} f(k) \). But although it gives some information about the sum, it does not directly allow a calculation of the exact sum. See ( )

Of course, when using this test, as with any test, one must check that the hypotheses are satisfied.

Application: \( p \)-Series

We use the Integral Test to give an alternate proof of the convergence or divergence of the \( p \)-series (IV.2.14.); cf. IV.2.16.

IV.2.3.5. Theorem. The \( p \)-series with exponent \( p \) converges if and only if \( p > 1 \).

Proof: Suppose \( p > 0, p \neq 1 \). We apply the Integral Test to the function \( f(t) = t^{-p} \), which is continuous, nonnegative, and nonincreasing on \([1, \infty)\). Then we have
\[
\int_{1}^{b} t^{-p} \, dt = \frac{t^{-p+1}}{-p+1} \bigg|_{1}^{b} = \frac{b^{1-p}}{1-p} - \frac{1}{1-p}.
\]
If \( p < 1 \), \( b^{1-p} \to +\infty \) as \( b \to \infty \) and the improper integral diverges, so the series diverges. If \( p > 1 \), \( b^{1-p} \to 0 \) as \( b \to \infty \) and the improper integral converges, so the series converges.

For completeness, we also do the case \( p = 1 \) using the integral test. We have
\[
\int_{1}^{b} t^{-1} \, dt = \log t \bigg|_{1}^{b} = \log b - \log 1 = \log b
\]
which goes to \( +\infty \) as \( b \to \infty \); hence the improper integral diverges and the series diverges too.

The Ratio and Root Tests

The Ratio Test and the Root Test are two of the most widely-used tests for convergence of nonnegative series. They are rather crude, in the sense that the tests fail (give no conclusion) for many series; in fact, they are successful only for series which converge or diverge rather spectacularly. But when they do work they are often quite easy to apply, so are quite useful.

The Root Test and the Ratio Test are sometimes called Cauchy’s Test and d’Alembert’s Test respectively, after their originators (although it seems generous to attribute the Ratio Test to d’ALEMBERT; see [Gra00, p.116-117]).
IV.2.3.6. Theorem. [Basic Root Test] Let \( \sum_{k=1}^{\infty} a_k \) be a nonnegative infinite series. Then

(i) If there is a \( u < 1 \) such that \( \sqrt[k]{a_k} = a_k^{1/k} \leq u \) for all sufficiently large \( k \), then the series converges.

(ii) If \( \sqrt[k]{a_k} = a_k^{1/k} \geq 1 \) for infinitely many \( k \), then the terms do not approach zero and the series diverges.

Proof: We first show (ii). If \( a_k^{1/k} \geq 1 \) for infinitely many \( k \), then \( a_k \leq k \) for infinitely many \( k \), and thus we cannot have \( \lim_{k \to \infty} a_k = 0 \), and the series diverges by the Divergence Criterion.

For (i), if \( a_k^{1/k} < u \) for all \( k \geq N \), then \( a_k \leq u^k \) for all \( k \geq N \). Comparing the series with the geometric series \( \sum_{k=1}^{\infty} u^k \), which converges since \( u < 1 \), we conclude from the Extended Comparison Test that the series converges.

The Root Test is usually phrased in terms of the \( \limsup \), although the divergence part is not quite as strong (but often easier to check):

IV.2.3.7. Corollary. [Root Test] Let \( \sum_{k=1}^{\infty} a_k \) be a nonnegative infinite series, and set

\[ r = \limsup_{k \to \infty} \sqrt[k]{a_k} = \limsup_{k \to \infty} a_k^{1/k}. \]

Then

(i) If \( r < 1 \), then the series converges.

(ii) If \( r > 1 \), then the terms do not approach zero and the series diverges.

(iii) If \( r = 1 \), then the series may or may not converge, and no conclusion may be drawn (the test fails).

In particular, if \( \lim_{k \to \infty} a_k^{1/k} \) exists, the limit is the \( r \) of the theorem and the series converges or diverges according to whether \( r < 1 \) or \( r > 1 \). But the test applies even if this limit does not exist; recall that the \( \limsup \) always exists for any sequence.

Proof: Part (i) is actually equivalent to IV.2.3.6.(i): suppose \( r < 1 \), and fix \( u \) with \( r < u < 1 \). Then there is an \( N \in \mathbb{N} \) with \( a_k^{1/k} < u \) for all \( k \geq N \) (\( ) \), so the hypotheses of IV.2.3.6.(i) are satisfied. Conversely, if there is a \( u \) such that IV.2.3.6.(i) holds, then \( r \leq u \) by (\( ) \).

For (ii), if \( r > 1 \), then \( a_k^{1/k} > 1 \) for infinitely many \( k \), so the hypotheses of IV.2.3.6.(ii) are satisfied. (However, the two are not equivalent: the hypotheses of IV.2.3.6 (ii) do not imply those of IV.2.3.7 (ii).)

To show the test fails in case (iii), it suffices to consider \( p \)-series. For the \( p \)-series, we have

\[ a_k^{1/k} = \frac{1}{[k^{1/p}]^{1/k}} = \frac{1}{[k^{1/k}]^p} \]

which has a limit of 1 for every \( p \) since \( \lim_{k \to \infty} k^{1/k} = 1 \) (\( ) \). But the \( p \)-series can either converge or diverge depending on \( p \). (Actually even the Basic Root Test fails to apply to \( p \)-series for \( p > 0 \).)
IV.2.3.8. Theorem. [Basic Ratio Test] Let \( \sum_{k=1}^{\infty} a_k \) be an infinite series with strictly positive terms. Then

(i) If there is a \( u < 1 \) such that \( \frac{a_{k+1}}{a_k} \leq u \) for all sufficiently large \( k \), then the series converges.

(ii) If \( \frac{a_{k+1}}{a_k} \geq 1 \) for all sufficiently large \( k \), then the terms do not approach zero and the series diverges.

Proof: The proof is quite similar to the proof of the Root Test.

(ii): Suppose there is an \( N \in \mathbb{N} \) such that \( \frac{a_{n+1}}{a_n} \geq 1 \), \( a_{n+1} \geq a_n \) for all \( n \geq N \). Then the terms of the series are eventually nondecreasing and so, since they are positive, they cannot converge to zero. Thus the series diverges by the Divergence Criterion.

(i): Suppose there is an \( N \in \mathbb{N} \) such that \( \frac{a_{k+1}}{a_k} < 1 \) for all \( k \geq N \). Then, for all \( k \in \mathbb{N} \), we have

\[
a_{N+k} \leq u a_{N+k-1} \leq u^2 a_{N+k-2} \leq \cdots \leq u^k a_N
\]

and we may apply the Extended Comparison Test to the given series and the series \( \sum_{k=1}^{\infty} a_N u^k \), which converges since \( u < 1 \).

As with the Root Test, the Ratio Test is usually phrased in terms of \( \limsup \) (and \( \liminf \)):

IV.2.3.9. Corollary. [Ratio Test] Let \( \sum_{k=1}^{\infty} a_k \) be an infinite series with strictly positive terms. Then

(i) If \( \limsup_{k \to \infty} \frac{a_{k+1}}{a_k} < 1 \), then the series converges.

(ii) If \( \liminf_{k \to \infty} \frac{a_{k+1}}{a_k} > 1 \), then the terms do not approach zero and the series diverges.

(iii) If \( \liminf_{k \to \infty} \frac{a_{k+1}}{a_k} \leq 1 \leq \limsup_{k \to \infty} \frac{a_{k+1}}{a_k} \), then the series may or may not converge, and no conclusion may be drawn (the test fails).

A more special version often applies which is slightly easier to state:

IV.2.3.10. Corollary. [Ratio Test, Limit Version] Let \( \sum_{k=1}^{\infty} a_k \) be an infinite series with strictly positive terms, and suppose \( r = \lim_{k \to \infty} \frac{a_{k+1}}{a_k} \) exists. Then

(i) If \( r < 1 \), then the series converges.
(ii) If \( r > 1 \), then the terms do not approach zero and the series diverges.

(iii) If \( r = 1 \), then the series may or may not converge, and no conclusion may be drawn (the test fails).

**Proof:** IV.2.3.10. (i)–(ii) are clearly special cases of IV.2.3.9. (i)–(ii). The proof of IV.2.3.9. (i)–(ii) is nearly identical to the proof of IV.2.3.7. from IV.2.3.6. and is left to the reader.

To show the test fails in case (iii), even in the case of IV.2.3.10., it suffices to consider \( p \)-series. For the \( p \)-series, we have

\[
\frac{a_{k+1}}{a_k} = \frac{1}{(k + 1)^p} = \left[ \frac{k}{k + 1} \right]^p
\]

which has a limit of 1 for every \( p \) since \( \lim_{k \to \infty} \frac{k}{k + 1} = 1 \). But the \( p \)-series can either converge or diverge depending on \( p \).

There are even convergent positive series where \( \lim \inf_{n \to \infty} \frac{a_{k+1}}{a_k} = 1 < \lim \sup_{n \to \infty} \frac{a_{k+1}}{a_k} \) (Exercise IV.2.16.2.) and divergent positive series where \( \lim \inf_{n \to \infty} \frac{a_{k+1}}{a_k} < 1 = \lim \sup_{n \to \infty} \frac{a_{k+1}}{a_k} \) (Exercise IV.2.16.3.), and both convergent and divergent positive series where \( \lim \inf_{n \to \infty} \frac{a_{k+1}}{a_k} < 1 < \lim \sup_{n \to \infty} \frac{a_{k+1}}{a_k} \) (Exercise IV.2.16.4.).

To compare the strength of the Ratio Test and Root Test, we use the following fact:

**IV.2.3.11. Proposition.** Let \((x_n)\) be a sequence of positive numbers. Then

\[
\lim \inf_{n \to \infty} \frac{x_{n+1}}{x_n} \leq \lim \inf_{n \to \infty} x_n^{1/n} \leq \lim \sup_{n \to \infty} x_n^{1/n} \leq \lim \sup_{n \to \infty} \frac{x_{n+1}}{x_n}.
\]

**Proof:** We prove only the last inequality; the first is similar (Exercise ()). Let \( r = \lim \sup_{n \to \infty} \frac{x_{n+1}}{x_n} \geq 0 \). If \( r = +\infty \), there is nothing to prove, so assume \( r \in [0, \infty) \). Then, for any \( s > r \), there is an \( N \in \mathbb{N} \) such that \( \frac{x_{n+1}}{x_n} < s \) for all \( n \geq N \). For \( m \in \mathbb{N} \), we have

\[
x_{N+m} < s x_{N+m-1} < s^2 x_{N+m-2} < \cdots < s^m x_N
\]

and so we obtain

\[
x_n < s^n \frac{x_N}{s^N}
\]

for all \( n \geq N \) (note that \( s > 0 \) since \( r \geq 0 \)). Taking \( n \)'th roots, we have

\[
x_n^{1/n} < t^{1/n}
\]

for all \( n \geq N \), where \( t = \frac{x_N}{s^N} \). So

\[
\lim \sup_{n \to \infty} x_n^{1/n} \leq s \cdot \lim \sup_{n \to \infty} t^{1/n} = s
\]

since \( \lim_{n \to \infty} t^{1/n} = 1 \). Since \( s \) is an arbitrary number \( > r \), we have

\[
\lim \sup_{n \to \infty} x_n^{1/n} \leq r.
\]
IV.2.3.12. Any or all of the inequalities in IV.2.3.11. can be strict; see Exercise ().

IV.2.3.13. **Corollary.** Let $\sum_{k=1}^{\infty} a_k$ be an infinite series with strictly positive terms. If the Ratio Test gives a conclusion about the convergence or divergence of the series (i.e. the Ratio Test does not fail), then the Root Test also gives the same conclusion (in particular, it does not fail).

In other words, the Root Test is, at least in principle, a more broadly applicable test than the Ratio Test. It is in fact strictly more broadly applicable (Exercise ()). However, in practice the Ratio Test is frequently simpler to use than the Root Test, so there is utility in having both tests available.

IV.2.4. **More Delicate Tests**

There are several refinements of the Ratio Test which can be used for certain series for which the Ratio Test fails. Most are special cases of the following blockbuster test:

IV.2.4.1. **Theorem. [Kummer’s Test]** Let $\sum_{k=1}^{\infty} a_k$ be an infinite series with strictly positive terms.

(i) If there are positive real numbers $r$ and $p_1, p_2, \ldots$ such that

$$p_k \frac{a_k}{a_{k+1}} - p_{k+1} \geq r$$

for all sufficiently large $k$, then $\sum_{k=1}^{\infty} a_k$ converges.

(ii) If there are positive real numbers $p_1, p_2, \ldots$ such that

$$p_k \frac{a_k}{a_{k+1}} - p_{k+1} \leq 0$$

for all sufficiently large $k$, and $\sum_{k=1}^{\infty} \frac{1}{p_k}$ diverges, then $\sum_{k=1}^{\infty} a_k$ diverges.

Note that the Basic Ratio Test is the special case where $p_k = 1$ for all $k$.

**Proof:** For both (i) and (ii), by passing to a tail of the series we may assume the inequalities hold for all $k$.

(i): For each $k$, we have $a_{k+1} \leq \frac{1}{r} [p_k a_k - p_{k+1} a_{k+1}]$, so for each $n > 1$,

$$s_n = \sum_{k=1}^{n} a_k = a_1 + \sum_{k=2}^{n} a_k \leq a_1 + \frac{1}{r} \sum_{k=1}^{n-1} (p_k a_k - p_{k+1} a_{k+1})$$

$$= a_1 + \frac{1}{r} \left[ \sum_{k=1}^{n-1} p_k a_k - \sum_{k=2}^{n} p_k a_k \right] = a_1 + \frac{p_1 a_1}{r} - \frac{p_n a_n}{r} \leq a_1 + \frac{p_1 a_1}{r}$$

451
and so the partial sums are bounded and the series converges.

(ii): We have that

\[
\frac{a_2}{a_2} \geq \frac{p_1 a_1}{p_2}, \quad \frac{a_3}{a_3} \geq \frac{p_2 a_2}{p_3}, \quad \ldots, \quad \frac{a_k}{a_k} \geq \frac{p_l a_{l-1}}{p_k}, \quad \ldots
\]

and so we can apply the Comparison Test to \( \sum_{k=1}^{\infty} a_k \) and the divergent series

\[
a_1 + \sum_{k=2}^{\infty} \frac{p_1 a_1}{p_k}.
\]

IV.2.4.2. Kummer’s Test is, in principle at least, a maximally applicable test: for any infinite series with strictly positive terms, there is a sequence \( \{p_k\} \) of positive numbers for which the test works to give either convergence or divergence (Exercise IV.2.16.1.). However, it can be extremely difficult to find such a sequence for a given series, so the general Kummer Test is of limited applicability in practice.

Special cases of Kummer’s Test with specific sequences \( \{p_n\} \) are more useful. Here is one of the most widely-used ones:

**IV.2.4.3. Theorem. [Raabe’s Test]** Let \( \sum_{k=1}^{\infty} a_k \) be an infinite series with strictly positive terms. Then

(i) If \( \liminf_{k \to \infty} k \left[ \frac{a_k}{a_{k+1}} - 1 \right] > 1 \), the series \( \sum_{k=1}^{\infty} a_k \) converges.

(ii) If \( k \left[ \frac{a_k}{a_{k+1}} - 1 \right] \leq 1 \) for all sufficiently large \( k \), the series \( \sum_{k=1}^{\infty} a_k \) diverges.

**Proof:** Apply Kummer’s Test with \( p_k = k \) for all \( k \) and, for (i), \( r \) a number with \( 0 < r < \liminf_{k \to \infty} k \left[ \frac{a_k}{a_{k+1}} - 1 \right] - 1 \).

A limit version is frequently applicable:

**IV.2.4.4. Corollary. [Raabe’s Test, Limit Version]** Let \( \sum_{k=1}^{\infty} a_k \) be an infinite series with strictly positive terms. Suppose

\[
L = \lim_{k \to \infty} k \left[ \frac{a_k}{a_{k+1}} - 1 \right]
\]

exists (as an extended real number). Then
(i) If \( L > 1 \), the series \( \sum_{k=1}^{\infty} a_k \) converges.

(ii) If \( L < 1 \), the series \( \sum_{k=1}^{\infty} a_k \) diverges.

(iii) If \( L = 1 \), then the series \( \sum_{k=1}^{\infty} a_k \) may or may not converge, and no conclusion may be drawn (the test fails).

Raabe’s Test is often written in a slightly different but equivalent form (cf. Exercise IV.2.16.9).

**IV.2.4.5. COROLLARY. [RAABE’S TEST, VERSION 2]** Let \( \sum_{k=1}^{\infty} a_k \) be an infinite series with strictly positive terms. Suppose

\[
L = \lim_{k \to \infty} k \left[ 1 - \frac{a_{k+1}}{a_k} \right]
\]

exists (as an extended real number). Then

(i) If \( L > 1 \), the series \( \sum_{k=1}^{\infty} a_k \) converges.

(ii) If \( L < 1 \), the series \( \sum_{k=1}^{\infty} a_k \) diverges.

(iii) If \( L = 1 \), then the series \( \sum_{k=1}^{\infty} a_k \) may or may not converge, and no conclusion may be drawn (the test fails).

Yet another formulation of Raabe’s Test is:

**IV.2.4.6. THEOREM. [RAABE’S TEST, VERSION 3]** Let \( \sum_{k=1}^{\infty} a_k \) be an infinite series with strictly positive terms. Suppose

\[
\frac{a_{k+1}}{a_k} = 1 - \frac{\lambda}{k} + o \left( \frac{1}{k} \right)
\]

for some fixed real number \( \lambda \). Then

(i) If \( \lambda > 1 \), the series \( \sum_{k=1}^{\infty} a_k \) converges.
(ii) If $\lambda < 1$, the series $\sum_{k=1}^{\infty} a_k$ diverges.

(iii) If $\lambda = 1$, then the series $\sum_{k=1}^{\infty} a_k$ may or may not converge, and no conclusion may be drawn (the test fails).

**Proof:** Applying IV.2.4.5., we have

$$k \left[ 1 - \frac{a_{k+1}}{a_k} \right] = \lambda + k \cdot o \left( \frac{1}{k} \right) = \lambda + o(1)$$

so we have $L = \lambda$. The converse implication is similar, and left as an exercise.

**IV.2.4.7.** Note that Raabe’s Test (even the limit version IV.2.4.4.) is more delicate than the Ratio Test: if $\limsup_{k \to \infty} \frac{a_{k+1}}{a_k} < 1$, then $L = +\infty$, and if $\liminf_{k \to \infty} \frac{a_{k+1}}{a_k} > 1$, then $L = -\infty$, so Raabe’s Test applies (and gives the same conclusion, of course).

Raabe’s test is delicate enough to handle $p$-series for $p \neq 1$: for the $p$-series we have

$$L = \lim_{k \to \infty} k \left[ \frac{a_k}{a_{k+1}} - 1 \right] = \lim_{k \to \infty} k \left[ \frac{(k+1)^p}{k^p} - 1 \right] = \lim_{k \to \infty} \frac{(k+1)^p - k^p}{k^{p-1}} = p$$

(See Exercise (i).)

However, Raabe’s Test does not work for the harmonic series (although the slight extension to Kummer’s Test for $p_k = k$ does), nor does it work for the log$^p$-series

$$\sum_{k=2}^{\infty} \frac{1}{k^{[\log k]^p}}$$

which converges for $p > 1$ and diverges for $p \leq 1$ (i). For these log$^p$-series, a “second-order Raabe’s Test” does apply:

**IV.2.4.8.** Theorem. Let $\sum_{k=1}^{\infty} a_k$ be an infinite series with strictly positive terms. Suppose

$$M = \lim_{k \to \infty} (\log k) \left( k \left[ \frac{a_k}{a_{k+1}} - 1 \right] - 1 \right)$$

exists (as an extended real number). Then

(i) If $M > 1$, the series $\sum_{k=1}^{\infty} a_k$ converges.
(ii) If \( M < 1 \), the series \( \sum_{k=1}^{\infty} a_k \) diverges.

(iii) If \( M = 1 \), then the series \( \sum_{k=1}^{\infty} a_k \) may or may not converge, and no conclusion may be drawn (the test fails).

**Proof:** Apply Kummer’s Test with \( p_k = k \log k \). (See Exercise (i).)

There is a variation of this second-order test similar to IV.2.4.6. The proof is left as an exercise.

**IV.2.4.9. Theorem.** Let \( \sum_{k=1}^{\infty} a_k \) be an infinite series with strictly positive terms. Suppose

\[
\frac{a_{k+1}}{a_k} = 1 - \frac{1}{k} - \frac{\mu}{k \log k} + o\left(\frac{1}{k \log k}\right)
\]

for some fixed real number \( \mu \). Then

(i) If \( \mu > 1 \), the series \( \sum_{k=1}^{\infty} a_k \) converges.

(ii) If \( \mu < 1 \), the series \( \sum_{k=1}^{\infty} a_k \) diverges.

(iii) If \( \mu = 1 \), then the series \( \sum_{k=1}^{\infty} a_k \) may or may not converge, and no conclusion may be drawn (the test fails).

**IV.2.4.10.** The second-order test will work for the \( \log^p \)-series with \( p \neq 1 \). It will not work for the \( \log \log^p \)-series

\[
\sum_{k=3}^{\infty} \frac{1}{k \log k [\log \log k]^p}
\]

(which again converges or diverges depending whether \( p > 1 \) or \( p \leq 1 \); cf. (i)), but a “third-order Raabe Test” will (for \( p \neq 1 \)), using

\[
L = \lim_{k \to \infty} \left( \log k \right) \left( k \left[ \frac{a_k}{a_{k+1}} - 1 \right] - 1 \right) - 1
\]

The process can be continued *ad infinitum* to higher orders. Details are left to the interested reader.
Gauss’s Test
As part of his work on hypergeometric series (), Gauss developed an early test which is closely related to Raabe’s test, but both the hypotheses and conclusion are slightly stronger. (Gauss actually only stated this test when the \( O \left( \frac{1}{k^p} \right) \) term is a rational function in \( k \).) Note that this test never fails (when the hypotheses are satisfied).

**IV.2.4.11. Theorem. [Gauss’s Test]** Let \( \sum_{k=1}^{\infty} a_k \) be an infinite series with strictly positive terms. Suppose

\[
\frac{a_{k+1}}{a_k} = 1 - \frac{\lambda}{k} + O \left( \frac{1}{k^p} \right)
\]

for some fixed real number \( \lambda \) and some fixed \( p > 1 \). Then

(i) If \( \lambda > 1 \), the series \( \sum_{k=1}^{\infty} a_k \) converges.

(ii) If \( \lambda \leq 1 \), the series \( \sum_{k=1}^{\infty} a_k \) diverges.

**Proof:** Since \( O \left( \frac{1}{k^p} \right) = o \left( \frac{1}{k} \right) \), if \( \lambda \neq 1 \) the result follows from IV.2.4.6. And if \( \lambda = 1 \), we have \( O \left( \frac{1}{k^p} \right) = o \left( \frac{1}{k \log k} \right) \) so the result follows from IV.2.4.9. with \( \mu = 0 \).

Cauchy’s Condensation Test and Yermakov’s Test
These two closely related tests reduce the question of convergence of a series with decreasing nonnegative terms to consideration of a “sparse” subseries. Cauchy’s Condensation Test is a generalization of the argument used in IV.2.2.11.

**IV.2.4.12. Theorem. [Cauchy’s Condensation Test]** Let \( (c_k) \) be a strictly increasing sequence of positive integers such that there is a constant \( M \) with

\[
c_{k+2} - c_{k+1} \leq M(c_{k+1} - c_k)
\]

for all \( k \). Then, if \( \sum_{k=1}^{\infty} a_k \) is an infinite series with nonincreasing nonnegative terms, the two series

\[
\sum_{k=1}^{\infty} a_k \quad \text{and} \quad \sum_{k=1}^{\infty} (c_{k+1} - c_k)a_{c_k}
\]

either both converge or both diverge.
Proof: If \( c_1 > 1 \), set \( r = \sum_{k=1}^{c_1-1} a_k \); if \( c_1 = 1 \), set \( r = 0 \). Write \( s_n \) and \( t_n \) for the \( n \)’th partial sums of the two series respectively. Then, for \( n \leq c_m \), we have

\[
s_n \leq s_{c_m} \leq r + (a_{c_1} + a_{c_1+1} + \cdots + a_{c_2-1}) + (a_{c_2} + \cdots + a_{c_3-1}) + \cdots + (a_{c_m} + \cdots + a_{c_{m+1}-1})
\]

\[
\leq r + (c_2 - c_1)a_{c_1} + \cdots + (c_{m+1} - c_m)a_{c_m} = r + t_m
\]

and so, if the second series converges, i.e. \((t_m)\) is bounded, the sequence \((s_n)\) is also bounded so the first series converges. On the other hand, if \( n > c_m \), we have

\[
s_n \geq s_{c_m} \geq (a_{c_1+1} + \cdots + a_{c_2}) + (a_{c_2+1} + \cdots + a_{c_3}) + \cdots + (a_{c_{m-1}+1} + \cdots + a_{c_m})
\]

\[
\geq (c_2 - c_1)a_{c_2} + (c_3 - c_2)a_{c_3} + \cdots + (c_m - c_{m-1})a_{c_m}
\]

\[
Ms_n \geq (c_1 - c_2)a_{c_2} + \cdots + (c_{m+1} - c_m)a_{c_m} = t_m - a_{c_1}
\]

and so if the first series converges, i.e. \((s_n)\) is bounded, the sequence \((t_m)\) is also bounded and the second series converges. 

The most commonly used case of this test is to take \( c_k = 2^k \) for all \( k \) (then we can take \( M = 2 \)). We obtain:

**IV.2.4.13.** Corollary. [Cauchy’s Condensation Test, Common Version] If \( \sum_{k=1}^{\infty} a_k \) is an infinite series with nonincreasing nonnegative terms, the two series

\[
\sum_{k=1}^{\infty} a_k \quad \text{and} \quad \sum_{k=1}^{\infty} 2^k a_{2^k}
\]

either both converge or both diverge.

This corollary suffices to show that the harmonic series converges, since the terms of the second series then become all 1, so the second series diverges by the Divergence Criterion. (This is essentially the argument of IV.2.2.11.) The corollary also suffices to show convergence and divergence of the series in (\( ) \).

The test of Yermakov (or Ermakoff) is similar in nature, but is based on the Integral Test and gives a direct criterion for convergence or divergence without making a comparison with another series:

**IV.2.4.14.** Theorem. [Yermakov’s Test] Let \( f \) be a nonincreasing strictly positive function on \([1, \infty)\), and \( \phi \) a strictly increasing differentiable function on \([1, \infty)\) with \( \phi(t) > t \) for all \( t \). Then

(i) If \( \limsup_{t \to \infty} \frac{\phi'(t)f(\phi(t))}{f(t)} < 1 \), then \( \sum_{k=1}^{\infty} f(k) \) converges.
(ii) If $\phi'(t)f(\phi(t)) \geq f(t)$ for all sufficiently large $t$ (in particular, if $\liminf_{t \to \infty} \frac{\phi'(t)f(\phi(t))}{f(t)} > 1$), then $\sum_{k=1}^{\infty} f(k)$ diverges.

**Proof:** (i): It suffices to show that $\int_{c}^{\infty} f(t) dt$ converges for some $c$ by the Integral Test. Under the hypothesis, there is an $r < 1$ and an $a$ such that $\phi'(t)f(\phi(t)) < r \cdot f(t)$ for all $t \geq a$. Then, for any $b > a$ (we restrict to $b > \phi(a)$), we have

$$\int_{a}^{b} f(\phi(t)) \phi'(t) dt < r \int_{a}^{b} f(t) dt$$

so, making the substitution $u = \phi(t)$ in the first integral, we obtain

$$\int_{\phi(a)}^{\phi(b)} f(u) du < r \int_{a}^{b} f(t) dt .$$

Writing the first integral as $\int_{\phi(a)}^{\phi(b)} f(t) dt$, we have

$$(1 - r) \int_{\phi(a)}^{\phi(b)} f(t) dt < r \left[ \int_{a}^{b} f(t) dt - \int_{\phi(a)}^{\phi(b)} f(t) dt \right]$$

$$= r \left[ \int_{a}^{\phi(a)} f(t) dt + \int_{\phi(a)}^{b} f(t) dt - \int_{a}^{b} f(t) dt - \int_{b}^{\phi(b)} f(t) dt \right] = r \left[ \int_{a}^{\phi(a)} f(t) dt - \int_{b}^{\phi(b)} f(t) dt \right]$$

and, since $b < \phi(b)$, the last integral is positive, so we have

$$(1 - r) \int_{\phi(a)}^{\phi(b)} f(t) dt < r \int_{a}^{\phi(a)} f(t) dt .$$

The right side is constant, so we have that the left side is bounded as $b \to +\infty$ (and hence $\phi(b) \to +\infty$). Thus $\int_{\phi(a)}^{\infty} f(t) dt$ converges.

(ii): Suppose $\phi'(t)f(\phi(t)) \geq f(t)$ for all $t \geq a$. Then we have, for any $b > a$,

$$\int_{a}^{b} f(\phi(t)) \phi'(t) dt \geq \int_{a}^{b} f(t) dt .$$

Changing variables as before, we obtain

$$\int_{\phi(a)}^{\phi(b)} f(t) dt \geq \int_{a}^{b} f(t) dt$$

$$\int_{\phi(a)}^{b} f(t) dt + \int_{b}^{\phi(b)} f(t) dt \geq \int_{a}^{\phi(a)} f(t) dt + \int_{\phi(a)}^{b} f(t) dt$$

458
\[
\int_b^{\phi(b)} f(t) \, dt \geq \int_a^{\phi(a)} f(t) \, dt.
\]

The right side is a strictly positive constant, and if \( \int_1^{\infty} f(t) \, dt \) converged, the left side would have to converge to 0 as \( b \to \infty \). Thus \( \int_1^{\infty} f(t) \, dt \) diverges, and the series also diverges by the Integral Test.

This test is commonly written in the special case \( \phi(t) = e^t \):

**IV.2.4.15. Corollary.** (Yermakov’s Test, Common Version) Let \( f \) be a nonincreasing strictly positive function on \([1, \infty)\). Then

(i) If \( \limsup_{t \to \infty} \frac{e^t f(e^t)}{f(t)} < 1 \), then \( \sum_{k=1}^{\infty} f(k) \) converges.

(ii) If \( \liminf_{t \to \infty} \frac{e^t f(e^t)}{f(t)} > 1 \), then \( \sum_{k=1}^{\infty} f(k) \) diverges.

**IV.2.4.16.** This version is sufficient to handle all the \( p \)-series, \( \log^{-p} \)-series, \( \log \log^{-p} \)-series, etc., of (Exercise ()). (Of course, these series can also be handled directly by the Integral Test, as well as by Cauchy’s Condensation Test.)

**IV.2.5. Absolute and Conditional Convergence**

Convergence or divergence of an infinite series is a much more subtle matter if it has both positive and negative terms, since there can be complicated cancellation in the partial sums. In fact, there are convergent series whose terms go to zero arbitrarily slowly. But series which converge because their terms go to zero rapidly (absolutely convergent series) are better behaved and do not have the pathologies possible in the general case where convergence depends delicately on such cancellation.

**IV.2.5.1. Definition.** Let \( \sum_{k=1}^{\infty} a_k \) be an infinite series. The series \( \sum_{k=1}^{\infty} a_k \) converges absolutely if \( \sum_{k=1}^{\infty} |a_k| \) converges. The series \( \sum_{k=1}^{\infty} a_k \) converges conditionally if \( \sum_{k=1}^{\infty} a_k \) converges but \( \sum_{k=1}^{\infty} |a_k| \) diverges.

Of course, convergence and absolute convergence are the same thing for nonnegative series (and, by IV.2.1.18., also for series with only negative terms). But there is a big difference for general series.

The first observation is that absolute convergence implies convergence. Buried in the proof is the Completeness Property of \( \mathbb{R} \), in the form of the Cauchy Criterion; in fact this result is another equivalent characterization of completeness of \( \mathbb{R} \) (cf. ())).

459
IV.2.5.2. Proposition. Every absolutely convergent series converges.

Proof: Let $\sum_{k=1}^{\infty} a_k$ be an infinite series, and suppose $\sum_{k=1}^{\infty} |a_k|$ converges. Let $\epsilon > 0$, and fix $N$ such that, whenever $N \leq n < m$, we have

$$\sum_{k=n+1}^{m} |a_k| < \epsilon$$

(IV.2.1.11.). Then, by the triangle inequality we have for $N \leq n < m$,

$$\left| \sum_{k=n+1}^{m} a_k \right| \leq \sum_{k=n+1}^{m} |a_k| < \epsilon$$

so $\sum_{k=1}^{\infty} a_k$ converges by the Cauchy Criterion (IV.2.1.11.).

For an alternate proof, see IV.2.16.10.

IV.2.5.3. Thus there are only three possibilities for an infinite series $\sum_{k=1}^{\infty} a_k$:

(i) The series converges absolutely, i.e. $\sum_{k=1}^{\infty} a_k$ and $\sum_{k=1}^{\infty} |a_k|$ both converge.

(ii) The series converges conditionally, i.e. $\sum_{k=1}^{\infty} a_k$ converges but $\sum_{k=1}^{\infty} |a_k|$ diverges.

(iii) The series diverges, i.e. both $\sum_{k=1}^{\infty} a_k$ and $\sum_{k=1}^{\infty} |a_k|$ diverge.

Of course, conditional convergence is only a possibility when there are infinitely many positive terms and also infinitely many negative terms.

The Fundamental Principle of Nonnegative Series (IV.2.2.2.) asserts that a series converges absolutely if and only if its terms go to zero sufficiently rapidly.

We have not yet seen an example of a conditionally convergent series, but there are (rather degenerate) simple examples where the terms go to zero arbitrarily slowly:

IV.2.5.4. Example. Let $(b_k)$ be a sequence of numbers converging to zero. For each $k$, set $a_{2k-1} = b_k$ and $a_{2k} = -b_k$. Then the partial sums $s_n$ of the series $\sum_{k=1}^{\infty} a_k$ satisfy $s_n = 0$ for $n$ even and $s_n = b_m$ if
\( n = 2m - 1 \) is odd. Thus \( s_n \to 0 \) and the series converges (with sum 0). The series \( \sum_{k=1}^{\infty} a_k \) converges absolutely if and only if \( \sum_{k=1}^{\infty} |b_k| \) converges; hence, for example, if \( b_k = \frac{1}{k} \), the series \( \sum_{k=1}^{\infty} a_k \) converges conditionally.

We will see more interesting examples of conditionally convergent series.

To further illustrate the nature of conditionally convergent series, we note:

**IV.2.5.5. Proposition.** Let \( \sum_{k=1}^{\infty} a_k \) be a conditionally convergent series, and let \( \sum_{k=1}^{\infty} b_k \) and \( \sum_{k=1}^{\infty} c_k \) be the infinite series whose terms are the positive and negative terms of \( \sum_{k=1}^{\infty} a_k \) respectively. Then \( \sum_{k=1}^{\infty} b_k \) and \( \sum_{k=1}^{\infty} c_k \) both diverge (i.e. the partial sums of both series are unbounded).

**Proof:** The series \( \sum_{k=1}^{\infty} b_k \) and \( \sum_{k=1}^{\infty} c_k \) cannot both converge, since then we would have, for any \( n \),

\[
\sum_{k=1}^{n} |a_k| \leq \sum_{k=1}^{\infty} b_k + \sum_{k=1}^{\infty} (-c_k)
\]

and \( \sum_{k=1}^{\infty} a_k \) would converge absolutely. If \( \sum_{k=1}^{\infty} b_k \) diverges but \( \sum_{k=1}^{\infty} c_k \) converges, there is an \( m > 0 \) such that all partial sums of \( \sum_{k=1}^{\infty} c_k \) are \( \geq -m \); for any \( M \) all sufficiently large partial sums of \( \sum_{k=1}^{\infty} b_k \) are \( \geq M \), so for all sufficiently large \( n \) we have

\[
\sum_{k=1}^{n} a_k \geq M - m
\]

and so \( \sum_{k=1}^{\infty} a_k \) cannot converge. The argument in the other case is almost identical.

What the proof actually shows is the following slightly more precise result:

**IV.2.5.6. Proposition.** Let \( \sum_{k=1}^{\infty} a_k \) be an infinite series with infinitely many terms of each sign, and let \( \sum_{k=1}^{\infty} b_k \) and \( \sum_{k=1}^{\infty} c_k \) be the infinite series whose terms are the positive and negative terms of \( \sum_{k=1}^{\infty} a_k \) respectively. Then
(i) If $\sum_{k=1}^{\infty} b_k$ and $\sum_{k=1}^{\infty} c_k$ both converge, then $\sum_{k=1}^{\infty} a_k$ converges absolutely.

(ii) If one of $\sum_{k=1}^{\infty} b_k$ and $\sum_{k=1}^{\infty} c_k$ converges and the other diverges, then $\sum_{k=1}^{\infty} a_k$ diverges.

Tests for Absolute Convergence

Any of the tests for convergence of nonnegative series become tests for absolute convergence if absolute values are inserted. We explicitly state the Root and Ratio Tests, and the Comparison Test:

IV.2.5.7. Theorem. [Root Test] Let $\sum_{k=1}^{\infty} a_k$ be an infinite series, and set

$$r = \limsup_{k \to \infty} \sqrt[k]{|a_k|} = \limsup_{k \to \infty} |a_k|^{1/k}.$$ 

Then

(i) If $r < 1$, then the series converges absolutely.

(ii) If $r > 1$, then the terms do not approach zero and the series diverges.

(iii) If $r = 1$, then the series may converge absolutely, converge conditionally, or diverge, and no conclusion may be drawn (the test fails).

IV.2.5.8. Theorem. [Ratio Test] Let $\sum_{k=1}^{\infty} a_k$ be an infinite series with nonzero terms. Then

(i) If $\limsup_{k \to \infty} \left| \frac{a_{k+1}}{a_k} \right| < 1$, then the series converges absolutely.

(ii) If $\liminf_{k \to \infty} \left| \frac{a_{k+1}}{a_k} \right| > 1$, then the terms do not approach zero and the series diverges.

(iii) If $\liminf_{k \to \infty} \left| \frac{a_{k+1}}{a_k} \right| \leq 1 \leq \limsup_{k \to \infty} \left| \frac{a_{k+1}}{a_k} \right|$, then the series may converge absolutely, converge conditionally, or diverge, and no conclusion may be drawn (the test fails).

The only part of these theorems which may not be obvious from earlier work is the assertion in (iii) of each that the series can converge conditionally. The series of IV.2.5.4. with $b_k = \frac{1}{k}$ is an example in both cases. (In fact, any conditionally convergent series must fall into case (iii) in each theorem.)

462
IV.2.5.9. **Theorem.** [Comparison Test] Let $\sum_{k=1}^{\infty} a_k$ and $\sum_{k=1}^{\infty} b_k$ be infinite series. Suppose $|a_k| \leq |b_k|$ for all $k$. If $\sum_{k=1}^{\infty} b_k$ converges absolutely, then $\sum_{k=1}^{\infty} a_k$ converges absolutely.

IV.2.5.10. **Caution:** We do not get a comparison test for simple convergence of series, i.e. if $\sum_{k=1}^{\infty} a_k$ and $\sum_{k=1}^{\infty} b_k$ are infinite series, with $|a_k| \leq |b_k|$ for all $k$, and $\sum_{k=1}^{\infty} b_k$ converges, then we cannot conclude that $\sum_{k=1}^{\infty} a_k$ converges. There are many counterexamples from the Alternating Series Test (IV.2.5.13.), e.g. $a_k = \frac{1}{k}$ and $b_k = \frac{(-1)^k}{k}$ (IV.2.5.14.(i)).

Combining the Comparison Test and the Triangle Inequality with IV.2.1.16., we obtain:

IV.2.5.11. **Proposition.** Let $\sum_{k=1}^{\infty} a_k$ and $\sum_{k=1}^{\infty} b_k$ be absolutely convergent infinite series. Then the series $\sum_{k=1}^{\infty} (a_k + b_k)$ converges absolutely, and $\sum_{k=1}^{\infty} (a_k + b_k) = \sum_{k=1}^{\infty} a_k + \sum_{k=1}^{\infty} b_k$.

It is more straightforward to see that if $\sum_{k=1}^{\infty} a_k$ is an absolutely convergent infinite series, and $c \in \mathbb{R}$, then $\sum_{k=1}^{\infty} ca_k$ is also absolutely convergent.

**Alternating Series**

There is a simple criterion for the convergence of infinite series in which the terms alternate sign. In such series the cancellation of positive and negative terms is regular enough to make the series converge under quite mild restrictions.

IV.2.5.12. **Definition.** An alternating series is an infinite series in which successive terms are of opposite signs.

The next theorem is the main result of this subsection. It is a special case of Dirichlet’s Test, but the proof is considerably simpler in this case, essentially reducing to the Nested Intervals Property of $\mathbb{R}$. This is also the most commonly used test for series with terms of varying sign.
IV.2.5.13. **Theorem. [Alternating Series Test]** Let $\sum_{k=1}^{\infty} a_k$ be an alternating series. If

(i) The terms decrease in absolute value, i.e. $|a_{k+1}| \leq |a_k|$ for all $k$, and

(ii) $\lim_{k \to \infty} a_k = 0$,

then the series $\sum_{k=1}^{\infty} a_k$ converges. The sum lies between any two consecutive partial sums.

Note that this result says nothing about absolute or conditional convergence; either type can occur under the hypotheses.

**Proof:** By discarding the first term of the series if necessary (cf. IV.2.1.6.), we may assume $a_1 > 0$, and hence $a_k > 0$ for $k$ odd, $a_k < 0$ for $k$ even. (This is not an essential restriction, but simplifies the notation of the proof.)

Let $s_n$ be the $n$'th partial sum of the series. By (i), we have

$s_2 \leq s_4 \leq s_6 \leq \cdots \leq s_5 \leq s_3 \leq s_1$

and thus for any $m$ we have $s_{2m} \leq s_k \leq s_{2m-1}$ for all $k \geq 2m - 1$. (This can be proved carefully by induction on $k$.) Thus, if $k, j \geq 2m - 1$, we have

$|s_k - s_j| \leq s_{2m-1} - s_{2m} = |a_{2m}|$.

For any $\epsilon > 0$, we have $|a_{2m}| < \epsilon$ for all sufficiently large $m$ by (ii), so the sequence $(s_n)$ is a Cauchy sequence and hence converges; the limit $s$ satisfies $s_{2m} \leq s \leq s_{2m-1}$ for any $m$.

IV.2.5.14. **Examples.** (i) The Alternating Series Test provides more interesting examples of conditionally convergent series than IV.2.5.4.; in fact, in the Alternating Series Test the terms can also go to zero arbitrarily slowly. For example, the alternating $p$-series

$$\sum_{k=1}^{\infty} \frac{(-1)^k}{k^p}$$

converges for any $p > 0$; the convergence is absolute for $p > 1$ and conditional for $0 < p \leq 1$.

(ii) In the Alternating Series Test, both hypotheses are necessary. Hypothesis (ii) is clearly necessary by the Divergence Criterion, and is easily remembered. It is more common to forget to check (i), but some version of (i) is necessary: for example, set $a_k = \frac{1}{k}$ for $k$ odd and $a_k = -\frac{1}{k}$ for $k$ even. Then the series $\sum_{k=1}^{\infty} a_k$ is alternating, and the terms approach zero; but the series of positive terms diverges and the series of negative terms converges, and hence $\sum_{k=1}^{\infty} a_k$ diverges by IV.2.5.6.

It does suffice, of course, that conditions (i) and (ii) (and even the fact that the series alternates) just hold from some point on in the series, by IV.2.1.6.; the statement that the sum of the series lies between successive partial sums then only holds beyond the point where the terms satisfy the hypotheses.
IV.2.6. Hypergeometric Series

Hypergeometric series are a generalization of geometric series which arise naturally in applications: many applied problems give rise to power series which are hypergeometric ( ). The theory of hypergeometric series was primarily developed by Gauss.

IV.2.6.1. Definition. A hypergeometric series is an infinite series \( \sum_{k=1}^{\infty} a_k \) in which all \( a_k \) are nonzero, and for which there are polynomials \( p \) and \( q \) such that

\[
\frac{a_{k+1}}{a_k} = \frac{p(k)}{q(k)}
\]

for all \( k \). The summation may also start at 0 or another integer.

IV.2.6.2. Examples. (i) A geometric series is a hypergeometric series where \( p \) and \( q \) are constant: if the ratio is \( x \), take \( p(k) = x \) (\( x \) is a constant!) and \( q(k) = 1 \).

(ii) For fixed \( x \), the series

\[
\sum_{k=0}^\infty \frac{x^k}{k!}
\]

for \( e^x \) is hypergeometric: we have

\[
\frac{a_{k+1}}{a_k} = \frac{k!x^{k+1}((k+1)!x^k)}{x^{k+1}} = \frac{x}{k+1}
\]

so we may take \( p(k) = x \) (constant) and \( q(k) = k + 1 \). The power series for \( \sin x \) and \( \cos x \) (\( x \) fixed) are also hypergeometric.

(iii) The basic hypergeometric series considered by Gauss was

\[
\sum_{k=0}^{\infty} \frac{\alpha(\alpha + 1)\cdots(\alpha + k - 1)\beta(\beta + 1)\cdots(\beta + k - 1)x^k}{k!(\gamma + 1)\cdots(\gamma + k - 1)}
\]

where \( \alpha, \beta, \gamma \) are real numbers which are not integers \( \leq 0 \), \( x \) is a fixed real number, and the \( k = 0 \) term is taken to be 1. We then have

\[
\frac{a_{k+1}}{a_k} = \frac{(\alpha + k)(\beta + k)x}{(1 + k)(\gamma + k)}
\]

so the series is hypergeometric. (The geometric series is the special case where \( \alpha = 1 \) and \( \beta = \gamma \).)

IV.2.6.3. Since \( p(k) \) and \( q(k) \) have constant sign for sufficiently large \( k \), it follows that the terms of a hypergeometric series either are eventually constant in sign or eventually alternate in sign.
IV.2.6.4. The Ratio Test is tailor-made for determining convergence of hypergeometric series, since

\[ \lim_{k \to \infty} \frac{p(k)}{q(k)} \]

always exists (as an extended real number) and is easily computed. (In fact, the Ratio Test was originally specifically developed largely to analyze hypergeometric series.) Thus the series converges absolutely if this limit is less than one in absolute value, and diverges if greater than one. In particular, we have:

IV.2.6.5. PROPOSITION. Let \( \sum_{k=1}^{\infty} a_k \) be a hypergeometric series with

\[ \frac{a_{k+1}}{a_k} = \frac{p(k)}{q(k)} \]

for all \( k \). Let \( c \) and \( d \) be the leading coefficients of \( p \) and \( q \) respectively. Then

(i) If the degree of \( q \) is greater than the degree of \( p \), the series converges absolutely.

(ii) If the degree of \( p \) is greater than the degree of \( q \), the series diverges.

(iii) If \( p \) and \( q \) have the same degree and \( |\frac{c}{d}| < 1 \), the series converges absolutely.

(iv) If \( p \) and \( q \) have the same degree and \( |\frac{c}{d}| > 1 \), the series diverges.

IV.2.6.6. COROLLARY. The basic hypergeometric series of IV.2.6.2.(iii) converges absolutely if \( |x| < 1 \) and diverges if \( |x| > 1 \).

The most interesting situation is when the Ratio Test fails, i.e. when \( p \) and \( q \) have the same degree and \( |\frac{c}{d}| = 1 \). (In the basic hypergeometric series, this is the case \( |x| = 1 \).) GAUSS was led to develop his test (IV.2.4.11.), which always applies in this situation.

IV.2.6.7. Suppose \( p \) and \( q \) have the same degree \( m \) and \( |\frac{c}{d}| = 1 \). Then

\[ \left| \frac{a_{k+1}}{a_k} \right| = \left| \frac{p(k)/c}{q(k)/d} \right| = \left| \frac{k^m + ak^{m-1} + r(k)}{k^m + bk^{m-1} + s(k)} \right| \]

where \( r \) and \( s \) are polynomials of degree \( \leq m - 2 \). Since the quotient in the last term is positive for large \( k \), the absolute values can be removed. We then have

\[ 1 - \left| \frac{a_{k+1}}{a_k} \right| = \frac{(k^m + bk^{m-1} + s(k)) - (k^m + ak^{m-1} + r(k))}{k^m + bk^{m-1} + s(k)} = \frac{(b - a)k^{m-1} + (r(k) - s(k))}{k^m + bk^{m-1} + s(k)} \]

and so

\[ \left| \frac{a_{k+1}}{a_k} \right| = 1 - \frac{(b - a)k^{m-1} + (s(k) - r(k))}{k^m + bk^{m-1} + s(k)} \]

466
\[ 1 - \frac{b - a}{k} + \left[ \frac{b - a}{k} - \frac{(b - a)k^{m-1} + ((s(k) - r(k))}{k^m + bk^{m-1} + s(k)} \right] \]

\[ = 1 - \frac{b - a}{k} + \frac{(b - a)(k^m + bk^{m-1} + s(k))}{k(k^m + bk^{m-1} + s(k))} - \frac{(b - a)k^m + k(s(k) - r(k))}{k(k^m + bk^{m-1} + s(k))} \]

\[ = 1 - \frac{b - a}{k} + \frac{\phi(k)}{k(k^m + bk^{m-1} + s(k))} \]

where \( \phi \) is a polynomial of degree \( \leq m - 1 \). The last term is \( O \left( \frac{1}{k^2} \right) \), so we have

\[ \frac{|a_{k+1}|}{|a_k|} = 1 - \frac{b - a}{k} + O \left( \frac{1}{k^2} \right). \]

Applying Gauss’s Test, we obtain:

**IV.2.6.8. Theorem.**

(i) If \( b - a > 1 \), the series converges absolutely.

(ii) If \( b - a \leq 1 \), the series does not converge absolutely.

This result completely settles the convergence question when the terms of the series eventually have constant sign. \textsc{Gauss} went on to completely analyze the case where the terms alternate in sign. (We are not following \textsc{Gauss}’s approach; see \textsc{Bre07} for a nice exposition of \textsc{Gauss}’s arguments, including a proof of the next result.)

**IV.2.6.9. Theorem.** If the terms of the series alternate in sign, then

(i) If \( b < a \), the terms go to infinity in absolute value so the series diverges.

(ii) If \( b = a \), the absolute values of the terms approach a nonzero finite limit and the series diverges.

(iii) If \( b > a \), the series converges.

The convergence in (iii) is conditional if \( a < b \leq a + 1 \) and absolute if \( b > a + 1 \).

We can then obtain the convergence for the basic hypergeometric series:
IV.2.6.10. Corollary. Let $\sum_{k=1}^{\infty} a_k$ be the hypergeometric series of IV.2.6.2.(iii) with parameters $\alpha, \beta, \gamma$, and $|x| = 1$. Then

(i) If $\alpha + \beta < \gamma$, the series converges absolutely.

(ii) If $\alpha + \beta - \gamma \geq 1$, the series diverges.

(iii) If $x = 1$ and $\alpha + \beta \geq \gamma$, the series diverges.

(iv) If $x = -1$ and $\gamma \leq \alpha + \beta < \gamma + 1$, the series converges conditionally.

Proof: We have

$$\frac{|a_{k+1}|}{|a_k|} = \frac{k^2 + (\alpha + \beta)k + \alpha \beta}{k^2 + (1 + \gamma)k + \gamma}$$

by a simple calculation. The terms of the series are eventually constant in sign if $x > 0$ and eventually alternate if $x < 0$.

IV.2.7. Scaling of Series

In this subsection, we examine what happens to the convergence of a series $\sum_{k=1}^{\infty} a_k$ when the terms $a_k$ are scaled by factors $c_k$. Of course, when the $c_k$ are constant, the scaling does not affect convergence, but when the $c_k$ vary, convergence can be affected very subtly.

The most obvious example where convergence can be affected is where the $c_k$ are unbounded. For bounded scaling, the simplest case where convergence changes is where $\sum_{k=1}^{\infty} a_k$ is a conditionally convergent alternating series and $c_k = (-1)^k$. But even if the $c_k$ are all nonnegative and/or converge to a limit (even 0), convergence or divergence can change by the scaling:

IV.2.7.1. Examples. (i) Let $a_k = \frac{(-1)^k}{\sqrt{k}}$ for all $k$. Set $c_k = \frac{1}{\sqrt{k}}$ for $k$ odd, and $c_k = \frac{1}{k}$ for $k$ even. Then $\sum_{k=1}^{\infty} a_k$ converges by the Alternating Series Test, but the series $\sum_{k=1}^{\infty} c_k a_k$ diverges since the series of positive terms (the even ones) converges, and the series of negative terms (the odd ones) diverges (IV.2.5.6.(ii)).

(ii) Let $a_k = c_k = \frac{(-1)^k}{\sqrt{k}}$ for all $k$. Then $\sum_{k=1}^{\infty} a_k$ and $\sum_{k=1}^{\infty} c_k$ both converge by the Alternating Series Test, but $\sum_{k=1}^{\infty} c_k a_k$ is the harmonic series, which diverges.

The simplest general result is for absolutely convergent series:
IV.2.7.2. PROPOSITION. Let \( \sum_{k=1}^{\infty} a_k \) be an absolutely convergent series, and \((c_k)\) a bounded sequence of real numbers. Then \( \sum_{k=1}^{\infty} c_k a_k \) also converges absolutely.

This result applies in particular if all the \( a_k \) and \( c_k \) are nonnegative.

PROOF: If \( |c_k| \leq m \) for all \( k \), compare \( \sum_{k=1}^{\infty} |c_k a_k| \) with \( \sum_{k=1}^{\infty} m|a_k| \).

IV.2.7.3. Conversely, if \( \sum_{k=1}^{\infty} a_k \) is an infinite series and \((d_k)\) a sequence of real numbers such that \( \inf d_k > 0 \), and \( \sum_{k=1}^{\infty} d_k a_k \) is absolutely convergent, then \( \sum_{k=1}^{\infty} a_k \) is also absolutely convergent, seen by applying IV.2.7.2. to scaling by \( c_k = \frac{1}{d_k} \).

On the other hand, if \((d_k)\) is a sequence of positive numbers with \( \inf d_k = 0 \), there is an infinite series \( \sum_{k=1}^{\infty} a_k \) with positive terms such that \( \sum_{k=1}^{\infty} a_k \) diverges but \( \sum_{k=1}^{\infty} d_k a_k \) converges absolutely. And if \((c_k)\) is an unbounded sequence of positive numbers, there is an absolutely convergent series \( \sum_{k=1}^{\infty} a_k \) with positive terms such that \( \sum_{k=1}^{\infty} c_k a_k \) diverges. See Exercise IV.2.16.14.

Abel's Partial Summation

To analyze the case where \( \sum_{k=1}^{\infty} a_k \) is not absolutely convergent, it is convenient to use a summation formula due to Abel in 1826. This formula is a discrete version of Integration by Parts, and will be used roughly to interchange the roles of the \( a_k \) and \( c_k \).

IV.2.7.4. PROPOSITION. Let \( \sum_{k=1}^{\infty} a_k \) be an infinite series, with partial sums \( s_n = \sum_{k=1}^{n} a_k \). Set \( s_0 = 0 \). If \((c_k)\) is a sequence of real numbers, then for any \( n \geq 0, m \geq 1 \),

\[
\sum_{k=n+1}^{n+m} c_k a_k = \sum_{k=n+1}^{n+m} (c_k - c_{k+1}) s_k - c_{n+1} s_n + c_{n+m+1} s_{n+m}.
\]

PROOF: For any \( k \geq 1 \) we have

\[
c_k a_k = c_k (s_k - s_{k-1}) = (c_k - c_{k+1}) s_k - c_k s_{k-1} + c_{k+1} s_k
\]
and summing from $n + 1$ to $n + m$ the last two terms telescope to $c_{n+m+1}s_{n+m} - c_{n+1}s_n$.

Essentially the same proof shows the following technical strengthening of the formula:

**IV.2.7.5. Proposition.** Let $\sum_{k=1}^{\infty} a_k$ be an infinite series, with partial sums $s_n = \sum_{k=1}^{n} a_k$. Set $s_0 = 0$. If $0 \leq r \leq n$, set $s_{n;r} = s_n - s_r = \sum_{k=r+1}^{n} a_k$. If $(c_k)$ is a sequence of real numbers, then for any $n \geq 0$, $m \geq 1$, and any $r$, $0 \leq r \leq n$,

$$\sum_{k=n+1}^{n+m} c_k a_k = \sum_{k=n+1}^{n+m} (c_k - c_{k+1}) s_{k;r} - c_{n+1}s_{n;r} + c_{n+m+1}s_{n+m;r}.$$ 

**Proof:** For any $k \geq r + 1$ we have

$$c_k a_k = c_k(s_{k;r} - s_{k-1;r}) = (c_k - c_{k+1}) s_{k;r} - c_{k}s_{k-1;r} + c_{k+1}s_{k;r}$$

and summing from $n + 1$ to $n + m$ the last two terms telescope to $c_{n+m+1}s_{n+m;r} - c_{n+1}s_{n;r}$. 

Proposition IV.2.7.4. is the case $r = 0$. The case $r = n$ is also useful (cf. V.15.3.16.). Note that if $r = n$, one term disappears from the right side since $s_{n;n} = 0$.

The first consequence of Abel’s summation formula is the following general test, which we will call the **Scaling Test**, a nonstandard name:

**IV.2.7.6. Theorem.** [Scaling Test] Let $\sum_{k=1}^{\infty} a_k$ be an infinite series with partial sums $s_n$, and $(c_k)$ a sequence of numbers. If

(i) $\sum_{k=1}^{\infty} (c_k - c_{k+1}) s_k$ converges and

(ii) $\lim_{m \to \infty} c_{m+1}s_m$ exists,

Then the series $\sum_{k=1}^{\infty} c_k a_k$ converges.

**Proof:** Abel’s partial summation formula for $n = 0$ and any $m$ gives

$$\sum_{k=1}^{m} c_k a_k = \sum_{k=1}^{m} (c_k - c_{k+1}) s_k + c_{m+1}s_m.$$ 

By hypothesis, the limit of the right side exists as $m \to \infty$. 

470
Abel’s Test
The first special case of the Scaling Test we consider is due to Abel:

**IV.2.7.7. Theorem. [Abel’s Test]** Let $\sum_{k=1}^{\infty} a_k$ be a convergent infinite series, and $(c_k)$ a bounded monotone sequence of numbers. Then $\sum_{k=1}^{\infty} c_k a_k$ converges.

**Proof:** We have that $(c_k)$ converges, and since $(s_m)$ converges by hypothesis, $(c_{m+1}s_m)$ converges. We also have that $\sum_{k=1}^{\infty} (c_k - c_{k+1})$ converges, and hence converges absolutely since the terms are all of the same sign.

Since the $s_k$ are bounded, $\sum_{k=1}^{\infty} (c_k - c_{k+1})s_k$ converges (absolutely) by IV.2.7.2.; thus the hypotheses of the Scaling Test are satisfied. $\blacksquare$

Dirichlet’s Test
Another consequence of the Scaling Test is called Dirichlet’s Test, although it has been suggested that it was probably also known to Abel previously:

**IV.2.7.8. Theorem. [Dirichlet’s Test]** Let $\sum_{k=1}^{\infty} a_k$ be an infinite series with bounded partial sums, and $(c_k)$ a nonincreasing sequence of (nonnegative) numbers converging to zero. Then $\sum_{k=1}^{\infty} c_k a_k$ converges.

The Alternating Series Test is the special case where $a_k = (-1)^k$ or $(-1)^{k+1}$.

**Proof:** As in the previous proof, the series $\sum_{k=1}^{\infty} (c_k - c_{k+1})s_k$ converges absolutely, and we have $\lim_{m \to \infty} c_{m+1}s_m = 0$ by ( ). Thus the hypotheses of the Scaling Test are satisfied. $\blacksquare$

As a nice application, we have:

**IV.2.7.9. Example.** If $x$ is any fixed real number, then the series $\sum_{k=1}^{\infty} \frac{\sin kx}{k}$ converges.
Note that for general \( x \), \( \sin kx \) jumps around through \([-1, 1]\) in an apparently chaotic manner as \( k \) increases, so the terms vary in size and sign in a seemingly unpredictable way. But the essence of the argument is that there is enough regularity to insure that the partial sums of the series

\[
\sum_{k=1}^{\infty} \sin kx
\]

are bounded. We can then take \( c_k = \frac{1}{k} \) and use Dirichlet’s Test.

To show that these partial sums are bounded, we use a clever argument due to Dirichlet involving the sum formula for \( \cos(\alpha + \beta) \). By periodicity, it suffices to prove the result for \( 0 < x < 2\pi \) (the case \( x = 0 \) is trivial). Fix \( x \in (0, 2\pi) \) and set

\[
s_n = \sum_{k=1}^{n} \sin kx.
\]

For any \( k \), we have

\[
\cos \left( \left[k - \frac{1}{2}\right] x \right) - \cos \left( \left[k + \frac{1}{2}\right] x \right)
= \left[ \cos kx \cos \frac{x}{2} + \sin kx \sin \frac{x}{2} \right] - \left[ \cos kx \cos \frac{x}{2} - \sin kx \sin \frac{x}{2} \right]
= 2 \sin kx \sin \frac{x}{2}
\]

so we have, by telescoping,

\[
2s_n \sin \frac{x}{2} = \sum_{k=1}^{n} 2 \sin kx \sin \frac{x}{2}
\]

\[
= \sum_{k=1}^{n} \left[ \cos \left( \left[k - \frac{1}{2}\right] x \right) - \cos \left( \left[k + \frac{1}{2}\right] x \right) \right]
= \cos \frac{x}{2} - \cos \left( \left[n + \frac{1}{2}\right] x \right).
\]

Thus we have, for all \( n \),

\[
|s_n| \leq \frac{\left| \cos \frac{x}{2} - \cos \left( \left[n + \frac{1}{2}\right] x \right) \right|}{2 \left| \sin \frac{x}{2} \right|} \leq \frac{1}{\left| \sin \frac{x}{2} \right|}.
\]

In fact, we get that

\[
\sum_{k=1}^{\infty} \frac{\sin kx}{k^p}
\]

converges for any \( x \in \mathbb{R} \) and \( p > 0 \), and that

\[
\sum_{k=2}^{\infty} \frac{\sin kx}{\log k}
\]

converges for any \( x \in \mathbb{R} \).
IV.2.8. Subseries and Rearrangements of Series

There are two natural procedures for manufacturing a new infinite series out of an old one:

IV.2.8.1. Definition. Let $\sum_{k=1}^{\infty} a_k$ be an infinite series.

(i) An infinite series $\sum_{k=1}^{\infty} b_k$ is a subseries of $\sum_{k=1}^{\infty} a_k$ if there is a strictly increasing function $\phi : \mathbb{N} \to \mathbb{N}$ such that $b_k = a_{\phi(k)}$ for all $k$.

(ii) An infinite series $\sum_{k=1}^{\infty} b_k$ is a rearrangement of $\sum_{k=1}^{\infty} a_k$ if there is a bijection $\phi : \mathbb{N} \to \mathbb{N}$ such that $b_k = a_{\phi(k)}$ for all $k$.

(iii) An infinite series $\sum_{k=1}^{\infty} b_k$ is a subarrangement of $\sum_{k=1}^{\infty} a_k$ if there is a one-to-one function $\phi : \mathbb{N} \to \mathbb{N}$ such that $b_k = a_{\phi(k)}$ for all $k$.

A subseries or a rearrangement is a special case of a subarrangement of a series. We have seen natural examples of subseries in IV.2.5.5. A natural example of a rearrangement of a series is to write the terms of a strictly positive convergent series $\sum_{k=1}^{\infty} a_k$ in nonincreasing order (check that this is a rearrangement: in particular, for any $k$ there can be only finitely many $j$ for which $a_j \geq a_k$).

Note that in a subarrangement, each term of the original series occurs at most once (if there are repeated terms in the original series, the term can be repeated in the subarrangement up to as many times as in the original series). In a rearrangement, each term in the original series occurs exactly once in the rearrangement.

The $\phi$ in a subarrangement is uniquely determined. (If there are repeated terms in the original series, more than one subarrangement can give the same new series.) If $\sum_{k=1}^{\infty} b_k$ is a rearrangement of $\sum_{k=1}^{\infty} a_k$ via $\phi$, then $\sum_{k=1}^{\infty} a_k$ is a rearrangement of $\sum_{k=1}^{\infty} b_k$ via $\phi^{-1}$.

Some authors rather colorfully call a rearrangement of a series a derangement of the series.

We have seen in IV.2.5.5. that a subseries of a convergent series need not converge. We will see () that a rearrangement of a convergent series need not converge, and even if it does it need not have the same sum. These difficulties do not occur for convergent nonnegative series (or for absolutely convergent series – see ()).
IV.2.8.2. **Proposition.** Let \( \sum_{k=1}^{\infty} a_k \) be a convergent nonnegative infinite series. Then any subarrangement \( \sum_{k=1}^{\infty} b_k \) of \( \sum_{k=1}^{\infty} a_k \) also converges, and satisfies

\[ \sum_{k=1}^{\infty} b_k \leq \sum_{k=1}^{\infty} a_k . \]

**Proof:** Let \( M = \sum_{k=1}^{\infty} a_k \). Any partial sum \( t_n \) of the nonnegative series \( \sum_{k=1}^{\infty} b_k \) consists of some, but not necessarily all, of the terms in a corresponding larger partial sum \( s_m \) of \( \sum_{k=1}^{\infty} a_k \) (where \( m = \max\{\phi(1), \ldots, \phi(n)\} \)), and hence \( t_n \leq s_m \leq M \). Thus the partial sums of \( \sum_{k=1}^{\infty} b_k \) are bounded by \( M \), so \( \sum_{k=1}^{\infty} b_k \leq M \). \( \Diamond \)

IV.2.8.3. **Corollary.** Let \( \sum_{k=1}^{\infty} a_k \) be an absolutely convergent infinite series. Then any subarrangement \( \sum_{k=1}^{\infty} b_k \) of \( \sum_{k=1}^{\infty} a_k \) also converges absolutely.

**Proof:** \( \sum_{k=1}^{\infty} |b_k| \) is a subarrangement of \( \sum_{k=1}^{\infty} |a_k| \). \( \Diamond \)

IV.2.8.4. **Corollary.** Let \( \sum_{k=1}^{\infty} a_k \) be a convergent nonnegative infinite series. Then any rearrangement \( \sum_{k=1}^{\infty} b_k \) of \( \sum_{k=1}^{\infty} a_k \) also converges, and satisfies

\[ \sum_{k=1}^{\infty} b_k = \sum_{k=1}^{\infty} a_k . \]

This result generalizes to absolutely convergent series:
IV.2.8.5. **Theorem.** Let $\sum_{k=1}^{\infty} a_k$ be an absolutely convergent infinite series. Then any rearrangement $\sum_{k=1}^{\infty} b_k$ of $\sum_{k=1}^{\infty} a_k$ also converges absolutely, and satisfies

$$\sum_{k=1}^{\infty} b_k = \sum_{k=1}^{\infty} a_k.$$ 

**Proof:** $\sum_{k=1}^{\infty} b_k$ converges absolutely by IV.2.8.3.

Let $s = \sum_{k=1}^{\infty} a_k$, and write $s_n = \sum_{k=1}^{n} a_k$ and $t_n = \sum_{k=1}^{n} b_k$ for the partial sums of the series. We will show that $t_n \to s$, i.e. for every $\epsilon > 0$ there is an $N$ such that $|t_n - s| < \epsilon$ for all $n > N$.

Let $\epsilon > 0$, and fix $m$ such that

$$|s_m - s| < \frac{\epsilon}{2} \quad \text{and} \quad \sum_{k=m+1}^{\infty} |a_k| < \frac{\epsilon}{2}$$

(the second condition is possible since $\sum_{k=1}^{\infty} a_k$ converges absolutely; in fact, the first condition follows automatically from the second). Now let

$$N = \max\{\phi(k) : 1 \leq k \leq m\}$$

where $\phi : \mathbb{N} \to \mathbb{N}$ is the bijection of the rearrangement. Now suppose $n > N$. We have that

$$t_n - s_m = \sum_{k=1}^{n} b_k - \sum_{k=1}^{m} a_k$$

is a sum consisting of various $a_k$’s and their negatives. Some $a_k$’s occur in both sums and therefore cancel; this happens for all $a_k$ with $k \leq m$ by the choice of $N$. Thus we have

$$t_n - s_m = \sum_{j=1}^{r} (\pm a_{k_j})$$

for some $r$ and some $k_j$’s, with $k_j > m$ for all $j$. So

$$|t_n - s_m| \leq \sum_{j=1}^{r} |a_{k_j}| \leq \sum_{k=m+1}^{\infty} |a_k| < \frac{\epsilon}{2}$$

and we get

$$|t_n - s| \leq |t_n - s_m| + |s_m - s| < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon$$

475
for all \( n > N \).

This is in stark contrast to what happens in a conditionally convergent series. If \( \sum_{k=1}^{\infty} a_k \) is conditionally convergent, then the series \( \sum_{k=1}^{\infty} b_k \) and \( \sum_{k=1}^{\infty} c_k \) of positive and negative terms, respectively, both diverge. Thus, if the series is rearranged to begin with many (or few) positive terms, then many (or few) negative ones, etc., the partial sums of the rearranged series can be made to oscillate wildly or to converge to any limit at all. Precisely:

**IV.2.8.6. Theorem.** Let \( \sum_{k=1}^{\infty} a_k \) be a conditionally convergent series, and let \( (u_n) \) and \( (v_n) \) be sequences of real numbers with \( v_n \leq u_n \) and \( v_n \leq u_{n+1} \) for all \( n \). Then there is a rearrangement \( \sum_{k=1}^{\infty} d_k \) of \( \sum_{k=1}^{\infty} a_k \) and natural numbers \( n_1 < m_1 < n_2 < m_2 < \cdots \) such that

(i) The partial sums \( t_n \) of \( \sum_{k=1}^{\infty} d_k \) increase for \( 1 \leq n \leq n_1 \) and for \( m_j \leq n \leq n_{j+1} \) for all \( j \), and decrease for \( n_j < n \leq m_j \) for all \( j \).

(ii) \( t_{n_j} \geq u_j \) and \( t_{m_j} \leq v_j \) for all \( j \).

(iii) \( \limsup_{n \to \infty} t_n = \limsup_{j \to \infty} u_j \) and \( \liminf_{n \to \infty} t_n = \liminf_{j \to \infty} v_j \).

**Proof:** Set \( d_1 = b_1 \), and \( d_k = b_k \) until the first index \( n_1 \) is reached with \( t_{n_1} = \sum_{k=1}^{n_1} b_k \geq u_1 \) (there is such an \( n_1 \) since \( \sum_{k=1}^{\infty} b_k \) diverges). Then \( u_1 \leq t_{n_1} \leq u_1 + b_{n_1} \). Set \( d_{n_1+1} = c_1 \), and \( d_{n_1+k} = c_k \) until the first index \( m_1 > n_1 \) is reached with \( t_{m_1} \leq v_1 \) (there is such an \( m_1 \) since \( \sum_{k=1}^{\infty} c_k \) diverges). Then \( v_1 + c_{m_1} \leq t_{m_1} \leq v_1 \). Set \( d_{m_1+1} = a_{n_1+1} \) and \( d_{m_1+k} = b_{n_1+k} \) until the first index \( n_2 > m_1 \) is reached with \( t_{n_2} \geq v_2 \). Continue the process inductively to define \( d_k, n_j, \) and \( m_j \) for all \( j \); the construction is possible at each step since all tails of \( \sum_{k=1}^{\infty} b_k \) and \( \sum_{k=1}^{\infty} c_k \) diverge. We have \( u_j \leq t_{n_j} \leq u_j + b_{r_j} \), where \( r_j = n_1 + \sum_{i=1}^{j-1} (n_{i+1} - n_i) \) is the number of \( b_k \) used in the first \( n_j \) steps, and similarly \( v_j + c_{s_j} \leq t_{m_j} \leq v_j \), where \( s_j = \sum_{i=1}^{j-1} (m_i - n_i) \) is the number of \( c_k \) used. Then \( r_j, s_j \) are strictly increasing, so \( b_{r_j} \to 0 \) and \( c_{s_j} \to 0 \) since \( a_k \to 0 \).

By construction, (i) and (ii) are satisfied for the rearrangement \( \sum_{k=1}^{\infty} d_k \) of \( \sum_{k=1}^{\infty} a_k \). We need only check (iii).

It is clear that

\[
\limsup_{n \to \infty} t_n = \limsup_{j \to \infty} t_{n_j}
\]

476
and we have

\[ u := \limsup_{j \to \infty} u_j \leq \limsup_{j \to \infty} t_{n_j} \leq \limsup_{j \to \infty} (u_j + b_{r_j}) = u \]

by (i) since \( b_{r_j} \to 0 \). Thus \( \limsup_{n \to \infty} t_n = u \). The argument for \( \liminf \) is similar. 

**IV.2.8.7.** **COROLLARY.** Let \( \sum_{k=1}^{\infty} a_k \) be a conditionally convergent series.

(i) For any \( t \in \mathbb{R} \) there is a rearrangement \( \sum_{k=1}^{\infty} d_k \) of \( \sum_{k=1}^{\infty} a_k \) which converges with sum \( t \).

(ii) For any \( u \) and \( v \), \( -\infty \leq v \leq u \leq +\infty \), there is a rearrangement \( \sum_{k=1}^{\infty} d_k \) of \( \sum_{k=1}^{\infty} a_k \) whose partial sums \( t_n \) satisfy

\[ \limsup_{n \to \infty} t_n = u \quad \text{and} \quad \liminf_{n \to \infty} t_n = v . \]

**PROOF:** Part (i) is the special case of (ii) with \( u = v = t \). For (ii), if \( u \) and/or \( v \) is in \( \mathbb{R} \) take \( u_j = u \) and/or \( v_j = v \) for all \( j \); if \( u \) and/or \( v \) is \( \pm \infty \), take \( u_j \) and/or \( v_j \) to be \( \pm j \). This result was obtained by RIEMANN in ( ). The argument applies more generally to any series \( \sum_{k=1}^{\infty} a_k \) in which \( a_k \to 0 \) for which both the series of positive terms and of negative terms diverge.

**Revisions of Infinite Series**

**IV.2.8.8.** **DEFINITION.** Let \( \sum_{k=1}^{\infty} a_k \) be an infinite series. A revision of the series is a contraction (IV.2.1.20.) of a rearrangement (IV.2.8.1.) of the series.

**IV.2.8.9.** A revision of the series is thus a new series

\[ (a_{k_1,1} + a_{k_1,2} + \cdots + a_{k_1,n_1}) + (a_{k_2,1} + a_{k_2,2} + \cdots + a_{k_2,n_2}) + \cdots \]

where each \( k \) occurs as exactly one \( k_{i,j} \), i.e. each group consists of a finite number of terms of the series, with each term occurring exactly once (in exactly one group). Then by IV.2.1.21. and IV.2.8.5. we obtain:

**IV.2.8.10.** **PROPOSITION.** Let \( \sum_{k=1}^{\infty} a_k \) be an absolutely convergent infinite series. Then any revision of the series converges, with the same limit.
IV.2.8.11. In this result, each group is allowed to include only finitely many terms of the series. In IV.2.10.16. we will show the result holds also for more drastic revisions where the groups are allowed to be infinite.

IV.2.9. Unordered Summations

IV.2.9.1. Let \( J \) be a set, possibly infinite, possibly even uncountable, and let \( \{a_j : j \in J\} \) be an indexed collection of real (or complex) numbers. We want to make sense out of the expression \( \sum_{j \in J} a_j \). If \( J \) is finite, there is an unambiguous meaning, but if \( J \) is infinite, there is no direct meaning. We have made sense of such a sum if \( J = \mathbb{N} \), but the theory of infinite series depends critically on having a fixed ordering on \( \mathbb{N} \). A general set \( J \) has no natural ordering, and even if a particular \( J \) has an ordering (e.g. if \( J = \mathbb{N} \)) we do not want our definition to depend on the ordering. It is to be expected from the case \( J = \mathbb{N} \) that we can only make sense of the sum under certain conditions, not in general.

Infinite series give a clue as to how to proceed: we will take a limit of sums over finite subsets of \( J \).

IV.2.9.2. Definition. Let \( J \) be a set, and let \( \{a_j : j \in J\} \) be an indexed collection of real numbers. We say the unordered sum \( \sum_{j \in J} a_j \) converges with sum \( s \) if for every \( \epsilon > 0 \) there is a finite subset \( F \) of \( J \) such that, for every finite subset \( E \) of \( J \) containing \( F \),

\[
| s - \sum_{j \in E} a_j | < \epsilon .
\]

When we write \( \sum_{j \in J} a_j = s \), we mean that the unordered sum converges to \( s \).

IV.2.9.3. Note that if \( J = \mathbb{N} \), this definition is not the same as the usual definition of convergence of the sum as an infinite series, since for an infinite series to converge only the partial sums, which are sums of initial segments, must converge, not, for example, finite sums made up mostly of even-numbered terms. If \( (a_k) \) is a sequence of real numbers, and the unordered sum \( \sum_{j \in J} a_j \) converges with sum \( s \), then the infinite series

\[
\sum_{k \in \mathbb{N}} a_k
\]

also converges, with sum \( s \). But we will see that the converse is false in general; in fact, it follows easily from IV.2.8.5. and IV.2.8.7. that the unordered sum converges if and only if the infinite series converges absolutely (cf. IV.2.9.9.).

IV.2.9.4. Proposition. Let \( (a_k) \) be a sequence of real numbers.

(i) If the unordered sum \( \sum_{k \in \mathbb{N}} a_k \) converges, then the infinite series \( \sum_{k=1}^{\infty} a_k \) converges, and the sums are the same.
(ii) If all the \( a_k \) are nonnegative, then the unordered sum \( \sum_{k=1}^{\infty} a_k \) converges if and only if the infinite series \( \sum_{k=1}^{\infty} a_n \) converges.

**Proof:** (i) Let \( s_n \) be the \( n \)'th partial sum of the infinite series. If the unordered sum converges to \( s \), and \( \epsilon > 0 \), choose \( F \) so that
\[
|s - \sum_{k \in E} a_k| < \epsilon
\]
for all finite \( E \) containing \( F \). If \( n \) is large enough that \( F \subseteq \{1, \ldots, n\} \), then \( |s - s_n| < \epsilon \). Thus the infinite series converges with sum \( s \).

(ii) Suppose all \( a_k \) are nonnegative, and that the infinite series converges to \( s \). If \( \epsilon > 0 \), choose \( n \) so that \( |s - s_n| < \epsilon \). If \( E \) is any finite subset of \( \mathbb{N} \) containing \( F = \{1, \ldots, n\} \), and \( m \) is the largest number in \( E \), then
\[
s_n \leq \sum_{k \in E} a_k \leq s_m \leq s
\]
and so
\[
|s - \sum_{k \in E} a_k| < \epsilon
\]
and \( \sum_{k \in \mathbb{N}} a_k \) converges with sum \( s \).

The first observation is an analog of the Divergence Criterion:

**IV.2.9.5. Proposition.** Let \( J \) be a set, and let \( \{a_j : j \in J\} \) be an indexed collection of real numbers. If \( \sum_{j \in J} a_j \) converges, then for any \( \epsilon > 0 \) there are only finitely many \( j \) for which \( |a_j| > \epsilon \).

**Proof:** Let \( s \) be the sum of the series, and \( \epsilon > 0 \). Then there is a finite subset \( F \) of \( J \) such that
\[
|s - \sum_{j \in E} a_j| < \frac{\epsilon}{2}
\]
for all finite subsets \( E \) of \( J \) containing \( F \). Let \( j_0 \in J \setminus F \), and \( E = F \cup \{j_0\} \). Then
\[
|a_{j_0}| = \left| \sum_{j \in E} a_j - \sum_{j \in F} a_j \right| \leq \left| \sum_{j \in E} a_j - s \right| + \left| s - \sum_{j \in F} a_j \right| < \epsilon.
\]
This is true for all \( j_0 \notin F \).

This has an interesting consequence. The index set \( J \) could very well be uncountable, but we can effectively reduce to the case where \( J \) is countable by the following result:
**IV.2.9.6.** Proposition. Let \( J \) be a set, and let \( \{a_j : j \in J\} \) be an indexed collection of real numbers. If \( \sum_{j \in J} a_j \) converges, then the set \( K = \{j \in J : a_j \neq 0\} \) is countable and \( \sum_{j \in K} a_j \) converges to \( \sum_{j \in J} a_j \).

Proof: By IV.2.9.5., the set \( K_n = \{j \in J : |a_j| > \frac{1}{n}\} \) is finite for each \( n \), and \( K = \cup_n K_n \). If \( F \) is any finite subset of \( J \), then \( \sum_{j \in F} a_j = \sum_{j \in F \cap K} a_j \).

As with infinite series, we can extend IV.2.9.5. to obtain a Cauchy criterion:

**IV.2.9.7.** Proposition. Let \( J \) be a set, and let \( \{a_j : j \in J\} \) be an indexed collection of real numbers. Then \( \sum_{j \in J} a_j \) converges if and only if, for any \( \epsilon > 0 \), there is a finite subset \( F \) of \( J \) such that

\[
\left| \sum_{j \in D} a_j \right| < \epsilon
\]

for every finite subset \( D \) of \( J \) disjoint from \( F \).

Proof: Suppose the unordered sum converges to \( s \), and let \( \epsilon > 0 \). Then there is a finite subset \( F \) of \( J \) such that

\[
\left| s - \sum_{j \in E} a_j \right| < \frac{\epsilon}{2}
\]

for all finite subsets \( E \) of \( J \) containing \( F \). Let \( D \) be a finite subset of \( J \) disjoint from \( F \). Then

\[
\left| \sum_{j \in D} a_j \right| = \left| \sum_{j \in D \cup F} a_j - \sum_{j \in F} a_j \right| \leq \left| \sum_{j \in D \cup F} a_j - s \right| + \left| s - \sum_{j \in F} a_j \right| < \epsilon.
\]

Conversely, suppose the other condition holds. Choose an increasing sequence \( (F_n) \) of finite subsets of \( J \) such that

\[
\left| \sum_{j \in D} a_j \right| < \frac{1}{n}
\]

for all finite \( D \) disjoint from \( F_n \). Then, for any finite \( E \) containing \( F_n \), we have

\[
\left| \sum_{j \in E} a_j - \sum_{j \in F_n} a_j \right| = \left| \sum_{j \in E \setminus F_n} a_j \right| \leq \frac{1}{n}.
\]

Set

\[
\alpha_n = \inf \left\{ \sum_{j \in E} a_j : F_n \subseteq E \text{ finite} \right\} \geq \sum_{j \in F_n} a_j - \frac{1}{n}.
\]
\[
\beta_n = \sup \left\{ \sum_{j \in E} a_j : F_n \subseteq \mathbb{R} \text{ finite} \right\} \leq \sum_{j \in F_n} a_j + \frac{1}{n}
\]
and set \( I_n = [\alpha_n, \beta_n] \). We have \( I_{n+1} \subseteq I_n \) since \( F_n \subseteq F_{n+1} \). Then \( \cap_n I_n = \{ s \} \) for some \( s \in \mathbb{R} \), and if \( E \) is any finite set containing \( F_n \) we have

\[
| s - \sum_{j \in E} a_j | \leq \frac{2}{n}
\]

(both numbers are in \( I_n \)), which can be made arbitrarily small. Thus \( \sum_{j \in J} a_j \) converges to \( s \). ☑

**IV.2.9.8.** We can extend the notion of unordered sum to arbitrary nonnegative sums. Let \( J \) be a set, and let \( \{ a_j : j \in J \} \) be an indexed collection of real numbers. If all the \( a_j \) are nonnegative, we can always make sense of the unordered sum as

\[
\sum_{j \in J} a_j = \sup \sum_{j \in F} a_j
\]

where the supremum is over all finite subsets \( F \) of \( J \). If the supremum is \( s < +\infty \), this definition agrees with the previous one: given \( \epsilon > 0 \), choose a finite \( F \) with

\[
| s - \sum_{j \in F} a_j | < \epsilon
\]

and this \( F \) works in the definition of convergence. If the supremum is \( +\infty \), we will not say the unordered sum converges, but we will write \( \sum_{j \in J} a_j = +\infty \).

We can now state the main result of this subsection:

**IV.2.9.9.** *Theorem.* Let \( J \) be a set, and let \( \{ a_j : j \in J \} \) be an indexed collection of real numbers. Then \( \sum_{j \in J} a_j \) converges if and only if \( \sum_{j \in J} |a_j| \) converges (i.e. \( \sum_{j \in J} |a_j| < +\infty \)).

**Proof:** If \( \sum_{j \in J} |a_j| \) converges, then for any \( \epsilon > 0 \) there is a finite set \( F \) such that

\[
\sum_{j \in D} |a_j| < \epsilon
\]

for every finite subset \( D \) of \( J \) disjoint from \( F \) by IV.2.9.7.. But then

\[
\left| \sum_{j \in D} a_j \right| \leq \sum_{j \in D} |a_j| < \epsilon
\]

for every finite subset \( D \) of \( J \) disjoint from \( F \), so \( \sum_{j \in J} a_j \) converges by IV.2.9.7..
Conversely, suppose $\sum_{j \in J} a_j$ converges. Let $F$ be a finite subset of $J$ such that

$$\left| \sum_{j \in D} a_j \right| < 1$$

for every finite subset $D$ of $J$ disjoint from $F$. Suppose $\sum_{j \in J} |a_j| = +\infty$; then there are finite subsets $D$ of $J$ disjoint from $F$ with $\sum_{j \in D} |a_j|$ arbitrarily large. In particular, there is such a $D$ with $\sum_{j \in D} |a_j| > 2$. For this $D$, let $D_+ = \{ j \in D : a_j > 0 \}$, $D_- = \{ j \in D : a_j < 0 \}$. Then either $\left| \sum_{j \in D_+} a_j \right| = \sum_{j \in D_+} |a_j| > 1$ or $\left| \sum_{j \in D_-} a_j \right| = \sum_{j \in D_-} |a_j| > 1$, a contradiction. Thus $\sum_{j \in J} |a_j| < +\infty$.

Thus there is no difference between convergence and “absolute convergence” for unordered sums.

**IV.2.9.10. Corollary.** Let $J$ be a countable index set, and $\{a_j : j \in J\}$ an indexed set of numbers. Then the following are equivalent:

(i) The unordered sum $\sum_{j \in J} a_j$ converges.

(ii) The infinite series $\sum_{k=1}^{\infty} a_{\phi(k)}$ converges absolutely for some bijection $\phi : \mathbb{N} \to J$.

(iii) The infinite series $\sum_{k=1}^{\infty} a_{\phi(k)}$ converges absolutely for every bijection $\phi : \mathbb{N} \to J$.

If the series converge, the sums are all equal.

Thus a convergent unordered sum can be converted to an ordinary infinite series by ordering the terms in an arbitrary way; the resulting infinite series will converge absolutely and have the same sum independently of how the terms are ordered.

**IV.2.9.11. Corollary.** Let $(a_k)$ be a sequence of real numbers. Then the unordered series $\sum_{k \in \mathbb{N}} a_k$ converges if and only if the infinite series $\sum_{k=1}^{\infty} a_k$ converges absolutely. If the series converge, the sums are equal.
IV.2.10. Double Summations

Suppose we have a double array

\[
\begin{array}{ccc}
  a_{11} & a_{12} & a_{13} \\
  a_{21} & a_{22} & a_{23} \\
  a_{31} & a_{32} & a_{33} \\
  \vdots & \vdots & \vdots \\
\end{array}
\]

of numbers, and we want to “add them all up.” There are many potentially reasonable ways to proceed, and we might hope (or even expect from commutativity of addition) that all these ways give the same answer. Experience with rearranging conditionally convergent series might make us suspicious that this works, and these suspicions are well founded: the various methods do not always give the same answer. But if the sums are all “absolutely convergent” in an appropriate sense, the methods all give the same sum.

IV.2.10.1. A first, somewhat naive, approach is to simply write all the elements down in some order to make an ordinary infinite series, and take the sum of this series (if it exists). More precisely, take the infinite series

\[
\sum_{k=1}^{\infty} a_{\phi(k)}
\]

where \( \phi \) is a bijection from \( \mathbb{N} \) to \( \mathbb{N} \times \mathbb{N} \). Of course, there are many ways to do this, and the series obtained are rearrangements of one another (and any rearrangement of one of the series is another such series). If one such series converges absolutely, so does any other and all have the same sum (IV.2.8.5.), so the procedure seems to be satisfactory; but if the series do not converge absolutely, the answers will differ drastically (IV.2.8.7.), and not all will even converge.

IV.2.10.2. As a variation, we could consider the unordered sum (IV.2.9.2.)

\[
\sum_{(j,k) \in \mathbb{N} \times \mathbb{N}} a_{jk} .
\]

This unordered sum will converge if and only if the sums in IV.2.10.1. converge absolutely (IV.2.9.11.), with the same sum. This unordered sum can be regarded as the double sum of the array.

IV.2.10.3. A somewhat different approach is to consider sums of the form

\[
\sum_{j,k=1}^{n} a_{jk} = \sum_{j=1}^{n} \left[ \sum_{k=1}^{n} a_{jk} \right]
\]

and let \( n \to \infty \). These are finite sums, so each sum can be computed in any order; in particular, we have

\[
\sum_{k=1}^{n} \sum_{j=1}^{n} a_{jk} = \sum_{j=1}^{n} \sum_{k=1}^{n} a_{jk} := \sum_{j=1}^{n} \left[ \sum_{k=1}^{n} a_{jk} \right]
\]

(such double sums are usually written without the brackets). These sums are often called square sums since the terms in a square in the upper left-hand corner of the array are added. As a variation, we could take
rectangular sums

\[
\sum_{j=1}^{m} \sum_{k=1}^{n} a_{jk}
\]

and take a limit as \( m, n \to \infty \).

The rectangular sum procedure is less likely to work (i.e. to have a limit), but if it does the square sum procedure will work and give the same sum. If the unordered sum procedure converges (i.e. the procedure of IV.2.10.1. gives absolutely convergent series), these rectangular and square sum procedures will also work and give the same sum, since they are limits of partial sums of contractions of certain of the series from IV.2.10.1..

**IV.2.10.4.** Another variation is to consider

\[
\sum_{n=2}^{\infty} \sum_{j+k=n} a_{jk}
\]

This is called a triangular sum, since the terms on each northeast-southwest diagonal are first added (a finite sum) and then the diagonal sums are added. This procedure is particularly natural when products of power series are considered (IV.2.11.4.). If the unordered sum converges, this procedure will also converge and give the same sum, for the same reason as for square and rectangular sums.

**IV.2.10.5.** As a quite different procedure, we can sum along each row, and then add the row sums, or sum along each column and then add the column sums. Specifically, for each fixed \( j \) we can set

\[
r_j = \sum_{k=1}^{\infty} a_{jk}
\]

if the series converges; \( r_j \) is the sum of the terms in the \( j \)'th row. We then take

\[
\sum_{j=1}^{\infty} r_j
\]

which is usually written

\[
\sum_{j=1}^{\infty} \sum_{k=1}^{\infty} a_{jk}
\]

(when an expression like this is written, it is implicitly assumed that the inside sum converges for each \( j \)).

We can similarly first add each column: for each fixed \( k \) set

\[
c_k = \sum_{j=1}^{\infty} a_{jk}
\]

if the series converges; \( c_k \) is the sum of the terms in the \( k \)'th column. We then take

\[
\sum_{k=1}^{\infty} c_k = \sum_{k=1}^{\infty} \sum_{j=1}^{\infty} a_{jk}
\]
It is not immediately clear whether these two iterated summation procedures are well defined (i.e. all the
infinite series will converge), or give the same answer if they are; and the relation between the convergence
of these procedures and the previous ones is also not obvious. The main results of this section will establish
the relationship in good cases.

Note that it is not quite correct to call such iterated summations infinite series; they are a different (but
closely related) type of infinite sum which involves many infinite series.

IV.2.10.6. Example. Here is the standard example illustrating some of what can go wrong. Set

\[
 a_{jk} = \begin{cases} 
 1 & \text{if } j = k \\
 -1 & \text{if } j = k + 1 \\
 0 & \text{otherwise}
\end{cases}
\]

i.e. the terms on the main diagonal are all 1, the terms on the first subdiagonal are −1, and all other terms
are 0. The row and column sums each have only finitely many nonzero terms (no more than 2), hence
converge absolutely. But we have \( r_1 = 1, r_j = 0 \) for \( j > 1 \), and \( c_k = 0 \) for all \( k \), so

\[
 1 = \sum_{j=1}^{\infty} \sum_{k=1}^{\infty} a_{jk} \neq \sum_{k=1}^{\infty} \sum_{j=1}^{\infty} a_{jk} = 0.
\]

The square sum procedure gives a sum of 1; but the rectangular and triangular procedures do not converge
since the rectangular or triangular sums can be either 0 or 1. The unordered sum diverges in this case; the
procedure of IV.2.10.1. always gives a divergent series since the terms do not approach 0.

To examine the convergence of such iterated summations, we first consider the case where all the terms
are nonnegative. In this case we can make sense of any iterated sum by taking the convention that an infinite
series with nonnegative terms and at least one term +1 has sum +∞. The next result is a special case of
Tonelli’s Theorem for integrals on product spaces (\()\).

IV.2.10.7. Theorem. [Tonelli’s Theorem for Double Summations] Let \( \{a_{jk} : j, k \in \mathbb{N}\} \) be an
array with all \( a_{jk} \geq 0 \). If one of the three sums

\[
 \sum_{j=1}^{\infty} \sum_{k=1}^{\infty} a_{jk}, \sum_{k=1}^{\infty} \sum_{j=1}^{\infty} a_{jk}, \sum_{(j,k) \in \mathbb{N} \times \mathbb{N}} a_{jk}
\]

converges (i.e. is finite), then all three converge and have the same sum.

Proof: First note that for any \( m, n \in \mathbb{N} \),

\[
 \sum_{j=1}^{m} \sum_{k=1}^{n} a_{jk} \leq \sup_{(j,k) \in \mathbb{N} \times \mathbb{N}} \sum_{F \subseteq \mathbb{N} \times \mathbb{N}} a_{jk}
\]

since \( \{1, \ldots, m\} \times \{1, \ldots, n\} \) is a finite subset of \( \mathbb{N} \times \mathbb{N} \). Conversely, for any finite \( F \subseteq \mathbb{N} \times \mathbb{N} \), we have

\[
 \sum_{(j,k) \in F} a_{jk} \leq \sum_{j=1}^{m} \sum_{k=1}^{n} a_{jk}
\]
for sufficiently large \( m, n \) (large enough that \( F \subseteq \{1, \ldots, m\} \times \{1, \ldots, n\} \)); thus

\[
\sum_{(j,k) \in \mathbb{N} \times \mathbb{N}} a_{jk} = \sup_{m,n \in \mathbb{N}} \sum_{j=1}^{m} \sum_{k=1}^{n} a_{jk}.
\]

Also, for any \( m, n \),

\[
\begin{align*}
\sum_{j=1}^{m} \sum_{k=1}^{n} a_{jk} &\leq \sum_{j=1}^{m} \sum_{k=1}^{\infty} a_{jk} \leq \sum_{j=1}^{\infty} \sum_{k=1}^{\infty} a_{jk},
\end{align*}
\]

so we get

\[
\sum_{(j,k) \in \mathbb{N} \times \mathbb{N}} a_{jk} = \sup_{m,n \in \mathbb{N}} \sum_{j=1}^{m} \sum_{k=1}^{n} a_{jk} \leq \sum_{j=1}^{\infty} \sum_{k=1}^{\infty} a_{jk}.
\]

For the reverse inequality, suppose

\[
\sum_{j=1}^{\infty} \sum_{k=1}^{\infty} a_{jk} = \sup_{m,n \in \mathbb{N}} \sum_{j=1}^{m} \sum_{k=1}^{n} a_{jk} = s \leq +\infty
\]

and fix \( r < s \). Then there is an \( m \) such that

\[
r < \sum_{j=1}^{m} \sum_{k=1}^{\infty} a_{jk}.
\]

But by repeated applications of IV.2.1.16., we have

\[
\sum_{j=1}^{m} \sum_{k=1}^{\infty} a_{jk} = \sum_{k=1}^{\infty} \sum_{j=1}^{m} a_{jk}
\]

so

\[
\sum_{k=1}^{\infty} \sum_{j=1}^{m} a_{jk} = \sup_{n \in \mathbb{N}} \sum_{k=1}^{n} \sum_{j=1}^{m} a_{jk} > r
\]

and thus there is an \( n \) such that

\[
\sum_{k=1}^{n} \sum_{j=1}^{m} a_{jk} > r
\]

and we conclude that

\[
\sum_{(j,k) \in \mathbb{N} \times \mathbb{N}} a_{jk} = \sup_{m,n \in \mathbb{N}} \sum_{j=1}^{m} \sum_{k=1}^{n} a_{jk} \geq s.
\]

Thus

\[
\sum_{j=1}^{\infty} \sum_{k=1}^{\infty} a_{jk} = \sum_{(j,k) \in \mathbb{N} \times \mathbb{N}} a_{jk}.
\]

A nearly identical argument shows that

\[
\sum_{k=1}^{\infty} \sum_{j=1}^{\infty} a_{jk} = \sum_{(j,k) \in \mathbb{N} \times \mathbb{N}} a_{jk}.
\]
We now turn to the general absolutely convergent case. This result is a special case of Fubini’s Theorem for integrals on product spaces (\(\cdot\)).

**IV.2.10.8. Theorem. [Fubini’s Theorem for Double Summations]** Let \(\{a_{jk} : j, k \in \mathbb{N}\}\) be an array of numbers. If one (hence each by IV.2.10.7.) of the three sums

\[
\sum_{j=1}^{\infty} \sum_{k=1}^{\infty} |a_{jk}|, \quad \sum_{k=1}^{\infty} \sum_{j=1}^{\infty} |a_{jk}|, \quad \sum_{(j,k)\in \mathbb{N}\times \mathbb{N}} |a_{jk}|
\]

converges (i.e. is finite), then each of the three summations

\[
\sum_{j=1}^{\infty} \sum_{k=1}^{\infty} a_{jk}, \quad \sum_{k=1}^{\infty} \sum_{j=1}^{\infty} a_{jk}, \quad \sum_{(j,k)\in \mathbb{N}\times \mathbb{N}} a_{jk}
\]

converges absolutely, and the sums are equal. In particular, the iterated summations are equal.

**Proof:** The argument is similar to the proof of IV.2.8.5. First note that the three sums in the conclusion (and all the infinite series in the iterated summations) converge absolutely, hence converge, so we need only show the three sums are equal. We will show

\[
\sum_{j=1}^{\infty} \sum_{k=1}^{\infty} a_{jk} = s := \sum_{(j,k)\in \mathbb{N}\times \mathbb{N}} a_{jk}
\]

and the proof that the other iterated sum equals \(s\) is almost identical.

Let \(\epsilon > 0\). Then, since \(\sum_{(j,k)\in \mathbb{N}\times \mathbb{N}} |a_{jk}| < \infty\), there is a finite set \(F \subseteq \mathbb{N} \times \mathbb{N}\) such that

\[
\sum_{(j,k)\in \mathbb{N}\times \mathbb{N}\setminus F} |a_{jk}| < \frac{\epsilon}{3}
\]

and \(M, N \in \mathbb{N}\) such that \(F \subseteq \{1, \ldots, M\} \times \{1, \ldots, N\}\). Thus if \(m \geq M, n \geq N\),

\[
\left| s - \sum_{j=1}^{m} \sum_{k=1}^{n} a_{jk} \right| < \frac{\epsilon}{3}.
\]

We have

\[
\sum_{j=1}^{\infty} \sum_{k=1}^{\infty} a_{jk} = \lim_{m \to \infty} \sum_{j=1}^{m} \sum_{k=1}^{\infty} a_{jk}.
\]

Fix \(m \geq M\) such that

\[
\left| \sum_{j=1}^{m} \sum_{k=1}^{\infty} a_{jk} - \sum_{j=1}^{\infty} \sum_{k=1}^{\infty} a_{jk} \right| < \frac{\epsilon}{3}.
\]

487
Since $m$ is fixed, we have

$$\sum_{j=1}^{m} \sum_{k=1}^{\infty} a_{jk} = \lim_{n \to \infty} \sum_{j=1}^{m} \sum_{k=1}^{n} a_{jk}$$

by (), so there is an $n \geq N$ such that

$$\left| \sum_{j=1}^{m} \sum_{k=1}^{n} a_{jk} - \sum_{j=1}^{m} \sum_{k=1}^{\infty} a_{jk} \right| < \frac{\epsilon}{3}.$$  

We then have

$$\left| s - \sum_{j=1}^{\infty} \sum_{k=1}^{\infty} a_{jk} \right| \leq \left| s - \sum_{j=1}^{m} \sum_{k=1}^{n} a_{jk} \right| + \left| \sum_{j=1}^{m} \sum_{k=1}^{n} a_{jk} - \sum_{j=1}^{m} \sum_{k=1}^{\infty} a_{jk} \right| + \left| \sum_{j=1}^{m} \sum_{k=1}^{\infty} a_{jk} - \sum_{j=1}^{\infty} \sum_{k=1}^{\infty} a_{jk} \right| < \frac{\epsilon}{3} + \frac{\epsilon}{3} + \frac{\epsilon}{3} = \epsilon$$

and since $\epsilon > 0$ is arbitrary, the iterated sum equals $s$.

**IV.2.10.9.** We have retained the commonly-used names “Tonelli’s Theorem” and “Fubini’s Theorem” for IV.2.10.7. and IV.2.10.8. since they are special cases of the general results commonly called “Tonelli’s Theorem” () and “Fubini’s Theorem” (), even though it is likely that the double sum results predated FUBINI and TONELLI (at least IV.2.10.7. was undoubtedly “known” to EULER, although it was probably only really proved later). I have been unable to discover who first explicitly stated and proved the double sum versions (very likely sometime in the nineteenth century). See XIV.3.4.34. for additional historical comments.

**IV.2.10.10.** Actually, we must be careful in saying what it means for an iterated summation

$$\sum_{j=1}^{\infty} \sum_{k=1}^{\infty} a_{jk}$$

to converge absolutely. The strong (and proper) interpretation is that the iterated summation

$$\sum_{j=1}^{\infty} \sum_{k=1}^{\infty} |a_{jk}|$$

should converge. Fubini’s Theorem IV.2.10.8. says that if an iterated sum

$$\sum_{j=1}^{\infty} \sum_{k=1}^{\infty} a_{jk}$$

converges absolutely in this sense, then the iterated sum

$$\sum_{k=1}^{\infty} \sum_{j=1}^{\infty} a_{jk}$$

488
in the opposite order (which also converges absolutely by IV.2.10.7.) has the same sum, i.e. the order of summation can be reversed.

We could instead consider a weaker sense in which an iterated summation
\[ \sum_{j=1}^{\infty} \sum_{k=1}^{\infty} a_{jk} \]
converges absolutely: we could just require

(i) For each \( j \), the infinite series \( \sum_{k=1}^{\infty} a_{jk} \) converges absolutely with sum \( b_j \).

(ii) The infinite series \( \sum_{j=1}^{\infty} b_j \) converges absolutely, i.e.
\[ \sum_{j=1}^{\infty} \left| \sum_{k=1}^{\infty} a_{jk} \right| \]
converges.

But example IV.2.10.6. shows that even if both iterated summations
\[ \sum_{j=1}^{\infty} \sum_{k=1}^{\infty} a_{jk}, \quad \sum_{k=1}^{\infty} \sum_{j=1}^{\infty} a_{jk} \]
converge absolutely in this weak sense, the sums may not be equal. In fact, if the iterated summation in one order converges absolutely in the weak sense, the iterated sum in the other order need not, and need not even make sense: consider, for example, the case where for all \( j \) \( a_{j1} = 1 \), \( a_{j2} = -1 \), and \( a_{jk} = 0 \) for all \( k > 2 \).

Combining IV.2.10.8. with the previous observations, we obtain:

**IV.2.10.11. Corollary.** Let \( \{a_{jk} : j, k \in \mathbb{N}\} \) be an array of numbers. If one (hence each) of the three sums
\[ \sum_{j=1}^{\infty} \sum_{k=1}^{\infty} |a_{jk}|, \quad \sum_{k=1}^{\infty} \sum_{j=1}^{\infty} |a_{jk}|, \quad \sum_{(j,k) \in \mathbb{N} \times \mathbb{N}} |a_{jk}| \]
converges (i.e. is finite), then each of the following summations converges absolutely, and the sums are equal:

(i) \[ \sum_{j=1}^{\infty} \sum_{k=1}^{\infty} a_{jk} . \]

(ii) \[ \sum_{k=1}^{\infty} \sum_{j=1}^{\infty} a_{jk} . \]

(iii) \[ \sum_{(j,k) \in \mathbb{N} \times \mathbb{N}} a_{jk} . \]
(iv) The rectangular sum \( \lim_{m,n \to \infty} \sum_{j=1}^{m} \sum_{k=1}^{n} a_{jk} \).

(v) The square sum \( \lim_{n \to \infty} \sum_{j=1}^{n} \sum_{k=1}^{n} a_{jk} \).

(iv) The triangular sum \( \sum_{n=2}^{\infty} \sum_{j+k=n} a_{jk} \).

(vii) Any sum of the form \( \sum_{k=1}^{\infty} a_{\phi(k)} \) where \( \phi \) is a bijection from \( \mathbb{N} \) to \( \mathbb{N} \times \mathbb{N} \).

IV.2.10.12. These results are stated for double summations, but by repeated applications of the double summation result the same conclusions hold for triple or \( n \)-fold summations for any \( n \).

**Drastic Revisions of an Infinite Series**

**IV.2.10.13.** A drastic revision of an infinite series

\[ \sum_{k=1}^{\infty} a_k \]

is a sum of the form

\[ (a_{k_1,1} + a_{k_1,2} + \cdots) + (a_{k_2,1} + a_{k_2,2} + \cdots) + \cdots \]

which resembles a revision (IV.2.8.8.) of the series except that the groups are allowed to be infinite. More precisely:

**IV.2.10.14.** **Definition.** A drastic revision of the infinite series \( \sum_{k=1}^{\infty} a_k \) is an iterated summation of the form

\[ \sum_{j=1}^{\infty} \sum_{k=1}^{\infty} a_{\phi_j(k)} \]

where \( \phi_1, \phi_2, \ldots \) is a sequence of one-to-one functions from \( \mathbb{N} \) to \( \mathbb{N} \times \mathbb{N} \) with disjoint ranges whose union is all of \( \mathbb{N} \).

**IV.2.10.15.** We can also allow some of the groups to be finite; such a sum is technically a drastic revision of a series obtained by inserting an infinite number of 0’s into the original series, which makes no essential change to the series. Thus an ordinary revision is a drastic revision.

The main result about drastic revisions is:
IV.2.10.16. Theorem. Let $\sum_{k=1}^{\infty} a_k$ be an absolutely convergent infinite series. Then any drastic revision of the series converges absolutely, and has the same sum as the original series.

Proof: This is an almost immediate corollary of Fubini’s Theorem. Set $a_{jk} = a_{\phi_j(k)}$. Since the original series converges absolutely, we have that the unordered sum

$$\sum_{(j,k)\in\mathbb{N} \times \mathbb{N}} a_{jk} = \sum_{k\in\mathbb{N}} a_k$$

converges absolutely to the sum of the original series by IV.2.9.11. and IV.2.9.4.(i), and hence the iterated sum does too by IV.2.10.8.

IV.2.10.17. Fubini’s Theorem is usually thought of as a result justifying interchanging the order of summation or integration in an iterated sum or integral. But IV.2.10.16. is an interesting and useful application not involving interchange of order; the relevant part of Fubini’s Theorem is that the iterated sum is equal to the unordered sum (double sum).

IV.2.10.18. We could more generally consider drastic revisions of drastic revisions of a series, etc. If the series converges absolutely, all these will converge absolutely to the same sum. The process can be taken to any finite level, or to an infinite or even transfinite level. Details are left to the interested reader.

Drastic Revisions of Unordered Sums

IV.2.10.19. Suppose $\sum_{j\in J} a_j$ is an unordered summation, and we have a decomposition $J = \cup_{k\in K} J_k$ of $J$ as a disjoint union of subsets. For each $k$ we may form the unordered sum

$$\sum_{j\in J_k} a_j$$

and, if these sums all converge, we can form the unordered sum

$$\sum_{k\in K} \left( \sum_{j\in J_k} a_j \right).$$

Such a sum is called a drastic revision of the unordered sum $\sum_{j\in J} a_j$.

IV.2.10.20. Theorem. Let $\sum_{j\in J} a_j$ be a convergent unordered sum, and $J = \cup_{k\in K} J_k$ a decomposition of $J$. Then

(i) The unordered sum $\sum_{j\in J_k} a_j$ converges for each $k$.  

491
(ii) The unordered sum (drastic revision)
\[
\sum_{k \in K} \left( \sum_{j \in J_k} a_j \right)
\]
converges, and
\[
\sum_{k \in K} \left( \sum_{j \in J_k} a_j \right) = \sum_{j \in J} a_j .
\]

**Proof:** We have \(a_j \neq 0\) for only countably many \(J\) (IV.2.9.6.), and there are only countably many \(k\) for which \(J_k\) contains a nonzero term. Thus there is no loss of generality in assuming \(J\) and \(K\) are countable.

Fix bijections from \(\mathbb{N}\) to \(K\) and to \(J_k\) for each \(k\) (the **Countable AC** is needed to do this; zero terms may have to be added to the unordered sum if some \(J_k\) are finite). The unordered sums thus become ordinary infinite series using these orderings, and the infinite series corresponding to IV.1 is a drastic revision of the original sum as an infinite series. The result then follows from IV.2.10.16. and IV.2.9.11.

**IV.2.10.21.** The converse of this theorem is true if all the terms of the unordered sum are nonnegative. But the converse is not true in general: if a drastic revision of an unordered sum converges, the original unordered sum need not converge, and if two drastic revisions of an unordered sum both converge, the sums may not be equal. Example IV.2.10.6. gives a counterexample if the series are regarded as unordered sums. The situation is essentially the same as the problem described in IV.2.10.10.

**IV.2.10.22.** Just as with ordinary series, we can take such drastic revisions to multiple levels. If the original unordered sum converges, so will all multiple-level drastic revisions, with the same sum.

**IV.2.11. Products of Infinite Series**

**IV.2.11.1.** Suppose we have two convergent infinite series
\[
\sum_{k=0}^{\infty} a_k \quad \text{and} \quad \sum_{k=0}^{\infty} b_k
\]
with sums \(s\) and \(t\) respectively (it is notationally convenient to start the sums at 0 instead of 1). What should we mean by the product of the two series
\[
\left( \sum_{k=0}^{\infty} a_k \right) \left( \sum_{k=0}^{\infty} b_k \right)
\]
and what should its sum be? However we define the product its “sum” should be \(st\).

**IV.2.11.2.** A natural approach is to consider the double array \((c_{jk})\), where \(c_{jk} = a_j b_k\); this array would be obtained by formally multiplying out the series
\[
(a_0 + a_1 + a_2 + \cdots)(b_0 + b_1 + b_2 + \cdots)
\]
as though they were finite sums. Thus any of the sums considered in the last section would be a potential interpretation of the product of the series. Several of these automatically converge:
**IV.2.11.3. Proposition.** Using the above notation, the following sums converge with sum $st$:

(i) The iterated sum $\sum_{j=0}^{\infty} \sum_{k=0}^{\infty} a_j b_k$.

(ii) The iterated sum $\sum_{k=0}^{\infty} \sum_{j=0}^{\infty} a_j b_k$.

(iii) The rectangular sum $\lim_{m,n \to \infty} \sum_{j=0}^{m} \sum_{k=0}^{n} a_j b_k$.

(iv) The square sum $\lim_{n \to \infty} \sum_{j=0}^{n} \sum_{k=0}^{n} a_j b_k$.

**Proof:** (i) and (ii) each follow directly from two applications of **IV.2.11.3.**. For (iii) and (iv), set

$$s_m = \sum_{j=0}^{m} a_j \quad \text{and} \quad t_n = \sum_{k=0}^{n} b_k$$

and note that

$$\sum_{j=0}^{m} \sum_{k=0}^{n} a_j b_k = s_m t_n$$

and that

$$\lim_{m,n \to \infty} s_m t_n = \lim_{n \to \infty} s_n t_n = st.$$ 

**IV.2.11.4.** However, the triangular sum is more problematic. And it is the triangular sum which is the most natural definition of the product of the two series. For one thing, it is the only systematically obtained sum of the types previously considered which is actually a single infinite series. More importantly, it is especially natural when power series are considered (cf. **III.5.3.2., V.16.3.11.**): if

$$\sum_{k=0}^{\infty} a_k x^k \quad \text{and} \quad \sum_{k=0}^{\infty} b_k x^k$$

are power series, if we collect together like powers of $x$ in the array $c_{jk} = a_j b_k x^{j+k}$ we get the triangular sum

$$\sum_{n=0}^{\infty} \sum_{j+k=n} a_j b_k x^n = \sum_{n=0}^{\infty} \left[ \left( \sum_{k=0}^{n} a_k b_{n-k} \right) x^n \right].$$

We thus make the definition:
IV.2.11.5. Definition. Let
\[ \sum_{k=0}^{\infty} a_k \quad \text{and} \quad \sum_{k=0}^{\infty} b_k \]
be infinite series. Then the product, or Cauchy product, of the series is the triangular sum
\[ \left( \sum_{k=0}^{\infty} a_k \right) \left( \sum_{k=0}^{\infty} b_k \right) = \sum_{n=0}^{\infty} \sum_{j+k=n} a_j b_k = \sum_{n=0}^{\infty} \sum_{k=0}^{n} a_k b_{n-k} \].

IV.2.11.6. Example. The product of two convergent infinite series can diverge. Set
\[ a_k = b_k = \frac{(-1)^k}{\sqrt{k}} \]
for all \( k \geq 1 \). Then
\[ \sum_{k=1}^{\infty} a_k \quad \text{and} \quad \sum_{k=1}^{\infty} b_k \]
converge by the Alternating Series Test. But the product series
\[ \sum_{n=2}^{\infty} (-1)^n \left( \sum_{k=1}^{n-1} \frac{1}{\sqrt{k(n-k)}} \right) \]
diverges since the terms do not approach 0:
\[ \frac{1}{\sqrt{k(n-k)}} \geq \frac{2}{n} \quad \text{for} \quad 1 \leq k \leq n - 1. \]

IV.2.11.7. If the series
\[ \sum_{k=0}^{\infty} a_k \quad \text{and} \quad \sum_{k=0}^{\infty} b_k \]
both converge absolutely to \( s \) and \( t \) respectively, then the iterated sum
\[ \sum_{j=0}^{\infty} \sum_{k=0}^{j} |a_j b_k| \]
converges, and thus by IV.2.10.11. all the associated sums, and in particular the triangular sum, converge absolutely to the same sum, which must be \( st \). Thus we obtain:

IV.2.11.8. Theorem. Let
\[ \sum_{k=0}^{\infty} a_k \quad \text{and} \quad \sum_{k=0}^{\infty} b_k \]
be absolutely convergent infinite series with sums \( s \) and \( t \) respectively. Then the product series
\[ \sum_{n=0}^{\infty} \sum_{k=0}^{n} a_k b_{n-k} \]
converges absolutely, with sum $st$.

While the absolutely convergent case is usually the most important one, the convergence result can be extended to the case where only one of the series converges absolutely. Note, however, that absolute convergence of the product series is not guaranteed in this case. This theorem is due to MERTENS.

**IV.2.11.9.** Theorem. Let
\[ \sum_{k=0}^{\infty} a_k \quad \text{and} \quad \sum_{k=0}^{\infty} b_k \]
be convergent infinite series with sums $s$ and $t$ respectively. Suppose at least one of the series converges absolutely. Then the product series
\[ \sum_{n=0}^{\infty} \sum_{k=0}^{n} a_k b_{n-k} \]
converges, with sum $st$.

Actually, convergence of the product series is the only issue: if the product series converges, its sum is automatically the right thing. This result is due to Abel.

**IV.2.11.10.** Theorem. Let
\[ \sum_{k=0}^{\infty} a_k \quad \text{and} \quad \sum_{k=0}^{\infty} b_k \]
be convergent infinite series with sums $s$ and $t$ respectively. If the product series
\[ \sum_{n=0}^{\infty} \sum_{k=0}^{n} a_k b_{n-k} \]
converges, its sum is $st$.

**IV.2.11.11.** We have considered products of two series. But we may iterate to obtain products of any finite number of series, and the extension of IV.2.11.8. applies: if each of the series converges absolutely, so does the product series. We should note the following technicality, which is proved by a straightforward calculation left to the reader:

**IV.2.11.12.** Proposition. The product of infinite series is associative and commutative: if
\[ \sum_{k=0}^{\infty} a_k, \quad \sum_{k=0}^{\infty} b_k, \quad \sum_{k=0}^{\infty} c_k \]
are infinite series, then
\[
\left( \sum_{k=0}^{\infty} a_k \right) \left( \sum_{k=0}^{\infty} b_k \right) \left( \sum_{k=0}^{\infty} c_k \right) = \left( \sum_{k=0}^{\infty} a_k \right) \left[ \left( \sum_{k=0}^{\infty} b_k \right) \left( \sum_{k=0}^{\infty} c_k \right) \right]
\]
\[
\left( \sum_{k=0}^{\infty} a_k \right) \left( \sum_{k=0}^{\infty} b_k \right) = \left( \sum_{k=0}^{\infty} b_k \right) \left( \sum_{k=0}^{\infty} a_k \right).
\]

IV.2.12. Infinite Products

IV.2.12.1. An infinite product is an expression of the form
\[
\prod_{k=1}^{\infty} u_k
\]
where the \( u_k \) are numbers (or later functions). The \( u_k \) are called the factors of the product.

Infinite products have a long history, and there are some famous examples such as the following expressions involving \( \pi \) due respectively to Viète (1646) and Wallis (1653):
\[
\frac{2}{\pi} = \sqrt{\frac{1}{2}} \cdot \sqrt{\frac{1}{2} + \frac{1}{2} \sqrt{\frac{1}{2}}} \cdot \sqrt{\frac{1}{2} + \frac{1}{2} \sqrt{\frac{1}{2} + \frac{1}{2} \sqrt{\frac{1}{2}}}} \cdots
\]
\[
\frac{\pi}{2} = \frac{2}{1} \cdot \frac{2}{3} \cdot \frac{4}{3} \cdot \frac{4}{5} \cdot \frac{6}{5} \cdots \cdot \frac{2m}{2m+1} \cdot \frac{2m+2}{2m+1} \cdots
\]

In this section, we will make sense out of such expressions and discuss convergence.

IV.2.12.2. In analogy with the definition for infinite series, we could define partial products
\[
p_n = \prod_{k=1}^{n} u_k
\]
and say that the infinite product converges, with product \( p \), if the sequence \((p_n)\) converges to \( p \). But there are two serious difficulties with this approach in general. First, if one of the \( u_k \) is zero, then all the partial products from that point on will be zero no matter what the rest of the factors are. And secondly, even if all the \( u_k \) are nonzero, so all the \( p_k \) are nonzero, we can easily have \( p = 0 \). In either of these cases it is not reasonable to say that the infinite product converges. Thus we make the following definition:

IV.2.12.3. Definition. Let \( \prod_{k=1}^{\infty} u_k \) be an infinite product. Then the product converges, with product \( p \), if \( p \neq 0 \) and the sequence \((p_n)\) of partial products converges to \( p \). If there is no such \( p \), the infinite product diverges.
The factors of a convergent infinite product are necessarily nonzero. We can extend the definition by allowing a finite number of zero factors and determining convergence by the tail products after the last zero factor (this is useful when the factors are functions, to allow the product to be defined when one factor is zero).

The next fundamental observation is analogous to the Divergence Criterion for series:

**IV.2.12.4.** Prop. Let \( \prod_{k=1}^{\infty} u_k \) be a convergent infinite product. Then \( \lim_{k \to \infty} u_k = 1 \).

**Proof:** We have \( \lim_{k \to \infty} p_k = p \neq 0 \) and \( \lim_{k \to \infty} p_{k+1} = p \), and hence by ()

\[
\lim_{k \to \infty} u_k = \lim_{k \to \infty} \frac{p_{k+1}}{p_k} = \frac{\lim_{k \to \infty} p_{k+1}}{\lim_{k \to \infty} p_k} = \frac{p}{p} = 1.
\]

Note that \( \lim_{k \to \infty} u_k = 1 \) is a necessary condition for convergence of the infinite product, but not a sufficient one, just as with infinite series.

**IV.2.12.5.** Two important consequences of **IV.2.12.4.** are:

(i) Since the factors of a convergent infinite product are eventually close to 1, they are eventually positive, i.e. a convergent infinite product can have only finitely many negative factors. For convenience, we will usually only consider infinite products with positive factors; ones with finitely many negative (or zero) factors can be reduced to this case by considering a tail product (in obvious analogy with **IV.2.1.6.**, an infinite product converges if and only if some (every) tail product converges).

(ii) In light of **IV.2.12.4.**, it is customary to write the factor \( u_k \) as \((1 + a_k)\) and to call the \( a_k \) the terms of the infinite product. **IV.2.12.4.** then says that the terms of a convergent infinite product tend to zero.

We will eventually see that the infinite product \( \prod_{k=1}^{\infty} (1 + a_k) \) converges roughly (but not exactly) if and only if \( \sum_{k=1}^{\infty} a_k \) converges.

As a strengthening of (i), for convenience we often only consider infinite products with \(|a_k| < 1\) for all \( k \); this will be true in some tail of any convergent infinite product.

The next result in a sense completely reduces the convergence question for infinite products to a question about infinite series:
IV.2.12.6. Proposition. Let \( \prod_{k=1}^{\infty} u_k \) be an infinite product with \( u_k > 0 \) for all \( k \). Then the infinite product converges if and only if the infinite series \( \sum_{k=1}^{\infty} \log u_k \) converges.

Proof: If we have \( p_n \to p > 0 \), we have

\[
\log p_n = \sum_{k=1}^{n} \log u_k \to \log p
\]

by continuity of the logarithm function, so \( \sum_{k=1}^{\infty} \log u_k \) converges. Conversely, if \( s_n = \sum_{k=1}^{n} \log u_k \) converges to \( s \), we have \( p_n = e^{s_n} \to e^s \) by continuity of the exponential function, so the infinite product converges.

IV.2.12.7. Thus, if we want to analyze the convergence of the infinite product \( \prod_{k=1}^{\infty} (1 + a_k) \) with all \( |a_k| < 1 \), we can just consider convergence of the infinite series \( \sum_{k=1}^{\infty} \log(1 + a_k) \). But it would be preferable to have a criterion in terms of the closely related but simpler series \( \sum_{k=1}^{\infty} a_k \). We can do this using the following lemma:

IV.2.12.8. Lemma. There is a \( \delta > 0 \) such that

\[
x - x^2 < \log(1 + x) < x - \frac{1}{3} x^2
\]

whenever \( |x| < \delta \).

Proof: It suffices to show that

\[
-1 < \lim_{x \to 0} \frac{\log(1 + x) - x}{x^2} < -\frac{1}{3}.
\]

But this limit is \(-\frac{1}{2}\) by l’Hôpital’s Rule.

IV.2.12.9. Proposition. Let \((a_n)\) be a sequence of numbers with \( |a_n| < 1 \) for all \( n \). If \( \sum_{k=1}^{\infty} a_k^2 \) converges absolutely, then \( \sum_{k=1}^{\infty} a_k \) converges if and only if \( \sum_{k=1}^{\infty} \log(1 + a_k) \) converges.
Proof: We have \( a_k \to 0 \). For each \( k \), write \( \log(1 + a_k) = a_k + \theta_k a_k^2 \). Then \( (\theta_k) \) is a bounded sequence since \(-1 < \theta_k < -\frac{1}{4}\) for sufficiently large \( k \) by IV.2.12.8. (actually \( \theta_k \to -\frac{1}{2} \)). Since \( \sum_{k=1}^{\infty} a_k^2 \) converges absolutely, we have that \( \sum_{k=1}^{\infty} \theta_k a_k^2 \) converges (absolutely) by IV.2.7.2. Hence \( \sum_{k=1}^{\infty} \log(1 + a_k) \) and \( \sum_{k=1}^{\infty} a_k \) either both converge or both diverge by IV.2.16.

**IV.2.12.10.** Corollary. Let \( \prod_{k=1}^{\infty} (1 + a_k) \) be an infinite product. If \( \sum_{k=1}^{\infty} a_k^2 \) converges absolutely, then the infinite product converges if and only if \( \sum_{k=1}^{\infty} a_k \) converges.

**IV.2.12.11.** If the \( a_k \) are real numbers, then \( \sum_{k=1}^{\infty} a_k^2 \) is a nonnegative series, so convergence and absolute convergence are the same thing. But these results also hold for complex series and products, where absolute convergence of \( \sum_{k=1}^{\infty} a_k^2 \) does not necessarily follow from convergence.

**IV.2.12.12.** The convergence of \( \sum_{k=1}^{\infty} a_k^2 \) is not necessary for the convergence of the infinite product, however; see the example in Exercise IV.2.16.11. See also Exercise IV.2.16.12. for an example of a divergent infinite product where \( \sum_{k=1}^{\infty} a_k \) converges.

However, if all terms have the same sign, convergence of \( \sum_{k=1}^{\infty} a_k \) is both necessary and sufficient for convergence of the infinite product:

**IV.2.12.13.** Theorem. Let \( \prod_{k=1}^{\infty} (1 + a_k) \) be an infinite product. If all \( a_k \) have the same sign, then the infinite product converges if and only if \( \sum_{k=1}^{\infty} a_k \) converges.

Proof: One direction follows from IV.2.12.10: if \( \sum_{k=1}^{\infty} a_k \) converges, it converges absolutely, and hence \( \sum_{k=1}^{\infty} a_k^2 \) converges (absolutely) by the Comparison Test. The converse does not follow from IV.2.12.10, however.
To prove the converse, suppose first that all $a_k > 0$. If $s_n = \sum_{k=1}^{n} a_k$, then we have

$$p_n = (1 + a_1)(1 + a_2) \cdots (1 + a_n) = 1 + a_1 + a_2 + \cdots + a_n + \text{(higher-order terms)} \geq s_n$$

since the higher-order terms are all nonnegative. If the infinite product converges, the $p_n$ are bounded, so the $s_n$ are bounded and $\sum_{k=1}^{\infty} a_k$ converges.

Now assume the $a_k$ are all negative. By passing to a tail, we may assume $|a_k| < 1$ for all $k$. Assume the infinite product converges with product $p$; then $p_n \geq p$ for all $n$. We have

$$1 - x \leq \frac{1}{1 + x}$$

for any $x > -1$, since $(1 + x)(1 - x) = 1 - x^2$. Thus we have

$$1 - a_k \leq \frac{1}{1 + a_k}$$

for all $k$, and thus

$$\prod_{k=1}^{n} (1 - a_k) \leq \frac{1}{p_n} \leq \frac{1}{p}.$$ 

Thus the infinite product $\prod_{k=1}^{\infty} (1 - a_k)$ converges, and hence $\sum_{k=1}^{\infty} (-a_k)$ converges by the previous argument.

Absolutely Convergent Infinite Products

**IV.2.12.14.** Definition. An infinite product $\prod_{k=1}^{\infty} (1 + a_k)$ converges absolutely if $\prod_{k=1}^{\infty} (1 + |a_k|)$ converges.

Just as in the sum case (IV.2.5.2.), we have:

**IV.2.12.15.** Proposition. An absolutely convergent infinite product converges.

The proof is left to the reader (Exercise IV.2.16.13.).

The next result is an immediate corollary of IV.2.12.14., and along with the previous examples shows that there are many convergent infinite products which are not absolutely convergent.

**IV.2.12.16.** Corollary. An infinite product $\prod_{k=1}^{\infty} (1 + a_k)$ converges absolutely if and only if $\sum_{k=1}^{\infty} a_k$ converges absolutely.
Rearrangement

Just as with infinite series, we may rearrange the order of factors in an absolutely convergent infinite product without affecting convergence or changing the product; however, rearrangement of order in a non-absolutely convergent infinite product can affect convergence and/or change the product.

IV.2.13. Infinite Series of Complex Numbers

Infinite series of complex numbers behave almost identically to series of real numbers. Almost all results about real infinite series carry over to the complex case, with identical proofs. We state the essentials here.

IV.2.13.1. Definition. The infinite series \( \sum_{k=1}^{\infty} a_k \) of complex numbers converges, with sum \( s \in \mathbb{R} \), if the sequence \((s_n)\) of partial sums converges to \( s \) in \( \mathbb{C} \).

The infinite series \( \sum_{k=1}^{\infty} a_k \) of complex numbers converges absolutely if \( \sum_{k=1}^{\infty} |a_k| \) converges. The series converges conditionally if it converges but does not converge absolutely.

The next observation allows many aspects of the theory of complex infinite series to be reduced to the real case.

IV.2.13.2. Proposition. Let \( \sum_{k=1}^{\infty} a_k \) be an infinite series of complex numbers. For each \( k \), write \( a_k = b_k + ic_k \) with \( b_k, c_k \in \mathbb{R} \). Then \( \sum_{k=1}^{\infty} a_k \) converges if and only if both \( \sum_{k=1}^{\infty} b_k \) and \( \sum_{k=1}^{\infty} c_k \) converge, and

\[
\sum_{k=1}^{\infty} a_k = \sum_{k=1}^{\infty} b_k + i \sum_{k=1}^{\infty} c_k .
\]

The series \( \sum_{k=1}^{\infty} a_k \) converges absolutely if and only if both \( \sum_{k=1}^{\infty} b_k \) and \( \sum_{k=1}^{\infty} c_k \) converge absolutely.

Proof: Let \( r_n = \sum_{k=1}^{n} a_k, s_n = \sum_{k=1}^{n} b_k, t_n = \sum_{k=1}^{n} c_k \) be the partial sums. Then \( r_n = s_n + it_n \) for each \( n \), so the first result follows from (\). The second result follows immediately from the Comparison Test and IV.2.1.16. since, for every \( k \),

\[
|b_k|, |c_k| \leq |a_k| \leq |b_k| + |c_k| .
\]

IV.2.13.3. Proposition. Every absolutely convergent series of complex numbers converges.

The proof is identical to the proof of IV.2.5.2. Alternately, the result follows immediately from IV.2.13.2.
Since $\sum_{k=1}^{\infty} |a_k|$ is an infinite series with nonnegative real terms, all the tests for convergence of nonnegative real series are tests for absolute convergence of complex series as well.

The theorems about termwise addition and scalar multiplication (IV.2.1.16., IV.2.1.18.), including multiplication by complex scalars, hold also for complex series. The theorems about rearrangements and subarrangements (IV.2.8.3., IV.2.8.5.), on unordered and iterated summations, and the theorem on products of series (IV.2.11.8.), hold for absolutely convergent complex series. All the proofs are the same as in the real case, and/or the results follow immediately from the real case using IV.2.13.2. (Riemann’s Theorem on rearranging conditionally convergent series (IV.2.8.6.) is more subtle, however: see Exercise ().)
(a) Show that \( \limsup_{k \to \infty} \frac{a_{k+1}}{a_k} = 2 \) and \( \liminf_{k \to \infty} \frac{a_{k+1}}{a_k} = 1 \).

(b) Show that \( \sum a_k \) converges.

(c) Construct a similar convergent positive series \( \sum b_k \) with \( \limsup_{k \to \infty} \frac{b_{k+1}}{b_k} = +\infty \) and \( \liminf_{k \to \infty} \frac{b_{k+1}}{b_k} = 1 \).

**IV.2.16.3.** Choose an increasing sequence \( (k_n) \) such that \( \frac{1}{k_n} > 4^n \), and for \( k_n < k \leq k_{n+1} \) let \( a_k = \frac{2 - n}{k} \).

(a) Show that \( \limsup_{k \to \infty} \frac{a_{k+1}}{a_k} = 1 \) and \( \liminf_{k \to \infty} \frac{a_{k+1}}{a_k} = \frac{1}{2} \).

(b) Show that \( \sum a_k \) diverges.

(c) Construct a similar divergent positive series \( \sum b_k \) with \( \limsup_{k \to \infty} \frac{b_{k+1}}{b_k} = 1 \) and \( \liminf_{k \to \infty} \frac{b_{k+1}}{b_k} = 0 \).

**IV.2.16.4.** Let \( p > 0 \) be fixed, and set

\[
 a_k = \begin{cases} 
  \frac{1}{k^p} & \text{if } \ k \ \text{odd} \\
  \frac{2}{k^p} & \text{if } \ k \ \text{even}
\end{cases}
\]

(a) Show that \( \limsup_{k \to \infty} \frac{a_{k+1}}{a_k} = 2 \) and \( \liminf_{k \to \infty} \frac{a_{k+1}}{a_k} = \frac{1}{2} \).

(b) Show that \( \sum a_k \) converges if \( p > 1 \) and diverges if \( p \leq 1 \).

**IV.2.16.5.** [?] Let \( \sum_{k=1}^{\infty} a_k \) be a convergent infinite series with strictly positive terms, and for each \( n \) let \( t_n = \sum_{k=n}^{\infty} a_k \) be the \( n \)‘th tail sum. Set \( b_k = \sqrt{t_k} - \sqrt{t_{k+1}} \) for each \( k \). Show that \( \sum_{k=1}^{\infty} b_k \) also converges, and that \( \lim_{k \to \infty} \frac{b_k}{a_k} = +\infty \) (note that \( a_k = t_k - t_{k+1} \)), i.e. \( (b_k) \) converges to zero “more slowly” than \( (a_k) \).

**IV.2.16.6.** Let \( \sum_{k=1}^{\infty} a_k \) be a divergent infinite series with strictly positive terms, and for each \( n \) let \( s_n = \sum_{k=1}^{n} a_k \) be the \( n \)‘th partial sum. Set \( b_k = \frac{\sqrt{s_k}}{a_k} \) for each \( k \). Show that \( \sum_{k=1}^{\infty} b_k \) also diverges (its \( n \)‘th partial sum is at least \( \sqrt{s_n} \)), and that \( \lim_{k \to \infty} \frac{b_k}{a_k} = 0 \), i.e. \( (b_k) \) converges to zero “more rapidly” than \( (a_k) \).
IV.2.16.7. Let \( \sum_{k=1}^{\infty} a_k \) be an infinite series with nonincreasing nonnegative terms. Use the Cauchy Condensation Test to show that \( \sum_{k=1}^{\infty} a_k \) converges if and only if \( \sum_{k=1}^{\infty} (2k+1)a_{k^2} \) converges. Then show by the Limit Comparison Test that this series converges if and only if \( \sum_{k=1}^{\infty} ka_{k^2} \) converges.

IV.2.16.8. Let \((x_k)\) be a sequence of positive numbers. Show that
\[
\liminf_{k \to \infty} [k(x_k - 1)] = \liminf_{k \to \infty} \left[k \left(1 - \frac{1}{x_k}\right)\right] \quad \text{and} \quad \limsup_{k \to \infty} [k(x_k - 1)] = \limsup_{k \to \infty} \left[k \left(1 - \frac{1}{x_k}\right)\right]
\]
as follows:
(a) Suppose \( L = \liminf_{k \to \infty} [k(x_k - 1)] \neq -\infty \), and let \( r \in \mathbb{R}, \ r < L \). Then \( k(x_k - 1) > r \) for all sufficiently large \( k \). Show that
\[
\liminf_{k \to \infty} \left[k \left(1 - \frac{1}{x_k}\right)\right] \geq \liminf_{k \to \infty} \frac{kr}{k+r} = r.
\]
(b) Suppose \( L' = \liminf_{k \to \infty} \left[k \left(1 - \frac{1}{x_k}\right)\right] \neq -\infty \), and let \( r \in \mathbb{R}, \ r < L' \). Then \( k \left(1 - \frac{1}{x_k}\right) > r \) for all sufficiently large \( k \). Show that
\[
\liminf_{k \to \infty} [k(x_k - 1)] \geq \liminf_{k \to \infty} \frac{kr}{k-r} = r.
\]
(c) Prove the \( \liminf \) equality in the case where one side is \( -\infty \).
(d) Replace \( x_k \) by \( \frac{1}{x_k} \) in the \( \liminf \) equality to obtain the \( \limsup \) equality.

IV.2.16.9. (a) Use Exercise IV.2.16.8. to prove the version IV.2.4.5. of Raabe’s Test from IV.2.4.4., and the converse implication.
(b) Similarly prove the equivalence of IV.2.4.8. and IV.2.4.9..

IV.2.16.10. This problem gives an alternate proof that an absolutely convergent series of real numbers converges (IV.2.5.2.).

Let \( \sum_{k=1}^{\infty} a_k \) be an absolutely convergent infinite series. For each \( k \) set
\[
b_k = \frac{1}{2}(|a_k| + a_k), \quad c_k = \frac{1}{2}(|a_k| - a_k).
\]
Note that \( a_k = b_k - c_k \) and \( |a_k| = b_k + c_k \).

(a) Show that \( \sum_{k=1}^{\infty} b_k \) and \( \sum_{k=1}^{\infty} c_k \) are nonnegative series which converge by the comparison test.
(b) Conclude from IV.2.16. and IV.2.18. that \( \sum_{k=1}^{\infty} a_k \) also converges.

(c) Where was completeness of \( \mathbb{R} \) used in this proof?
This proof is arguably simpler than the one in IV.2.5.2., but the one in IV.2.5.2. is more widely applicable since it works verbatim for infinite series in \( \mathbb{C} \) and in Banach spaces ().

**IV.2.16.11.** For each \( k \) set \( a_{2k-1} = \frac{1}{\sqrt{k}} \) and \( a_{2k} = \frac{1}{k} - \frac{1}{\sqrt{k}} \).

(a) Show that \( \sum_{k=1}^{\infty} a_k \) and \( \sum_{k=1}^{\infty} a_k^2 \) both diverge.

(b) Show that \( \prod_{k=1}^{\infty} (1 + a_k) \) converges.

**IV.2.16.12.** For each \( k \) set \( a_k = \frac{(-1)^k}{\sqrt{k}} \).

(a) Show that \( \sum_{k=1}^{\infty} a_k \) converges and \( \sum_{k=1}^{\infty} a_k^2 \) diverges.

(b) Show that \( \prod_{k=1}^{\infty} (1 + a_k) \) diverges.

**IV.2.16.13.** (a) Prove the following Cauchy Criterion for infinite products: An infinite product \( \prod_{k=1}^{\infty} u_k \) converges if and only if, for every \( \epsilon > 0 \) there is an \( N \) such that
\[
\left| \left[ \prod_{k=n+1}^{m} u_k \right] - 1 \right| < \epsilon
\]
whenever \( N \leq n < m \).

(b) If \( a_1, \ldots, a_n \) are any numbers, prove that
\[
\left| \left[ \prod_{k=1}^{n} (1 + a_k) \right] - 1 \right| \leq \left[ \prod_{k=1}^{n} (1 + |a_k|) \right] - 1 .
\]

(c) Prove that an absolutely convergent infinite product converges.

**IV.2.16.14.** (a) Let \( (c_k) \) be an unbounded sequence of positive numbers. Choose a strictly increasing sequence \( (k_j) \) such that \( c_{k_j} \geq 2^j \). Set \( a_{k_j} = 2^{-j} \), and \( a_k = 2^{-k} \) for \( k \) not one of the \( k_j \). Show that \( \sum_{k=1}^{\infty} a_k \) converges and \( \sum_{k=1}^{\infty} c_k a_k \) diverges.
(b) Let \((d_k)\) be a sequence of positive numbers with \(\inf_k d_k = 0\). Choose a strictly increasing sequence \((k_j)\) such that \(d_{k_j} \leq 2^{-j}\). Set \(a_{k_j} = 1\); for \(k\) not one of the \(k_j\) set \(a_k = 2^{-k}\) if \(d_k \leq 1\) and \(a_k = \frac{1}{2^n d_k}\) if \(d_k > 1\).

Show that \(\sum_{k=1}^{\infty} a_k\) diverges but \(\sum_{k=1}^{\infty} d_k a_k\) converges.

IV.2.16.15. (a) Let \(\sum_{k=1}^{\infty} a_k\) be a divergent nonnegative infinite series, with partial sums \(s_n > 0\). Show that \(\sum_{k=1}^{\infty} \frac{a_k}{s_k}\) also diverges. [Show that if \(n < m\), then
\[
\sum_{k=n+1}^{m} \frac{a_k}{s_k} \geq 1 - \frac{s_n}{s_m}
\]
and use that \(s_n \to +\infty\).]

(b) Show that \(\sum_{k=1}^{\infty} \frac{a_k}{s_k}\) converges if \(p > 1\). (The case \(p = 1/2\) is Exercise IV.2.16.6.)

This result was proved independently by Abel and Dini.

IV.2.16.16. (a) Let \(\sum_{k=1}^{\infty} a_k\) be a convergent nonnegative infinite series, with tail sums \(t_n > 0\). Show that \(\sum_{k=1}^{\infty} \frac{a_k}{t_k}\) diverges.

(b) Show that \(\sum_{k=1}^{\infty} \frac{a_k}{t_k^{1/p}}\) converges if \(p < 1\).

This result was proved by Dini.

IV.2.16.17. Let \(\sum_{k=1}^{\infty} a_k^{(1)}, \sum_{k=1}^{\infty} a_k^{(2)}, \ldots\) be a sequence of convergent positive infinite series.

(a) Inductively find for each \(m\) a convergent positive series \(\sum_{k=1}^{\infty} b_k^{(m)}\) such that \(\lim_{k \to \infty} \frac{a_k^{(j)}}{b_k^{(m)}} = 0\) for \(1 \leq j \leq m\) and \(\lim_{k \to \infty} \frac{b_k^{(j)}}{b_k^{(m)}} = 0\) for \(j < m\). [Apply the argument of Exercise IV.2.16.5. to the series \(\sum_{k=1}^{\infty} (b_k^{(m-1)} + a_k^{(m)})\).]

(b) Construct a convergent positive infinite series \(\sum_{k=1}^{\infty} b_k\) such that \(\lim_{k \to \infty} \frac{a_k^{(m)}}{b_k} = 0\) for all \(m\), i.e. such that the \(b_k\) go to zero “more slowly” than \(a_k^{(m)}\) for every \(m\). [Let \(b_k = b_k^{(m)}\) for \(n_{m-1} + 1 \leq k \leq n_m\), for a suitably chosen increasing sequence \((n_m)\).]
(c) If each \( \sum_{k=1}^{\infty} a_k^{(m)} \) diverges, similarly construct a divergent positive infinite series \( \sum_{k=1}^{\infty} b_k \) such that \( \lim_{k \to \infty} \frac{b_k}{a_k^{(m)}} = 0 \) for all \( m \), i.e. such that the \( b_k \) go to zero “more rapidly” than \( a_k^{(m)} \) for every \( m \).

**IV.2.16.18. (Euler)** Let \( p_k \) be the \( k \)th prime number (in increasing order). The goal of this problem is to prove that \( \sum \frac{1}{p_k} \) diverges. (This provides another proof that there are infinitely many primes.)

(a) For each \( n \), let \( m_n \) be the integer part of \( \log_2 n \), i.e. \( 2^{m_n} \) is the largest power of 2 which is \( \leq n \). Show that, if \( r \leq n \) and \( r = p_1^{e_1} p_2^{e_2} \cdots p_s^{e_s} \), then \( e_j \leq m_n \) for all \( j \).

(b) Let \( n \in \mathbb{N} \), and let \( r \) be the largest index for which \( p_r \leq n \). Show that

\[
\left( \sum_{j=0}^{m_n} \frac{1}{p_1^j} \right) \left( \sum_{j=0}^{m_n} \frac{1}{p_2^j} \right) \cdots \left( \sum_{j=0}^{m_n} \frac{1}{p_r^j} \right) \geq \sum_{k=1}^{n} \frac{1}{p_k} .
\]

[Multiply out the left side.]

(c) Show that the left side of the inequality in (b) is dominated by

\[
\prod_{k=1}^{r} \frac{p_k}{p_k - 1} .
\]

[The factors are partial sums of geometric series.]

(d) Conclude that there are infinitely many \( p_k \), and that the infinite product

\[
\prod_{k=1}^{\infty} \frac{p_k}{p_k - 1}
\]

diverges, and hence that

\[
\sum_{k=1}^{\infty} \frac{1}{p_k}
\]

do also diverges. [Use IV.2.12.16.]

**IV.2.16.19.**

(a) Show that a revision of a revision of an infinite series \( \sum a_k \) is a revision of \( \sum a_k \).

(b) Say that two infinite series are **associates** if they are both revisions of the same infinite series. Find necessary and sufficient conditions that two given series are associates.

(c) Say that two absolutely convergent infinite series are **strong associates** if they are both revisions of the same absolutely convergent infinite series. Find necessary and sufficient conditions that two given absolutely convergent series are strong associates.

(d) Is the property of being associates [resp. strong associates] an equivalence relation on infinite series [resp. absolutely convergent infinite series]?

(e) Answer the same questions if “revisions” is replaced by “drastic revisions.”

507
IV.3. Convergence of Sequences of Functions

If \((x_n)\) is a sequence of numbers, the meaning of an expression like \(x_n \to x\) is unambiguous: there is only one notion of convergence for sequences of numbers (except in rare instances where an exotic topology is being considered, which need not concern us here). Similarly, there is one standard and universal notion of convergence for sequences of points in Euclidean space.

The situation with functions is dramatically different. If \((f_n)\) is a sequence of functions, there is no unambiguous meaning for an expression like \(f_n \to f\). There are many possible meanings (some dependent on context); some of the most common ones are pointwise convergence, uniform convergence, u.c. convergence, a.e. convergence, convergence in measure, mean convergence, weak convergence, \ldots. The reader should form the habit of clearly specifying, or at least clearly understanding, what kind of convergence is being considered in any situation, to avoid writing “meaningless” expressions like \(f_n \to f\). The conceptual understanding that sequences of functions can converge in some senses but not others is one of the most important and basic mindsets an analyst must develop.

Some of the notions of convergence of sequences of functions are stronger (more restrictive) than others. Properties of functions (e.g. continuity) are sometimes automatically preserved under certain types of convergence, but not others; the stronger the notion of convergence, the more properties are preserved, and the larger the number of desirable consequences of the convergence. There are a number of useful results in analysis and topology which allow one to deduce a stronger type of convergence from a weaker one under certain circumstances.

In this section, we will discuss a few of the most important and widely-used notions of convergence of sequences of functions; other notions will appear in certain contexts in other sections. We will emphasize the setting of functions from \(\mathbb{R}\) to \(\mathbb{R}\), but point out how the notions can be extended to more general situations.

IV.3.1. Pointwise and Uniform Convergence

IV.3.1.1. More than once CAUCHY asserted that a (pointwise) limit of a sequence (or sum of an infinite series) of continuous functions is continuous, even after ABEL had observed in 1826 that the statement in CAUCHY’s 1821 text *Cours d’analyse* was false; CAUCHY still claimed in 1833 that the sum of a pointwise convergent Fourier series is continuous, and even in 1853 when he in effect added uniform convergence to the statement in the *Cours d’analyse* (and to its proof), he pointedly declined to retract his previous assertions, representing the change as a “clarification” rather than a “correction.”

A. ROBINSON [Rob66], I. LAKATOS [Lak78], and D. LAUGWITZ [Lau87–Lau89] have tried to claim that CAUCHY could not have just made a mistake about such a thing and that he was thinking either about transfinite “sequences” of functions or the nonstandard real line (or both). This is no more than a combination of wishful thinking and hero worship. CAUCHY was simply wrong. He was a great mathematician (and a strong proponent of increased rigor in mathematics), but he was somewhat prone to errors in his writing (e.g. his “proof” of the Mean Value Theorem; cf. [Bre07]), and his understanding of the foundations of analysis, while far ahead of his predecessors, was still fairly murky compared to today; the mistake in this case was a lack of understanding of the distinction between pointwise and uniform convergence, which was not definitively clarified (by WEIERSTRASS) until considerably later. CAUCHY’S concept of limit was still based on infinitesimals, but to CAUCHY an infinitesimal was a dynamic concept, a variable real number converging to zero. See [Gra00], [Jah03], [Koe91], and [Bre07] for a discussion.
IV.3.2. U.C. Convergence

Uniform convergence is very nice and has important consequences, but it is in a sense too nice – in many natural situations we do not have uniform convergence. But it turns out that a slightly weaker form of convergence is almost as good, and much more common: uniform convergence on compact sets, or u.c. convergence.

IV.3.2.1. Definition. Let \( X \) be a topological space, and \((f_n)\) a sequence of functions from \( X \) to \( \mathbb{R} \) (or a metric space \( Y \)). If \( f : X \to \mathbb{R} \) (or \( Y \)), then \( f_n \to f \) uniformly on compact sets (u.c.) on \( X \) if \( f_n|_K \to f|_K \) uniformly for every compact subset \( K \) of \( X \).

Note that since singletons are compact, u.c. convergence implies pointwise convergence (but usually turns out to be considerably stronger). Uniform convergence obviously implies u.c. convergence. If \( X \) itself is compact, u.c. convergence on \( X \) is the same as uniform convergence.

IV.3.2.2. Perhaps the most common and important situation is when \( X = \mathbb{R}^n \) or a (usually open) subset. Since a subset of \( \mathbb{R}^n \) is compact if and only if it is closed and bounded, \( f_n \to f \) u.c. on \( X \) if and only if \( f_n|_K \to f|_K \) uniformly for every closed bounded subset \( K \) of \( X \) (note that “closed” means closed in \( \mathbb{R}^n \), not just relatively closed in \( X \)).

The name “u.c. convergence” is not as standard as it should be; it is a very convenient and appropriate abbreviation which we will use frequently (and not just because the author got his Ph.D. at Berkeley!) In Complex Analysis, u.c. convergence of sequences of holomorphic functions on an open set in \( \mathbb{C} \) is usually called normal convergence (X.4.1.1.), but this name seems to be rarely used in a broader context.

IV.3.2.3. By considering partial sums, we can also say what is meant for an infinite series of functions to converge u.c.

Here are some examples showing that u.c. convergence is common and considerably weaker than uniform convergence.

IV.3.2.4. Examples. (i) Let \( f_n : \mathbb{R} \to \mathbb{R} \) be given by \( f_n(x) = x/n \). Then \( f_n \to 0 \) pointwise, but not uniformly. But restricted to any bounded set, \( f_n \to 0 \) uniformly, i.e. \( f_n \to 0 \) u.c.

(ii) On \((0, +\infty)\) (or any subset, e.g. \((0, 1)\)), let \( f_n(x) = \frac{1}{nx} \). Again the sequence converges pointwise to 0 but not uniformly. But any compact subset of \((0, +\infty)\) is contained in an interval \([\epsilon, M]\) for some \( \epsilon, M, 0 < \epsilon < M < +\infty \), and on any such interval the sequence converges uniformly to 0. Thus \( f_n \to 0 \) u.c.

(iii) Consider the infinite series \( \sum_{k=0}^{\infty} x^k \) where the terms are regarded as real-valued functions on \((-1, 1)\) (which is the set of \( x \) for which the series converges). The infinite series converges pointwise to \( f(x) = \frac{1}{1-x} \). More precisely,

\[
\begin{align*}
s_n &= \sum_{k=0}^{n} x^k = \frac{1}{1-x} - \frac{x^n}{1-x} \\
\end{align*}
\]

so, if \( 0 < r < 1 \), for \( x \in [-r, r] \), we have

\[
\left| \frac{1}{1-x} - s_n \right| = \left| \frac{x^n}{1-x} \right| \leq \frac{r^n}{1-r}
\]
which can be made uniformly small by taking \( n \) large enough (depending on \( r \)). Since every closed (in \( \mathbb{R} \)) subset of \((-1, 1)\) is contained in \([-r, r]\) for some \( r < 1 \), the infinite series converges u.c. on \((-1, 1)\).

More generally, any power series converges u.c. on its interval (or open disk) of convergence (\( ) \).

(iii) Let \( (f_n) \) be the sequence of \( ) \) of functions from \([0, 1]\) to \( \mathbb{R} \). Then \( f_n \to 0 \) pointwise but not u.c. (i.e. not uniformly since \([0, 1]\) is compact).

**IV.3.2.5.** **Proposition.** Let \( X \) be a locally compact topological space, and \( f_n, f : X \to \mathbb{R} \) (or a metric space). Then \( f_n \to f \) u.c. if and only if \( f_n \to f \) uniformly on some neighborhood of each point of \( X \).

**Proof:** One direction is obvious, since every point of a locally compact space has a compact neighborhood. Conversely, suppose \( f_n \to f \) on some neighborhood of each point of \( X \). If \( K \) is a compact subset of \( X \), for each \( x \in K \) there is an open neighborhood \( U_x \) of \( x \) on which \( f_n \to f \) uniformly. Finitely many \( U_{x_1}, \ldots, U_{x_m} \) of the \( U_x \) cover \( K \), and \( f_n \to f \) uniformly on \( U_{x_1} \cup \cdots \cup U_{x_m} \) and hence on \( K \).

**IV.3.2.6.** A uniform limit of continuous functions is continuous \( ) \). The same is not true for u.c. convergence in complete generality (XI.16.4.1 (b)); the problem is that a general \( X \) may not have enough compact subsets, illustrated by the fact that there are nondiscrete topological spaces in which every compact subset is finite, and on such a space u.c. convergence is just pointwise convergence, which does not necessarily preserve continuity. But under a mild restriction, u.c. convergence does preserve continuity:

**IV.3.2.7.** **Theorem.** Let \( X \) be a topological space, and \( (f_n) \) a sequence of functions from \( X \) to \( \mathbb{R} \) (or a metric space) converging u.c. to a function \( f \). If each \( f_n \) is continuous on compact sets, then \( f \) is continuous on compact sets.

**Proof:** This is an immediate corollary of \( ) \).

**IV.3.2.8.** **Corollary.** Let \( X \) be a compactly generated (e.g. first countable) topological space (XI.11.11.1.), and \( (f_n) \) a sequence of functions from \( X \) to \( \mathbb{R} \) (or a metric space) converging u.c. to a function \( f \). If each \( f_n \) is continuous, then \( f \) is continuous.

**IV.3.2.9.** The corollary applies if \( X \) is any subset of \( \mathbb{R}^n \), or more generally any subset of a metrizable space. The conclusion is obvious from \( ) \) if \( X \) is locally compact, since continuity is a local property.

**IV.3.3.** **Mean and Mean-Square Convergence**

**IV.3.4.** **Exercises**

**IV.3.4.1.** [Dug78, XII.7.5] Let \( X \) and \( Y \) be topological spaces, and \( f, f_n (n \in \mathbb{N}) \) functions from \( X \) to \( Y \). Say \( f_n \to f \) **continuously** if, whenever \( (x_n) \) is a sequence in \( X \) and \( x_n \to x \), then \( f_n(x_n) \to f(x) \) in \( Y \). Show that if \( X \) is first countable and \( Y \) is a metric space, and \( f \) and the \( f_n \) are continuous, then \( f_n \to f \) continuously if and only if \( f_n \to f \) u.c.
Chapter V

Calculus
V.1. Limits of Functions

The limit of a function at a point is a variation of the notion of limit of a sequence, and is one of the most fundamental ideas in calculus and analysis. In this section, we consider only limits of functions from $\mathbb{R}$ to $\mathbb{R}$; in later sections, the situation will be generalized in a number of ways.

V.1.1. Ordinary Limits

V.1.1.1. Suppose $f$ is a real-valued function defined at least on an interval around a real number $a$, except possibly at $a$ itself (i.e. defined at least on a deleted neighborhood of $a$). If we don’t know the value $f(a)$ or even whether this value exists, but can calculate $f(x)$ for all $x$ near $a$ but different from $a$, we want to determine what $f(a)$ “ought to be” (it will be impossible to determine whether this prediction is correct without knowledge about the value precisely at $a$). Geometrically, we consider the graph $y = f(x)$ and cover up the vertical line $x = a$, and try to determine where the point of the graph on this line should be from what can be seen:

When I teach limits in Calculus, I take a piece of string to class and cover up the line $x = a$ on various graphs, and ask the students where the point, if any, under the string is and where it should be. Note that it will be impossible to determine from what can be seen whether there is in fact a point of the graph on this line, or, if so, where it is, but it can in many (but not all) cases be determined where it ought to be. Informally, we will say the limit of the function as $x$ approaches $a$ will be the $y$-coordinate of the point on
this vertical line (i.e. with $x$-coordinate $a$) which “should” be on the graph, if it can in fact be determined, and otherwise that the limit does not exist.

**V.1.1.2.** More formally, as in the case of limits of sequences, we will say that the limit of $f(x)$ as $x$ approaches $a$ is $L$, written

$$\lim_{x \to a} f(x) = L$$

or $f(x) \to L$ as $x \to a$, if $f(x)$ can be made arbitrarily close to $L$ by making $x$ close enough to $a$, but never equal to $a$. This can be phrased similarly to the definition of limit of a sequence, with a slight variation:

**V.1.1.3.** Definition. Let $V$ be a deleted neighborhood of $a \in \mathbb{R}$, $F : V \to \mathbb{R}$ a function, and $L \in \mathbb{R}$. Then the limit of $f(x)$ as $x$ approaches $a$ is $L$ if, for every $\epsilon > 0$, there is a $\delta > 0$ such that

$$|f(x) - L| < \epsilon$$

for all $x \in V$ for which $0 < |x - a| < \delta$.

Note that the inequality “$0 < |x - a| < \delta$” is just a slick way of writing “$a - \delta < x < a + \delta$ and $x \neq a$.”

**V.1.1.4.** Geometrically, $\lim_{x \to a} f(x) = L$ if, for any $\epsilon > 0$, no matter how small, if we draw the horizontal lines $y = L + \epsilon$ and $y = L - \epsilon$ above and below $y = L$, then there are vertical lines $x = a - \delta$ and $x = a + \delta$ to the left and right of $a$, such that the part of the graph $y = f(x)$ between these two vertical lines lies between the two horizontal lines, except possibly when $x = a$ (Figure V.2).

**V.1.1.5.** As with sequences (IV.1.3.9.), the definition of limit of a function can be described as a game or bet. If I claim that $\lim_{x \to a} f(x) = L$ and you challenge me, you give me an $\epsilon > 0$ and I must produce a $\delta > 0$ that works in the definition for your $\epsilon$. If I can, I win; if I can’t, you win. The smaller your $\epsilon$ is, the harder it is for me to find a $\delta$, and the smaller it will have to be in general. But I don’t have to choose my $\delta$ until you give me your $\epsilon$; my $\delta$ can (and in general will) depend on your $\epsilon$. If one $\delta$ works for a given $\epsilon$, then any smaller $\delta$ also works for the same $\epsilon$, so I don’t have to find the largest possible $\delta$ for your $\epsilon$; a smaller one which is easier to find will work just as well. Similarly, a $\delta$ which works for one $\epsilon$ will also work for any larger $\epsilon$. A limit proof will be a demonstration that I can always win the bet no matter what $\epsilon$ you give me.

**V.1.1.6.** To apply the definition of limit directly, the limit $L$ must be “guessed.” Thus, to just show that a limit exists, and especially to show that a limit does not exist, one must work somewhat indirectly in a manner similar to the one in ( ).

**V.1.1.7.** Note that in the definition of limit, the $x$ is allowed to be either to the right of $a$ ($x > a$) or to the left of $a$ ($x < a$). Thus the limit is often called the “two-sided limit” for emphasis. (But “limit” will always for us mean “two-sided limit” unless otherwise specified.) The “limit” as defined in V.1.1.3. is also sometimes called the “ordinary limit” to distinguish it from the extended notions of limit discussed in ( ).

**V.1.1.8.** Of course, $\lim_{x \to a} f(x)$ depends not only on the function $f$ but also on the number $a$: for a fixed $f$, the limit can potentially be defined for any $a$, although in practice the limit is particularly important only for certain $a$’s depending on $f$. 513
Note that there is a huge conceptual difference for a function $f$ between the value of $f$ at $a$ and the limit of $f$ as $x$ approaches $a$. Either can exist without the other, and if they both exist they may or may not be numerically equal. It turns out that for “most” functions encountered naturally, and for “most” $a$, the two both exist and are numerically equal (the notion of continuity discussed in ()); this fact is ultimately very pleasant and significant, but can be confusing for beginners trying to distinguish between the concepts.

The following principle is basic in the study of limits:

**Proposition.** Let $f$ and $g$ be functions defined in at least a deleted neighborhood of $a$. If $f(x) = g(x)$ for all $x$ in a deleted neighborhood of $a$, and $\lim_{x \to a} f(x)$ exists, then $\lim_{x \to a} g(x)$ also exists and equals $\lim_{x \to a} f(x)$.

Note that we do not require that $f(a) = g(a)$, or even that either or both of these numbers are defined.

**Examples.** (i) Let $f(x) = x + 1$, $g(x) = \frac{x^2 - 1}{x - 1}$,

$$h(x) = \begin{cases} x + 1 & \text{if } x \neq 1 \\ 3 & \text{if } x = 1 \end{cases}.$$
We have that $f(1) = 2$, $g(1)$ does not exist, and $h(1) = 3$. The graph of $f$ is a straight line with slope 1 and $y$-intercept 1; the graph of $g$ is the same line with the point $(1, 2)$ removed, and the graph of $h$ is the line with $(1, 2)$ removed and $(1, 3)$ added. If the vertical line $x = 1$ is covered, the graphs appear identical.

We guess that $\lim_{x \to 1} f(x) = 2$. To prove this, let $\epsilon > 0$. We must find a $\delta > 0$ such that

$$|f(x) - 2| = |x + 1 - 2| = |x - 1| < \epsilon$$

whenever $0 < |x - 1| < \delta$. We can clearly take $\delta = \epsilon$, proving the result. This simple formula makes sense since the graph is a straight line with slope 1 (if the line had slope $m$ we would take $\delta = \frac{\epsilon}{m}$; if the function were nonlinear the formula would generally be more complicated).

Since $g(x) = h(x) = f(x)$ for $x \neq 1$, we also have

$$\lim_{x \to 1} g(x) = \lim_{x \to 1} h(x) = 2$$

by V.1.1.10.; these can be proved directly with exactly the same argument as for $f$. Note that $g$ has a limit but no value at 1, while $h$ has both a value and a limit at 1 but they are not numerically equal.

(ii) Set

$$f(x) = \frac{|x|}{x} = \begin{cases} 
1 & \text{if } x > 0 \\
-1 & \text{if } x < 0 
\end{cases}$$

$$g(x) = \begin{cases} 
1 & \text{if } x \geq 0 \\
-1 & \text{if } x < 0 
\end{cases}$$

Then neither $\lim_{x \to 0} f(x)$ nor $\lim_{x \to 0} g(x)$ exists, by an argument almost identical to the one in (i). (These functions have one-sided limits at 0.) Although $f(0)$ does not exist, we have that $g(0) = 1$. Thus $g$ has a value but no limit at 0.

(iii) Let $f(x) = \sin \frac{1}{x}$, $g(x) = x \sin \frac{1}{x}$ for $x \neq 0$. Neither $f$ nor $g$ has a value at 0. Also, $\lim_{x \to 0} f(x)$ does not exist; there are not even one-sided limits. See Figure (). But $\lim_{x \to 0} g(x)$ does exist: it equals 0. For let $\epsilon > 0$. Set $\delta = \epsilon$. If $0 < |x - 0| = |x| < \delta$, we have

$$|g(x) - 0| = \left| x \sin \frac{1}{x} \right| \leq |x| < \delta = \epsilon$$

since $|\sin \frac{1}{x}| \leq 1$ for all $x \neq 0$. See Figure ().

(iv) Let $f(x) = \sqrt{x}$. If $a > 0$, $\lim_{x \to a} f(x)$ exists and equals $\sqrt{a}$. But $\lim_{x \to 0} f(x)$ cannot exist since $f$ is not defined in any entire deleted neighborhood of 0. We do have a one-sided limit of 0 from the right in this case ().

V.1.3. Limit Theorems and Indeterminate Forms
V.1.4. One-Sided Limits
V.1.5. Extended Limits
V.1.6. Limit Superior and Limit Inferior
V.1.7. Exercises

V.1.7.1. ([dlVP46, 87, Ex.6], attributed to CAUCHY) Let $\phi$ be a real-valued function on an interval $(a, +\infty)$. Suppose $\lim_{x \to +\infty} [\phi(x + 1) - \phi(x)]$ exists (in the usual or extended sense) and equals $L$.

(a) If $\phi$ is bounded on $[b, b + 1]$ for all sufficiently large $b$ (e.g., if $\phi$ is continuous), show that $\lim_{x \to +\infty} \frac{\phi(x)}{x}$ also exists and equals $L$.

(b) Show that $\lim_{x \to +\infty} \frac{\phi(x)}{x}$ need not exist if no boundedness assumption is made. [Consider a Hamel basis for $\mathbb{R}$ over $\mathbb{Q}$ which contains 1 and is not bounded above, and let $\phi(x)$ be the coefficient of 1 in the expansion of $x$ with respect to this basis.] But if the limit does exist, it must equal $L$.

(c) Suppose $\psi$ is a function from $(a, +\infty)$ to $(0, +\infty)$ for which $\lim_{x \to +\infty} \frac{\psi(x + 1)}{\psi(x)}$ exists and equals $L$. Find similar conditions on $\psi$ insuring that $\lim_{x \to +\infty} [\psi(x)]^{1/x}$ exists (and then necessarily equals $L$). [Consider $\phi = \log \psi$.] Compare with IV.2.3.11.
V.2. Continuity on $\mathbb{R}$

“[Mathematicians before the early 19th century] assumed that any sensible formula, such as a polynomial, automatically defined a continuous function. But they had never proved this. In fact, they couldn’t prove it, because they hadn’t defined ‘continuous.’ The whole area was awash with vague intuitions, most of which were wrong.”

Ian Stewart

V.2.1. Continuity at a Point

V.2.2. Continuity on a Set

In discussions and uses of continuity, it is much more common to use the notion of continuity on a set rather than continuity at a point. The transition between the two is simple but involves a subtlety which must be understood. It should be noted that conventions vary in references as to the meaning of the phrase “continuity on a set $A$,” and the convention in any reference should be noted carefully. We have picked the convention which seems the most common and useful.

The definition is a slight variation of ():

V.2.2.1. Definition. Let $f$ be a real-valued function defined on a subset of $\mathbb{R}$, and let $A$ be a subset of the domain of $f$. Then $f$ is continuous on $A$ if, for every $a \in A$ and $\epsilon > 0$, there is a $\delta > 0$ such that $|f(x) - f(a)| < \epsilon$ whenever $x \in A$ and $|x - a| < \delta$.

V.2.2.2. If $f$ is continuous (in the sense of ()) at every point of $A$, then $f$ is continuous on $A$. The converse is false in general, since in V.2.2.1. only values of the function at points of $A$ are considered; if a point $a$ of $A$ is a limit point of $A^c$ the behavior of $f$ on $A^c$ can force $f$ to be discontinuous at $a$, but will not affect whether $f$ is continuous on $A$.

V.2.2.3. Examples. (i) Let

$$f(x) = \begin{cases} 1 & \text{if } x \geq 0 \\ 0 & \text{if } x < 0 \end{cases}.$$  

Then $f$ is discontinuous at 0, but it is continuous on $[0, \infty)$.

(ii) More generally, if $f = \chi_A$ is the indicator function of a set $A \subseteq \mathbb{R}$, then $f$ is continuous on $A$ since it is a constant function on $A$. Similarly, $f$ is continuous on $A^c$. But $f$ can be discontinuous at many numbers: e.g. if $A = \mathbb{Q}$, $f$ is discontinuous everywhere (i.e. at every $a \in \mathbb{R}$).

(iii) If $A = \{a\}$, then any real-valued function defined at $a$ is continuous on $\{a\}$ since the condition in the definition is essentially vacuous. Thus “continuity on $\{a\}$” is quite different from “continuity at $a$.” The similarity of the terminology is somewhat unfortunate, but such near-ambiguity is unavoidable.

V.2.2.4. Continuity on a set $A$ is most frequently used when $A$ is either an open set or a closed or half-open interval. In these cases, the ambiguities largely disappear:

1[?, p. 151].

517
**V.2.2.5.** Proposition. Let \( f \) be a real-valued function on a subset of \( \mathbb{R} \), and \( U \) an open set in \( \mathbb{R} \) contained in the domain of \( f \). Then \( f \) is continuous on \( U \) if and only if \( f \) is continuous (in the sense of (i)) at \( a \) for every \( a \in U \).

**V.2.2.6.** Proposition. Let \( f \) be a real-valued function on a subset of \( \mathbb{R} \), and \( I \) an interval in \( \mathbb{R} \) contained in the domain of \( f \). Then \( f \) is continuous on \( I \) if and only if \( f \) is continuous (in the sense of (i)) at \( a \) for every \( a \) in the interior of \( I \), and right continuous () at the left endpoint of \( I \) and left continuous () at the right endpoint of \( I \) when there are such endpoints in \( I \).

In other words, \( f \) is continuous on \([a, b]\) if and only if it is continuous at every point of \((a, b)\), right continuous at \( a \), and left continuous at \( b \); it is continuous on \([a, b]\) if and only if it is continuous at every point of \((a, b)\) and right continuous at \( a \), etc.

**V.2.2.7.** We say a function \( f \) defined on a subset of \( \mathbb{R} \) is **continuous** if it is continuous on its domain.

### Three Characterizations of Continuity

There is a sequential criterion for continuity on a set:

**V.2.2.8.** Theorem. [Sequential Criterion] Let \( f \) be a real-valued function on a subset of \( \mathbb{R} \), and \( A \) a subset of \( \mathbb{R} \) contained in the domain of \( f \). Then \( f \) is continuous on \( A \) if and only if, whenever \( (x_n) \) is a sequence in \( A \), \( x_n \to x \), and \( x_n \to x \), we have \( f(x_n) \to f(x) \).

Note that in this criterion, the terms \( x_n \) of the sequence and the limit \( x \) must all be in \( A \).

**Proof:** Suppose \( f \) is continuous on \( A \), and let \( (x_n) \) be a sequence in \( A \) converging to \( x \in A \). Let \( \epsilon > 0 \). Since \( f \) is continuous at \( x \), there is a \( \delta > 0 \) such that \( |f(y) - f(x)| < \epsilon \) for all \( y \in A \) with \( |y - x| < \delta \). There is an \( N \) such that \( |x_n - x| < \delta \) for all \( n \geq N \). Then \( |f(x_n) - f(x)| < \epsilon \) for all \( n \geq N \). Thus \( f(x_n) \to f(x) \).

Conversely, suppose the sequential criterion is satisfied. If \( f \) is not continuous on \( A \), then there is an \( x \in A \) and \( \epsilon > 0 \) for which there is no corresponding \( \delta \) with \( |f(y) - f(x)| < \epsilon \) whenever \( y \in A \) and \( |y - x| < \delta \); thus, for this \( x \) and \( \epsilon \), for each \( n \in \mathbb{N} \) there is an \( x_n \in A \) with \( |x_n - x| < \frac{1}{n} \) but \( |f(x_n) - f(x)| \geq \epsilon \). So \( x_n \to x \) but \( f(x_n) \not\to f(x) \), a contradiction.

Note that the Countable AC is used in this proof. (In fact, this theorem cannot be proved in ZF.)

There is a third standard characterization of continuity in terms of preimages:

**V.2.2.9.** Theorem. Let \( A \subseteq \mathbb{R} \), and \( f : A \to \mathbb{R} \) a function. Then the following are equivalent:

(i) \( f \) is continuous on \( A \).

(ii) The preimage of every open set in \( \mathbb{R} \) is (relatively) open in \( A \).

(iii) The preimage of every open interval in \( \mathbb{R} \) is (relatively) open in \( A \).

(iv) The preimage of every closed set in \( \mathbb{R} \) is (relatively) closed in \( A \).
Proof: (ii) and (iv) are transparently equivalent since preimages respect complements (). (ii) \( \Rightarrow \) (iii) is trivial.

(i) \( \Rightarrow \) (ii): Suppose \( f \) is continuous, and let \( U \) be an open set in \( \mathbb{R} \), and \( x \in f^{-1}(U) \). There is an \( \epsilon > 0 \) such that \( \{ y \in \mathbb{R} : |y - f(x)| < \epsilon \} \subseteq U \) since \( U \) is open, and there is a \( \delta > 0 \) such that \( |f(z) - f(x)| < \epsilon \) whenever \( z \in A \) and \( |z-x| < \delta \) since \( f \) is continuous at \( x \). Thus if \( z \in A \), \( |z-x| < \delta \), then \( f(z) \in U \), i.e. \( z \in f^{-1}(U) \).

So \( f^{-1}(U) \) is open.

(iii) \( \Rightarrow \) (i): Let \( x \in A \) and \( \epsilon > 0 \). Let \( U = \{ y \in \mathbb{R} : |y - x| < \epsilon \} \). Then \( U \) is an open interval, so \( f^{-1}(U) \) is relatively open in \( A \) by assumption. Since \( x \in f^{-1}(U) \), there is a \( \delta > 0 \) such that \( A \cap (x-\delta, x+\delta) \subseteq f^{-1}(U) \).

If \( z \in A \), \( |z-x| < \delta \), then \( z \in f^{-1}(U) \), i.e. \( f(z) \in U \), \( |f(z) - f(x)| < \epsilon \). So \( f \) is continuous at \( x \).

V.2.2.10. Thus we have three equivalent characterizations of continuous functions:

(i) The \( \epsilon - \delta \) characterization (definition).

(ii) The sequential criterion.

(iii) The preimage characterization.

Each is useful in different contexts: some applications are much easier using one or the other characterization.

There are more general settings for continuity: metric spaces () and, even more generally, topological spaces (). Characterization (i) is special to metric spaces. The sequential criterion is valid more generally in topological spaces for which sequences determine the topology (first-countable topological spaces). Only the third is appropriate in general topological spaces, and is taken as the definition of continuity in general spaces. The three characterizations are equivalent in metric spaces (). The definition V.2.2.1. precisely says that a function from \( \mathbb{R} \) (or a subset) to \( \mathbb{R} \) is continuous on a subset \( A \) of its domain if and only if the restriction of \( f \) to \( A \) is continuous in this generalized sense when \( A \) is given the relative or subspace topology.

V.2.3. The Intermediate Value Theorem

One of the most important properties of a continuous function on an interval is that its range is also an interval, i.e. that it takes all intermediate values between any two of its values:

V.2.3.1. **Theorem.** [Intermediate Value Theorem (IVT)] Let \( I \) be an interval in \( \mathbb{R} \), \( f : I \to \mathbb{R} \) a continuous function, and \( a, b \in I \). If \( d \) is any real number between \( f(a) \) and \( f(b) \), then there is at least one \( c \) between \( a \) and \( b \) with \( f(c) = d \).

V.2.3.2. Geometrically, the graph of \( f \) gives an “unbroken” curve between \( (a, f(a)) \) and \( (b, f(b)) \), and thus any horizontal line of intermediate height must intersect it (Figure () is the case \( f(a) < f(b) \); the other case is similar).

This picture, although informal, gives a clue how to prove the theorem from the Completeness Axiom (): take the supremum of the \( x \)-coordinates of all points on the graph below (or on) the line; this should be the \( x \)-coordinate of the “last” point of intersection (we could equally well take the infimum for points above the line, giving the “first” point of intersection; of course, there may be many other points of intersection too). In fact, the IVT is equivalent to the Completeness Axiom (Exercise ()).
Proof: We may assume without loss of generality that $a < b$. Suppose $f(a) < f(b)$ (the case $f(a) > f(b)$ is similar, and if $f(a) = f(b)$ there is nothing to prove). Fix $d$ with $f(a) < d < f(b)$, and set

$$S = \{ x \in [a,b] : f(x) \leq d \}.$$  

Then $S$ is a nonempty subset of $[a,b]$ since $a \in S$. Set $c = \sup S$. We claim $f(c) = d$. If $f(c) \neq d$, then there is a $\delta > 0$ such that $|f(x) - f(c)| < |f(c) - d|$ for $x \in [a,b]$, $|x - c| < \delta$. If $f(c) > d$, then $f(x) > d$ for $c - \delta < x < c$ and $c - \delta$ is an upper bound for $S$, a contradiction. And if $f(c) < d$, then $c \neq b$ and if $x \in [a,b]$, $c < x < c + \delta$, then $f(x) < d$, contradicting that $c$ is an upper bound for $S$. 

**V.2.3.3.** Corollary. Let $f$ be a continuous real-valued function on an interval $I$. Then $f(I)$ is an interval (or single point if $f$ is constant on $I$).

**V.2.3.4.** This result can be done in the more general context of connected subsets of topological spaces: a continuous image of a connected set is connected (XI.13.2.1). The connected subsets of $\mathbb{R}$ are precisely the intervals and singletons (degenerate intervals); cf. XI.13.1.7.

**V.2.3.5.** The IVT has many applications. For example, we get a simple proof of III.1.12.2: if $f(x) = x^n$, then $f(0) = 0$ and $f(1) = 1$, and $f$ is continuous, so $f$ takes all values between 0 and 1 on $[0,1]$, i.e. every number between 0 and 1 has an $n$’th root between 0 and 1 (which is unique since $f$ is strictly increasing). For numbers larger than 1, consider reciprocals.

We also get the following important algebraic fact:

**V.2.3.6.** Theorem. Every polynomial of odd order with real coefficients has at least one real root.

Proof: There is no loss of generality to consider monic polynomials. So let

$$f(x) = x^n + a_{n-1}x^{n-1} + \cdots + a_1x + a_0$$

be a monic polynomial with $n$ odd and $a_k \in \mathbb{R}$. We have

$$\frac{f(x)}{x^n} = 1 + \frac{a_{n-1}}{x} + \cdots + \frac{a_0}{x^n}$$

for $x \neq 0$, so if

$$|x| > \max (1, n|a_0|, \ldots, n|a_{n-1}|)$$

we have $\frac{f(x)}{x^n} > 0$. Thus, if $x$ is sufficiently large positive, $f(x) > 0$. And, since $n$ is odd, $x^n < 0$ if $x < 0$, so $f(x) < 0$ if $x$ is sufficiently large negative. Thus $f$ takes both positive and negative values, so also takes the value 0 by the IVT since it is continuous.
V.2.3.7. This can also be proved from the Fundamental Theorem of Algebra (X.1.4.2.), since for polynomials with real coefficients the nonreal complex roots come in conjugate pairs, so there are an even number of nonreal roots. This argument gives the slightly stronger result that a polynomial of odd degree with real coefficients always has an odd number of real roots (counted with multiplicity); this can be proved directly from V.2.3.6. by dividing out a linear factor for each root. If an even number of factors is divided out, the resulting polynomial still has odd degree.

V.2.3.8. A similar argument can be efficiently used to locate real roots of a polynomial or any other continuous function: find a decreasing sequence of subintervals on which the function changes sign, say by successive bisection; the point of intersection of the intervals is a root.

V.2.4. The Max-Min Theorem
A second crucial result about continuous functions concerns attaining maximum and minimum values on closed bounded sets. The proof uses the Bolzano-Weierstrass Theorem (); in fact this result is also equivalent to the Completeness Axiom (Exercise ()).

V.2.4.1. Theorem. [Max-Min Theorem or Extreme Value Theorem] Let \( f \) be a continuous real-valued function on a closed bounded subset \( A \) of \( \mathbb{R} \). Then \( f \) is bounded on \( A \), and attains its maximum and minimum on \( A \): there are \( c,d \in A \) such that \( f(d) \leq f(x) \leq f(c) \) for all \( x \in A \).

Proof: We first show that \( f \) is bounded above. If not, then there is a sequence \( (x_n) \) in \( A \) with \( f(x_n) \geq n \) for all \( n \). By Bolzano-Weierstrass, there is a convergent subsequence \( (x_{k_n}) \) since \( A \) is bounded, say \( x_{k_n} \to a \). We have \( a \in A \) since \( A \) is closed. But then \( f(x_{k_n}) \to f(a) \) by the Sequential Criterion, a contradiction since \( (f(x_{k_n})) \) is unbounded (IV.1.3.16.).

Let \( M = \sup_{x \in A} f(x) \). Then, for each \( n \in \mathbb{N} \), there is an \( x_n \in A \) with \( f(x_n) > M - \frac{1}{n} \). Thus \( f(x_n) \to M \). By B-W, there is a convergent subsequence \( (x_{k_n}) \). Set \( c = \lim_{n \to \infty} x_{k_n} \). Then \( c \in A \), and \( f(x_{k_n}) \to f(c) \) by the Sequential Criterion. But \( f(x_{k_n}) \to M \) by (); thus \( f(c) = M \).

The argument that \( f \) is bounded below and attains its minimum is almost identical. \( \Box \)

Note that this proof uses the Countable AC. (But the result does not require any form of choice; cf. XI.11.1.8.) Also note that, as in the IVT, the \( c \) and \( d \) are not necessarily unique.

V.2.4.2. What is really going on here is compactness: a subset of \( \mathbb{R} \) is compact if and only if it is closed and bounded (XI.11.1.5.), and a continuous image of a compact set is compact (XI.11.1.7.).

V.2.4.3. Examples. The result may fail if the set \( A \) is not closed or not bounded, or if \( f \) is not continuous on \( A \).

(i) The function \( f(x) = x \) is not bounded on \( [0, \infty) \). It is bounded on \( A = [0,1) \) but does not attain a maximum on \( A \).

(ii) The function \( g(x) = \frac{1}{x} \) is continuous on the bounded set \( (0,1] \) but is not bounded above. If we set

\[
g(x) = \begin{cases} \frac{1}{x} & \text{if } x \neq 0 \\ 0 & \text{if } x = 0 \end{cases}
\]
then $g$ is not bounded above on the closed bounded interval $[0, 1]$ (of course, it is not continuous on $[0, 1]$).

(iii) Set

$$f(x) = \begin{cases} x & \text{if } x \neq 1 \\ 0 & \text{if } x = 1 \end{cases}$$

Then $f$ is bounded above on $[0, 1]$, but does not attain a maximum on $[0, 1]$ (again, it is not continuous on $[0, 1]$).

**V.2.5. Continuity and Oscillation**

It is often fruitful to think of continuity of functions in terms of oscillations.

**V.2.5.1. Definition.** Let $f$ be a real-valued function defined on an interval $I$.

(i) If $\emptyset \neq A \subseteq I$, define the oscillation of $f$ on $A$ to be

$$\omega(f, A) = \sup\{|f(x) - f(y)| : x, y \in A\} \in [0, +\infty].$$

(ii) If $x \in I$, define the oscillation of $f$ at $x$ to be

$$\omega(f, x) = \inf\{\omega(f, U) : U \text{ a neighborhood of } x\} \in [0, +\infty].$$

The next proposition is obvious.

**V.2.5.2. Proposition.** (i) If $\emptyset \neq A \subseteq B \subseteq I$, then $\omega(f, A) \leq \omega(f, B)$.

(ii) If $x \in I$, then $\omega(f, x) = \inf\{\omega(f, U) : U \text{ an open neighborhood of } x\}$.

(iii) $f$ is continuous at $x \in I$ if and only if $\omega(f, x) = 0$.

*Proof of (iii):* If $\omega(f, x) = 0$, then for every $\epsilon > 0$ there is a neighborhood $U$ of $x$ such that $\omega(f, U) < \epsilon$. There is a $\delta > 0$ such that $(x - \delta, x + \delta) \subseteq U$. Then $\omega(f, (x - \delta, x + \delta)) < \epsilon$ by (i), so if $y \in (x - \delta, x + \delta)$, we have $|f(x) - f(y)| < \epsilon$.

Conversely, suppose $f$ is continuous at $x$, and $\epsilon > 0$. There is a $\delta > 0$ such that if $y \in (x - \delta, x + \delta)$, $|f(x) - f(y)| < \frac{\epsilon}{2}$. Then, if $y, z \in (x - \delta, x + \delta)$,

$$|f(y) - f(z)| \leq |f(y) - f(x)| + |f(x) - f(z)| < \epsilon$$

so $\omega(f, (x - \delta, x + \delta)) \leq \epsilon$. Since $\epsilon > 0$ is arbitrary, $\omega(f, x) = 0$.

The next observation is important and useful:
V.2.5.3. **Proposition.** Let \( f \) be a real-valued function on an open interval \( I \), and \( \epsilon > 0 \). Then
\[
\{ x \in I : \omega(f, x) < \epsilon \}
\]
is an open set.

**Proof:** Call the set \( A \). If \( x \in A \), then there is an open neighborhood \( U \) of \( x \) with \( \omega(f, U) < \epsilon \). If \( y \in U \), then \( U \) is also an open neighborhood of \( y \), so \( \omega(f, y) \leq \omega(f, U) < \epsilon \). Thus \( y \in A \), \( U \subseteq A \).

V.2.5.4. **Corollary.** Let \( f \) be a real-valued function on an interval \( I \). Then the set of points where \( f \) is continuous is a \( G_\delta \), i.e. the set of discontinuities of \( f \) is an \( F_\sigma \).

**Proof:** We may assume that \( I \) is open (why?) If \( A \) is the set of points where \( f \) is continuous, then
\[
A = \{ x \in I : \omega(f, x) = 0 \} = \bigcap_{n=1}^{\infty} \left\{ x \in I : \omega(f, x) < \frac{1}{n} \right\}.
\]
V.3. Differentiation and Derivatives

The derivative of a function is of great importance, both theoretical and practical. It is the principal topic in any calculus course. The process of finding and using the derivative of a function is called differentiation.

V.3.1. The Derivative

The derivative of a function can be described in many ways: the instantaneous rate of change of the function, the slope of the tangent line to the graph of the function, and the best linear approximation to the function are three of the most common.

The Tangent Line to the Graph of a Function

V.3.1.1. There is an intuitive notion of “tangent line” to a curve at a point on the curve. Informally, the tangent line to the curve at the point $P$ is the line which just “touches” the curve at $P$ but does not cross it (indeed, the word “tangent” comes from the Latin tangere, which means “to touch”). This definition is adequate for some simple curves: for example, the tangent line to a circle at a point $P$ is the line perpendicular to the diameter line of the circle through $P$ (this is easily seen to be the only line through $P$ which does not “cross” the curve). Indeed, this turns out to be the “generic” situation.

V.3.1.2. But simple examples show that this intuitive definition is inadequate in general. For example, the $x$-axis is clearly the only reasonable candidate for the tangent line to the curve $y = x^3$ at the origin, but it “crosses” the curve there:

![Maple plot of graph of $f(x) = x^3$](maple_plot.png)

Figure V.3: Maple plot of graph of $f(x) = x^3$
V.3.1.3. For more complicated curves, such as the graph of \( f(x) = x^2 \sin \frac{1}{x^2} \) (extended by setting \( f(0) = 0 \)), this definition is even more inadequate (Figure V.4).

![Maple plot of graph of \( f(x) = x^2 \sin \frac{1}{x^2} \)](image)

Figure V.4: Maple plot of graph of \( f(x) = x^2 \sin \frac{1}{x^2} \)

It is clear that the “tangent line” at the origin, if it exists, must again be the \( x \)-axis, but this line crosses the curve infinitely often in any interval around 0.

V.3.1.4. In addition, if there is a line through \( P \) which does not “cross” the curve, there may be more than one. For example, consider the curve \( y = |x| \). Any line through the origin with slope strictly between \(-1\) and \(1\) just “touches” the curve and does not cross it. Which, if any, of these lines should be considered the “tangent line”?

V.3.1.5. Finally, suppose the curve itself is a straight line. What could the “tangent line” be but the line itself? But how does this line just “touch” the original line?
The Difference Quotient

**V.3.1.6.** Mathematicians wrestled for a long time with the difficulties in making a proper definition of tangent line, and finally came up with a satisfactory dynamic definition, now recognized as a limit.

If we want to define the tangent line at \( P \), we take an indirect approach. Suppose \( Q \) is another point on the curve. Then there is a unique line through \( P \) and \( Q \), called the *secant line* to the curve through \( P \) and \( Q \). (Note that, as with tangent lines, the term “secant line” has nothing to do with trigonometry; the word “secant” comes from the Latin *secare*, “to cut”.) If \( P \) is held fixed and \( Q \) “approaches” \( P \), the secant line should “approach” the tangent line at \( P \).

**V.3.1.7.** To make this precise, suppose the curve is the graph of a function \( f \), and that \( P = (a; f(a)) \). If \( Q = (b; f(b)) \), the line through \( P \) and \( Q \) has slope
\[
\frac{f(b) - f(a)}{b - a}
\]
as long as \( P \neq Q \), i.e. \( b \neq a \).

We want to regard \( a \) as fixed and let \( b \) vary, so we usually use a variable name like \( x \) or \( t \) instead of \( b \).

**V.3.1.8.** Definition. Let \( f \) be a function defined on an open interval \( I \) around \( a \in \mathbb{R} \). Then the *difference quotient* of \( f \) at \( a \) with variable \( x \) is
\[
\frac{f(x) - f(a)}{x - a}
\]
which is defined for \( x \in I, x \neq a \).

**Definition of the Derivative**

We can then make the main definition:

**V.3.1.9.** Definition. Let \( f \) be defined in an open interval around \( a \in \mathbb{R} \). Then \( f \) is *differentiable at \( a \)* if
\[
\lim_{x \to a} \frac{f(x) - f(a)}{x - a}
\]
exists. If it exists, it is called the *derivative* of \( f \) at \( a \), denoted \( f'(a) \).

Note that this is an *ordinary two-sided limit*, i.e. \( x \) can be either larger or smaller than \( a \), and the limit must be finite, not \( \pm \infty \).

Then we can make a careful definition of tangent line:

**V.3.1.10.** Definition. Let \( f \) be a function defined on an open interval \( I \), and \( a \in I \). If \( f \) is differentiable at \( a \), then the *tangent line* to the graph \( y = f(x) \) at \( a \) is the line through \( (a, f(a)) \) with slope \( f'(a) \).

**V.3.1.11.** If \( f \) is not differentiable at \( a \), we will generally say that the graph has no tangent line at \( (a, f(a)) \). (This may not always be accurate: the graph of a function can have a vertical tangent line at some points. We will discuss this more carefully in ( ).)
Differentiability vs. Continuity

We will see in the next few sections that “most” functions which are naturally encountered are differentiable wherever they are defined. However, there is one obvious situation which prevents differentiability: a discontinuity. Since a differentiable function is “approximately linear” near \( a \), and linear functions are continuous, it is not surprising that differentiable functions are continuous:

**V.3.1.12. Proposition.** Let \( f \) be a function defined on an open interval \( I \), and \( a \in I \). If \( f \) is differentiable at \( a \), then \( f \) is continuous at \( a \).

**Proof:** If \( f \) is differentiable at \( a \), then

\[
\lim_{x \to a} \frac{f(x) - f(a)}{x - a}
\]

exists. Since \( \lim_{x \to a} (x - a) = 0 \), we must also have \( \lim_{x \to a} (f(x) - f(a)) = 0 \) by (). But this is just the definition of continuity of \( f \) at \( a \). \( \blacksquare \)

**V.3.1.13.** However, continuity of \( f \) at \( a \) is not sufficient to give differentiability at \( a \), as the following example shows. Thus differentiability at \( a \) is a strictly stronger than condition than continuity.

**V.3.1.14. Example.** Let \( f(x) = |x| \). Then \( f \) is continuous at \( 0 \) (). But \( f \) is not differentiable at \( 0 \): the difference quotient

\[
\frac{f(x) - f(0)}{x - 0} = \frac{|x|}{x}
\]

is 1 if \( x > 0 \) and \(-1\) if \( x < 0 \). Thus the limit as \( x \to 0 \) does not exist ().

Here is a dramatic example that shows that differentiability at \( a \) does not imply continuity anywhere except at \( a \):

**V.3.1.15. Example.** Let

\[
f(x) = \begin{cases} 
x^2 & \text{if } x \in \mathbb{Q} \\
0 & \text{if } x \notin \mathbb{Q}
\end{cases}
\]

Then \( f \) is discontinuous everywhere except at \( 0 \) (). But \( f \) is differentiable at \( 0 \) since

\[
\left| \frac{f(x) - f(0)}{x - 0} \right| = \left| \frac{f(x)}{x} \right| \leq |x|
\]

for \( x \neq 0 \), and hence \( f'(0) \) exists and equals 0 by the Squeeze Theorem ().
**Geometric Interpretation of the Tangent Line**

**V.3.1.16.** A somewhat informal but conceptually excellent way to interpret the tangent line to a curve is by magnification. If a curve has a tangent line at the point \( P \), then when smaller and smaller pieces of the curve around \( P \) are magnified more and more, they become increasingly almost indistinguishable from the tangent line at \( P \) (see e.g. https://www.ima.umn.edu/~arnold/calculus/tangent/tangent-g.html, http://archives.math.utk.edu/visual.calculus/2/tangents.5/, or https://www.geogebra.org/material/simple/id/335793).

Conversely, if the curve becomes more and more indistinguishable from a straight line in small neighborhoods of \( P \), then this line is the tangent line at \( P \), and if the curve is the graph of a function and the tangent line is not vertical, its slope is the derivative of the function at that point.

Although this approach to the tangent line is not rigorous without additional work, it is much more precise and universally applicable than the idea of the tangent line just “touching” the curve at the point of tangency.

**V.3.1.17.** The magnification interpretation gives a satisfactory geometric explanation of why a function such as \( f(x) = |x| \) is not differentiable. If an arbitrarily small segment of this graph around 0 is magnified arbitrarily much, it still looks exactly like the original curve and does not ever resemble a straight line segment.

**V.3.1.18.** Note, however, that even if a curve has a tangent line at a point \( P \), and a small segment of the curve near \( P \) when magnified looks approximately like the tangent line, if an even smaller piece of the magnified segment not including the point \( P \) is further magnified, it does not need to bear any resemblance to the tangent line:

The magnification principle only applies to segments of the curve around \( P \). In fact, the curve need not even have a tangent line at any other point than \( P \), i.e. if it is the graph of a function, the function need not be differentiable except at \( P \); it can even fail to be continuous except at \( P \)! For examples, see V.3.1.15. and V.3.9.6.

**Rate of Change Interpretation**

**V.3.1.19.** The difference quotient and derivative can be interpreted as rates of change. If \( f \) is a function defined on an interval containing \( a \) and \( b \), then the average rate of change of \( f \) from \( a \) to \( b \) can be reasonably defined as the total change in \( f \) divided by the total change in \( x \). The total change in \( f \) from \( a \) to \( b \) is \( f(b) - f(a) \), and the total change in \( x \) from \( a \) to \( b \) is \( b - a \). Thus the average rate of change in \( f \) from \( a \) to \( b \) is

\[
\frac{f(b) - f(a)}{b - a}
\]

provided \( b \neq a \). (Here we could have \( a < b \) or \( a > b \).)

**V.3.1.20.** If we hold \( a \) fixed and let \( b \) vary, i.e. replace \( b \) by a variable \( x \), then as \( x \to a \) the average rate of change of \( f \) from \( a \) to \( x \) should approach the “instantaneous rate of change of \( f \) at \( a \)” Thus

\[
f'(a) = \lim_{x \to a} \frac{f(x) - f(a)}{x - a}
\]

can be interpreted as the instantaneous rate of change of \( f \) at \( a \).
V.3.1.21. The most natural instance of this interpretation is if \( f(t) \) denotes the position of an object at time \( t \). Then
\[
\frac{f(b) - f(a)}{b - a}
\]
naturally denotes the average velocity of the object between \( t = a \) and \( t = b \), and
\[
f'(a) = \lim_{t \to a} \frac{f(t) - f(a)}{t - a}
\]
has a natural interpretation as the instantaneous velocity of the object at \( t = a \).

The Derivative as a Function

Other Notations for the Derivative

V.3.1.22. The formula for the derivative \( f'(a) \) in V.3.1.9. is frequently rewritten by writing \( h = x - a \), so that \( x = a + h \); then
\[
f'(a) = \lim_{h \to 0} \frac{f(a + h) - f(a)}{h}.
\]

V.3.1.23. Another variation is that the \( h = x - a \) is written \( \Delta x \), thought of as the “change in \( x \).” Note that \( \Delta x \) is regarded as a single symbol and that the \( \Delta \) and \( x \) have no independent meaning related to this symbol. Thus
\[
f'(a) = \lim_{\Delta x \to 0} \frac{f(a + \Delta x) - f(a)}{\Delta x}.
\]
This notation is more commonly used when the \( a \) is replaced by \( x \), which is treated like a constant in the calculation of the limit, and then as a variable:
\[
f'(x) = \lim_{\Delta x \to 0} \frac{f(x + \Delta x) - f(x)}{\Delta x}.
\]
If another symbol such as \( t \) is used for the independent variable (e.g. when it is interpreted as time), the corresponding replacement is normally made in the change symbol:
\[
f'(t) = \lim_{\Delta t \to 0} \frac{f(t + \Delta t) - f(t)}{\Delta t}.
\]

V.3.1.24. Carrying this a step further, we often work with the equation \( y = f(x) \) and define
\[
\Delta y = \Delta f = f(x + \Delta x) - f(x)
\]
where \( x \) and \( x + \Delta x \) are in the domain of \( f \). With this notation,
\[
f'(x) = \lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x} = \lim_{\Delta x \to 0} \frac{\Delta f}{\Delta x}.
\]
This notation nicely matches up with the “rate of change” interpretation: \( \frac{\Delta y}{\Delta x} \) is the average rate of change of \( y \) with respect to \( x \) between \( x \) and \( x + \Delta x \).
V.3.1.25. This leads to the notation originally used by Leibniz in his development of calculus, not surprisingly called Leibniz notation. We use the symbol $\frac{dy}{dx}$ or $\frac{df}{dx}$ to denote the derivative:

$$\frac{dy}{dx} = \lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x}.$$  

Note that $\frac{dy}{dx}$ (pronounced “d-y-d-x”) is regarded as a single symbol and is not a fraction, i.e. the $dy$ and $dx$ have no independent meaning (although meanings are sometimes attached to them in such a way as to make the quotient equal to $\frac{dy}{dx}$). The $x$ and $y$ can be replaced by any other variable names.

V.3.1.26. This notation arose because Leibniz thought of $dx$ as an “infinitesimal change” in $x$ and $dy$ the corresponding “infinitesimal change” in $y = f(x)$; the quotient $\frac{dy}{dx}$ should then (up to an “infinitesimal error”) be the exact slope of the tangent line. (Actually functional notation did not exist at that time, and one thought only about independent and dependent variables related by some formula.) The exact meaning of the term “infinitesimal change” was unclear, and was the principal logical weak point of calculus until the nineteenth century when infinitesimals were effectively eliminated from the rigorous calculus developed then. They have reappeared in a rigorous way in “nonstandard analysis” (1). Infinitesimals have never disappeared as a useful intuitive device in calculus and its applications, however.

V.3.1.27. In some ways, the Leibniz notation is inferior to the prime notation, mainly because in Leibniz notation it is not explicit where the derivative is being evaluated. However, for many purposes Leibniz notation is efficient and suggestive, so it continues to be commonly used. For example, if $y$ is a function of $t$, then $\frac{dy}{dt}$ has a natural interpretation as the (instantaneous) rate of change of $y$ with respect to $t$.

V.3.1.28. As a variation of Leibniz notation, we define an operator $\frac{d}{dx}$, which operates on (differentiable) functions and yields the derivative, i.e.

$$\frac{d}{dx} \left( f(x) \right) = f'(x).$$

This notation is often convenient for expressing differentiation formulas; cf. V.3.2.1. Again, $\frac{d}{dx}$ is regarded as a single symbol.

V.3.2. Elementary Rules of Differentiation

V.3.2.1. Theorem. [Power Rule, Version 1] Let $n \in \mathbb{N}$, and $f : \mathbb{R} \to \mathbb{R}$ be defined by $f(x) = x^n$. Then $f$ is differentiable at any $a \in \mathbb{R}$, and

$$f'(a) = na^{n-1}.$$  

As the Power Rule is often written,

$$\frac{d}{dx} (x^n) = nx^{n-1}.$$  

Proof: The following formula for any $x$ and $a$ in $\mathbb{R}$ can be quickly verified by multiplying out the right side and telescoping:

$$x^n - a^n = (x - a) \sum_{k=0}^{n-1} x^{n-1-k}a^k.$$
(This formula should technically be proved by induction.) Thus we have

\[ f'(a) = \lim_{x \to a} \frac{f(x) - f(a)}{x - a} = \lim_{x \to a} \frac{x^n - a^n}{x - a} = \lim_{x \to a} \sum_{k=0}^{n-1} x^{n-1-k} a^k. \]

The last expression is a polynomial \( p(x) \), hence by (1) the last limit exists and equals \( p(a) = na^{n-1} \).

**V.3.2.2.** This result will be extended to negative integer \( n \) in (1), to fractional \( n \) in (1), and to arbitrary real \( n \) in (1). The same derivative formula holds in all cases.

The Power Rule can be proved for positive integer \( n \) more easily by induction using the Product Rule (cf. Exercise V.3.10.7.). It can also be proved using the Binomial Theorem (Exercise V.3.10.1.).

**The Sum and Constant Multiple Rules**

**V.3.2.3.** Proposition. [Sum Rule] Let \( f \) and \( g \) be functions from an open interval \( I \) to \( \mathbb{R} \), and \( h = f + g : I \to \mathbb{R} \). If \( f \) and \( g \) are differentiable at \( a \in I \), then \( h \) is differentiable at \( a \) and

\[ h'(a) = f'(a) + g'(a). \]

**Proof:** By (1), we have

\[
\lim_{x \to a} \left[ \frac{f(x) + g(x)}{x - a} - \frac{f(a) + g(a)}{x - a} \right] = \lim_{x \to a} \left[ \frac{f(x) - f(a) + g(x) - g(a)}{x - a} \right]
\]

\[
= \lim_{x \to a} \left[ \frac{f(x) - f(a)}{x - a} + \frac{g(x) - g(a)}{x - a} \right] = \lim_{x \to a} \frac{f(x) - f(a)}{x - a} + \lim_{x \to a} \frac{g(x) - g(a)}{x - a}.
\]

**V.3.2.4.** Proposition. [Constant Multiple Rule] Let \( f \) be a function from an open interval \( I \) to \( \mathbb{R} \), \( c \in \mathbb{R} \), and \( h = cf : I \to \mathbb{R} \). If \( f \) is differentiable at \( a \in I \), then \( h \) is differentiable at \( a \) and

\[ h'(a) = cf'(a). \]

**Proof:** By (1), we have

\[
\lim_{x \to a} \frac{cf(x) - cf(a)}{x - a} = \lim_{x \to a} \left[ c \cdot \frac{f(x) - f(a)}{x - a} \right] = c \cdot \lim_{x \to a} \frac{f(x) - f(a)}{x - a}.
\]
V.3.2.5. Note that the Sum Rule and the Constant Multiple Rule are not merely formulas. They are (easy) theorems, with hypotheses and a conclusion with a theoretical part (that \( h \) is differentiable at \( a \)) and a formula part (the derivative of \( h \) at \( a \)).

V.3.3. The Product and Quotient Rules

V.3.3.1. It is not true that a derivative of a product of two functions is the product of the derivatives; almost any product where one is able to compute derivatives directly (e.g. a product of two power functions) is a counterexample. In fact, if it were true that the derivative of a product is the product of the derivatives, it would force the derivative of any differentiable function to be zero: if \( f \) is differentiable, we would have

\[
\lim_{x \to 0} \frac{f(x)}{x} = \lim_{x \to 0} \left( \frac{1}{x} \right) = 0.
\]

Actually, the derivative of a composition of two functions is the product of the derivatives; see V.3.4.3. for a precise statement.

V.3.3.2. Instead, the derivative of a product of two differentiable functions is given by a more complicated formula with two terms, in each of which one of the factors is differentiated and the other left unchanged.

V.3.3.3. Theorem. [Product Rule] Let \( f \) and \( g \) be functions from an open interval \( I \) to \( \mathbb{R} \), and \( h = fg : I \to \mathbb{R} \). If \( f \) and \( g \) are differentiable at \( a \in I \), then \( h \) is differentiable at \( a \) and

\[
h'(a) = f'(a)g(a) + f(a)g'(a).
\]

Proof: Write \( u = f(a) \) and \( v = g(a) \), and \( y = h(a) = uv \). If \( \Delta x \neq 0 \), write \( \Delta u = f(a + \Delta x) - f(a) \), \( \Delta v = g(a + \Delta x) - g(a) \), \( \Delta y = h(a + \Delta x) - h(a) = (u + \Delta u)(v + \Delta v) - uv \). Then we have

\[
\frac{\Delta y}{\Delta x} = \frac{(u + \Delta u)(v + \Delta v) - uv}{\Delta x} = \frac{v \cdot \Delta u + u \cdot \Delta v + \Delta u \cdot \Delta v}{\Delta x} + \frac{v \Delta u}{\Delta x} + u \Delta v \Delta x.
\]

By assumption, \( \lim_{\Delta x \to 0} \frac{\Delta u}{\Delta x} \) exists and equals \( f'(a) \), and \( \lim_{\Delta x \to 0} \frac{\Delta v}{\Delta x} \) exists and equals \( g'(a) \). We also have \( \lim_{\Delta x \to 0} \Delta u = 0 \) since \( f \) is differentiable at \( a \), hence continuous at \( a \) (VIII.3.1.13.). Thus, by (1) and (2), since \( u \) and \( v \) are constants we have that \( h'(a) = \lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x} \) exists and equals

\[
v \left[ \lim_{\Delta x \to 0} \frac{\Delta u}{\Delta x} \right] + u \left[ \lim_{\Delta x \to 0} \frac{\Delta v}{\Delta x} \right] + \left[ \lim_{\Delta x \to 0} \frac{\Delta u}{\Delta x} \right] \left[ \lim_{\Delta x \to 0} \frac{\Delta v}{\Delta x} \right] = f'(a)g(a) + f(a)g'(a) + 0 \cdot g'(a).
\]

532
V.3.3.4. The above proof is a natural one, but requires introduction of some new notation. We can write essentially the same proof more compactly in straightforward notation, but when the proof is done in this way it involves the “trick” of adding and subtracting the same quantity, so does not seem as natural:

**Proof:** We have, for \( x \neq a \),

\[
\frac{h(x) - h(a)}{x - a} = \frac{f(x)g(x) - f(a)g(a)}{x - a} = \frac{[f(x)g(x) - f(a)g(x)] + [f(a)g(x) - f(a)g(a)]}{x - a}
\]

\[
= g(a) \frac{f(x) - f(a)}{x - a} + f(x) \frac{g(x) - g(a)}{x - a}.
\]

We have that \( \lim_{x \to a} \frac{f(x) - f(a)}{x - a} \) exists and equals \( f'(a) \), and that \( \lim_{x \to a} \frac{g(x) - g(a)}{x - a} \) exists and equals \( g'(a) \). Also, \( \lim_{x \to a} f(x) \) exists and equals \( f(a) \) since \( f \) is differentiable at \( a \), hence continuous at \( a \). Thus by (1) and (2) we have that \( h'(a) = \lim_{x \to a} \frac{h(x) - h(a)}{x - a} \) exists and equals

\[
g(a) \left[ \lim_{x \to a} \frac{f(x) - f(a)}{x - a} \right] + \left[ \lim_{x \to a} f(x) \right] \left[ \lim_{x \to a} \frac{g(x) - g(a)}{x - a} \right] = g(a)f'(a) + f(a)g'(a).
\]

\[\Box\]

V.3.3.5. **Corollary.** Let \( f \) and \( g \) be differentiable functions on an interval \( I \). Then the product \( fg \) is also differentiable on \( I \).

V.3.3.6. Now we turn to the Quotient Rule. Just as with products, the derivative of a quotient is not the quotient of the derivatives (try taking as denominator the constant function 1!) Again, the Quotient Rule is a theorem with hypotheses and a theoretical part to the conclusion as well as a formula for the derivative of the quotient. The one additional technical complication concerns the domain of the quotient function.

The quotient of the derivatives of numerator and denominator of a quotient of two functions does appear in l’Hôpital’s Rule (1), but there it does not represent the derivative of the quotient.

V.3.3.7. **Theorem.** **[Quotient Rule]** Let \( f \) and \( g \) be functions from an open interval \( I \) to \( \mathbb{R} \). If \( f \) and \( g \) are differentiable at \( a \in I \) and \( g(a) \neq 0 \), then \( h = \frac{f}{g} \) is defined in an interval around \( a \) and differentiable at \( a \), and

\[
h'(a) = \frac{g(a)f'(a) - f(a)g'(a)}{(g(a))^2}.
\]

**Proof:** Since \( g \) is differentiable at \( a \) and hence continuous at \( a \), and \( g(a) \neq 0 \), there is an \( \epsilon > 0 \) such that, whenever \( |x - a| < \epsilon \), \( x \in I \) and \( g(x) \neq 0 \). Thus \( h \) is defined at least on the interval \((a - \epsilon, a + \epsilon)\).

Write \( u = f(a) \) and \( v = g(a) \), and \( y = h(a) = \frac{u}{v} \). If \( 0 < |\Delta x| < \epsilon \), write \( \Delta u = f(a + \Delta x) - f(a) \), \( \Delta v = g(a + \Delta x) - g(a) \) (note that \( v + \Delta v \neq 0 \)), \( \Delta y = h(a + \Delta x) - h(a) = \frac{u + \Delta u}{v + \Delta v} - \frac{u}{v} \). Then, using a common denominator, we have

\[
\frac{\Delta y}{\Delta x} = \frac{1}{\Delta x} \left[ \frac{u + \Delta u}{v + \Delta v} - \frac{u}{v} \right]
\]

533
By assumption, $\lim_{\Delta x \to 0} \frac{\Delta u}{\Delta x}$ exists and equals $f'(a)$, and $\lim_{\Delta x \to 0} \frac{\Delta v}{\Delta x}$ exists and equals $g'(a)$. We also have

$$h'(a) = \lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x} = \lim_{\Delta x \to 0} \frac{\Delta u}{\Delta x} \cdot \frac{1}{v(v + \Delta v)} = \frac{1}{v} \lim_{\Delta x \to 0} \left( v \frac{\Delta u}{\Delta x} - u \frac{\Delta v}{\Delta x} \right).$$

**V.3.3.8.** Corollary. Let $f$ and $g$ be differentiable functions on an interval $I$, with $g(x) \neq 0$ for all $x \in I$. Then $\frac{f}{g}$ is differentiable on $I$.

**V.3.3.9.** Corollary. Every rational function $\left( \frac{p(x)}{q(x)} \right)$ is differentiable on its domain.

**V.3.3.10.** The proof of V.3.3.7. can be rewritten in straightforward notation as in V.3.3.4.; cf. Exercise V.3.10.2. We write this version only in a simplified special case, which can be combined with the Product Rule to give an alternate proof of the Quotient Rule (cf. V.3.10.3):

**V.3.3.11.** Corollary. Let $g$ be a function from an open interval $I$ to $\mathbb{R}$ which is differentiable at $a \in I$, with $g(a) \neq 0$. Then $h = \frac{1}{g}$ is defined in an open interval around $a$ and differentiable at $a$, and

$$h'(a) = -\frac{g'(a)}{|g(a)|^2}.$$  

**Proof:** This is the special case of V.3.3.7. with $f(x) = 1$. We give an alternative proof. Let $\epsilon > 0$ be as in the proof of V.3.3.7.; then $h$ is defined at least on the interval $(a - \epsilon, a + \epsilon)$.

If $0 < |x - a| < \epsilon$, we have

$$\frac{h(x) - h(a)}{x - a} = \frac{1}{g(x)} - \frac{1}{g(a)} = \frac{1}{x - a} \left( \frac{g(a) - g(x)}{g(x)g(a)} \right) = -\frac{1}{g(x)g(a)} \cdot \frac{g(x) - g(a)}{x - a}.\]$$

Since $\lim_{x \to a} \frac{g(x) - g(a)}{x - a}$ exists and equals $g'(a)$, and $\lim_{x \to a} g(x) = g(a) \neq 0$ since $g$ is continuous at $a$, we have that $h'(a) = \lim_{x \to a} \frac{h(x) - h(a)}{x - a}$ exists and equals

$$-\left[ \lim_{x \to a} \frac{1}{g(x)g(a)} \right] \left[ \lim_{x \to a} \frac{g(x) - g(a)}{x - a} \right] = -\frac{1}{|g(a)|^2} g'(a).$$
V.3.3.12. Corollary. [Power Rule, Version 2] Let $n$ be a negative integer. Then the function $f(x) = x^n$ is differentiable on $\mathbb{R} \setminus \{0\}$, with derivative

$$f'(x) = nx^{n-1}.$$  

Proof: Let $m = -n \in \mathbb{N}$, and let $g(x) = x^m$. Then $f(x) = \frac{1}{g(x)}$, so $f$ is differentiable wherever $g$ is nonzero and

$$f'(x) = -\frac{g'(x)}{(g(x))^2} = -\frac{mx^{m-1}}{|x^m|^2} = -m \cdot \frac{x^{m-1}}{x^{2m}} = -mx^{m-1-2m} = nx^{n-1}.$$  

V.3.3.13. Caution: The derivative of a power function is a multiple of a power function with exponent one smaller than the exponent in the original. But if the original exponent is negative, the exponent in the derivative is more negative. Thus, for example,

$$\frac{d}{dx}(x^5) = 5x^4$$

but

$$\frac{d}{dx}(x^{-5}) = -5x^{-6}.$$  

V.3.4. The Chain Rule

The Chain Rule is a result about differentiation of composite functions. As with the Product Rule and Quotient Rule, the Chain Rule is a theorem, not simply a formula; it has a theoretical part (that a composition of differentiable functions is differentiable) and a computational part (a formula for the derivative of the composite function).

V.3.4.1. The motivation and general idea of the Chain Rule is that if $y$ is indirectly a function of $x$ via an intermediate variable $u$, i.e. $u = f(x)$ and $y = g(u)$ for some functions $f$ and $g$, and $f$ and $g$ are differentiable, we want to describe the rate of change $\frac{dy}{dx}$ in terms of $\frac{du}{dx} = g'(u)$ and $\frac{du}{dx} = f'(x)$. Roughly, if $x$ is changed by a small amount $\Delta x$, then $u$ is changed by an approximately proportional amount with constant of proportionality $f'(x)$, i.e. $\Delta u \approx f'(x) \cdot \Delta x$. Similarly, $\Delta y \approx g'(u) \cdot \Delta u$. So

$$\Delta y \approx g'(u) \cdot \Delta u \approx g'(u) f'(x) \cdot \Delta x.$$  

Thus we should have that $y = g(f(x))$ is a differentiable function of $x$ and

$$\frac{dy}{dx} = \frac{dy}{du} \frac{du}{dx}.$$  

This formula is easily remembered by pretending that $\frac{du}{dx}$ and $\frac{du}{dx}$ are fractions (which they are not!) and “dividing out” the $du$’s. This is a prime example of the utility of the Leibniz notation for derivatives, although this notation is somewhat imprecise as to exactly where the relevant functions are evaluated.
If $f$ and $g$ are linear functions, this all works out properly and quite simply. If $u = f(x) = mx+b$ and $y = g(u) = nu + c$, then $f'(x) = \frac{du}{dx}$ and $g'(u) = \frac{dy}{du}$ are the constant functions $m$ and $n$ respectively. If $h = g \circ f$, then $y = h(x) = g(f(x))$ is also a linear function with formula

\[ y = h(x) = n f(x) + c = n(mx + b) + c = nm x + (nb + c) \]

and we have

\[ \frac{dy}{dx} = h'(x) = nm = \frac{dy}{du} \frac{du}{dx} . \]

Thus the slope of a composition of two linear functions is the product of the slopes of the component functions.

The general Chain Rule asserts that if $f$ and $g$ are “approximately linear” (i.e. differentiable), then $g \circ f$ is also approximately linear, with slope equal to the product of the slopes of $f$ and $g$. But one must be careful about where the derivatives are evaluated since they are not constant. Here is the precise statement.

**Theorem.** [Chain Rule] Let $f$ be defined on a neighborhood $U$ of $a \in \mathbb{R}$ and differentiable at $a$, with $f(a) = b \in \mathbb{R}$, and let $g$ be defined on a neighborhood $V$ of $b$ and differentiable at $b$, with $f(U) \subseteq V$. Set $h = g \circ f$ on $U$. Then $h$ is differentiable at $a$, and

\[ h'(a) = (g \circ f)'(a) = g'(b) f'(a) = g'(f(a)) f'(a) . \]

A straightforward and essentially correct proof can be given which contains a subtle fallacy; see Exercise V.3.10.5. A fully correct proof is not much harder if done right, but requires a slightly modified approach which is not so obvious. We first define a new function we will use in the proof:

**Definition.** Let $g$ and $b$ be as in V.3.4.3. Define a function $G_b$ on $V$ by

\[ G_b(u) = \begin{cases} g(u) - g(b) & \text{if } u \neq b \\ \frac{g(u) - g(b)}{u - b} & \text{if } u = b \end{cases} . \]

**Lemma.** $G_b$ is continuous at $b$.

**Proof:** We need to check that $G_b(b) = \lim_{u \to b} G_b(u)$. But this is true by definition of $g'(b)$. \(\Box\)

536
V.3.4.6. Lemma. Using the notation of V.3.4.3., if \( x \in \mathcal{U}, x \neq a \), we have

\[
\frac{h(x) - h(a)}{x - a} = G_b(f(x)) \cdot \frac{f(x) - f(a)}{x - a}.
\]

Proof: If \( f(x) \neq b = f(a) \), we have

\[
G_b(f(x)) \cdot \frac{f(x) - f(a)}{x - a} = \frac{g(f(x)) - g(b)}{f(x) - b} \cdot \frac{f(x) - f(a)}{x - a}
\]

and, since \( b = f(a) \), \( h(x) = g(f(x)) \), and \( h(a) = g(b) \), the formula holds. If \( f(x) = b \), then both sides of the equation are zero, so the formula again holds.

We now prove V.3.4.3.

Proof: Since \( f \) is continuous at \( a \) by () and \( G_b \) is continuous at \( b = f(a) \), \( G_b \circ f \) is continuous at \( a \) by () and

\[
\lim_{x \to a} G_b(f(x)) = G_b(f(a)) = G_b(b) = g'(b).
\]

Also, we have

\[
\lim_{x \to a} \frac{f(x) - f(a)}{x - a} = f'(a)
\]

So by (), we have

\[
\lim_{x \to a} \frac{h(x) - h(a)}{x - a} = \left[ \lim_{x \to a} G_b(f(x)) \right] \left[ \lim_{x \to a} \frac{f(x) - f(a)}{x - a} \right] = g'(b)f'(a).
\]

Here are some of the most important standard applications of the Chain Rule:

V.3.4.7. Corollary. [Chain Rule for Powers] Let \( f \) be differentiable at \( a \), \( f(a) > 0 \), and \( r \in \mathbb{R} \). Then \( h(x) = [f(x)]^r \) is differentiable at \( a \), and \( h'(a) = r[f(a)]^{r-1}f'(a) \). Alternatively,

\[
\frac{d}{dx} ([f(x)]^r) = r[f(x)]^{r-1}f'(x).
\]

Proof: Apply V.3.4.3. with \( g(u) = u^r \).

V.3.4.8. Corollary. [Chain Rule for Exponentials] Let \( f \) be differentiable at \( a \). Then \( h(x) = e^{f(x)} \) is differentiable at \( a \), and \( h'(a) = e^{f(a)}f'(a) \). Alternatively,

\[
\frac{d}{dx} (e^{f(x)}) = f'(x)e^{f(x)}.
\]
V.3.4.9. Corollary. [Chain Rule for Logarithms] Let \( f \) be differentiable at \( a \), with \( f(a) \neq 0 \). Then \( h(x) = \log |f(x)| \) is differentiable at \( a \), and \( h'(a) = \frac{1}{f(a)} f'(a) \). Alternatively,

\[
\frac{d}{dx} (\log |f(x)|) = \frac{f'(x)}{f(x)}.
\]

The proofs of V.3.4.8. and V.3.4.9. are similar to the proof of V.3.4.7., and are left to the reader.

V.3.5. Derivatives of Inverse Functions

V.3.6. Critical Points and Local Extrema

One of the most important elementary applications of the derivative is the location and analysis of local extrema.

V.3.6.1. Definition. Let \( f \) be a function defined on an interval \( I \), and \( a \) an interior point of \( I \). The function \( f \) has a local maximum, or relative maximum, at \( a \) if there is a \( \delta > 0 \) such that \( f(x) \leq f(a) \) for all \( x \) with \( |x - a| < \delta \). The function \( f \) has a local minimum, or relative minimum, at \( a \) if there is a \( \delta > 0 \) such that \( f(x) \geq f(a) \) for all \( x \) with \( |x - a| < \delta \). A local extremum, or relative extremum, is a local maximum or local minimum.

V.3.6.2. A continuous function \( f \) on a closed bounded interval attains a maximum and minimum on the interval \( I \). If the maximum is attained at an interior point \( a \) of the interval, then \( f \) has a local maximum at \( a \). The converse is false: if \( f \) has a local maximum at \( a \), its value there may not be the maximum value of \( f \) on the entire interval (it is only the maximum on some sufficiently small subinterval around \( a \)). Indeed, \( f \) may have two or more local maxima in the interval, where it may or may not attain the maximum on the whole interval, and the maximum on the interval can occur at an endpoint and not at a local maximum; in fact, \( f \) need not have any local maxima. Corresponding statements hold for local minima.

The crucial relation between local extrema and the derivative is:

V.3.6.3. Theorem. Let \( f \) be a function defined on an interval \( I \), and \( a \) an interior point of \( I \). If \( f \) has a local extremum at \( a \), and \( f \) is differentiable at \( a \), then \( f'(a) = 0 \).

Proof: We prove the statement for a local maximum; the proof for a local minimum is identical with a few inequalities reversed. Fix \( \delta > 0 \) such that \( f(x) \leq f(a) \) for \( |x - a| < \delta \). If \( a < x < a + \delta \), then we have

\[
\frac{f(x) - f(a)}{x - a} \leq 0
\]

and thus by ()

\[
\lim_{x \to a^+} \frac{f(x) - f(a)}{x - a} \leq 0
\]
(if the limit exists). Similarly, If \( a - \delta < x < a \), then we have
\[
\frac{f(x) - f(a)}{x - a} \geq 0
\]
since numerator and denominator are both negative (nonpositive), and thus
\[
\lim_{x \to a^-} \frac{f(x) - f(a)}{x - a} \geq 0
\]
(assuming the limit exists). So, if \( f \) is differentiable at \( a \), both limits exist and are equal, hence 0; thus
\[
f'(a) = \lim_{x \to a} \frac{f(x) - f(a)}{x - a} = \lim_{x \to a^+} \frac{f(x) - f(a)}{x - a} = \lim_{x \to a^-} \frac{f(x) - f(a)}{x - a} = 0 .
\]

V.3.6.4. A continuous function need not be differentiable at a local extremum: consider \( f(x) = |x| \) at 0 (cf. V.4.2.7.). And if \( f \) is differentiable at \( a \) and \( f'(a) = 0 \), then \( f \) need not have a local extremum at \( a \): consider \( f(x) = x^3 \) at 0. However, the places where \( f'(a) = 0 \) (or does not exist) are the candidates for where \( f \) can have local extrema. Thus we make the following definition:

V.3.6.5. DEFINITION. Let \( f \) be a function defined on an interval \( I \), and \( a \) an interior point of \( I \). Then \( a \) is a critical number for \( f \) if either \( f \) is not differentiable at \( a \), or \( f \) is differentiable at \( a \) and \( f'(a) = 0 \).

V.3.6.6. Thus every local extremum is at a critical number, but not conversely in general. The term critical point is often used as a synonym for critical number, but “critical point” is also sometimes used to refer to the corresponding point on the graph, so “critical number” is less ambiguous. Technically, the terms local maximum, etc., also refer to points on the graph; thus we say “\( f \) has a local extremum at \( a \)” rather than “\( a \) is a local extremum of \( f \).”

Increasing and Decreasing Functions at a Point

There is a sharper form of the contrapositive to V.3.6.3. We first make a definition:

V.3.6.7. DEFINITION. Let \( f \) be a function defined on an interval \( I \), and \( a \) an interior point of \( I \). Then \( f \) is increasing at \( a \) if there is a \( \delta > 0 \) such that \( f(x) < f(a) \) for \( a - \delta < x < a \) and \( f(x) > f(a) \) for \( a < x < a + \delta \). Similarly, \( f \) is decreasing at \( a \) if there is a \( \delta > 0 \) such that \( f(x) > f(a) \) for \( a - \delta < x < a \) and \( f(x) < f(a) \) for \( a < x < a + \delta \).

Note that this is strictly a pointwise definition: we only compare \( f(x) \) with \( f(a) \) for \( x \) near \( a \), we do not compare \( f(x_1) \) and \( f(x_2) \) for \( x_1, x_2 \) near \( a \), which is a much more problematic matter (cf. VIII.6.6.2.).
V.3.6.8. COROLLARY. Let \( f \) be a function defined on an interval \( I \), and \( a \) an interior point of \( I \). Suppose \( f \) is differentiable at \( a \). Then

(i) If \( f'(a) > 0 \), then \( f \) is increasing at \( a \).

(ii) If \( f'(a) < 0 \), then \( f \) is decreasing at \( a \).

Proof: The proof of each part is essentially a piece of the proof of V.3.6.3. For (i), suppose \( f \) is not increasing at \( a \). Then for any \( \varepsilon > 0 \) there is an \( x \) with \( 0 < |x - a| < \delta \) and

\[
\frac{f(x) - f(a)}{x - a} \leq 0.
\]

Thus

\[
f'(a) = \lim_{x \to a} \frac{f(x) - f(a)}{x - a} \leq 0.
\]

The proof of (ii) is the same with inequalities reversed.

V.3.6.9. Thus, if \( f \) is differentiable on an interval \( I \) and \( f'(x) > 0 \) for all \( x \in I \), then \( f \) is increasing at every point of \( I \). It stands to reason that \( f \) should actually be strictly increasing on \( I \), i.e. that \( f(x_1) < f(x_2) \) if \( x_1, x_2 \in I, \ x_1 < x_2 \). This turns out to be true, but is subtle to prove (V.8.2.1., V.8.6.12.). A symmetric result holds if \( f' < 0 \) on \( I \).

Endpoint Extrema

We can analyze endpoint behavior in the same way.

V.3.6.10. DEFINITION. (i) Let \( f \) be a function defined on an interval with left endpoint \( a \). Then \( f \) has an endpoint maximum at \( a \) if there is a \( \delta > 0 \) such that \( f(x) \leq f(a) \) for all \( x \) with \( a < x < a + \delta \). Similarly, \( f \) has an endpoint minimum at \( a \) if there is a \( \delta > 0 \) such that \( f(x) \geq f(a) \) for \( a < x < a + \delta \).

(ii) Let \( f \) be a function defined on an interval with right endpoint \( b \). Then \( f \) has an endpoint maximum at \( b \) if there is a \( \delta > 0 \) such that \( f(x) \leq f(b) \) for all \( x \) with \( b - \delta < x < b \). Similarly, \( f \) has an endpoint minimum at \( b \) if there is a \( \delta > 0 \) such that \( f(x) \geq f(b) \) for \( b - \delta < x < b \).

An endpoint extremum is an endpoint maximum or endpoint minimum.

V.3.6.11. COROLLARY. Let \( f \) be a function on an interval \( I \), and \([a, b]\) a closed bounded interval in the interior of \( I \). Then

(i) If \( f \) has an endpoint maximum at \( a \) and \( f \) is differentiable at \( a \), then \( f'(a) \leq 0 \).

(ii) If \( f \) has an endpoint minimum at \( a \) and \( f \) is differentiable at \( a \), then \( f'(a) \geq 0 \).

(iii) If \( f \) has an endpoint maximum at \( b \) and \( f \) is differentiable at \( b \), then \( f'(b) \geq 0 \).

(iv) If \( f \) has an endpoint minimum at \( b \) and \( f \) is differentiable at \( b \), then \( f'(b) \leq 0 \).

The proof is again pieces of the proof of V.3.6.3.
V.3.7. Higher Derivatives

V.3.7.1. If $f$ is a real-valued function defined on a subset $A$ of $\mathbb{R}$, then the derivative $f'$ is another function defined on a subset (proper subset in general) of $A$. Thus $f'$ itself has a derivative on a subset of its domain, called the second derivative of $f$. The process can be repeated to define the third derivative and higher derivatives of all orders.

V.3.7.2. Definition. Let $A \subseteq \mathbb{R}$, $a \in A$, and $f : A \to \mathbb{R}$ a function. If $f'$ is differentiable at $a$, then $f$ is second-order differentiable, or twice differentiable, at $a$ and

$$f''(a) = (f')(a) = \lim_{x \to a} \frac{f'(x) - f'(a)}{x - a}$$

is the second derivative of $f$ at $a$, also denoted $f^{(2)}(a)$. (Also write $f^{(0)} = f$ and $f^{(1)} = f'$; $f'$ is called the first derivative of $f$.)

Inductively, if $n \in \mathbb{N}$ and $f^{(n-1)}$ is differentiable at $a$, then $f$ is differentiable to order $n$ at $a$, or $n$-times differentiable at $a$, and $f^{(n)}(a) = (f^{(n-1)})'(a)$ is the $n$'th derivative of $f$ at $a$.

If $I$ is an interval contained in $A$, then $f$ is differentiable to order $n$ on $I$, or $n$-times differentiable on $I$, if $f^{(n)}(a)$ is differentiable at all $a \in I$, i.e. $f^{(n-1)}$ is differentiable on $I$. If $f$ is $n$'th-order differentiable on $I$ and $f^{(n)}$ is continuous on $I$, then $f$ is $C^n$ on $I$ (continuously $n$'th order differentiable on $I$).

V.3.7.3. Note that for $f^{(n)}(a)$ to be defined, it is necessary for $f^{(n-1)}$ to be defined in an entire interval around $a$ and continuous at $a$ (VIII.3.1.13.). Thus if $f$ is $n$'th order differentiable on $I$, then it is $C^{n-1}$ on $I$ (the converse is false in general). Note that “$f$ is $C^n$ on $I$” just means “$f$ is continuous on $I$.”

V.3.7.4. Notation: We can use additional primes to denote higher derivatives: $f''$ for the third derivative $f^{(3)}$, $f'''$ for $f^{(4)}$, etc. Three seems to be the conventional dividing line: the second derivative is usually denoted $f''$, the third derivative commonly denoted either $f'''$ or $f^{(3)}$, and only rarely are primes used for $f^{(n)}$, $n > 3$.

Leibniz notation is also commonly used for higher derivatives: we write

$$\frac{d^2 f}{dx^2} = \frac{d^2 f}{dx^2}(x) = \frac{d^2 f}{dx^2}(f(x)) = \frac{d}{dx} \left( \frac{d}{dx} (f(x)) \right) = \left( \frac{d}{dx} \right)^2 (f(x)) = f''(x)$$

and more generally

$$\frac{d^n f}{dx^n} = \frac{d^n f}{dx^n}(x) = f^{(n)}(x)$$

(note the position of the exponents: we write $d^2 f$, not $\frac{d^2 f}{dx^2}$ or $\frac{d^2 f}{dx^2}$; think of $\frac{d^n f}{dx^n} = \left( \frac{d}{dx} \right)^n$ as an operator).

V.3.7.5. Second derivatives are especially important in physics: for example, acceleration is the second derivative of position. Higher derivatives beyond the second are not so commonly used in applications.

Geometric Interpretation

V.3.7.6. All the higher derivatives of a function $f$ have geometric interpretations in the shape of the graph of $f$, but the interpretations of $f^{(n)}$ are increasingly subtle as $n$ increases and are only easily described for $n = 2$ (V.8.3.).
The Formula of Faà di Bruno

V.3.7.7. Under the hypotheses of the Chain Rule V.3.4.3., if \( f \) and \( g \) are differentiable to order \( n \) at \( a \), it follows inductively from the Product Rule and Chain Rule that the composite function \( g \circ f \) is also differentiable to \( n \)-th order at \( a \). If \( n = 2 \), we have

\[
(g \circ f)''(a) = g'(f(a))f''(a) + g''(f(a))[f'(a)]^2
\]

and if \( n = 3 \),

\[
(g \circ f)'''(a) = g'(f(a))f'''(a) + 3g''(f(a))f'(a)f''(a) + g'''(f(a))[f'(a)]^3.
\]

What is the general formula for \( (g \circ f)^{(n)} \)? It is a nontrivial exercise to even find a general expression, much less prove it. The most commonly written version of the formula is:

\[
h^{(n)}(a) = (g \circ f)^{(n)}(a) = \sum \frac{n!}{k_1! \cdots k_n!} g^{(k)}(b) \left( \frac{f'(a)}{k_1!} \right)^{k_1} \cdots \left( \frac{f^{(n)}(a)}{k_n!} \right)^{k_n}
\]

where the sum is over all sets of nonnegative integers \( k_1, \ldots, k_n \) with \( k_1 + 2k_2 + \cdots nk_n = n \), and \( k = k_1 + k_2 + \cdots + k_n \).

The formula is named after Francesco Faà di Bruno, a respected Italian mathematician of the mid-nineteenth century; however, the attribution is not historically accurate since he was not the first to prove or publish it. The formula is essentially combinatorial, and there are many forms and variations, arising in various contexts throughout mathematics. In principle it can be proved by induction, but this is very difficult in practice, and the standard proofs generally employ power series, Bell polynomials, or umbral calculus instead. The variations, proofs, and the complicated history of the formula are discussed in detail in [Joh02], which contains an extensive list of references.

V.3.8. Continuous but Nondifferentiable Functions

It came as quite a shock to many mathematicians when in ( \( \text{Weierstrass} \) gave an example of a function which is continuous everywhere but differentiable nowhere. There have since been many other explicit examples given (sometimes essentially the same examples have been rediscovered and republished), and it is now known (XI.12.2.5.) that “most” continuous functions are not differentiable anywhere, quite contrary to our standard naive mental picture of a “typical” continuous function.

Van der Waerden’s Example

V.3.8.1. Example. Here is one of the simplest examples of a continuous function which is not differentiable anywhere, due to B. L. Van der Waerden [vdW30] (cf. [? , ]). (The first example of this sort was given by T. Takagi in 1903 [?], and other similar examples were constructed by several other mathematicians.)
For each $k \in \mathbb{N} \cup \{0\}$, define $f_k : \mathbb{R} \to \mathbb{R}$ by letting $f_k(x)$ be the distance from $x$ to the closest decadent rational number of the form $\frac{m}{10^k}$ for $m \in \mathbb{Z}$. See Figure V.5.

It is clear that $f_k$ is continuous, periodic with period $\frac{1}{10^k}$, and that

$$0 \leq f_k(x) \leq \frac{1}{2 \cdot 10^k}$$

for all $x$. Then set

$$f(x) = \sum_{k=0}^{\infty} f_k(x).$$

Since the series is uniformly convergent, $f$ is continuous on all of $\mathbb{R}$. See Fig. V.6.

We claim that $f$ is not differentiable anywhere. Fix $x \in \mathbb{R}$, and write

$$x = r.d_1 d_2 d_3 \cdots$$

in a decimal expansion. (If $x < 0$, take the decimal expansion of $x + s$ for some $s \in \mathbb{N}$, $s > |x|$ instead. The $d_n$ are independent of $s$. There is the usual ambiguity if $x$ is a decadent rational; in this case, either decimal expansion will do.) We will show that $f$ is not differentiable at $x$. 

543
For each \( n \in \mathbb{N} \) set \( x_n = x - \frac{1}{10^n} \) if \( d_n \) is 4 or 9, and \( x_n = x + \frac{1}{10^n} \) otherwise. Then \( x_n \to x \), so if \( f \) is differentiable at \( x \) we must have
\[
\lim_{n \to \infty} \frac{f(x_n) - f(x)}{x_n - x} = f'(x) \in \mathbb{R}
\]
and thus the limit must exist (in the ordinary sense).

However, if \( k < n \), we have that the closest number \( y \) of the form \( \frac{m}{10^n} \) to \( x_n \) is also the closest one to \( x \), and \( x \) and \( x_n \) are on the same side of \( y \), so we have
\[
|f_k(x_n) - f_k(x)| = |(x_n - y) - (x - y)| = |x_n - x|.
\]
On the other hand, if \( k \geq n \), then \( \frac{1}{10^n} = |x_n - x| \) is an integer multiple of \( \frac{1}{10^n} \) and \( f_k(x_n) - f_k(x) = 0 \) by periodicity of \( f_k \). We thus have
\[
f(x_n) - f(x) = \sum_{k=0}^{n-1} |f_k(x_n) - f_k(x)| = p_n(x_n - x)
\]
where \( p_n \) is an integer of the same parity (odd or even) as \( n \). Thus
\[
\frac{f(x_n) - f(x)}{x_n - x} = p_n
\]
cannot have a limit in \( \mathbb{R} \) (i.e. be eventually constant) as \( n \to \infty \).

V.3.8.2. Unlike Weierstrass’s example, for this example there are uncountably many points where some or all of the Dini derivatives are finite (cf. Exercise V.3.10.13.), although such points form a set of measure zero by the Denjoy-Young-Saks Theorem.

V.3.9. The Bush-Wunderlich-Swift Example

We now describe a particularly simple example of a continuous nondifferentiable function. The example we give is from [Swi61], a special case of an example from [Bus52] and [Wun52].

V.3.9.1. Let \( x \) be a real number. Write the ternary (base 3) decimal expansion of the fractional part of \( x \) as
\[.t_1t_2t_3\cdots\]
where each \( t_k \) is 0, 1, or 2 (if \( x \) is a triadic rational number, there will be two such expansions, one ending in a string of 0’s and one in a string of 2’s). Define \( f(x) \) to be the number in the unit interval with binary expansion
\[.d_1d_2d_3\cdots\]
\((d_k = 0 \text{ or } 1)\) defined by the following inductive rule: \( d_1 = 1 \) if and only if \( t_1 = 1 \), and \( d_{n+1} = d_n \) if and only if \( t_{n+1} = t_n \).
V.3.9.2. **Proposition.** The function $f$ is well defined.

**Proof:** The definition of $f$ is via a definite procedure which gives a well-defined binary decimal for every ternary decimal. Thus we need only show that if $x$ is a ternary rational, the two ternary decimal representations of $x$ give binary decimals representing the same number. This is completely elementary, but a little ugly. Note that if a triadic expansion ends in a constant sequence, the corresponding dyadic expansion also ends in a constant sequence. Denote by $t_1t_2\cdots$ the ternary expansion of $x$ ending in 2's, and $t'_1t'_2\cdots$ the ternary expansion ending in 0's, and $d_1d_2\cdots$ and $d'_1d'_2\cdots$ the corresponding dyadic expansions. There are six cases to check. The first is

$$t_1t_2\cdots = \cdots 00222\cdots$$

$$t'_1t'_2\cdots = \cdots 0100\cdots$$

where the omitted initial segments are equal, and the displayed segments start with $t_n$ and $t'_n$. Then either $d_n = d'_n = 0$, in which case

$$d_1d_2\cdots = \cdots 00111\cdots$$

$$d'_1d'_2\cdots = \cdots 0100\cdots$$

with the omitted initial segments equal, or $d_n = d'_n = 1$, in which case

$$d_1d_2\cdots = \cdots 1100\cdots$$

$$d'_1d'_2\cdots = \cdots 1011\cdots$$

and in either case the dyadic rational numbers represented are equal. The other five cases where $t_1t_2\cdots$ is $\cdots 10222\cdots$, $\cdots 0222\cdots$, $\cdots 01222\cdots$, $\cdots 1222\cdots$, or $\cdots 21222\cdots$ can be checked similarly. The cases $0222\cdots$ and $1222\cdots$ must be checked separately. 

V.3.9.3. **Proposition.** The function $f$ is continuous.

**Proof:** Recall () that if $x_n, x \in \mathbb{R}$, then $x_n \to x$ if and only if, for each $k$ there is an $N$ such that, for all $n \geq N$, the triadic expansion of $x_n$ (at least one expansion if $x_n$ is triadic rational) agrees with the triadic expansion of $x$ (at least one expansion if $x$ is triadic rational) at least up to the $k$‘th decimal place, and similarly for dyadic expansions. Since first $k$ decimal places of the dyadic expansion of $f(x)$ are completely determined by the first $k$ decimal places of the triadic expansion of $x$, it follows that if $x_n \to x$, then $f(x_n) \to f(x)$. 

V.3.9.4. **Proposition.** Let $x \in \mathbb{R}$. Then either $D^+f(x) = +\infty$ or $D_+f(x) = -\infty$, and either $D^-f(x) = +\infty$ or $D_-f(x) = -\infty$. In particular, $f$ is not differentiable anywhere.

**Proof:** Let $t_1t_2\cdots$ be the ternary expansion for the fractional part of $x$ not ending in a string of 2’s, and let $d_1d_2\cdots$ be the corresponding expansion of $f(x)$. There are infinitely many $n$ such that $t_{n+1} = t_n$ and $t_{n+1} \neq 2$. Fix such an $n$. Let $t'_{n+1} = 2$ if $t_{n+1} = t_n < 2$ and $t'_{n+1} = t_n$ if $t_{n+1} < t_n$. Then successively choose $t'_k$ for $k > n + 1$ so that the number $y$ with integer part the same as $x$ and fractional part $\cdots t_1t_2t_{n+1}t'_{n+1}t'_{n+2}\cdots$
has image

\[ f(y) = d_1 \cdots d_n d'_{n+1} d_{n+2} \cdots \]
i.e. \( d'_{n+1} \neq d_{n+1} \) but \( d'_k = d_k \) for all \( k \neq n + 1 \). We then have

\[ 0 < y - x \leq 3^{-n} \]
\[ |f(y) - f(x)| = 2^{-(n+1)} \]

so

\[ \left| \frac{f(y) - f(x)}{y - x} \right| \geq \frac{1}{2} \left( \frac{3}{2} \right)^n . \]

Since there are infinitely many such \( n \), the result for \( D^+ f(x) \) and \( D^- f(x) \) follows. The proof for \( D^- f(x) \) and \( D^- f(x) \) is similar.

V.3.9.5. The function takes values in \([0, 1]\), and takes the value 0 at the integers; thus, if \( x \) is an integer, we must have \( D^- f(x) \leq 0 \) and \( D_+ f(x) \geq 0 \), so \( D^+ f(x) = +\infty \) and \( D^- f(x) = -\infty \). Similarly, \( f(1/2) = 1 \), so if \( x \) is \( 1/2 \) or an integer translate, then \( D_+ f(x) \geq 0 \) and \( D^+ f(x) \leq 0 \), so \( D^- f(x) = +\infty \) and \( D_+ f(x) = -\infty \).

Continuous Functions Differentiable at Only One Point

V.3.9.6. Example. Let \( f \) be a continuous function from \( \mathbb{R} \) to \( \mathbb{R} \) which is not differentiable anywhere, e.g. one of the above examples. Set \( g(x) = x^2 f(x) \). Then \( g \) is a continuous function from \( \mathbb{R} \) to \( \mathbb{R} \). We claim that \( g \) is differentiable at 0, and only at 0.

To see that \( g \) is differentiable at 0, note that \( f \) is bounded on the interval \([-1, 1]\) since it is continuous there; say \( |f(x)| \leq M \) for \( |x| \leq 1 \). Then, for \( 0 < |x| \leq 1 \), we have

\[ \left| \frac{g(x) - g(0)}{x - 0} \right| = \left| \frac{x^2 f(x)}{x} \right| \leq M|x| \]

and thus \( g'(0) \) exists and equals 0 by the Squeeze Theorem.

But \( g \) is not differentiable anywhere except at 0, since if it were \( f(x) = \frac{g(x)}{x^2} \) would also be differentiable there by the Quotient Rule.
Figure V.6: Maple plot of graph of $f$
Figure V.7: Maple plot of $f(x) = \sum_{k=1}^{\infty} 2^{-k} \cos(4^k x)$
V.3.10. Exercises

V.3.10.1. Write out the proof of the power rule by writing, for \( f(x) = x^n \) (\( n \in \mathbb{N} \)) and \( a \in \mathbb{R} \),

\[
f'(a) = \lim_{h \to 0} \frac{f(a + h) - f(a)}{h} = \lim_{h \to 0} \frac{(a + h)^n - a^n}{h}
\]

and expanding \((a + h)^n\) using the Binomial Theorem (V.17.7.3).

V.3.10.2. Write the proof of the full Quotient Rule along the lines of the proofs of V.3.3.4 and V.3.3.11.

V.3.10.3. Here is an alternate derivation of the quotient formula and “proof” of the Quotient Rule which has appeared in some textbooks.

Let \( f \) and \( g \) be defined in a neighborhood of \( a \) and differentiable at \( a \), with \( g(a) \neq 0 \).

(i) Set \( h = \frac{f}{g} \). Then, since \( g \) is continuous at \( a \) and \( g(a) \neq 0 \), \( h \) is defined in a neighborhood of \( a \), and \( f = gh \) on this neighborhood.

(ii) By the Product Rule, \( f'(a) = g'(a)h(a) + g(a)h'(a) \).

(iii) Solve this equation for \( h'(a) \) to obtain the Quotient Rule formula.

(iv) What is wrong with this argument as a proof of the Quotient Rule? What does this argument actually prove?

V.3.10.4. (a) Show by direct calculation that if \( a \neq 0 \), then \( f(x) = \frac{1}{x} \) is differentiable at \( a \) and \( f'(a) = \frac{-1}{a^2} \).

(b) Use (a) and the Chain Rule to give an alternate proof of V.3.3.11.

(c) Conclude that the Quotient Rule is a consequence of (a), the Product Rule, and the Chain Rule.

V.3.10.5. What is wrong with the following “proof” of the Chain Rule? [Hint: the problem is very similar to the problem in ().]

Let \( f \) be defined on a neighborhood \( U \) of \( a \) and differentiable at \( a \), with \( f(a) = b \), and let \( g \) be defined on a neighborhood \( V \) of \( b \) and differentiable at \( b \), with \( f(U) \subseteq V \). Set \( h = g \circ f \) on \( U \).

(i) For \( x \in U \), \( x \neq a \), write

\[
\frac{h(x) - h(a)}{x - a} = \frac{g(f(x)) - g(f(a))}{f(x) - f(a)} \cdot \frac{f(x) - f(a)}{x - a}
\]

(ii) For \( x \in U \), write \( u = f(x) \). Since \( \lim_{x \to a} \frac{f(x) - f(a)}{x - a} \) exists and \( \lim_{x \to a} (x - a) = 0 \), we have \( \lim_{x \to a} (u - b) = 0 \).

(iii) Combining (i) and (ii), we have

\[
\lim_{x \to a} \frac{h(x) - h(a)}{x - a} = \left[ \lim_{u \to b} \frac{g(u) - g(b)}{u - b} \right] \left[ \lim_{x \to a} \frac{f(x) - f(a)}{x - a} \right] = g'(b)f'(a).
\]
V.3.10.6. What is wrong with the following “proof” of the Inverse Function Rule? What does this argument actually prove?

Let \( f \) be continuous and strictly monotone in a neighborhood of \( a \), and differentiable at \( a \). If \( f(a) = b \), then \( g = f^{-1} \) is defined, continuous, and strictly monotone in a neighborhood of \( b \) by (i).

(i) Set \( h = g \circ f = f^{-1} \circ f \). Then \( h(x) = x \) in a neighborhood of \( a \). Thus \( h \) is differentiable at \( a \), and \( h'(a) = 1 \).

(ii) Using the Chain Rule, differentiate \( h \) at \( a \) to obtain

\[
1 = h'(a) = g'(f(a))f'(a) = (f^{-1})'(b)f'(a) .
\]

(iii) If \( f'(a) \neq 0 \), divide both ends of the equation by \( f'(a) \) to obtain

\[
(f^{-1})'(b) = \frac{1}{f'(a)} .
\]

V.3.10.7. Prove the formula \( \frac{d}{dx} ([f(x)]^n) = n[f(x)]^{n-1}f'(x) \) for \( n \in \mathbb{N} \) by induction using the Product Rule instead of the Chain Rule.

V.3.10.8. (S. Chang\(^2\)) Let \( f(x) = \sum_{k=1}^{100} \frac{\sin(2\pi k^2 x)}{4\pi^2 k^3} + x^2 \). Note that \( f \) is \( C^\infty \) (in fact, analytic) on \( \mathbb{R} \).

Use a computer algebra system to plot \( f \), \( f' \), and \( f'' \). Could you have predicted the behavior of \( f'' \) from the appearance of the graph of \( f \), or even the graph of \( f' \)?

V.3.10.9. Formally define the “derivative” of a polynomial \( p(x) = \sum_{k=0}^{n} a_k x^k \) to be

\[
p#(x) = \sum_{k=1}^{n} k a_k x^{k-1} .
\]

Give a purely algebraic proof that \( p \rightarrow p# \) is linear and satisfies the “Product Rule”

\[
(pq)# = p#q + pq#
\]

for polynomials \( p \) and \( q \). (This argument is valid over any field or even any ring.)

V.3.10.10. Let \( f(x) = 2x^2 + x^2 \sin \frac{1}{x^2} \) for \( x \neq 0 \), \( f(0) = 0 \).

(a) Show that \( f \) is differentiable everywhere.

(b) Show that \( f \) has a strict local minimum (actually absolute minimum) at 0.

(c) Show that the first derivative test fails at 0.

V.3.10.11. There is a unique differentiable function \( f \) with \( f'(x) = \frac{1}{x} x + x^2 \sin \frac{1}{x^2} \) for \( x \neq 0 \) and \( f(0) = f'(0) = 0 \) (V.8.5.9.).

(a) Show that by the first derivative test, \( f \) has a local minimum at 0 (which is in fact a strict absolute minimum).

(b) In what sense is the graph of \( f \) concave upward around 0?

Let $f$ and $g$ be differentiable on an open interval $I$, and suppose that $f'g = fg'$ on $I$.

(a) Can we conclude from the quotient rule applied to $\frac{f}{g}$ that $\frac{f}{g}$ is constant on $I$, i.e. that $f$ is a constant multiple of $g$ on $I$?

(b) Consider the case where $I = \mathbb{R}$, $g(x) = x^2$ for all $x$, $f(x) = x^2$ if $x \leq 0$, and $f(x) = 2x^2$ for $x > 0$.

(c) Suppose we assume $f$ and $g$ are $C^\infty$. [Consider Cauchy’s examples V.17.2.3., especially the last two and their reflections.]

Let $f$ be van der Waerden’s example (V.3.8.1.).

(a) Let $a$ be a real number whose decimal part is $d_1d_2d_3\cdots$, where $d_n$ is in the range $0-4$ for $n$ odd and in the range $5-9$ for $n$ even. Show that $D_-f(a) = D_+f(a) = 0$ and $D^-f(a) = D^+f(a) = 1$.

(b) Show that if $m, n \in \mathbb{Z}$, $m < n$, there are uncountably many points $a$ in $[0, 1]$ with $D_-f(a) = D_+f(a) = m$ and $D^-f(a) = D^+f(a) = n$. [If $n > 0$, take the first $n$ decimal places in the range $0-4$, the next $n-m$ in the range $5-9$, etc.]

(c) Extend the argument of $b$ to cover the cases where $m$ and/or $n$ is $\pm \infty$. (Both can be $+\infty$ or both $-\infty$, or we can have $m = -\infty$ and $n = +\infty$.)

(d) For how many points $a$ is $D_-f(a) \neq D_+f(a)$ and/or $D^-f(a) \neq D^+f(a)$? What are the possibilities?
V.3.11. Calculus of Finite Differences

“The analysis of the infinite ... is nothing but a special case of the method of differences, ... wherein the differences are infinitely small ...”

*L. Euler*

In this section, we discuss a discrete version of derivatives. This procedure is important historically as a motivation of much of differential and integral calculus (cf. e.g. [Eul00]), and is still very useful in numerical analysis.

V.3.11.1. We start with a functional relation $y = f(x)$, where $f$ is a function defined, say, on all of $\mathbb{R}$ (simply to make the discussion simpler by not having to worry about domain questions). Fix an $x_0 \in \mathbb{R}$, and an “increment” $h > 0$ ($h$ is often written $\Delta x$). Form the sequence

$$x_0, x_1 = x_0 + h, x_2 = x_0 + 2h, \ldots, x_n = x_0 + nh, \ldots$$

which is an arithmetic sequence whose successive differences are each equal to $h = \Delta x$. Set

$$\Delta x_n = x_{n+1} - x_n$$

for each $n$; of course, $\Delta x_n = h$ for all $n$ since the $x_n$ were chosen evenly spaced.

V.3.11.2. Now form the sequence

$$y_0, y_1, y_2, \ldots$$

where $y_n = f(x_n)$ for each $n$. This sequence is rarely an arithmetic sequence (it will be arithmetic if $f$ is linear or affine); its properties are closely connected to the properties of the function $f$. Set

$$\Delta y_n = y_{n+1} - y_n = f(x + (n + 1)h) - f(x + nh)$$

for each $n$. The $\Delta y_n$ are called the sequence of first differences of $y$ (or $f$) corresponding to the increment $h = \Delta x$. This sequence is rarely constant (it will be constant if $f$ is linear or affine); its properties are closely connected to the properties of the function $f$. If $f$ is a quadratic polynomial, the first differences will form an arithmetic progression.

V.3.11.3. Go on to form the second differences

$$\Delta^2 y_n = \Delta y_{n+1} - \Delta y_n$$

for each $n$. The second differences are all zero if and only if the first differences are constant, e.g. if $f$ is affine. If $f$ is a quadratic polynomial, the second differences will be constant.

V.3.11.4. Successively form higher differences

$$\Delta^{k+1} x_n = \Delta^k y_{n+1} - \Delta^k y_n$$

for each $k$ and $n$. The sequence of $(k+1)$’st differences of $(y_n)$ is the sequence of first differences of $(\Delta^k y_n)$. If $f$ is a polynomial of degree $\leq k$, then the sequence of $k$’th differences will be constant, so the sequence of $(k+1)$’st differences will be $0$.

---

3[Eul00, p. 64].
V.3.11.5. The successive differences can be conveniently displayed in a table

\[
\begin{array}{cccccc}
  y_0 & y_1 & y_2 & y_3 & \cdots \\
\Delta y_0 & \Delta y_1 & \Delta y_2 & \Delta y_3 & \cdots \\
\Delta^2 y_0 & \Delta^2 y_1 & \Delta^2 y_2 & \cdots \\
\Delta^3 y_0 & \Delta^3 y_1 & \Delta^3 y_2 & \cdots \\
\vdots & \vdots & \vdots & \vdots & \ddots
\end{array}
\]

where the first row is computed from the function \( f \) and each other entry is the difference of the two entries just above it.

V.3.11.6. The sequence of \( k \)'th differences is a discrete version of the \( k \)'th derivative \( f^{(k)} \) (although the differences are defined for any \( f \) whether or not it is differentiable or even continuous).

V.3.11.7. Examples. (i) suppose \( f(x) = mx \). Then the table becomes

\[
\begin{array}{cccccc}
  mx_0 & mx_1 & mx_2 & mx_3 & \cdots \\
  m\Delta x & m\Delta x & m\Delta x & m\Delta x & \cdots \\
  0 & 0 & 0 & \cdots \\
  0 & 0 & 0 & \cdots \\
\vdots & \vdots & \vdots & \ddots
\end{array}
\]

since \( mx_{n+1} - mx_n = m\Delta x \) for all \( n \).

(ii) Let \( f(x) = x^2 \). Then the table becomes

\[
\begin{array}{cccccc}
  x_0^2 & x_1^2 & x_2^2 & x_3^2 & \cdots \\
  (x_0 + x_1)\Delta x & (x_1 + x_2)\Delta x & (x_2 + x_3)\Delta x & (x_3 + x_4)\Delta x & \cdots \\
  2(\Delta x)^2 & 2(\Delta x)^2 & 2(\Delta x)^2 & \cdots \\
  0 & 0 & 0 & \cdots \\
\vdots & \vdots & \vdots & \ddots
\end{array}
\]

since \( x_{n+1}^2 - x_n^2 = (x_n + x_{n+1})(x_{n+1} - x_n) = (x_n + x_{n+1})\Delta x \) for all \( n \). Since \( x_{n+1} = x_n + \Delta x \), we have
\[ \Delta y_n = 2x_n \Delta x + (\Delta x)^2, \] so the table becomes

\[
\begin{array}{cccccc}
& x_0^2 & x_1^2 & x_2^2 & x_3^2 & \cdots \\
2x_0 \Delta x + (\Delta x)^2 & 2x_1 \Delta x + (\Delta x)^2 & 2x_2 \Delta x + (\Delta x)^2 & 2x_3 \Delta x + (\Delta x)^2 & \cdots \\
\end{array}
\]

\[
\begin{array}{cccccc}
& 2(\Delta x)^2 & 2(\Delta x)^2 & 2(\Delta x)^2 & \cdots \\
0 & 0 & 0 & \cdots & \cdots \\
\end{array}
\]

(iii) Let \( f(x) = x^k, k \in \mathbb{N}. \) The binomial theorem shows that

\[ \Delta y_n = (x_n + \Delta x)^k - x_n^k = kx_n^{k-1} \Delta x + \binom{k}{2} x_n^{k-2} (\Delta x)^2 + \cdots + k x_n (\Delta x)^{k-1} + (\Delta x)^k \]

\[ = \left( x_n^{k-1} + x_n^{k-2} x_{n+1} + x_n^{k-3} x_{n+1}^2 + \cdots + x_n x_{n+1}^{k-2} + x_{n+1}^{k-1} \right) \Delta x. \]

The succeeding rows can be similarly calculated. The general formula is complicated, but the \((k+1)\)st row is constant, \( \Delta^k y_n = k!(\Delta x)^k \) for all \( n \), and the succeeding rows are 0.

(iv) Let \( f(x) = \frac{1}{x}. \) (This is not defined for all \( x \in \mathbb{R} \), but we only need that it is defined for \( x \geq x_0 \) to make the above construction of the differences work, so we just need to take \( x_0 > 0 \).) Then

\[ \Delta y_n = \frac{1}{x_n + \Delta x} - \frac{1}{x_n} = -\frac{1}{x_n(x_n + \Delta x)} \Delta x = -\frac{1}{x_n x_{n+1}} \Delta x \]

\[ \Delta^2 y_n = -\frac{1}{x_{n+1} x_{n+2}} \Delta x + \frac{1}{x_n x_{n+1}} \Delta x = \frac{x_{n+2} - x_n}{x_n x_{n+1} x_{n+2}} \Delta x = \frac{2 \Delta x}{x_n x_{n+1} x_{n+2}} (\Delta x)^2 \]

and higher differences can be calculated similarly. In this case the rows never become identically zero.

(v) Let \( f(x) = \sqrt{x} = x^{1/2}. \) Then

\[ \Delta y_n = \sqrt{x_n + \Delta x} - \sqrt{x_n} = \left( \sqrt{x_n + \Delta x} - \sqrt{x_n} \right) \sqrt{x_n + \Delta x} + \sqrt{x_n} = \frac{1}{\sqrt{x_n + \Delta x} + \sqrt{x_n}} \Delta x = \frac{1}{\sqrt{x_n} + \sqrt{x_{n+1}}} \Delta x. \]

Again, no row of higher differences becomes zero.

(vi) Let \( f(x) = a^x \) for fixed \( a > 0 \) (the comment from (iv) applies to this function). Then the sequence \( (y_0, y_1, \ldots) \) is a geometric progression with successive ratios \( b = a^h \). We have

\[ \Delta y_n = a^{x_0 + (n+1)h} - a^{x_0 + nh} = a^{x_0 + nh}(a^h - 1) = cy_n \]

where \( c = a^h - 1 \). Thus each succeeding row is also a geometric progression.
V.3.11.8. The $x_0$ is fixed in these calculations. But at the end we want to allow the $x_0$ to be any number (in the domain), and thus often write $x$ in place of $x_0$ and $y$ in place of $y_0$, and hence $\Delta^m y$ in place of $\Delta^m y_0$. Thus the above formulas become:

(i) If $f(x) = mx$, then $\Delta y = m\Delta x$ and $\Delta^k y = 0$ for $k > 1$.

(ii) If $f(x) = x^2$, then $\Delta y = 2x\Delta x + (\Delta x)^2$, $\Delta^2 y = 2(\Delta x)^2$, and $\Delta^m y = 0$ for $m > 2$.

(iii) If $f(x) = x^k$, then

\[
\Delta y = kx^{k-1}\Delta x + \left(\frac{k}{2}\right)x^{k-2}(\Delta x)^2 + \cdots + kx(\Delta x)^{k-1} + (\Delta x)^k
\]

and $\Delta^k y = k!(\Delta x)^k$.

(iv) If $f(x) = \frac{1}{x}$, then $\Delta y = -\frac{1}{x(x+\Delta x)}\Delta x$.

(v) If $f(x) = \sqrt{x}$, then $\Delta y = \frac{1}{\sqrt{x+\sqrt{x+\Delta x}}}\Delta x$.

(vi) If $f(x) = a^x$, then $\Delta y = ca^x = cy$, where $c = a^{\Delta x} - 1$.

V.3.11.9. The formulas from these examples are analogous to differentiation formulas, and suggest that the derivative of a power function should be a power function whose exponent is reduced by one, and that the derivative of an exponential function should be another exponential function. Here is a nonrigorous but suggestive closer link to differentiation. If we regard $h = \Delta x$ as “infinitesimally small,” so that the $x_n$ are essentially equal to $x = x_0$ (at least for $n$ small), in the case $f(x) = x^k$ we have

\[
\Delta y_n = (x_n^{k-1} + x_n^{k-2}x_n+1 + x_n^{k-3}x_n^{2} + \cdots + x_n^{k-2}x_n+1 + x_n+1)\Delta x \approx kx^{k-1}\Delta x
\]

for small $n$, and if $f(x) = a^x$ we have

\[
\Delta y_n = a^{x+(n+1)h} - a^{x+nh} = a^{x+nh}(a^h - 1) \approx cy = ca^x
\]

where $c = a^h - 1$.

V.3.11.10. More rigorously, we have

\[
f'(x) = \lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x}
\]

(to be completely rigorous we should also allow $h < 0$) so in the case where $f(x) = x^k$ we get $f'(x) = kx^{k-1}$, and in the case $f(x) = a^x$ we get

\[
f'(x) = a^x \left[ \lim_{h \to 0} \frac{a^h - 1}{h} \right].
\]

Of course, these are in fact the correct formulas. Note also that in these cases we have

\[
f^{(m)}(x) = \lim_{\Delta x \to 0} \frac{\Delta^m y}{(\Delta x)^m}
\]

for all $m$. This is one of the origins of the notation $\frac{d^m y}{dx^m}$ for $f^{(m)}(x)$. 
V.3.11.11. One can also consider the inverse problem, which is the discrete antiderivative problem: given the sequence of first differences \((\Delta y_n)\), find the sequence \((y_n)\) it comes from. The \(y_n\) are not uniquely determined: an arbitrary constant can be added to all the \(y_n\). This amounts to making an arbitrary choice of \(y_0\). Once \(y_0\) has been chosen, there is a unique solution:

\[
y_n = y_0 + \sum_{m=0}^{n-1} \Delta y_m .
\]
V.4. Extensions of the Derivative

There are a number of ways to extend the derivative concept which prove to be useful. We discuss several of these generalizations in this section.

V.4.1. One-Sided Derivatives

The first generalization we consider is one-sided derivatives. The definition is quite straightforward:

V.4.1.1. Definition. (i) Let $f$ be a real-valued function on the interval $[x_0, b)$. If

$$\lim_{h \to 0^+} \frac{f(x_0 + h) - f(x_0)}{h} = \lim_{x \to x_0^+} \frac{f(x) - f(x_0)}{x - x_0}$$

exists (as a real number), then $f$ is right differentiable at $x_0$, and this number is the right derivative of $f$ at $x_0$, denoted $D_R f(x_0)$.

(ii) Let $f$ be a real-valued function on the interval $(a, x_0]$. If

$$\lim_{h \to 0^-} \frac{f(x_0 + h) - f(x_0)}{h} = \lim_{x \to x_0^-} \frac{f(x) - f(x_0)}{x - x_0}$$

exists (as a real number), then $f$ is left differentiable at $x_0$, and this number is the left derivative of $f$ at $x_0$, denoted $D_L f(x_0)$.

Various notations are used for left and right derivatives, such as $D_l f$ and $f'$ for $D_L f$ and $D_r f$ and $f'_+$ for $D_R f$.

The next proposition is obvious from (i).

V.4.1.2. Proposition. Let $f$ be a real-valued function on an interval $(a, b)$, and $x_0 \in (a, b)$. Then $f$ is differentiable at $x_0$ if and only if it is both left and right differentiable at $x_0$ and $D_L f(x_0) = D_R f(x_0)$. We then have

$$f'(x_0) = D_L f(x_0) = D_R f(x_0).$$

We can have left and right derivatives which are not equal, or one or both may fail to exist:

V.4.1.3. Examples. (i) Let $f(x) = |x|$. Then $D_L f(0) = -1$ and $D_R f(x) = 1$. Thus $f$ is both left and right differentiable at 0, but not differentiable at 0.

(ii) Let $f(x) = \sqrt{x}$ on $[0, \infty)$. Then $D_R f(0)$ does not exist (we sometimes say $D_R f(0) = +\infty$), and $D_L f(0)$ is undefined since $f$ is undefined to the left of 0. So $f$ is neither left or right differentiable at 0.

(iii) Let $f(x) = \sqrt{x}$ for $x \geq 0$ and $f(x) = 0$ for $x < 0$. Then $D_R f(0)$ does not exist and $D_L f(0) = 0$. So $f$ is left differentiable but not right differentiable at 0.

(iv) Let $f(x) = x \sin \frac{1}{x}$ for $x \neq 0$ and $f(0) = 0$. Then neither $D_R f(0)$ nor $D_L f(0)$ exists. So $f$ is neither left or right differentiable at 0.
All these examples are continuous. We have the following slight generalization of (\ref{eq:cont}), whose proof is nearly identical and is left to the reader. Recall the definition of left and right continuity (\ref{eq:lrcont}).

V.4.1.4. **PROPOSITION.** (i) Let $f$ be a real-valued function on an interval $[x_0, b)$. If $f$ is right differentiable at $x_0$, then $f$ is right continuous at $x_0$.

(ii) Let $f$ be a real-valued function on an interval $(a, x_0]$. If $f$ is left differentiable at $x_0$, then $f$ is left continuous at $x_0$.

**Endpoint Differentiability and Differentiability on an Interval**

If $x_0$ is an endpoint of the domain of a function, it does not make sense to say that $f$ is differentiable at $x_0$. But one-sided differentiability does make sense, and is called *endpoint differentiability* in this context. So we may make the following definition in analogy with (\ref{eq:cont}):

V.4.1.5. **DEFINITION.** Let $f$ be a real-valued function on an interval $[a, b]$. Then $f$ is differentiable on $[a, b)$ if it is differentiable at all points of $(a, b)$, right differentiable at $a$, and left differentiable at $b$. Differentiability on an interval of the form $[a, b)$ or $(a, b]$ is defined analogously.

V.4.2. **Dini Derivatives**

A further generalization is very useful. Recall the definition of $\limsup$ and $\liminf$ from (\ref{eq:limsupinf}).

V.4.2.1. **DEFINITION.** (i) Let $f$ be a real-valued function on the interval $[x_0, b)$. Set

\[
D^+ f(x_0) = \limsup_{h \to 0^+} \frac{f(x_0 + h) - f(x_0)}{h} = \limsup_{x \to x_0^+} \frac{f(x) - f(x_0)}{x - x_0}
\]

\[
D_+ f(x_0) = \liminf_{h \to 0^+} \frac{f(x_0 + h) - f(x_0)}{h} = \liminf_{x \to x_0^+} \frac{f(x) - f(x_0)}{x - x_0}
\]

(as extended real numbers). $D^+ f(x_0)$ and $D_+ f(x_0)$ are the *upper and lower right Dini derivatives* of $f$ at $x_0$.

(i) Let $f$ be a real-valued function on the interval $(a, x_0]$. Set

\[
D^- f(x_0) = \limsup_{h \to 0^-} \frac{f(x_0 + h) - f(x_0)}{h} = \limsup_{x \to x_0^-} \frac{f(x) - f(x_0)}{x - x_0}
\]

\[
D_- f(x_0) = \liminf_{h \to 0^-} \frac{f(x_0 + h) - f(x_0)}{h} = \liminf_{x \to x_0^-} \frac{f(x) - f(x_0)}{x - x_0}
\]

(as extended real numbers). $D^- f(x_0)$ and $D_- f(x_0)$ are the *upper and lower left Dini derivatives* of $f$ at $x_0$.

V.4.2.2. **Note that the Dini derivatives are always defined, provided only that the function is defined on an interval to the appropriate side of $x_0$. We clearly always have $D_+ f(x_0) \leq D^+ f(x_0)$ and $D_- f(x_0) \leq D^- f(x_0)$.**

We then have an obvious characterization of left and right differentiability (cf. (\ref{eq:limsupinf})): 558
V.4.2.3. **Proposition.** (i) Let $f$ be a real-valued function on an interval $[x_0, b)$. Then $f$ is right differentiable at $x_0$ if and only if $D^+ f(x_0)$ and $D_+ f(x_0)$ are equal and finite. We then have

$$D_R f(x_0) = D^+ f(x_0) = D_+ f(x_0).$$

(ii) Let $f$ be a real-valued function on an interval $(a, x_0]$. Then $f$ is left differentiable at $x_0$ if and only if $D^- f(x_0)$ and $D_- f(x_0)$ are equal and finite. We then have

$$D_L f(x_0) = D^- f(x_0) = D_- f(x_0).$$

(iii) Let $f$ be a real-valued function on an interval $(a, b)$, and $x_0 \in (a, b)$. Then $f$ is differentiable at $x_0$ if and only if all four Dini derivatives at $x_0$ are equal and finite. We then have

$$f'(x_0) = D^+ f(x_0) = D_+ f(x_0) = D^- f(x_0) = D_- f(x_0).$$

V.4.2.4. **Examples.** (i) Let $f(x) = |x|$. Then $D^- f(0) = D_- f(0) = -1$ and $D^+ f(0) = D_+ f(x) = 1$.

(ii) Let $f(x) = \sqrt{x}$ on $[0, \infty)$. Then $D^+ f(0) = D_+ f(0) = +\infty$, and $D^- f(0)$ and $D_- f(0)$ are undefined since $f$ is undefined to the left of 0.

(iii) Let $f(x) = \sqrt{|x|}$. Then $D^+ f(0) = D_+ f(0) = +\infty$ and $D^- f(0) = D_- f(0) = -\infty$.

(iv) Let $f(x) = x \sin \frac{1}{x}$ for $x \neq 0$ and $f(0) = 0$. Then $D^+ f(0) = D_- f(0) = 1$ and $D_+ f(0) = D_- f(0) = -1$.

(v) Let $f(x) = x \sin \frac{1}{x}$ for $x > 0$ and $f(x) = 0$ for $x \leq 0$. Then $D^+ f(0) = 1$, $D_+ f(0) = -1$, and $D^- f(0) = D_- f(0) = 0$.

(vi) Let $f(x) = \sqrt{x} \sin \frac{1}{x}$ for $x \neq 0$ and $f(0) = 0$. Then $D^+ f(0) = D^- f(0) = +\infty$ and $D_+ f(0) = D_- f(0) = -\infty$.

(vii) Let $f(x) = x^{1/3}$. Then $D^+ f(0) = D_+ f(0) = D^- f(0) = D_- f(0) = +\infty$.

We have a version of (i) also for Dini derivatives:

V.4.2.5. **Proposition.** (i) Let $f$ be a real-valued function on an interval $[x_0, b)$. If $f$ is not right continuous at $x_0$, then at least one right Dini derivative at $x_0$ is infinite.

(ii) Let $f$ be a real-valued function on an interval $(a, x_0]$. If $f$ is not left continuous at $x_0$, then at least one left Dini derivative at $x_0$ is infinite.

**Proof:** The proofs of both (i) and (ii) consist of four nearly identical cases. We do only one of the cases for (i), and leave the rest of the cases to the reader.

In (i), if $f$ is not right continuous at $x_0$, then either $f(x_0) \neq \liminf_{x \to x_0^+} f(x)$ or $f(x_0) \neq \limsup_{x \to x_0^+} f(x)$ (or both). Suppose $f(x_0) < \liminf_{x \to x_0^+} f(x)$. Then

$$\liminf_{x \to x_0^+} [f(x) - f(x_0)] > 0$$

559
and, since $\lim_{x \to x_0^+} \frac{1}{x - x_0} = +\infty$, by (i) we have

$$D_+ f(x_0) = \liminf_{x \to x_0^+} \frac{f(x) - f(x_0)}{x - x_0} = +\infty.$$  

V.4.2.6. Note that the converse is not true by Examples V.4.2.4.(iii),(v),(vi). In fact, there are (many!) continuous functions $f$ on $\mathbb{R}$ for which $D^+ f(x) = D^- f(x) = +\infty$ and $D_+ f(x) = D_- f(x) = -\infty$ for every $x \in \mathbb{R}$.

Local Extrema

Here is a general version of V.3.6.3. The proof is essentially the same.

V.4.2.7. **Proposition.** Let $f$ be a function on an interval $(a,b)$, and $x_0 \in (a,b)$.

(i) If $f$ has a local maximum at $x_0$, then $D^- f(x_0) \geq 0$ and $D^+ f(x_0) \leq 0$.

(ii) If $f$ has a local minimum at $x_0$, then $D^- f(x_0) \leq 0$ and $D^+ f(x_0) \geq 0$.

This result also applies when $x_0$ is an endpoint of an interval in the domain of $f$, except that the Dini derivatives on the outside of the interval are not defined (or not relevant):

V.4.2.8. **Proposition.** Let $f$ be a real-valued function on $[a,b]$. Then

(i) If $f$ has an endpoint maximum at $a$, then $D^+ f(a) \leq 0$.

(ii) If $f$ has an endpoint minimum at $a$, then $D_- f(a) \geq 0$.

(iii) If $f$ has an endpoint maximum at $b$, then $D_- f(a) \geq 0$.

(iv) If $f$ has an endpoint minimum at $b$, then $D^+ f(a) \leq 0$.

V.4.2.9. Converses of these statements are, of course, false; the counterexamples in the differentiable case, such as $f(x) = x^3$ at 0, are also counterexamples here. But there is a version of the First Derivative Test in this generality (i).

V.4.2.10. At a single point, there may be no relation between the left and right Dini derivatives. However, at “most” points both upper Dini derivatives are greater than both lower derivatives:
V.4.2.11. Theorem. Let \( f \) be a real-valued function on an open interval \( I \). Set
\[
A = \{ x \in I : D^- f(x) < D_+ f(x) \}
\]
\[
B = \{ x \in I : D^+ f(x) < D_- f(x) \}.
\]
Then \( A \) and \( B \) are countable.

Proof: We prove that \( A \) is countable; the proof for \( B \) is essentially identical. Let \( x \in A \). Choose \( r_x \in \mathbb{Q} \) with \( D^- f(x) < r_x < D_+ f(x) \), and then fix \( s_x, t_x \in \mathbb{Q} \cap I \) with \( s_x < x < t_x \) and
\[
\frac{f(y) - f(x)}{y - x} < r_x \text{ for all } y, s_x < y < x
\]
\[
\frac{f(y) - f(x)}{y - x} > r_x \text{ for all } y, x < y < t_x.
\]
Then, for any \( y \neq x \) with \( s_x < y < t_x \), we have
\[
f(y) - f(x) > r_x (y - x).
\]
Define \( \phi : A \to \mathbb{Q}^3 \) by \( \phi(x) = (r_x, s_x, t_x) \). We show that \( \phi \) is one-to-one; then, since \( \mathbb{Q}^3 \) is countable, it will follow that \( A \) is countable. Suppose \( \phi(x) = \phi(z) \) for \( x, z \in A, x \neq z \). Since \( s_x = s_z < z < t_z = t_x \), we have
\[
f(z) - f(x) > r_x (z - x).
\]
Similarly, since \( s_z < x < t_z \), we have
\[
f(x) - f(z) > r_z (x - z).
\]
But \( r_x = r_z \), a contradiction. \( \diamondsuit \)

We get the following immediate consequence, which is not so obvious geometrically:

V.4.2.12. Corollary. Let \( f \) be a function on an interval \( I \). Then the set of \( x \in I \) for which \( D^- f(x) \) and \( D^+ f(x) \) are both defined (even allowing infinite values) but unequal is countable. In particular, if \( f \) is left and right differentiable everywhere in \( I \), then \( f \) is differentiable at all but countably many points of \( I \).

A far deeper result is the remarkable theorem proved successively for larger classes of functions by A. Denjoy, Grace Chisholm Young, and S. Saks:

V.4.2.13. Theorem. [Denjoy-Young-Saks] Let \( f \) be an arbitrary real-valued function on an interval \([a, b]\). Then for almost all \( x \in [a, b] \), one of the following four conditions holds:

1. \( f \) is differentiable at \( x \).
2. \( D^- f(x) = D_+ f(x) \in \mathbb{R}, D_+ f(x) = -\infty \), and \( D^- f(x) = +\infty \).
3. \( D^+ f(x) = D_- f(x) \in \mathbb{R}, D_- f(x) = -\infty \), and \( D^+ f(x) = +\infty \).
(4) \( D_- f(x) = D_+ f(x) = -\infty \) and \( D^- f(x) = D^+ f(x) = +\infty \).

In particular, for almost all \( x \in [a, b] \), either \( f \) is differentiable at \( x \) or else \( \max(D^- f(x), D^+ f(x)) = +\infty \) and \( \min(D_- f(x), D_+ f(x)) = -\infty \).

If \( f \) is measurable, then for almost all \( x \), either condition (1) or condition (4) holds (i.e. conditions (2) and (3) hold only on sets of measure zero).

The proof uses some sophisticated machinery, and will be given in \( () \). This result is closely related to a result about approximate tangents to rectifiable sets in geometric measure theory [Mor09, 3.12].

V.4.3. Symmetric First and Second Derivatives

V.4.4. Approximate and Weak Derivatives

V.4.5. Exercises

V.4.5.1. Define a function \( f : [0, 1) \rightarrow [0, 1) \) as follows. If \( x \in [0, 1) \), write

\[
x = .d_1d_2d_3\ldots
\]

in its decimal expansion not ending in an infinite string of 9’s. Set

\[
f(x) = .0d_10d_20d_3\ldots.
\]

(a) Show that \( f \) is a strictly increasing function.

(b) Show that \( f \) is right continuous everywhere.

(c) Show that \( f \) is left continuous except at the decadent rationals \( () \).

(d) Show that \( D_R f(x) \) exists and equals 0 everywhere.
V.5. Exponential and Trigonometric Functions

Anyone who has studied mathematics through calculus knows that exponential and trigonometric functions are of great importance, both theoretical and practical. However, the theoretical subtleties involved in properly defining these functions and establishing their properties are often underappreciated. Since the functions are so important and useful, they are usually introduced in the mathematics curriculum before the necessary tools (from calculus) for a proper treatment are available; and by the time the right tools are discussed, the functions are so familiar that they are often taken for granted. (These comments also apply to the historical development of exponential and trigonometric functions.)

A careful and rigorous treatment of exponential and/or trigonometric functions can be done in several ways. The two most common methods are: (1) defining one of the inverse functions (log or arcsin) as the antiderivative of a familiar function, or (2) using infinite series. In the case of exponential functions, there is a third approach which proceeds directly from algebraic rules of exponents. This third approach is the one we will take for exponential and logarithm functions in this section; see Exercise () for the first approach via integrals, and () for the infinite series approach. Our treatment of trigonometric functions will follow approach (1) (see () for the infinite series approach here).

V.5.1. Rational Exponents

V.5.1.1. Recall that if \( x \in \mathbb{R} \) and \( n \in \mathbb{N} \), then \( x^n = x \cdot x \cdots x \) (\( n \) times). If \( x \neq 0 \), extend this to \( n \in \mathbb{Z} \) by \( x^0 = 1 \) and \( x^{-n} = \frac{1}{(x^{-1})^n} = (x^n)^{-1} \). The usual rules of exponents hold: \( x^{m+n} = x^m x^n \), \( x^{m-n} = \frac{x^m}{x^n} \), \( (x^m)^n = x^{mn} \), \( (xy)^n = x^ny^n \) for all \( x, y \neq 0 \) and all \( m, n \in \mathbb{Z} \).

If \( n \in \mathbb{N} \) and \( x > 1 \), then \( x^n > x^m \). So if \( n \in \mathbb{N} \) and \( 0 < x < y \), then \( x^n < y^n \). If \( x > 1 \), then \( f(x) = x^n \) is strictly increasing on \((0, \infty)\). Similarly, if \( n \in \mathbb{Z} \), \( n < 0 \), then \( f(x) = x^n \) is strictly decreasing on \((0, \infty)\). For any \( n \in \mathbb{Z} \), \( f(x) = x^n \) is continuous and even differentiable on \((0, \infty)\), and its range is unbounded above and below in \((0, \infty)\) if \( n \neq 0 \).

Thus, by the IVT, if \( n \in \mathbb{Z} \), \( n \neq 0 \), then the range of \( f(x) = x^n \) is all of \((0, \infty)\), and by () \( f \) has a continuous inverse function \( f^{-1} \) which also maps \((0, \infty)\) onto \((0, \infty)\), and \( f^{-1} \) is strictly increasing if \( n > 0 \), strictly decreasing if \( n < 0 \). If \( x > 0 \), write \( x^{1/n} \) for \( f^{-1}(x) \). If \( n > 0 \), the definition of \( x^{1/n} \) can also be extended to \( x = 0 \) by setting \( 0^{1/n} = 0 \), and if \( n \) is odd, to \( x < 0 \) by \( x^{1/n} = -(x^{-1})^{1/n} \); the extended function is continuous on its domain.

V.5.1.2. Proposition. If \( p, q \in \mathbb{Z} \), \( q \neq 0 \), for \( x > 0 \) define \( x^{p/q} = (x^p)^{1/q} \). We then have:

(i) For \( p, q \in \mathbb{Z} \), \( q \neq 0 \), and \( x > 0 \), \( [(x^p)^{1/q}]^q = x^p = [(x^{1/q})^q]^p = [(x^{1/q})^p]^q \), so \( (x^p)^{1/q} = (x^{1/q})^p \) since \( f(x) = x^q \) is one-to-one.

(ii) Similarly, if \( p, q, r, s \in \mathbb{Z} \), \( q, s \neq 0 \), and \( x > 0 \), then \( [(x^{p/q})^{r/s}]^{q/s} = x^{p/r} = [(x^{r/s})^{p/q}]^{q/s} \), so \( (x^{p/q})^{r/s} = (x^{r/s})^{p/q} \). In particular, \( x^{p/s} = x^{p/q} \), and hence \( x^t \) is well defined for any \( t \in \mathbb{Q} \).

(iii) If \( r, s \in \mathbb{Q} \), \( x, y \in (0, \infty) \), we have \( (x^r)^s = x^{rs} \), \( x^{1+s} = x^{1}x^{s} \), \( x^{-s} = \frac{x}{x^s} \), \( (xy)^r = x^ry^r \).

(iv) If \( r \in \mathbb{Q} \), \( r \neq 0 \), the function \( f(x) = x^r \) is a composition of two strictly monotone continuous functions from \((0, \infty)\) onto \((0, \infty)\), hence strictly monotone and continuous, strictly increasing if \( r > 0 \) and strictly decreasing if \( r < 0 \).

(v) \( 1^r = 1 \) for all \( r \in \mathbb{Q} \), so if \( x > 1 \), then \( x^r > 1 \) for \( r > 0 \) and \( 0 < x^r < 1 \) for \( r < 0 \).
V.5.1.3. **Proposition.** If \( r \in \mathbb{Q} \), then \( f(x) = x^r \) is differentiable on \((0, \infty)\), and \( f'(x) = rx^{r-1} \) on \((0, \infty)\).

**Proof:** If \( n \in \mathbb{N} \), then \( \frac{d}{dx} (x^n) = nx^{n-1} \) \((v)\). The formula also obviously holds if \( n = 0 \). If \( n \in \mathbb{N} \), then using the Quotient Rule \( x^{-n} \) is differentiable on \((0, \infty)\) and

\[
\frac{d}{dx} (x^{-n}) = \frac{d}{dx} \left( \frac{1}{x^n} \right) = \frac{0 - nx^{-n-1}}{x^{2n}} = -nx^{-n-1}
\]

so the formula holds for all \( r \in \mathbb{Z} \). If \( q \in \mathbb{Z} \), \( q \neq 0 \), then by the Inverse Function Theorem \((v)\) \( x^{1/q} \) is differentiable on \((0, \infty)\) and

\[
\frac{d}{dx} \left( x^{1/q} \right) = \frac{1}{q(x^{1/q})^{q-1}} = \frac{1}{q x^{1-1/q}} = \frac{1}{q} x^{(1/q)-1}
\]

If \( r = \frac{p}{q} \), then by the Chain Rule \( x^r \) is differentiable on \((0, \infty)\) and

\[
\frac{d}{dx} \left( x^{p/q} \right) = \frac{d}{dx} \left( (x^p)^{1/q} \right) = \frac{1}{q} (x^p)^{(1/q)-1} \cdot px^{p-1} = \frac{p}{q} x^{(p/q)-1} = \frac{p}{q} x^{(p/q)-1}.
\]

V.5.2. **Irrational Exponents and Exponential Functions**

Now fix \( b > 1 \) and look at the function \( f(x) = b^x \) with domain \( \mathbb{Q} \).

V.5.2.1. **Proposition.** \( b^x \) is strictly increasing.

**Proof:** If \( x, y \in \mathbb{Q} \) with \( x < y \), then \( b^y = b^{x + (y-x)} = b^x b^{y-x} \), and \( b^{y-x} > 1 \) by \((v)\).

V.5.2.2. **Proposition.** \( \{b^n : n \in \mathbb{N}\} \) is unbounded.

**Proof:** If \( S = \{b^n : n \in \mathbb{N}\} \) is bounded, let \( a = \sup(S) \). Since \( b > 1 \), \( \frac{a}{b} < a \), so there is an \( n \in \mathbb{N} \) with \( b^n > \frac{a}{b} \). Then \( b^{n+1} > a \), a contradiction.

V.5.2.3. **Corollary.** \( \lim_{n \to \infty} b^{1/n} = 1 \).

**Proof:** The sequence \( (b^{1/n}) \) is decreasing and bounded below by 1, hence \( \lim_{n \to \infty} b^{1/n} \) exists and equals \( c := \inf_{n \in \mathbb{N}} b^{1/n} \). Then \( c \geq 1 \) and \( c^n \leq b \) for all \( n \in \mathbb{N} \), so \( c = 1 \) by V.5.2.2..
V.5.2.4. Proposition. If \( a \in \mathbb{Q} \), then the function \( f(x) = b^x \) is uniformly continuous on \((-\infty, a) \cap \mathbb{Q}\).

Proof: If \( \epsilon > 0 \), then there is an \( n \in \mathbb{N} \) with \( b^{1/n} - 1 < b^{-a} \epsilon \). Set \( \delta(\epsilon) = 1/n \). Then, if \( x, y \in \mathbb{Q} \), \( x < y < a \), \( y - x < \delta(\epsilon) \), we have

\[
0 < b^y - b^x = b^x (b^{y-x} - 1) < b^x (b^{y-x} - 1) < \epsilon.
\]

V.5.2.5. Corollary. The function \( f(x) = b^x \ (x \in \mathbb{Q}) \) extends to a continuous strictly increasing function on all of \( \mathbb{R} \), also denoted \( b^x \), with range \((0, \infty)\).

Proof: The extension is guaranteed by ??, and is continuous and increasing. To see that it is strictly increasing, let \( x, y \in \mathbb{R} \), \( x < y \), and let \( r, s \in \mathbb{Q} \), \( x < r < s < y \). Then \( b^x \leq b^r < b^s \leq b^y \). The range is an interval (??) which must be all of \((0, \infty)\) by V.5.2.2.

V.5.2.6. Definition. The function \( f(x) = b^x \) thus has a continuous strictly increasing inverse function \( f^{-1} \) with domain \((0, \infty)\) and range \( \mathbb{R} \). The number \( f^{-1}(x) \) is called the logarithm of \( x \) with base \( b \), denoted \( \log_b(x) \).

V.5.2.7. Proposition. The following laws of exponents and logarithms hold: if \( x, y \in \mathbb{R} \) and \( b, c > 1 \), then

\[
\begin{align*}
    b^{x+y} &= b^x b^y, \\
b^{x-y} &= \frac{b^x}{b^y}, \\
b^{xy} &= (b^x)^y, \\
b^{(bc)x} &= b^x c^x; \\
    \text{if } s, t > 0, r \in \mathbb{R}, \text{ then } \log_b(st) &= \log_b(s) + \log_b(t), \\
    \log_b(st) &= \log_b(s) - \log_b(t), \\
    \log_b(s^r) &= r \log_b(s). 
\end{align*}
\]

If \( c > 1 \), then \( \log_b(s) = \log_c(s) \log_b(c) \). In particular, \( \log_b 1 = 0 \) and \( \log_b(c) = \frac{1}{\log_b(b)} \).

Proof: The laws of exponents have already been established for \( x, y \in \mathbb{Q} \). They follow for general \( x, y \) by continuity: for example, if \( (x_n) \) and \( (y_n) \) are sequences of rational numbers with \( x_n \to x \) and \( y_n \to y \), then \( b^{x_n} \to b^x \), \( b^{y_n} \to b^y \), \( b^{x_n + y_n} \to b^{x+y} \), and \( b^{x_n y_n} \to b^{x+y} \) by continuity of \( b^x \) and standard limit theorems. The laws of logarithms follow from the laws of exponents by setting \( x = \log_b(s) \) and \( y = \log_b(t) \), so \( s = b^x \) and \( t = b^y \): for example, \( st = b^x b^y = b^{x+y} \), so \( \log_b(st) = x + y \). For the last formula, if \( z = \log_c(s) \), then \( s = c^z = (b^{\log_b c})^z = b^{z \log_b c} \), so \( \log_b(s) = z \log_b c \).

If \( 0 < b < 1 \) and \( x \in \mathbb{R} \), we can define \( b^x = (b^{-1})^{-x} \). Then \( b^x \) is strictly decreasing, as is the inverse function \( \log_b(x) \). The same rules of exponents and logarithms hold. We can also define \( 1^x = 1 \) for all \( x \).

An important property of the exponential function \( b^x \ (b > 0, b \neq 1) \) is that it is strictly convex (??):

V.5.2.8. Lemma. If \( b > 1, k \in \mathbb{R}, \) and \( x > 0 \), then \( b^{k+2x} - b^k > 2(b^{k+x} - b^k) \).

Proof:

\[
b^{k+2x} - b^k = b^k (b^{2x} - 1) = b^k (b^x + 1)(b^x - 1) = (b^x + 1)(b^{k+x} - b^k).
\]

565
V.5.2.9. Proposition. If $b > 1$ and $x, y, z \in \mathbb{R}$ with $z < y < x$, then

$$
\frac{b^y - b^z}{y - z} < \frac{b^x - b^z}{x - z} < \frac{b^x - b^y}{x - y}.
$$

(It follows that $f(x) = b^x$ is a strictly convex function.)

Proof: Lemma V.5.2.8. means that on any interval $[x_1, x_2]$ with midpoint $c$, the point $(c, b^c)$ lies below the line between $(x_1, b^{x_1})$ and $(x_2, b^{x_2})$. Thus the first inequality follows from repeated applications of V.5.2.8. if $y - z$ is a dyadic rational multiple of $x - z$ (see Exercise 1). By continuity the first inequality holds with $a$ for all $x, y, z$. To show that the strict inequality holds in general, choose $w$ with $y < w < x$ and $y - z$ a dyadic rational multiple of $w - z$. Then

$$
\frac{b^y - b^z}{y - z} < \frac{b^w - b^z}{w - z} < \frac{b^x - b^z}{x - z}.
$$

For the second inequality, suppose that $\frac{b^x - b^y}{x - y} < \frac{b^x - b^z}{x - z}$. Then

$$
b^x - b^z = (y - z)\frac{b^y - b^z}{y - z} + (x - y)\frac{b^x - b^y}{x - y} < (y - z)\frac{b^x - b^z}{x - z} + (x - y)\frac{b^x - b^z}{x - z} = b^x - b^z
$$

which is a contradiction.

V.5.2.10. Corollary. Let $b > 1$, and $0 < z < y < x$. Then

$$
\frac{\log_b x - \log_b y}{x - y} < \frac{\log_b x - \log_b z}{x - z} < \frac{\log_b y - \log_b z}{y - z}.
$$

Note that V.5.2.9. and V.5.2.10. also hold for $0 < b < 1$. For V.5.2.9.,

$$
\frac{(b^{-1})^{-y} - (b^{-1})^{-x}}{-y + x} < \frac{(b^{-1})^{-z} - (b^{-1})^{-x}}{-z + x} < \frac{(b^{-1})^{-z} - (b^{-1})^{-y}}{-z + y}.
$$

V.5.3. The Number $e$

V.5.3.1. Lemma. If $x > 0$ and $k > 1$, then $(1 + x)^k > 1 + kx$.

Proof: Fix $k > 1$ rational, and let $f(x) = (1 + x)^k - 1 - kx$ for $x \geq 0$. Then $f$ is differentiable for $x \geq 0$, $f(0) = 0$, and $f'(x) = k(1 + x)^{k-1} - k = k[(1 + x)^{k-1} - 1] > 0$ for $x > 0$. The formula thus holds for $k$ rational, and thus for $k$ irrational with $\geq$ by continuity. To see that the strict inequality holds for general $k > 1$, choose rational $r$ with $1 < r < k$. Then

$$
(1 + x)^k = [(1 + x)^r]^k/r > [1 + rx]^{k/r} \geq 1 + \frac{k}{r}rx.
$$

566
V.5.3.2. **Corollary.** The function \( g(x) = (1 + x)^{1/x} \) is decreasing for \( x > 0 \).

**Proof:** Let \( x > 0 \) and \( k > 1 \). Then \( (1 + kx)^{1/kx} < ([1 + x]^k)^{1/kx} = (1 + x)^{1/x} \).

Thus, to show that \( \lim_{x \to 0^+} (1 + x)^{1/x} \) exists, it suffices to show that \( (1 + x)^{1/x} \) is bounded for \( x > 0 \).

V.5.3.3. **Theorem.** Let \( h(x) = (1 + x)^{1+1/x} \) for \( x > 0 \). Then

(i) \( h \) is increasing.

(ii) \( g(x) < h(z) \) for all \( x, z > 0 \).

(iii) \( \lim_{x \to 0^+} g(x) \) and \( \lim_{x \to 0^+} h(x) \) exist and are equal.

V.5.3.4. **Lemma.** Let \( b > 1 \), \( x > 0 \), and \( 0 < y < 1 \). Then

\[
\log_b([1 + x]^{1/x}) = \frac{\log_b(1 + x)}{x} < -\frac{\log_b(1 - y)}{y} = \log_b\left(\frac{1}{1 - y}\right)^{1/y}.
\]

**Proof:** Apply V.5.2.10. to \( 1 - y, 1, 1 + x \).

We now prove Theorem V.5.3.3.

**Proof:** For (i) and (ii), fix \( b > 1 \) and for \( z > 0 \) set \( y = \frac{z}{1+z} \). Then \( 0 < y < 1 \) and \( z = \frac{1}{1-y} - 1 \), and \( z \) increases from 0 to \( +\infty \) as \( y \) increases from \( 0 \) to \( 1 \). By V.5.2.10., \( -\frac{\log_b(1 - y)}{y} = \log_b\left(\frac{1}{1 - y}\right)^{1/y} \) increases in \( y \) for \( 0 < y < 1 \) [if \( 0 < y_1 < y_2 < 1 \), apply V.5.2.10. to \( 1 - y_2, 1 - y_1, 1 \), so \( \log_b([1 + z]^{1+z}) \) increases in \( z \) for \( z > 0 \), proving (i), and V.5.3.4. with \( y \) converted to \( z \) gives (ii).

Thus \( g(x) \) is increasing and bounded above as \( x \to 0^+ \), and \( h(x) \) is decreasing and bounded below, so \( \lim_{x \to 0^+} g(x) = \sup_{x>0} g(x) \) and \( \lim_{x \to 0^+} h(x) = \inf_{x>0} h(x) \) exist; call the limits \( d \) and \( e \) respectively. Then

\[
2 = (1 + 1)^1 < d \leq e,
\]

and \( \lim_{x \to 0^+} \frac{h(x)}{g(x)} = \frac{e}{d} \). But \( \frac{h(x)}{g(x)} = 1 + x \), so \( \lim_{x \to 0^+} \frac{h(x)}{g(x)} = 1 = \frac{e}{d}, \ d = e. \)

V.5.3.5. **Definition.** The number \( e \) is the limit \( \lim_{x \to 0^+} (1 + x)^{1/x} \).

The number \( e \) is one of the most important constants in mathematics, comparable in importance to \( \pi \).

V.5.3.6. **Corollary.** \( e > (1 + 1)^1 = 2 > 1 \), so \( f(x) = e^x \) is strictly increasing and continuous, and its inverse function \( \ln x = \log_e x \) is continuous.

The function \( \ln x \) is called the natural logarithm function, and mathematicians usually write it \( \log x \).
V.5.3.7. We can of course get better estimates of the numerical value of \(e\) using V.5.3.3. for small \(x\): for example, if \(x = .01\), we get \(2.704 < 1.01^{100} < e < 1.01^{101} < 2.732\). The average of \(1.01^{100}\) and \(1.01^{101}\), \(2.7183\), is an even better estimate (the geometric mean, \(2.7183\), is better yet). The exact numerical value of \(e\) is \(2.718281828\) (the decimal does not continue to repeat; \(e\) is an irrational number, in fact transcendental – see III.9.3.1.). There are more efficient ways to compute \(e\) using infinite series; see ??.

V.5.4. Derivatives of Exponential and Logarithm Functions

V.5.4.1. Theorem. The function \(f(x) = e^x\) is differentiable, and \(f'(x) = e^x\).

V.5.4.2. Lemma. If \(f(x) = e^x\), then \(f\) is differentiable at 0 and \(f'(0) = \lim_{h \to 0} \frac{e^h - 1}{h} = 1\).

Proof: Let \(x = e^h - 1\). Then \(h = \ln(1 + x)\) and \(x \to 0\) as \(h \to 0\) (i.e. \(\lim_{h \to 0} e^h - 1 = 0\) and \(\lim_{x \to 0} \ln(1 + x) = 0\) by continuity of \(e^x\) and \(\ln x\), and \(x > 0\) if and only if \(h > 0\). Thus

\[
\lim_{h \to 0^+} \frac{e^h - 1}{h} = \lim_{x \to 0^+} \frac{x}{\ln(1 + x)} = \lim_{x \to 0^+} \frac{1}{x \ln(1 + x)} = \lim_{x \to 0^+} \frac{1}{(1 + x)^{1/2}} = \frac{1}{\ln e} = 1
\]

since \(\lim_{x \to 0^+} (1 + x)^{1/2} = e\) and \(\ln x\) is continuous at \(e\). We also have

\[
\lim_{h \to 0^-} \frac{e^h - 1}{h} = \lim_{h \to 0^+} \frac{e^{-h} - 1}{-h} = \lim_{h \to 0^+} \frac{e^{-h}(1 - e^h)}{-h} = \left[ \lim_{h \to 0^+} e^{-h} \right] \left[ \lim_{h \to 0^+} \frac{e^h - 1}{h} \right] = 1
\]

We now prove Theorem V.5.4.1.

Proof: Fix \(x\). Then

\[
f'(x) = \lim_{h \to 0} \frac{e^{x+h} - e^x}{h} = \lim_{h \to 0} \frac{e^x e^h - e^x}{h} = \lim_{h \to 0} \frac{e^x (e^h - 1)}{h} = e^x \lim_{h \to 0} \frac{e^h - 1}{h} = e^x
\]

V.5.4.3. Corollary. Let \(b > 0\), and \(f(x) = b^x\). Then \(f\) is differentiable everywhere and \(f'(x) = (\ln b) b^x\) for all \(x\).

Proof: Since \(b^x = e^{x \ln b}\), the result follows from V.5.4.1. and the Chain Rule.

V.5.4.4. Corollary. If \(b > 0\), \(b \neq 1\), then \(f(x) = \log_b(x)\) is differentiable on \((0, \infty)\), and \(\frac{d}{dx} (\log_b(x)) = \frac{1}{x \ln b}\). In particular, \(\frac{d}{dx} (\ln x) = \frac{1}{x}\).

Proof: This follows immediately from V.5.4.3. and the Inverse Function Theorem:

\[
\frac{d}{dx} (\log_b x) = \frac{1}{(\ln b) b^{\log_b x}} = \frac{1}{x \ln b}.
\]
V.5.4.5. Corollary. For all \( r \in \mathbb{R} \), the function \( f(x) = x^r \) is differentiable (hence continuous) on \((0, \infty)\), and the formula \( \frac{d}{dx} (x^r) = r x^{r-1} \) holds on \((0, \infty)\).

Proof: Since \( x^r = e^{r \ln x} \) for \( x > 0 \), \( f \) is differentiable by V.5.4.1, V.5.4.4, and the Chain Rule, and we have

\[
\frac{d}{dx} (x^r) = \frac{d}{dx} (e^{r \ln x}) = e^{r \ln x} \frac{r}{x} = r x^{r-1}.
\]

\( \Box \)

V.5.5. Exercises

V.5.5.1. (a) Write out the details of the proof of V.5.1.2(ii).
(b) Prove the rules of exponents in V.5.1.2(iii), using arguments similar to those in (i). (Note that the first rule has already been proved in (ii).)

V.5.5.2. (a) Prove the assertion in the first sentence in the proof of V.5.2.9.
(b) Prove the rules of exponents in V.5.2.9, by induction, using the statement \( P(n) \): “For every \( u, v, w \in \mathbb{R} \) with \( w < v < u \) and \( \frac{w-u}{v-u} = \frac{k}{2^n} \) for some \( k \in \mathbb{N} \), \( k < 2^n \), \( \frac{u-v}{v-w} < \frac{k}{u-v} \cdot \frac{v-u}{w-u} \).

To prove \( P(n+1) \) for a set \( u, v, w \), apply \( P(n) \) to either the first or second half of the interval \([w, u]\) depending where \( v \) is.

V.5.5.3. Here is an alternate approach to the definition of \( e \) (cf. [?, III.4].) Let \( x_n = (1 + \frac{1}{n})^n \).
(a) Using the Binomial Theorem, show that

\[
x_n = 1 + 1 + \frac{1}{2!} \left(1 - \frac{1}{n}\right) + \frac{1}{3!} \left(1 - \frac{1}{n}\right) \left(1 - \frac{2}{n}\right) + \cdots + \frac{1}{k!} \left(1 - \frac{1}{n}\right) \left(1 - \frac{2}{n}\right) \cdots \left(1 - \frac{k-1}{n}\right).
\]

(b) Using (a), show that \( x_n < x_{n+1} \) for any \( n \in \mathbb{N} \).
(c) Let \( y_n = \sum_{k=0}^n \frac{1}{k!} \). Show that \( x_n < y_n \) for all \( n \).
(d) Since \( k! > 2^{k-1} \) for all \( k > 2 \), show that \( y_n < 2 + \sum_{k=2}^n \frac{1}{2^{k-1}} < 3 \) for \( n > 2 \). Thus the sequence \( (x_n) \) is a bounded increasing sequence, hence convergent. Call the limit \( e \). Show that \( 2 < e < 3 \).

V.5.5.4. Use the notation of V.5.5.3.
(a) If \( 1 < k < n \), set

\[
z_{k,n} = 1 + 1 + \frac{1}{2!} \left(1 - \frac{1}{n}\right) + \frac{1}{3!} \left(1 - \frac{1}{n}\right) \left(1 - \frac{2}{n}\right) + \cdots + \frac{1}{k!} \left(1 - \frac{1}{n}\right) \left(1 - \frac{2}{n}\right) \cdots \left(1 - \frac{k-1}{n}\right).
\]

Show that \( z_{k,n} < x_n \), so \( z_{k,n} < e \).
(b) Fix \( k \). Show \( \lim_{n \to \infty} z_{k,n} = y_k \). Conclude that \( y_k \leq e \) for all \( k \). (In fact, since \( y_k < y_{k+1} \leq e \), we have \( y_k < e \) for all \( k \).)

(c) Since \( x_k < y_k < e \) for all \( k \), and \( \lim_{k \to \infty} x_k = e \), we have \( \lim_{k \to \infty} y_k = e \).

569
V.5.5.5. Use the notation of V.5.5.3–V.5.5.4. The sequence \((y_n)\) converges to \(e\) fairly rapidly (unlike \((x_n)\), which converges rather slowly):

(a) For each \(n\) and each \(m > 1\), show that

\[
y_{n+m} - y_n = \frac{1}{(n+1)!}\left(1 + \sum_{k=2}^{m} \frac{1}{(n+2)\cdots(n+k)}\right)
\]

and thus, since \(\lim_{m \to \infty} y_{n+m} = e\), \(e - y_n \leq \frac{1}{(n+1)!}\left(1 + \sum_{k=2}^{\infty} \frac{1}{(n+2)\cdots(n+k)}\right)\).

(b) By comparing terms and using \(\sum_{k=0}^{\infty} r^k = \frac{1}{1-r}\) for \(|r| < 1\),

\[
e - y_n \leq \frac{1}{(n+1)!}\left(1 + \sum_{k=2}^{\infty} \frac{1}{(n+2)\cdots(n+k)}\right)
\]

Thus, for example, \(e - y_{10} < \frac{12}{101} \approx 2.17 \times 10^{-8}\), so \(y_{10}\) agrees with \(e\) to 7 decimal places. \(e - y_{100} < \frac{102}{100.107^2} \approx 10^{-156}\), so \(y_{100}\) (which can be quickly computed on a programmable hand calculator) agrees with \(e\) to at least 155 decimal places. (In contrast, \(x_{100} = 2.704\cdots\) only agrees with \(e\) to one decimal place.)

(c) Since \(\frac{n(n+2)}{(n+1)^2} = \frac{n^2 + 2n}{n^2 + 2n + 1} < 1\), we have \(y_n \leq e < y_n + \frac{1}{n+1}\). We can write \(e = y_n + \frac{\theta_n}{n+1}\) for some \(\theta_n\), \(0 < \theta_n < 1\).

(d) Using (b) and \(y_{n+1} < e\), show that

\[
\frac{n}{n+1} < \theta_n < \frac{n^2 + 2n}{n^2 + 2n + 1}
\]

and thus \(\theta_n \to 1\) as \(n \to \infty\).

V.5.5.6. Continue to use the notation of V.5.5.3–V.5.5.5. Show that \(e\) is irrational as follows. Suppose \(e = \frac{m}{n}\). Then

\[
m = 1 + \frac{1}{2!} + \cdots + \frac{1}{n!} + \frac{\theta_n}{n!} n
\]

Multiply both sides by \(n!\) to conclude that \(\frac{\theta_n}{n!}\) is an integer. This is a contradiction since \(0 < \theta_n < 1\).

V.5.5.7. Let \(f : \mathbb{R} \to \mathbb{R}\) be a continuous function with \(f(x + y) = f(x) + f(y)\) for all \(x, y \in \mathbb{R}\).

(a) Let \(a = f(1)\). Show that \(f(n) = an\) for all \(n \in \mathbb{Z}\).

(b) Show that \(f(r) = ar\) for all \(r \in \mathbb{Q}\).

(c) Use continuity to show that \(f(x) = ax\) for all \(x \in \mathbb{R}\). Thus \(f\) is linear.

(d) The continuity hypothesis cannot be removed. (However, the continuity hypothesis can be relaxed to Lebesgue measurability; see ??.) \(\mathbb{R}\) is a vector space over \(\mathbb{Q}\) of dimension \(2^{\aleph_0}\). Let \(B\) be a basis for \(\mathbb{R}\) over \(\mathbb{Q}\). Then every function from \(B\) to \(\mathbb{R}\) extends to a \(\mathbb{Q}\)-linear (hence additive) function from \(\mathbb{R}\) to \(\mathbb{R}\). There are \(2^{2^{\aleph_0}}\) functions from \(B\) to \(\mathbb{R}\). But there are only \(2^{\aleph_0}\) \(\mathbb{R}\)-linear functions from \(\mathbb{R}\) to \(\mathbb{R}\). Using the Axiom of Choice, construct a discontinuous example.

570
V.5.5.8. Let \( g \) be a continuous function from \( \mathbb{R} \) to \( \mathbb{R} \) which is not identically 0 and with the property that \( g(x+y) = g(x)g(y) \) for all \( x, y \in \mathbb{R} \).

(a) Show that \( g \) takes only positive values. \([g(x) = g(x/2)^2]\)

(b) Show using Exercise V.5.5.7. that \( g(x) = b^x \) for all \( x \), where \( b = g(1) > 0 \). So \( g \) is an exponential function. \([\text{Consider } f(x) = \log g(x).]\)

(c) The continuity hypothesis cannot be removed here either: construct a discontinuous example.

(d) Prove similarly that a continuous function \( h : (0, \infty) \to \mathbb{R} \) which is not identically 0 and which has the property that \( h(xy) = h(x) + h(y) \) for all \( x, y > 0 \) must be a logarithm function.

V.5.5.9. Redevop the entire theory of exponential and logarithm functions by first defining \( \log x = \int_1^x \frac{1}{t} \, dt \) for \( x > 0 \) and then letting \( f(x) = e^x \) be the inverse function of \( \log x \).

V.5.5.10. Here is an alternate approach to proving differentiability of exponential functions. Let \( b > 1 \). Then \( g_b(x) = b^x \) is continuous on \( \mathbb{R} \) (??).

(a) If \( k \in \mathbb{R} \), \( \int_{-k}^{-1} b^t \, dt < b^{-k} \). Thus, if \( n \in \mathbb{N} \), \( \int_{-n}^{0} b^t \, dt < \sum_{k=0}^{n-1} b^{-k} = \frac{1-b^{-n}}{1-b^{-1}} \).

(b) Conclude that the improper integral \( \int_{-\infty}^{\infty} b^t \, dt \) converges, and hence \( \int_{-\infty}^{\infty} b^t \, dt \) converges for any \( x \). For \( x \in \mathbb{R} \), set \( f_b(x) = \int_{-\infty}^{x} b^t \, dt \). Show that \( f_b \) is differentiable and \( f'_b(x) = g_b(x) = b^x \) for all \( x \).

(c) By changing variables in the improper integral, show that \( f_b(x) = b^x \cdot f_b(0) \) for any \( x \). Thus \( g_b \) is infinitely differentiable, and \( g'_b = k_b g_b \), where \( \frac{1}{k_b} = \int_{-\infty}^{0} b^t \, dt \).

(d) If \( a, b > 1 \), apply the product rule to \( g_{ab} = g_a g_b \) to conclude that \( k_{ab} = k_a + k_b \). Prove that \( \ell(b) = k_b \) is continuous. Thus \( \ell \) is a logarithm function.

V.6. Trigonometric Functions

There is a dark secret behind the usual (precalculus) development of the theory of trigonometric functions: the entire theory is based on logical quicksand. All of trigonometry is based on the assumption that a circle has a finite “circumference” (“arc length”), which is never really defined; the number \( \pi \) is “defined” to be the ratio of the “circumference” to the diameter, and empirically calculated to be a little more than three. This assumption, while eminently believable and experimentally verifiable, is logically untenable, especially in the absence of a real definition of arc length. The notion of arc length can only be rigorously defined using limits (\( \)). See I.5.1.3.ff. for a fuller discussion.

In this section, we will give a rigorous and efficient treatment of trigonometric functions, the properties and identities they satisfy, and their calculus. We will actually define one of the inverse trigonometric functions first, an approach which may seem oddly backwards to readers familiar with the traditional approach, but which has the advantage of being logically impeccable.

V.6.1. Arc Length of a Circle and the Arcsine Function

We will consider the unit circle \( \{(x, y) : x^2 + y^2 = 1\} \) in \( \mathbb{R}^2 \).

V.6.1.1. PROPOSITION. The arc length of the circle is finite.

To prove this, consider the arc from \((0,1)\) to \((1,0)\), which is a quarter circle. By symmetry, it is enough to prove that this arc has finite length. We give two arguments.
V.6.1.2. First consider the arc from \((0, 1)\) to \((b, \sqrt{1-b^2})\) for \(0 < b < 1\). This arc is the graph of the continuously differentiable function \(y = \sqrt{1 - x^2}\) on \([0, b]\), so by ?? the arc length is finite and given by

\[
L(0, b) = \int_0^b \sqrt{1 + \frac{x^2}{1-x^2}} \, dx = \int_0^b \frac{1}{\sqrt{1-x^2}} \, dx
\]

Thus, for example, the arc from \((0, 1)\) to \((\frac{1}{2}, \frac{\sqrt{3}}{2})\) has finite length. Since this arc is congruent to the arc from \((\frac{1}{2}, \frac{\sqrt{3}}{2})\) to \((1, 0)\) (via interchanging \(x\) and \(y\)), this arc also has finite length, and the quarter circle is the union, hence also has finite length which we will call \(L(0, 1)\).

V.6.1.3. We give an alternate argument which gives a (rather crude) estimate of the length. As \(b \to 1\), \(L(0, b) \to L(0, 1)\) (??), and \(L(0, b)\) is increasing as \(b\) increases, so we only need show that \(\{L(0, b) : 0 \leq b < 1\}\) is bounded. But if \(0 < x < 1\), \(x^2 < x\), so \(\frac{1}{\sqrt{1-x^2}} < \frac{1}{\sqrt{1-x}}\), and

\[
L(0, b) = \int_0^b \frac{1}{\sqrt{1-x^2}} \, dx < \int_0^b \frac{1}{\sqrt{1-x}} \, dx = -2\sqrt{1-x}\bigg|_0^b = 2 - 2\sqrt{1-b} < 2
\]

for all \(b < 1\); thus \(L(0, 1)\) is finite and less than 2.

V.6.1.4. To get a lower bound for \(L(0, 1)\), since it is the length of an arc from \((0, 1)\) to \((1, 0)\), it must be greater than the straight-line distance between the points, which is \(\sqrt{2}\). A better lower bound, for example, is the sum of the distance from \((0, 1)\) to \((\frac{1}{2}, \frac{\sqrt{3}}{2})\) and the distance from \((\frac{1}{2}, \frac{\sqrt{3}}{2})\) to \((1, 0)\), which is \(\sqrt{\frac{3}{1}} + \sqrt{\frac{2}{1}} = 1.52688 \cdots\).

V.6.1.5. Definition. The number \(\pi\) is the arc length of half the unit circle.

By symmetry, \(\pi = 2L(0, 1)\). By the above estimates, we have \(2(\sqrt{\frac{3}{1}} + \sqrt{\frac{2}{1}}) = 3.05 \cdots < \pi < 4\). Of course, it is well known that the exact value of \(\pi\) is \(3.1415926535 \cdots\); we will discuss efficient ways to calculate \(\pi\) later (??).

V.6.1.6. Definition. If \(-1 \leq x \leq 1\), the \textit{arcsine} of \(x\) is the number

\[
\arcsin x = \int_0^x \frac{1}{\sqrt{1-t^2}} \, dt
\]

(If \(x = \pm 1\), this is an improper integral; we can define \(\arcsin 1 = L(0, 1) = \frac{\pi}{2}\) and \(\arcsin(-1) = -L(0, 1) = -\frac{\pi}{2}\).)

Thus \(\arcsin x\) is the antiderivative of \(\frac{1}{\sqrt{1-x^2}}\), i.e. by the Fundamental Theorem of Calculus, \(\frac{d}{dx} \left(\arcsin x\right) = \frac{1}{\sqrt{1-x^2}}\) for \(-1 < x < 1\). Thus \(f(x) = \arcsin x\) is continuous on \([-1, 1]\) and differentiable on \((-1, 1)\), and \(f'(x) = \frac{1}{\sqrt{1-x^2}} > 0\) on \((-1, 1)\), so \(\arcsin x\) is strictly increasing on \([-1, 1]\). We have \(\arcsin 0 = 0\) and \(\arcsin(-x) = -\arcsin x\) for \(-1 \leq x \leq 1\).

V.6.2. The Sine and Cosine Functions

Since \(f(x) = \arcsin x\) is continuous and strictly increasing on \([-1, 1]\), with range \([-\frac{\pi}{2}, \frac{\pi}{2}]\), it has a continuous inverse function \(g(x)\) on \([-\frac{\pi}{2}, \frac{\pi}{2}]\).
V.6.2.1. **Definition.** If \( x \in \left[ -\frac{\pi}{2}, \frac{\pi}{2} \right] \), the *sine* of \( x \) is \( \sin x = g(x) \), and the *cosine* of \( x \) is \( \cos x = \sqrt{1 - g(x)^2} = \sqrt{1 - (\sin x)^2} \).

We usually write \( \sin^2 x \) instead of \( (\sin x)^2 \), i.e. \( \cos^2 x = (\cos x)^2 \). Thus \( \sin^2 x + \cos^2 x = 1 \) for all \( x \in \left[ -\frac{\pi}{2}, \frac{\pi}{2} \right] \) (of course, \( \cos^2 x = (\cos x)^2 \)).

V.6.2.2. Since \( \arcsin(x) = \arcsin(x) \), \( \sin x \) has the same property:

\[
\sin(-x) = -\sin x \\
\cos(-x) = \cos x
\]

We have \( \sin 0 = 0, \cos 0 = 1, \sin(\frac{\pi}{2}) = 1, \cos(\frac{\pi}{2}) = 0, \sin(-\frac{\pi}{2}) = -1, \cos(-\frac{\pi}{2}) = 0. \)

V.6.2.3. From the Inverse Function Theorem, \( g(x) = \sin x \) is differentiable on \( \left( -\frac{\pi}{2}, \frac{\pi}{2} \right) \) and

\[
g'(x) = \frac{1}{f'(g(x))} = \frac{1}{\sqrt{1 - \sin^2 x}} = \sqrt{1 - \sin^2 x} = \cos x
\]

and from the Chain Rule \( h(x) = \cos x \) is differentiable on \( \left( -\frac{\pi}{2}, \frac{\pi}{2} \right) \) and

\[
h'(x) = \frac{d}{dx} \left( \sqrt{1 - \sin^2 x} \right) = \frac{1}{2} \left( \sqrt{1 - \sin^2 x} \right)^{-1/2} (-2 \sin x \cos x)
\]

\[
= -\frac{\sin x \cos x}{\sqrt{1 - \sin^2 x}} = -\frac{\sin x \cos x}{\cos x} = -\sin x
\]

and thus we obtain:

V.6.2.4. **Theorem.** The functions \( \sin x \) and \( \cos x \) are infinitely differentiable on \( \left( -\frac{\pi}{2}, \frac{\pi}{2} \right) \), and

\[
\frac{d}{dx} (\sin x) = \cos x, \quad \frac{d}{dx} (\cos x) = -\sin x
\]

for \( -\frac{\pi}{2} < x < \frac{\pi}{2} \).

V.6.2.5. By the properties of inverse functions, if \( 0 \leq x \leq \frac{\pi}{2} \), \( \sin x = b \) means

\[
x = \arcsin b = L(0, b) = \int_0^b \frac{1}{\sqrt{1 - t^2}} dt
\]

so the point \( P \) on the circle (in the first quadrant) for which the arc from \( (0,1) \) to \( P \) has length \( x \) has first coordinate \( \sin x \). The second coordinate is then \( \sqrt{1 - \sin^2 x} = \cos x \), i.e. \( P = (\sin x, \cos x) \). It is more customary to measure arcs of the circle counterclockwise from \( (1,0) \), and then the coordinates of the point of arc length \( x \) are \( (\cos x, \sin x) \) (just apply the transformation interchanging \( x \) and \( y \)).
We extend the definition of \( \sin x \) and \( \cos x \) to all real numbers by taking \((\cos x, \sin x)\) to be the coordinates of the point of arc length \(x\) traveling counterclockwise around the circle from \((1,0)\) (clockwise a distance \(|x|\) if \(x < 0\)). Since the circumference of the circle is \(2\pi\), we obtain that \(\sin\) and \(\cos\) are periodic with period \(2\pi\): for all \(x\),
\[
\sin (x + 2\pi) = \sin x, \quad \cos (x + 2\pi) = \cos x
\]
It can in fact be easily checked that, for all \(x\),
\[
\sin(-x) = -\sin x, \quad \cos(-x) = \cos x
\]
\[
\sin \left(x + \frac{\pi}{2}\right) = \cos x, \quad \cos \left(x + \frac{\pi}{2}\right) = -\sin x
\]
since when the point \((a, b)\) is rotated a quarter circle counterclockwise, its coordinates become \((-b, a)\). Then replacing \(x\) by \(x - \frac{\pi}{2}\),
\[
\sin \left(x - \frac{\pi}{2}\right) = -\cos x, \quad \cos \left(x - \frac{\pi}{2}\right) = \sin x
\]
Repeating the process twice, we obtain
\[
\sin (x \pm \pi) = -\sin x, \quad \cos (x \pm \pi) = -\cos x
\]
for all \(x\). Of course, \(|\sin x| \leq 1\) and \(|\cos x| \leq 1\) for all \(x\).

**Theorem.** The functions \(\sin x\) and \(\cos x\) are infinitely differentiable on all of \(\mathbb{R}\), and
\[
\frac{d}{dx} (\sin x) = \cos x, \quad \frac{d}{dx} (\cos x) = -\sin x
\]
for all \(x \in \mathbb{R}\).

**Proof:** By V.6.2.6., the result holds on \((-\frac{\pi}{2}, \frac{\pi}{2})\). Then, since \(\sin x = \cos \left(x - \frac{\pi}{2}\right)\), \(\sin x\) is differentiable on \((0, \pi)\), and by the chain rule
\[
\frac{d}{dx} (\sin x) = \frac{d}{dx} \left(\cos \left(x - \frac{\pi}{2}\right)\right) = -\sin \left(x - \frac{\pi}{2}\right) = \cos x
\]
on \((0, \pi)\), and similarly \(\cos x\) is differentiable on \((0, \pi)\) with derivative \(-\sin x\). From \(\sin x = -\cos \left(x + \frac{\pi}{2}\right)\) we similarly get that \(\sin x\) is differentiable on \((-\pi, 0)\) with derivative \(\cos x\), and similarly for \(\cos x\). Thus the result holds on the interval \((-\pi, \pi)\). Since \(\sin (x \pm \pi) = -\sin x\) and \(\cos (x \pm \pi) = -\cos x\) for all \(x\), the result holds on \(((n-1)\pi, (n+1)\pi)\) for any \(n \in \mathbb{Z}\), and hence for the whole real line.

### V.6.3. Other Trigonometric Functions

**Definition.** If \(x \in \mathbb{R}\), define the *tangent*, *cotangent*, *secant*, and *cosecant* of \(x\), respectively denoted \(\tan x\), \(\cot x\), \(\sec x\), \(\csc x\), by
\[
\tan x = \frac{\sin x}{\cos x}, \quad \cot x = \frac{\cos x}{\sin x} = \frac{1}{\tan x}
\]
\[
\sec x = \frac{1}{\cos x}, \quad \csc x = \frac{1}{\sin x}
\]
V.6.3.2. These functions are defined wherever the denominators are nonzero. Thus the tangent and secant are defined except at $\pm \frac{\pi}{2} \pm n\pi$, and the cotangent and cosecant are defined except at (integer) multiples of $\pi$. We have

$$\lim_{x \to \frac{\pi}{2}^-} \tan x = +\infty, \quad \lim_{x \to \frac{\pi}{2}^+} \tan x = -\infty$$

$$\lim_{x \to \frac{\pi}{2}^-} \sec x = +\infty, \quad \lim_{x \to \frac{\pi}{2}^+} \sec x = +\infty$$

$$\lim_{x \to \pi^-} \cot x = -\infty, \quad \lim_{x \to 0^+} \cot x = +\infty$$

$$\lim_{x \to \pi^-} \csc x = +\infty, \quad \lim_{x \to 0^+} \csc x = +\infty$$

Since $|\sin x|$ and $|\cos x|$ are always $\leq 1$, we have $|\sec x| \geq 1$ and $|\csc x| \geq 1$ whenever defined.

The functions sec and csc are periodic with period $2\pi$. But since $\sin(x+\pi) = -\sin x$ and $\cos(x+\pi) = -\cos x$, the functions tan and cot are actually periodic with period $\pi$.

If $0 \leq x < \frac{\pi}{2}$, the number tan $x$ is the slope of the line through the origin and the point $(\cos x, \sin x)$ in the first quadrant whose arc length along the unit circle from $(1, 0)$ is $x$.

V.6.3.3. These functions, where defined, satisfy the identities

$$1 + \tan^2 x = \frac{\cos^2 x}{\cos^2 x} + \frac{\sin^2 x}{\cos^2 x} = \frac{\cos^2 x + \sin^2 x}{\cos^2 x} = \frac{1}{\cos^2 x} = \sec^2 x$$

and similarly $1 + \cot^2 x = \csc^2 x$ (where, as usual, $\tan^2 x = (\tan x)^2$, etc.)

V.6.3.4. These functions are infinitely differentiable on their domains, and their derivatives can be calculated using the quotient rule and power rule:

$$\frac{d}{dx} (\tan x) = \frac{(\cos x)(\cos x) - (\sin x)(-\sin x)}{\cos^2 x} = \frac{1}{\cos^2 x} = \sec^2 x$$

$$\frac{d}{dx} (\cot x) = \frac{(\sin x)(-\sin x) - (\cos x)(\cos x)}{\sin^2 x} = -\frac{1}{\sin^2 x} = -\csc^2 x$$

$$\frac{d}{dx} (\sec x) = \frac{d}{dx} ((\cos x)^{-1}) = (-1)(\cos x)^{-2}(-\sin x) = \frac{\sin x}{\cos^2 x} = \sec x \tan x$$

$$\frac{d}{dx} (\csc x) = \frac{d}{dx} ((\sin x)^{-1}) = (-1)(\sin x)^{-2}(\cos x) = -\frac{\cos x}{\sin^2 x} = -\csc x \cot x$$

V.6.4. The Inverse Trigonometric Functions

We have already defined an inverse function, arcsin $x$, for $\sin x$. Actually, if we start with the sine function and try to define an inverse, since $\sin x$ is periodic and not one-to-one, we must restrict it to an interval on which it is one-to-one; it is conventional to take the interval $[-\frac{\pi}{2}, \frac{\pi}{2}]$. Similarly, for $\cos x$ we conventionally take the interval $[0, \pi]$, which is mapped one-one onto $[-1, 1]$.

V.6.4.1. Definition. The inverse function to $\cos x$ with domain $[-1, 1]$ and range $[0, \pi]$ is called the arccosine function, denoted $\arccos x$. 575
V.6.4.2. Since the function \( g(x) = \cos x \) is continuous on \([0, \pi]\) and differentiable on \((0, \pi)\) with nonzero derivative, the function \( f(x) = \arccos x \) is continuous on \([-1, 1]\) and differentiable on \((-1, 1)\) with derivative given by the Inverse Function Theorem:

\[
\frac{d}{dx} \arccos x = f'(x) = \frac{1}{g'(f(x))} = -\frac{1}{\sin(\arccos x)}
\]

\[
= -\frac{1}{\sqrt{1 - \cos^2(\arccos x)}} = -\frac{1}{\sqrt{1 - x^2}}
\]

Actually, from \( \sin x = \cos \left( \frac{\pi}{2} - x \right) \) it follows that \( \arccos x = \frac{\pi}{2} - \arcsin x \).

V.6.4.3. Now consider \( \tan x \). The interval \((-\frac{\pi}{2}, \frac{\pi}{2})\) is one period of the tangent, and \( \tan x \) maps this interval one-one onto \((-\infty, \infty)\), so we conventionally take the inverse function for the tangent function to have this range:

V.6.4.4. Definition. The inverse function to \( \tan x \) with domain \((-\infty, \infty)\) and range \((-\frac{\pi}{2}, \frac{\pi}{2})\) is called the \textit{arctangent} function, denoted \( \arctan x \).

Since the function \( g(x) = \tan x \) is differentiable on \((-\frac{\pi}{2}, \frac{\pi}{2})\) with nonzero derivative, \( f(x) = \arctan x \) is differentiable on \((-\infty, \infty)\) with derivative

\[
\frac{d}{dx} \arctan x = f'(x) = \frac{1}{g'(f(x))} = \frac{1}{\sec^2(\arctan x)} = \frac{1}{1 + \tan^2(\arctan x)} = \frac{1}{1 + x^2}
\]

V.6.4.5. We can similarly define an \textit{arccotangent} function with domain \((-\infty, \infty)\), range \((0, \pi)\), and derivative \(-\frac{1}{1+x^2}\). Actually, \( \arccot x = \frac{\pi}{2} - \arctan x \) since \( \cot x = \tan \left( \frac{\pi}{2} - x \right) \).

We could also define arcsecant and arccosecant functions, but these are rarely used.

It is very common to write \( \sin^{-1} x \) for \( \arcsin x \), etc. This notation is consistent with the usual notation for inverse functions, but incompatible with the convention of writing \( \sin^2 x \) for \( (\sin x)^2 \), etc., and thus can be confusing. (Note that \( \sin^{-1} x \neq (\sin x)^{-1} \))

V.6.5. The Area of a Circle

V.6.5.1. We can use trigonometry to calculate the area of a circle. Actually, we should first define what we mean by “area” of a subset of the plane. This is not as easy as it sounds: the general problem is essentially the basic subject matter of measure theory. It would take us too far afield to try to treat this question here (cf. ()), so we will just assume that area is defined for sufficiently well-behaved subsets of the plane, and satisfies

(i) If \( f \) is a nonnegative continuous function on a closed bounded interval \([a, b]\), then the region \( R = \{(x, y) : a \leq x \leq b, 0 \leq y \leq f(x)\} \) has area \( A(R) = \int_a^b f(x) \, dx \).

(ii) If \( R \subseteq S \), then \( A(R) \leq A(S) \).

(iii) If \( R_1, \ldots, R_n \) are nonoverlapping regions (“nonoverlapping” means the intersection of any two is contained in the boundary of both), then

\[
A(R_1 \cup \cdots \cup R_n) = A(R_1) + \cdots + A(R_n).
\]
(iv) Congruent regions have the same area.

(There is actually a subtle technical problem with (iii), since the boundary of a region can have positive measure, but this will not cause difficulty if we consider only regions bounded by finitely many smooth curves.)

A circle (technically a disk) or any wedge of a circle has a well-defined area under these assumptions. If \( D \) is the unit disk, then \( A(D) = 2 \int_1^1 \sqrt{1-x^2} \, dx < 4 \). We want to calculate the exact value of \( A(D) \).

**V.6.5.2. Theorem.** \( A(D) = \pi \).

The simplest way to calculate this area is using vector calculus, but we will proceed in an alternate way. We have that \( A(D) = \pi p \) for some \( p > 0 \); we want to show that \( p = 1 \).

**V.6.5.3.** Define a function \( \phi : [0, 2\pi] \to \mathbb{R} \) by setting \( \phi(x) \) equal to the area of a wedge of a circle with arc length \( x \). Any two such wedges are congruent, so \( \phi(x) \) is well defined, and strictly increasing; we have \( \phi(0) = 0 \) and \( \phi(2\pi) = A(D) = \pi p \). For each \( n \in \mathbb{N} \), we have \( \phi \left( \frac{2\pi}{n} \right) = \frac{\pi p}{n} \) by (iii), i.e. \( \phi(x) = \frac{p}{2} x \) if \( x = \frac{2\pi}{n} \) for some \( n \). (Actually this formula holds for all \( x \in [0, 2\pi] \), although we will not need this fact for the Proof: it holds for \( x = \frac{2\pi m}{n} \) for \( m \leq n \) by (iii), and hence for all \( x \) since such numbers are dense in \( [0, 2\pi] \) and \( \phi \) is strictly increasing.)

![Figure V.8](image-url)

If \( 0 < x < \frac{\pi}{2} \), draw the picture in Figure 1, with \( OA = 1, OX = 1 \), and \( \angle AOX = x \), so \( X = (\cos x, \sin x) \).

Then \( BX = \sin x \) and \( AZ = \tan x \). Let \( T_1 \) be the triangle \( \triangle AOX \) and \( T_2 \) the triangle \( \triangle AOZ \). Then \( A(T_1) \leq \phi(x) \leq A(T_2) \), so if \( x_n = \frac{2\pi}{n} \) for \( n > 4 \) we have

\[
\frac{1}{2} \sin x_n \leq \frac{p}{2} x_n \leq \frac{1}{2} \tan x_n
\]

\[
\frac{\sin x_n}{x_n} \leq p \leq \frac{\tan x_n}{x_n}
\]

577
Since \( \lim_{n \to \infty} \frac{\sin x_n}{x_n} = \lim_{n \to \infty} \frac{\tan x_n}{x_n} = 1 \), we have \( p = 1 \). This completes the proof of the theorem.

**V.6.5.4.** It follows from the argument of the proof that \( \phi(x) = \frac{1}{2}x \) for all \( x \), giving an alternate geometric interpretation of the angle \( x \) as area rather than arc length. See Exercise () for another derivation of this formula.

**V.6.6. The Hyperbolic Functions**

The trigonometric functions are sometimes called the *circular functions*, for obvious reasons. We can define analogous functions related to a hyperbola which are formally similar to the circular functions; it turns out that the connections are much more than formal, although these deep connections are beyond the scope of this chapter (cf. X.1.1.8.).

There are actually two apparently totally different ways the hyperbolic functions can be defined, one using the hyperbola in the way the circle was used for the trigonometric functions, and the other using exponential functions. It is remarkable that the same functions are obtained by the two methods. We will describe both methods in this section.

**V.6.6.1.** We begin with the unit hyperbola \( y^2 - x^2 = 1 \). (It is more customary to use the hyperbola \( x^2 - y^2 = 1 \) with base point \((1,0)\), but our approach facilitates computations.) Since the upper half of the hyperbola has equation \( y = \sqrt{1 + x^2} \), in analogy with the formula defining \( \arcsin x \) we define the *hyperbolic arcsine* \( \arcsinh x \) by

\[
\arcsinh x = \int_0^x \frac{1}{\sqrt{1 + t^2}} \, dt
\]

Unfortunately, there is no interpretation of this as arc length in the hyperbolic case. (See Exercise () for a connection with area similar to the one for the trigonometric functions.)

Then \( \arcsinh x \) is defined for all \( x \) and is differentiable on \((-\infty, \infty)\) with derivative \( \frac{1}{\sqrt{1 + x^2}} \). We obviously have \( \arcsinh(-x) = -\arcsinh x \) for all \( x \).

**V.6.6.2.** Proposition. The range of \( \arcsinh x \) is \((-\infty, \infty)\).

Proof: Since \( \lim_{x \to +\infty} \frac{x}{\sqrt{1 + x^2}} = 1 \), there is an \( n \) such that \( \frac{1}{\sqrt{1 + x^2}} > \frac{1}{2x} \) for \( x > n \). Thus, if \( b > n \), we have

\[
\int_n^b \frac{1}{\sqrt{1 + x^2}} \, dx > \int_n^b \frac{1}{2x} \, dx = (\ln b - \ln n)
\]

which goes to infinity as \( b \to +\infty \). So \( \arcsinh x \) becomes arbitrarily large as \( x \to +\infty \). Since \( \arcsinh(-x) = -\arcsinh x \) and the range is an interval, it must be the whole real line.

**V.6.6.3.** So \( f(x) = \arcsinh x \) is strictly increasing and has an inverse function which we call the *hyperbolic sine*, denoted \( \sinh x \). By V.6.6.2., the domain of \( \sinh x \) is all of \( \mathbb{R} \). We then define the *hyperbolic cosine* \( \cosh x \) to be \( \sqrt{1 + \sinh^2 x} \), so \( \cosh^2 x - \sinh^2 x = 1 \) for all \( x \). We have \( \sinh(-x) = -\sinh x \) and \( \cosh(-x) = \cosh x \) for all \( x \), \( \sinh 0 = 0 \), and \( \cosh 0 = 1 \).
V.6.6.4. The function $g(x) = \sinh x$ is differentiable on $\mathbb{R}$, with derivative given by
\[
\frac{d}{dx} (\sinh x) = g'(x) = \frac{1}{\cosh^2 x} = \frac{1}{\sqrt{1 + \sinh^2 x}} = \cosh x
\]
and by the Chain Rule,
\[
\frac{d}{dx} (\cosh x) = \frac{d}{dx} \left( \sqrt{1 + \sinh^2 x} \right) = \frac{1}{2} (1 + \sinh^2 x)^{-1/2} (2 \sinh x \cosh x)
= \frac{\sinh x \cosh x}{\sqrt{1 + \sinh^2 x}} = \sinh x
\]
and thus $\sinh x$ and $\cosh x$ are infinitely differentiable.

The functions $\sinh x$ and $\cosh x$ thus behave formally in a similar way to $\sin x$ and $\cos x$, with occasional sign differences. The analogy only goes so far, however: $\sinh x$ and $\cosh x$ are not periodic and unbounded.

In fact, $\cosh x \geq 1$ for all $x$.

V.6.6.5. We can define analogs of the other trigonometric functions, called the hyperbolic tangent, cotangent, secant, and cosecant:
\[
\tanh x = \frac{\sinh x}{\cosh x}, \quad \coth x = \frac{\cosh x}{\sinh x} = \frac{1}{\tanh x}
\]
\[
\text{sech} x = \frac{1}{\cosh x}, \quad \text{csch} x = \frac{1}{\sinh x}
\]

It is useful to have a one-syllable pronunciation of the names of the hyperbolic functions, since the names “hyperbolic sine,” etc., are cumbersome. There is an obvious pronunciation for “cosh”, and also for the seldom-used “coth” and “sech”. The names “sinh” and “tanh” are normally pronounced “cinch” and “tanch” respectively. Your guess is as good as mine about how to pronounce “csch” (or “csc” for that matter!)

V.6.6.6. The domain of $\tanh x$ and $\text{sech} x$ is all of $\mathbb{R}$; the domain of $\coth x$ and $\text{csch} x$ is $\mathbb{R} \setminus \{0\}$. We have $\tanh 0 = 0$, $\tanh(-x) = -\tanh x$ and $|\tanh x| < 1$ for all $x$, and $\lim_{x \to \pm \infty} \tanh x = 1$, $\lim_{x \to -\infty} \tanh x = -1$. Similarly, $\text{sech} 0 = 1$, $\text{sech}(-x) = \text{sech} x$ and $|\text{sech} x| \leq 1$ for all $x$, and $\lim_{x \to \pm \infty} \text{sech} x = \lim_{x \to -\infty} \text{sech} x = 0$. They satisfy identities similar to the ones for trigonometric functions; for example:
\[
1 - \tanh^2 x = 1 - \frac{\sinh^2 x}{\cosh^2 x} = \frac{\cosh^2 x - \sinh^2 x}{\cosh^2 x} = \frac{1}{\cosh^2 x} = \text{sech}^2 x
\]

V.6.6.7. These hyperbolic functions are all infinitely differentiable on their domains, with derivatives given by standard rules:
\[
\frac{d}{dx} (\tanh x) = \frac{(\cosh x)(\cosh x) - (\sinh x)(\sinh x)}{\cosh^2 x} = \frac{1}{\cosh^2 x} = \text{sech}^2 x
\]
\[
\frac{d}{dx} (\coth x) = \frac{(\sinh x)(\sinh x) - (\cosh x)(\cosh x)}{\sinh^2 x} = -\frac{1}{\sinh^2 x} = -\text{csch}^2 x
\]
\[
\frac{d}{dx} (\text{sech} x) = \frac{d}{dx} \left((\cosh x)^{-1}\right) = -\frac{1}{\text{cosh}^2 x} = -\text{sech} x \tanh x
\]
\[
\frac{d}{dx} (\text{csch} x) = \frac{d}{dx} \left((\sinh x)^{-1}\right) = -\frac{1}{\text{cosh}^2 x} = -\text{csch} x \coth x
\]
V.6.6.8. Other inverse hyperbolic functions can be defined. For example, the one most often used, the inverse hyperbolic tangent \( f(x) = \text{arctanh} \, x \) is the inverse function of \( g(x) = \tanh x \), with domain \((-1, 1)\), range \((-\infty, \infty)\), and derivative

\[
\frac{d}{dx} \text{arctanh} \, x = f'(x) = \frac{1}{g'(f(x))} = \frac{1}{\text{sech}^2(\text{arctanh} \, x)} = \frac{1}{1 - \text{tanh}^2(\text{arctanh} \, x)} = \frac{1}{1 - x^2}
\]

Since \( \frac{1}{1-x} = \frac{1}{2} \frac{1}{1+x} + \frac{1}{2} \frac{1}{1-x} \) by partial fractions, the derivative of \( \text{arctanh} \, x \) is the same as the derivative of

\[
h(x) = \frac{1}{2} \ln(1+x) - \frac{1}{2} \ln(1-x) = \frac{1}{2} \ln \left( \frac{1+x}{1-x} \right)
\]

Since \( h(0) = \text{arctanh} \, 0 = 0 \), we have \( h(x) = \text{arctanh} \, x \) for all \( x \), i.e.

\[
\text{arctanh} \, x = \frac{1}{2} \ln(1+x) - \frac{1}{2} \ln(1-x) = \frac{1}{2} \ln \left( \frac{1+x}{1-x} \right), \quad (-1 < x < 1)
\]

There is therefore a close connection between inverse hyperbolic functions and logarithm functions, and hence the hyperbolic functions are actually closely related to exponential functions. Since the connection is not so easy to motivate, we will simply define some new functions and show that they are the same as the hyperbolic functions.

V.6.6.9. Definition. Define \( s(x) = \frac{e^x - e^{-x}}{2} \) and \( c(x) = \frac{e^x + e^{-x}}{2} \).

V.6.6.10. Theorem. We have \( s(x) = \sinh x \) and \( c(x) = \cosh x \) for all \( x \).

To prove this theorem, note that \( s(x) \) and \( c(x) \) are differentiable on all of \( \mathbb{R} \), and that \( s'(x) = c(x) \), \( c'(x) = s(x) \). Since \( c(x) > 0 \) for all \( x \), it follows that \( s(x) \) is strictly increasing on \( \mathbb{R} \). We also have that \( s(0) = 0, s(-x) = -s(x) \) for all \( x \), and \( \lim_{x \to +\infty} s(x) = +\infty \), so it follows that the range of \( s(x) \) is all of \( \mathbb{R} \). We have, for all \( x \),

\[
1 + (s(x))^2 = 1 + \frac{(e^x - e^{-x})^2}{4} = \frac{4 + e^{2x} - 2 + e^{-2x}}{4} = \frac{e^{2x} + 2 + e^{-2x}}{4} = \frac{(e^x + e^{-x})^2}{4} = (c(x))^2
\]

and thus \( c(x) = \sqrt{1 + (s(x))^2} \) for all \( x \).

Thus \( s(x) \) has an inverse function \( h(x) \), which is defined and differentiable on all of \( \mathbb{R} \), with derivative given by the Inverse Function Theorem:

\[
h'(x) = \frac{1}{s'(h(x))} = \frac{1}{c(h(x))} = \frac{1}{\sqrt{1 + (s(h(x)))^2}} = \frac{1}{\sqrt{1 + x^2}}
\]

so the derivative of \( h(x) \) is the same as the derivative of \( \text{arcsinh} \, x \). Since \( h(0) = 0 = \text{arcsinh} \, 0 \), we have \( h(x) = \text{arcsinh} \, x \) for all \( x \), and thus the inverse functions are also equal: \( s(x) = \sinh x \). The derivatives of these functions are then also equal: \( c(x) = \cosh x \). This completes the proof of the theorem.
V.6.6.11. From this, we get formulas for the other hyperbolic functions:

\[
\begin{align*}
\tanh x &= \frac{\sinh x}{\cosh x} = \frac{e^x - e^{-x}}{e^x + e^{-x}}, \\
\coth x &= \frac{\cosh x}{\sinh x} = \frac{e^x + e^{-x}}{e^x - e^{-x}} \\
\text{sech} x &= \frac{1}{\cosh x} = \frac{2}{e^x + e^{-x}}, \\
\text{csch} x &= \frac{1}{\sinh x} = \frac{2}{e^x - e^{-x}}
\end{align*}
\]

See Exercise () for a direct algebraic derivation of the formula for \( \tanh x \).

V.6.6.12. Actually, the trigonometric functions also have similar formulas in terms of exponential functions, but the formulas involve complex numbers:

\[
\begin{align*}
\cos x &= \frac{e^{ix} + e^{-ix}}{2}, \\
\sin x &= \frac{e^{ix} - e^{-ix}}{2i}
\end{align*}
\]

(we will not attempt to explain these formulas here.) The rich and beautiful subject of complex analysis (calculus for functions on the complex numbers) reveals many deep and fascinating connections between trigonometric, hyperbolic, and exponential functions; see X.1.1.8.

V.6.7. Exercises

V.6.7.1. If \( 0 \leq x \leq \frac{\pi}{2} \), show that the function \( \phi(x) \) of the proof of V.6.5.2. is given by

\[
\phi(x) = \frac{1}{2} \cos x \sin x + \int_{\cos x}^{1} \frac{\sqrt{1-t^2}}{1-t^2} dt
\]

(see Figure ()). Using (), show that \( \phi'(x) \) is the constant function \( \frac{1}{2} \), so \( \phi(x) = \frac{1}{2} x \).

V.6.7.2. If \( x \geq 0 \), let \( \psi(x) \) be the area of the wedge bounded by the hyperbola \( x^2 - y^2 = 1 \), the line through the origin and \( (\cosh x, \sinh x) \), and the \( x \)-axis (Figure ()). Show that \( \psi(x) \) is given by

\[
\psi(x) = \frac{1}{2} \cosh x \sinh x - \int_{1}^{\cosh x} \sqrt{t^2 - 1} dt
\]

As in Exercise (), show that \( \psi'(x) \) is the constant function \( \frac{1}{2} \), so \( \psi(x) = \frac{1}{2} x \).

V.6.7.3. Derive the exponential formula for \( \tanh x \) from the formula \( \arctanh x = \frac{1}{2} \ln \left( \frac{1+x}{1-x} \right) \) by solving the equation

\[
2x = \ln \left( \frac{1 + y}{1 - y} \right)
\]

for \( y \).
V.6.7.4. [Bri98] Prove the sum formulas for sine and cosine

\[
\sin(\alpha + \beta) = \sin \alpha \cos \beta + \cos \alpha \sin \beta \\
\cos(\alpha + \beta) = \cos \alpha \cos \beta - \sin \alpha \sin \beta
\]

for \( \alpha, \beta \in \mathbb{R} \), as follows.

(a) Fix \( \beta \in \mathbb{R} \), and replace \( \alpha \) by a variable \( x \), and define

\[
f(x) = [\sin(x + \beta) - \sin x \cos \beta - \cos x \sin \beta]^2 + [\cos(x + \beta) - \cos x \cos \beta + \sin x \sin \beta]^2 .
\]

Then \( f \) is differentiable on \( \mathbb{R} \).

(b) Compute \( f' \) using the Chain Rule, and show that \( f' \) is identically 0. So \( f \) is constant.

(c) Since \( f(-\beta) = 0 \), \( f \) is identically 0. Conclude that the sum formulas hold.

(d) Prove the following identities from the above sum formulas, for every \( \alpha, \beta \in \mathbb{R} \) which make sense in the formulas:

\[
\sin(\alpha - \beta) = \sin \alpha \cos \beta - \cos \alpha \sin \beta \\
\cos(\alpha - \beta) = \cos \alpha \cos \beta + \sin \alpha \sin \beta \\
\sin \alpha \cos \beta = \frac{1}{2} [\sin(\alpha + \beta) + \sin(\alpha - \beta)] \\
\cos \alpha \cos \beta = \frac{1}{2} [\cos(\alpha + \beta) + \cos(\alpha - \beta)] \\
\sin \alpha \sin \beta = \frac{1}{2} [\cos(\alpha - \beta) - \cos(\alpha + \beta)] \\
\sin 2\alpha = 2 \sin \alpha \cos \alpha \\
\cos 2\alpha = \cos^2 \alpha - \sin^2 \alpha = 2 \cos^2 \alpha - 1 = 1 - 2 \sin^2 \alpha \\
\cos^2 \frac{\alpha}{2} = \frac{1 + \cos \alpha}{2} \\
\sin^2 \frac{\alpha}{2} = \frac{1 - \cos \alpha}{2} \\
\tan(\alpha + \beta) = \frac{\tan \alpha + \tan \beta}{1 - \tan \alpha \tan \beta}
\]
V.7. Big-O and Little-o Notation

In this section, we introduce some notation which is commonly used to describe the asymptotic behavior of functions or sequences, the big-O and little-o notation. Although some care must be exercised in using this notation, it is very helpful in simplifying formulas and arguments containing constants whose exact value is unimportant or functions which become negligible as a limit is approached, in addition to giving a clean and precise description of the essential quantitative behavior of limits of functions. Not only does use of this system often simplify arguments in form, but it also sometimes helps conceptually in that the essential ideas of the argument are clarified and highlighted; in addition, arguments written this way are usually closer in spirit to the way the founding fathers of calculus phrased their work (although our arguments have a much higher level of rigor than those of the early days of the subject.) In fact, a version of the little-o notation was used by Newton (it is unclear whether he invented it), who wrote:

“When I am investigating a truth or the solution to a Probleme I use all sorts of approximations and neglect to write down the letter o, but when I am demonstrating a Proposition I always write down the letter o & proceed exactly by the rules of Geometry.”

Isaac Newton

DEFINITION. Let \( a \) be an extended real number, and \( f \) and \( g \) functions defined in a deleted neighborhood of \( a \) (this does not preclude the possibility that they are also defined at \( a \) if \( a \in \mathbb{R} \)).

(i) If \( a \in \mathbb{R} \), then \( g(x) = O(f(x)) \) as \( x \to a \) if there exist constants \( M \geq 0 \) and \( \delta > 0 \) such that \( |g(x)| \leq M|f(x)| \) whenever \( 0 < |x - a| < \delta \).

(ii) If \( a \in \mathbb{R} \), then \( g(x) = o(f(x)) \) as \( x \to a \) if for every \( \epsilon > 0 \) there is a \( \delta > 0 \) such that \( |g(x)| \leq \epsilon |f(x)| \) whenever \( 0 < |x - a| < \delta \).

If \( a = \pm \infty \), the \( \delta \) and \( 0 < |x - a| < \delta \) must be replaced in the usual way by \( B \) and \( x \neq B \) for \( a = +\infty \), and by \( A \) and \( x < A \) if \( a = -\infty \).

An analogous definition can be made for one-sided approach if \( f \) and \( g \) are defined in a deleted one-sided neighborhood of \( a \), and for sequences. Thus we may write “\( g(x) = O(f(x)) \) as \( x \to a^+ \)” or “\( y_n = o(x_n) \) as \( n \to \infty \)”.

In the definition of \( O \), we can clearly assume that \( M > 0 \) since there is no harm in increasing \( M \).

The \( O \) and \( o \) stand for “order.” The expression \( g(x) = O(f(x)) \) as \( x \to a \) roughly means “\( |g(x)| \) is of the same order as (or not essentially larger than) \( |f(x)| \) for \( x \) near \( a \)”;

\( g(x) = o(f(x)) \) roughly means “\( |g(x)| \) is of smaller order than (or negligibly small compared to) \( |f(x)| \) for \( x \) near \( a \)”.

EXAMPLES.

(i) \( g(x) = O(f(x)) \) as \( x \to a \) roughly means that \( \frac{g(x)}{f(x)} \) is bounded in a neighborhood of \( a \).” In particular, \( g(x) = O(1) \) as \( x \to a \) exactly means that \( g \) is bounded in a neighborhood of \( a \). If \( \lim_{x \to a} \frac{g(x)}{f(x)} \) exists, then \( g(x) = O(f(x)) \) as \( x \to a \). But note that \( g(x) = O(f(x)) \) as \( x \to a \) does not imply that \( \lim_{x \to a} \frac{g(x)}{f(x)} \) exists; for example, \( \sin \frac{1}{x} = O(1) \) as \( x \to 0 \).
Proposition. Here are some rules that are valid:

(ii) \( g(x) = o(f(x)) \) as \( x \to a \) roughly means that \( \lim_{x \to a} \frac{g(x)}{f(x)} = 0 \); if \( \lim_{x \to a} \frac{g(x)}{f(x)} = 0 \), then \( g(x) = o(f(x)) \) as \( x \to a \), but not quite conversely: \( x \sin \frac{1}{x} = o(\sin \frac{1}{x}) \) as \( x \to 0 \). But \( g(x) = o(1) \) as \( x \to a \) exactly means that \( \lim_{x \to a} g(x) = 0 \).

(iii) \( x^m = O(x^n) \) as \( x \to 0 \) if and only if \( m \geq n; x^m = o(x^n) \) as \( x \to 0 \) if and only if \( m > n \). But \( x^m = O(x^n) \) as \( x \to +\infty \) if and only if \( m \leq n \), and \( x^m = o(x^n) \) as \( x \to +\infty \) if and only if \( m < n \).

Proposition. Let \( a \) be an extended real number, and \( f, g, \) and \( h \) real-valued functions defined in a neighborhood of \( a \).

(i) If \( g(x) = o(f(x)) \) as \( x \to a \), then \( g(x) = O(f(x)) \) as \( x \to a \).

(ii) If \( g(x) = O(f(x)) \) and \( h(x) = O(g(x)) \) as \( x \to a \), then \( h(x) = O(f(x)) \) as \( x \to a \).

(iii) If \( g(x) = o(f(x)) \) and \( h(x) = O(g(x)) \) as \( x \to a \), then \( h(x) = o(f(x)) \) as \( x \to a \).

(iv) If \( g(x) = O(f(x)) \) and \( h(x) = o(g(x)) \) as \( x \to a \), then \( h(x) = o(f(x)) \) as \( x \to a \).

In particular, if \( g(x) = O(f(x)) \) and \( f(x) = O(1) \), then \( g(x) = O(1) \); if \( g(x) = o(f(x)) \) and \( f(x) = O(1) \), or \( g(x) = O(f(x)) \) and \( f(x) = o(1) \), then \( g(x) = o(1) \).

Proof: (i) is obvious from the definitions.

(ii): By hypothesis, there is an \( M > 0 \) and \( \delta_1 > 0 \) such that \( |g(x)| \leq M|f(x)| \) for \( 0 < |x - a| < \delta_1 \), and an \( N > 0 \) and \( \delta_2 > 0 \) such that \( |h(x)| \leq N|g(x)| \) for \( 0 < |x - a| < \delta_2 \). Set \( \delta = \min(\delta_1, \delta_2) \). Then, if \( 0 < |x - a| < \delta \), we have

\[
|h(x)| \leq N|g(x)| \leq MN|f(x)|.
\]

(iii): Let \( \epsilon > 0 \). By hypothesis, there is an \( M > 0 \) and \( \delta_1 > 0 \) such that \( |h(x)| \leq M|g(x)| \) for \( 0 < |x - a| < \delta_1 \). There is then a \( \delta_2 > 0 \) such that \( |g(x)| \leq \frac{\epsilon}{M} |f(x)| \) for \( 0 < |x - a| < \delta_2 \). Set \( \delta = \min(\delta_1, \delta_2) \). Then, for \( 0 < |x - a| < \delta \),

\[
|h(x)| \leq M|g(x)| \leq M \cdot \frac{\epsilon}{M} |f(x)| = \epsilon |f(x)|.
\]

(iv) is almost identical to (iii), and is left to the reader.

We often just write “\( O(f(x)) \)” or “\( o(f(x)) \)” (along with “\( x \to a \)” if it is not understood from the context) to denote some function \( g(x) \) which satisfies \( g(x) = O(f(x)) \) or \( g(x) = o(f(x)) \) (\( x \to a \)).

Note that the expressions \( O(f(x)) \) and \( o(f(x)) \) do not necessarily represent specific functions of \( x \) (or, more precisely, different uses of \( O(f(x)) \) or \( o(f(x)) \) may represent different specific functions of \( x \)). Consequently, these expressions do not necessarily follow the usual algebraic rules. For example, from

\[
g(x) + o(f(x)) = h(x) + o(f(x))
\]

it cannot be concluded that \( g(x) = h(x) \); it only follows that \( g(x) = h(x) + o(f(x)) \) (i.e. \( g(x) - h(x) = o(f(x)) \)).

Here are some rules that are valid:

Proposition.

(i) If \( g_1(x) = O(f(x)) \) and \( g_2(x) = O(f(x)) \) as \( x \to a \), then \( g_1(x) + g_2(x) = O(f(x)) \) as \( x \to a \).
Proof: of the last two results is that $O$ and in particular is nonzero, so there is a

Proof: \[ \lim_{x \to a} g(x) \] and \[ k(x) \] and \[ h(x) \] and \[ O(g(x)) = O(f(x)g(x)), \] \[ o(g(x)) = o(f(x)g(x)) \]

One of the simplest and most common applications of the last two results is that $K \cdot O(f(x)) = O(f(x))$ and $K \cdot o(f(x)) = o(f(x))$ for any constant $K$.

PROOF: We prove only (iv); the other proofs are very similar (but slightly easier). Let $\epsilon > 0$. By hypothesis, there is an $M > 0$ and $\delta_2 > 0$ such that $|g_2(x)| \leq M |f_2(x)|$ for $0 < |x - a| < \delta_2$. Then there exists a $\delta_1 > 0$ such that $|g_1(x)| \leq \frac{\epsilon}{M} |f_1(x)|$ for $0 < |x - a| < \delta_1$. Set $\delta = \min(\delta_1, \delta_2)$. Then, for $0 < |x - a| < \delta$,

$$|g_1(x)g_2(x)| \leq \frac{\epsilon}{M} |f_1(x)| \cdot M |f_2(x)| = \epsilon |f_1(x)f_2(x)|.$$  

$\blacksquare$

The next result is fairly special, but is useful in dealing with quotients. It is awkward to even state this result without using the $o$-notation (try it!)

PROPOSITION. Let $a$ be an extended real number, and $g$, $h$, and $k$ real-valued functions defined on a deleted neighborhood of $a$, with $h(x) \neq 0$ for all $x$ in a deleted neighborhood of $a$. Suppose $g(x) = O(1), \frac{1}{h(x)} = O(1)$, and $k(x) = o(1)$ as $x \to a$ (i.e. $g$ is bounded and $h$ is bounded away from 0 in a deleted neighborhood of $a$, and $\lim_{x \to a} k(x) = 0$). Then

$$\frac{g(x)}{h(x) + k(x)} = \frac{g(x)}{h(x)} - \frac{g(x)}{h(x)} \cdot \frac{k(x)}{h(x)^2} + O((k(x))^2) \text{ as } x \to a.$$  

PROOF: The proof uses the algebraic formula

$$\frac{1}{1 + t} = 1 - t + \frac{t^2}{1 + t}$$

valid for $t \neq -1$, which is easily proved by multiplying both sides by $1 + t$. (This formula is a special case of the formula of $\cdot$.)

Under the hypotheses, there is an $M > 0$ and $\delta_1 > 0$ such that $|h(x)| \geq M$ for $0 < |x - a| < \delta_1$, and there is a $\delta_2 > 0$ such that $|k(x)| < M/2$ for $0 < |x - a| < \delta_2$. There is also an $N \geq 0$ and $\delta_3 > 0$ such that $|g(x)| \leq N$ for $0 < |x - a| < \delta_3$. Set $\delta = \min(\delta_1, \delta_2, \delta_3)$. Then if $0 < |x - a| < \delta$, $|h(x) + k(x)| > M/2$ and in particular is nonzero, so $\frac{g(x)}{h(x) + k(x)}$ is defined in a deleted neighborhood of 0. Also, if $0 < |x - a| < \delta$,

$$\frac{k(x)}{h(x)} < 1/2, \text{ so } \frac{k(x)}{h(x)} \neq -1.$$  

Thus, for $0 < |x - a| < \delta$, we have

$$\frac{g(x)}{h(x) + k(x)} = \frac{g(x)}{h(x)} \cdot \frac{1}{1 + \frac{k(x)}{h(x)}}.$$  

585
The last term is \( O([k(x)]^2) \) as \( x \to a \) since

\[
\left| \frac{g(x)}{h(x)} - \frac{g(x)}{[h(x)]^2} k(x) + \frac{g(x)}{[h(x)]^2(h(x) + k(x))} [k(x)]^2 \right| \leq \frac{N}{M^2 \left( \frac{M}{2} \right)} = \frac{2N}{M^3}
\]

for \( 0 < |x - a| < \delta \).  

**Corollary.** Let \( a \) be an extended real number, and \( f, g, h, \) and \( k \) real-valued functions defined on a deleted neighborhood of \( a \), with \( h(x) \neq 0 \) for all \( x \) in a deleted neighborhood of \( a \). Suppose \( g(x) = O(1) \), 

\[
\frac{1}{h(x)} = O(1),
\]

and \( f(x) = o(1) \) as \( x \to a \) (i.e. \( g \) is bounded and \( h \) is bounded away from 0 in a deleted neighborhood of \( a \), and \( \lim_{x \to a} f(x) = 0 \)).

(i) If \( k(x) = O(f(x)) \) as \( x \to a \), then

\[
\frac{g(x)}{h(x) + k(x)} = \frac{g(x)}{h(x)} + O(f(x)) \text{ as } x \to a.
\]

(ii) If \( k(x) = o(f(x)) \) as \( x \to a \), then

\[
\frac{g(x)}{h(x) + k(x)} = \frac{g(x)}{h(x)} + o(f(x)) \text{ as } x \to a.
\]

This result is sometimes abbreviated by the following curious algebraic formula: “Under the hypotheses on \( f, g, \) and \( h \),

\[
\frac{g(x)}{h(x) + o(f(x))} = \frac{g(x)}{h(x)} + o(f(x))
\]

(and similarly for \( O(f(x)) \).) The explanation of why this expression does not violate the rules of algebra is that the \( o(f(x)) \)'s on the two sides of the equation stand for (usually) different functions of \( x \).

**Proof:** First observe that \( \frac{g(x)}{[h(x)]^2} \) is bounded in a deleted neighborhood of \( a \). Using the notation of the proof of **V.7**, it is bounded by \( \frac{N}{M^2} \) for \( 0 < |x - a| < \delta \). Thus the second term is \( O(k(x)) \), which is \( O(f(x)) \) if \( k(x) = O(f(x)) \), and \( o(f(x)) \) if \( k(x) = o(f(x)) \). Also, the third term is \( O([k(x)]^2) = o(k(x)) = o(f(x)) \) in either part since \( k(x) = o(1) \).

The \( o \) is probably used more than the \( O \), since \( o \) denotes a function which becomes negligible and thus is very useful in limit or differentiability arguments (although the \( O \), if used carefully, gives a more precise description of asymptotic behavior). The next result, an almost immediate consequence of the definition of differentiability, is probably the most important example of use of the little-\( o \) notation:
Proposition. Let $f$ be a real-valued function defined in a neighborhood of $a \in \mathbb{R}$. Then $f$ is differentiable at $a$ if and only if there is an $m \in \mathbb{R}$ such that
\[ f(x) = f(a) + m(x-a) + o(x-a) \text{ as } x \to a \]
(or, more precisely, $f(x) - f(a) - m(x-a) = o(x-a)$ as $x \to a$). Such an $m$, if it exists, is unique and equals $f'(a)$.

As an example of use of the little-$o$ notation in simplifying arguments, here is a proof of the Product Rule (\ref{product-rule}). Note that this proof shows how the product rule follows naturally from the algebraic rule for multiplying multinomials. In addition, it avoids having to use the trick/technique of adding and subtracting something from an expression which may not be obvious, and also avoids explicitly using the result that a differentiable function is continuous.

Proof: Let $f$ and $g$ be real-valued functions defined in a neighborhood of $a \in \mathbb{R}$, and differentiable at $a$. Then
\[ f(x) = f(a) + f'(a)(x-a) + o(x-a) \]
and
\[ g(x) = g(a) + g'(a)(x-a) + o(x-a) \]
in a neighborhood of $a$. So, in a neighborhood of $a$,
\[ f(x)g(x) = [f(a) + f'(a)(x-a) + o(x-a)][g(a) + g'(a)(x-a) + o(x-a)] \]
\[ = f(a)g(a) + f'(a)g(a)(x-a) + f(a)g'(a)(x-a) + f'(a)g'(a)(x-a)^2 + g'(a)(x-a)g(x-a) + o(x-a) \cdot o(x-a) \]
\[ = f(a)g(a) + [f'(a)g(a) + f(a)g'(a)](x-a) \]
\[ + [g(a)g(x-a) + f'(a)g'(a)(x-a)^2 + g'(a)(x-a)g(x-a) + f(a)g(x-a) + f'(a)(x-a)g(x-a) + o(x-a) \cdot o(x-a)] \]
The expressions in the last brackets are all $o(x-a)$ since $f(a)$, $g(a)$, $f'(a)g(a)$, $f'(a)(x-a)$, $g'(a)(x-a)$, and $o(x-a)$ are all $O(1)$ as $x \to a$, and $(x-a)^2 = o(x-a)$ as $x \to a$. Thus
\[ f(x)g(x) = f(a)g(a) + [f'(a)g(a) + f(a)g'(a)](x-a) + o(x-a) \]
in a neighborhood of $a$, and so by \ref{v.7}, $fg$ is differentiable at $a$ and
\[ (fg)'(a) = f'(a)g(a) + f(a)g'(a) \cdot \]

We now give a proof of the Quotient Rule using the $o$-notation. This proof is not as clean or satisfying as the above proof of the Product Rule, but gives a better idea of where the Quotient Rule comes from algebraically than the usual proof, and also avoids the “adding and subtracting” trick/technique. It does, however, use in one place the fact that a differentiable function is continuous.

Proof: Let $f$ and $g$ be defined in a neighborhood of $a \in \mathbb{R}$ and differentiable at $a$, with $g(a) \neq 0$. Then, since $f$ and $g$ are continuous at $a$, there is a $\delta_1 > 0$ such that $|f(x)| < |f(a)| + 1$ for $|x-a| < \delta_1$, and there is $\delta_2 > 0$ such that $|g(x)| > \frac{|g(a)|}{2}$ for $|x-a| < \delta_2$. Thus $g$ is nonzero in a neighborhood of $a$, so $\frac{f}{g}$ is defined in a neighborhood of $a$, and $f$ and $\frac{1}{g}$ are bounded in a neighborhood of $a$. By \ref{v.7}, we can write
\[ f(x) = f(a) + f'(a)(x-a) + o(x-a) \]
and
\[ g(x) = g(a) + g'(a)(x-a) + o(x-a) \]
in a neighborhood of $a$, so
\[ \frac{f(x)}{g(x)} = \frac{f(a) + f'(a)(x-a) + o(x-a)}{g(a) + g'(a)(x-a) + o(x-a)} \]
First applying V.7(ii), and then applying V.7., we obtain
\[
\frac{f(x)}{g(x)} = \frac{f(a) + f'(a)(x-a) + o(x-a)}{g(a) + g'(a)(x-a) + o(x-a)}
\]
\[
= \frac{f(a) + f'(a)(x-a) + o(x-a)}{g(a) + g'(a)(x-a)} + o(x-a)
\]
\[
= \frac{f(a) + f'(a)(x-a) + o(x-a)}{g(a)}
\]
\[
- \frac{f(a) + f'(a)(x-a) + o(x-a)}{[g(a)]^2} g'(a)(x-a) + O([x-a]^2) + o(x-a)
\]
\[
= \frac{f(a) + f'(a)(x-a) + o(x-a)}{g(a)}
\]
\[
- \frac{f(a) + f'(a)(x-a) + o(x-a)}{[g(a)]^2} g'(a)(x-a) + o(x-a)
\].

Expanding and rearranging terms, we obtain:
\[
\frac{f(x)}{g(x)} = \frac{f(a) + f'(a)(x-a) + o(x-a)}{g(a) + g'(a)(x-a)} + \frac{f(a)g'(a)}{[g(a)]^2} (x-a)
\]
\[
- \frac{f'(a)g'(a)}{[g(a)]^2} (x-a)^2 - \frac{o(x-a)}{[g(a)]^2} (x-a) + o(x-a)
\]
\[
= \frac{f(a)}{g(a)} + \left[ \frac{f'(a)}{g(a)} - \frac{f(a)g'(a)}{[g(a)]^2} \right] (x-a)
\]
\[
+ \left[ \frac{o(x-a)}{g(a)} - \frac{f'(a)g'(a)}{[g(a)]^2} (x-a)^2 - \frac{o(x-a)}{[g(a)]^2} (x-a) + o(x-a) \right]
\].

All the terms in the last brackets are o(x-a), so in a neighborhood of a we have
\[
\frac{f(x)}{g(x)} = \frac{f(a)}{g(a)} + \left[ \frac{f'(a)}{g(a)} - \frac{f(a)g'(a)}{[g(a)]^2} \right] (x-a) + o(x-a)
\].

Thus by V.7., \( \frac{f}{g} \) is differentiable at a and
\[
\left( \frac{f}{g} \right)'(a) = \frac{f'(a)}{g(a)} - \frac{f(a)g'(a)}{[g(a)]^2} = \frac{g(a)f'(a) - f(a)g'(a)}{[g(a)]^2}.
\]

V.7.1. Exercises

1. Give careful definitions of (1) “g(x) = O(f(x)) as x → +∞” (2) “g(x) = O(f(x)) as x → a+” (3) “y_n = O(x_n) as n → ∞”, and similarly for o, and give versions of all the results of this section for these notions.
V.8. The Mean Value Theorem

“The Mean Value Theorem is the midwife of calculus – not very important or glamorous by itself, but often helping to deliver other theorems that are of major significance.”

E. Purcell and D. Varberg

The Mean Value Theorem (MVT) is one of the major theoretical results of calculus. It is the primary tool allowing information about a differentiable function to be obtained from properties of its derivative.

V.8.1. Rolle’s Theorem and the Mean Value Theorem

V.8.1.1. Theorem. [Mean Value Theorem] Let \( a, b \in \mathbb{R}, a < b \). Let \( f \) be a function which is continuous on \([a, b] \) and differentiable on \((a, b)\). Then there is at least one \( c \in (a, b) \) for which

\[
f(b) - f(a) = f'(c)(b - a).
\]

Alternatively, there is at least one \( c \in (a, b) \) with

\[
f'(c) = \frac{f(b) - f(a)}{b - a}.
\]

A geometric interpretation is that there is at least one point on the graph between \( a \) and \( b \) at which the tangent line is parallel to the secant line between \((a, f(a))\) and \((b, f(b))\) (Figure V.9).

V.8.1.2. The number \( f'(c) \) can be interpreted as the instantaneous rate of change of \( f \) at \( c \), while the number \( \frac{f(b) - f(a)}{b - a} \) is the average rate of change of \( f \) between \( a \) and \( b \). Thus, for example, if a driver’s average speed is 60 MPH over a period of time, there must be at least one instant of time during the period at which his instantaneous speed is exactly 60 MPH.

V.8.1.3. Three important points to note about the conclusion of the MVT:

(i) The \( c \) depends on the numbers \( a \) and \( b \), as well as on the function \( f \).

(ii) For a given \( f, a, \) and \( b \), there may be more than one \( c \), even infinitely many, satisfying the conclusion. (In Figure V.9 there are five, denoted \( c_1 - c_5 \).) Indeed, in the extreme case where \( f \) is linear, every \( c \in (a, b) \) works.

(iii) In practice it may be difficult if not impossible to explicitly find a \( c \) that works for a given \( a \) and \( b \), even for relatively well-behaved \( f \). The MVT is a prime example of a pure existence theorem, in which something is shown to exist without any clue as to how to find a specific example. As we will see, however, just the knowledge that such a \( c \) exists will be of great importance in obtaining conclusions about the function \( f \).
Rolle’s Theorem

We will give the standard modern proof of the MVT, due to O. Bonnet in 1868. Cauchy previously gave a more complicated and flawed proof (cf. [Bre07]). The essential step in Bonnet’s proof is to prove a special case, which is important enough in its own right to have a standard name:

V.8.1.4. **Theorem. [Rolle’s Theorem]** Let \( a, b \in \mathbb{R}, a < b \), and let \( f \) be continuous on \([a, b]\) and differentiable on \((a, b)\). If \( f(a) = f(b) \), then there is at least one \( c \in (a, b) \) with \( f'(c) = 0 \).

It is ironic that a theorem of calculus should be named after Rolle, since according to [Bal60, p. 318], Rolle, a contemporary of Newton and Leibniz, believed that calculus was “nothing but a collection of ingenious fallacies.” (It has been suggested that he later changed his mind.) Many references claim that Rolle first stated and proved this theorem; however, Rolle’s statement and proof only referred to polynomials and did not use any explicit calculus. It is unclear who first stated the result in its modern form. See the chapter by J. Barrow-Green in [RS09] for the full story. See also Exercise V.8.6.11.

**Proof:** Since \( f \) is continuous on a closed bounded interval, it attains a maximum \( M \) and a minimum \( m \) on \([a, b]\) (Max-Min Theorem). Then, since \( m \leq f(a) \leq M \), at least one of the following is true:

(i) \( M > f(a) \).

(ii) \( m < f(a) \).
(iii) \( f \) is constant on \([a, b] \).

In case (i), there is a \( c \in (a, b) \) with \( f(c) = M \). Then \( f'(c) = 0 \) by V.3.6.3.

In case (ii), there is a \( c \in (a, b) \) with \( f(c) = m \). Again by V.3.6.3. we have \( f'(c) = 0 \).

And in case (iii), \( f'(c) = 0 \) for all \( c \in (a, b) \).

Before going on to the MVT, we record some simple consequences of Rolle’s theorem which are basically just restatements or special cases of the theorem.

**V.8.1.5. Corollary.** Let \( a, b \in \mathbb{R}, a < b \), and let \( f \) be continuous on \([a, b]\) and differentiable on \((a, b)\).

If \( f'(x) \neq 0 \) for all \( x \in (a, b) \), then \( f(a) \neq f(b) \).

The next corollary is useful in locating the zeros of a function such as a polynomial:

**V.8.1.6. Corollary.** Let \( f \) be differentiable on an interval \( I \). Then between any two zeros of \( f \) in \( I \) there is at least one zero of \( f' \).

### The Mean Value Theorem

We now turn to the MVT. This theorem was first stated by Lagrange in (). We will actually prove the following more general theorem, due to Cauchy (with a flawed proof) in 1821; the usual MVT is the special case \( g(x) = x \).

**V.8.1.7. Theorem.** [Cauchy Mean Value Theorem] Let \( a, b \in \mathbb{R}, a < b \). Let \( f \) and \( g \) be functions which are continuous on \([a, b]\) and differentiable on \((a, b)\). Then there is at least one \( c \in (a, b) \) for which

\[
g'(c)[f(b) - f(a)] = f'(c)[g(b) - g(a)] .
\]

**Proof:** For \( x \in [a, b] \), set

\[
h(x) = f(x)[g(b) - g(a)] - g(x)[f(b) - f(a)] .
\]

Then \( h \) is continuous on \([a, b]\) and differentiable on \((a, b)\), and \( h(a) = h(b) \). By V.8.1.4. there is a \( c \in (a, b) \) such that

\[
0 = h'(c) = f'(c)[g(b) - g(a)] - g'(c)[f(b) - f(a)] .
\]

The following special case is commonly stated as Cauchy’s Mean Value Theorem:
**V.8.1.8.** Corollary. Let \( a, b \in \mathbb{R}, a < b \). Let \( f \) and \( g \) be functions which are continuous on \([a, b]\) and differentiable on \((a, b)\), such that \( g'(x) \neq 0 \) for all \( x \in (a, b) \). Then \( g(a) \neq g(b) \), and there is at least one \( c \in (a, b) \) for which

\[
\frac{f(b) - f(a)}{g(b) - g(a)} = \frac{f'(c)}{g'(c)}.
\]

Proof: The first conclusion follows from V.8.1.5., and then the second conclusion is V.8.1.7.

**V.8.1.9.** This corollary has a geometric interpretation. If \( \phi(t) = (g(t), f(t)) \), then \( \phi \) is the parametrization of a smooth curve in \( \mathbb{R}^2 \). The slope of the line through the endpoints of the curve is

\[
\frac{f(b) - f(a)}{g(b) - g(a)}
\]

and the slope of the tangent line at the point \( \phi(t) \) is \( \frac{f'(t)}{g'(t)} \). Cauchy’s MVT says that there is at least one point on the curve where the tangent line is parallel to the line through the two endpoints. (The requirement that \( g' \neq 0 \) on \((a, b)\) insures that this curve has no vertical tangents, and it turns out to actually be the graph of a differentiable function (cf. V.8.2.14.). The geometric result is true more generally as long as the endpoints are distinct and \( f' \) and \( g' \) do not simultaneously vanish (Exercise V.8.6.1.).)

**V.8.2. Applications of the Mean Value Theorem**

There are many important theoretical consequences of the MVT. We begin with a crucial one:

**V.8.2.1.** Corollary. Let \( a, b \in \mathbb{R}, a < b \). Let \( f \) be a function which is continuous on \([a, b]\) and differentiable on \((a, b)\). If \( f'(x) \geq 0 \) for all \( x \in (a, b) \), then \( f \) is nondecreasing on \([a, b]\), and in particular \( f(a) \leq f(b) \). If \( f' \) is not identically 0 on \((a, b)\), then \( f(a) < f(b) \).

Proof: If \( a \leq x_1 < x_2 \leq b \), applying the MVT to the interval \([x_1, x_2]\) we have

\[
f(x_2) - f(x_1) = f'(c)(x_2 - x_1) \geq 0
\]

for some \( c \in (x_1, x_2) \). Since \( f \) is nondecreasing on \([a, b]\), if \( f(a) = f(b) \) we must have \( f \) constant on \([a, b]\), and hence \( f' \) is identically 0.

Similarly, we have:

**V.8.2.2.** Corollary. Let \( a, b \in \mathbb{R}, a < b \). Let \( f \) be a function which is continuous on \([a, b]\) and differentiable on \((a, b)\). If \( f'(x) \leq 0 \) for all \( x \in (a, b) \), then \( f \) is nonincreasing on \([a, b]\), and in particular \( f(a) \geq f(b) \). If \( f' \) is not identically 0 on \((a, b)\), then \( f(a) > f(b) \).

Putting the last two together, we get a result of basic significance:
V.8.2.3. **Corollary.** Let \(a, b \in \mathbb{R}, a < b\). Let \(f\) be a function which is continuous on \([a, b]\) and differentiable on \((a, b)\). If \(f'(x) = 0\) for all \(x \in (a, b)\), then \(f\) is constant on \([a, b]\).

V.8.2.4. **Corollary.** Let \(a, b \in \mathbb{R}, a < b\). Let \(f\) and \(g\) be functions which are continuous on \([a, b]\) and differentiable on \((a, b)\). If \(f'(x) = g'(x)\) for all \(x \in (a, b)\), then \(f\) and \(g\) differ by a constant.

**Proof:** Apply V.8.2.3. to \(f - g\).

V.8.2.5. **Corollary.** Let \(a, b \in \mathbb{R}, a < b\). Let \(f\) and \(g\) be functions which are continuous on \([a, b]\) and differentiable on \((a, b)\). If \(f(a) = g(a)\) and \(f'(x) \geq g'(x)\) for all \(x \in (a, b)\), then \(f(x) \geq g(x)\) for all \(x \in [a, b]\), with strict inequality unless \(f' = g'\) on \((a, x)\).

**Proof:** Apply V.8.2.1. to \(f - g\).

The First Derivative Test for Local Extrema

One of the standard tests for local extrema is a direct consequence of the MVT:

V.8.2.6. **Theorem.** [First Derivative Test] Let \(f\) be continuous on an interval \(I\), and \(a\) an interior point of \(I\). Suppose

(i) There is an \(r \in I, r < a\), with \(f\) differentiable on \((r, a)\) and \(f'(x) \geq 0\) for all \(x \in (r, a)\).

(ii) There is an \(s \in I, s > a\), with \(f\) differentiable on \((a, s)\) and \(f'(x) \leq 0\) for all \(x \in (a, s)\).

Then \(f\) has a local maximum at \(a\). It is a strict local maximum unless \(f'\) is identically zero in an interval to the left or right of \(a\).

Similarly, suppose

(iii) There is an \(r \in I, r < a\), with \(f\) differentiable on \((r, a)\) and \(f'(x) \leq 0\) for all \(x \in (r, a)\).

(iv) There is an \(s \in I, s > a\), with \(f\) differentiable on \((a, s)\) and \(f'(x) \geq 0\) for all \(x \in (a, s)\).

Then \(f\) has a local minimum at \(a\). It is a strict local minimum unless \(f'\) is identically zero in an interval to the left or right of \(a\).

Note that differentiability of \(f\) at \(a\) is not assumed (if \(f'(a)\) exists, it must be 0 as a result of this theorem and V.3.6.3.).

**Proof:** In the first case, apply V.8.2.1. to \([r, a]\) and V.8.2.2. to \([a, s]\), and vice versa in the second case.

A one-sided version of this test also applies at endpoints of \(I\); the statement is left to the reader.

Differential Approximation with Error Estimates

We can obtain a variation of differential approximation with error estimates:
**V.8.2.7.** Corollary. Let \( a, b, M \in \mathbb{R} \), \( a < b \). Let \( f \) be a function which is continuous on \([a, b]\) and differentiable on \((a, b)\). If \( f'(x) < M \) for all \( x \in (a, b) \), then
\[
f(x_2) - f(x_1) < M(x_2 - x_1)
\]
for all \( x_1, x_2 \in [a, b], x_1 < x_2 \). The result also holds if \(< \) is replaced by \( \leq \) throughout.

**Proof:** Let \( x_1, x_2 \in [a, b], x_1 < x_2 \). Then, applying the MVT to \([x_1, x_2]\), for some \( c \in (x_1, x_2) \) we have
\[
f(x_2) - f(x_1) = f'(c)(x_2 - x_1) < M(x_2 - x_1).
\]

Similarly, we have

**V.8.2.8.** Corollary. Let \( a, b, m \in \mathbb{R} \), \( a < b \). Let \( f \) be a function which is continuous on \([a, b]\) and differentiable on \((a, b)\). If \( m < f'(x) \) for all \( x \in (a, b) \), then
\[
m(x_2 - x_1) < f(x_2) - f(x_1)
\]
for all \( x_1, x_2 \in [a, b], x_1 < x_2 \). The result also holds if \(< \) is replaced by \( \leq \) throughout.

Combining, we get the two-sided version:

**V.8.2.9.** Corollary. Let \( a, b, m, M \in \mathbb{R} \), \( a < b \). Let \( f \) be a function which is continuous on \([a, b]\) and differentiable on \((a, b)\). If \( m < f'(x) < M \) for all \( x \in (a, b) \), then
\[
m(x_2 - x_1) < f(x_2) - f(x_1) < M(x_2 - x_1)
\]
for all \( x_1, x_2 \in [a, b], x_1 < x_2 \). The result also holds if \(< \) is replaced by \( \leq \) throughout.

Taylor's theorem gives a higher-order version of these inequalities ().

**V.8.2.10.** V.8.2.7. is often called the **Mean Value Inequality**. It is an immediate consequence of the special case V.8.2.1. and linearity of the derivative. There is a direct proof of V.8.2.1. (in the special case where \( f \) is differentiable on \([a, b]\)) by the Method of Successive Bisections () (Exercise V.8.6.11.). This proof is arguably simpler and more elementary than the proof of the MVT since it only uses the Nested Intervals Theorem and not the Extreme Value Theorem, and several authors, e.g. [?, p. 152], [vRS82, p. 93], [Boa95, p. 8], [Kör04, p. 59], argue that the Mean Value Inequality is sufficient for most applications in analysis and that the MVT itself is overrated. I personally do not regard the proof of the MVT as very difficult given the Extreme Value Theorem, which one would want to include anyway in any treatment of real analysis.

**Lipschitz Continuity**

A similar consequence which will be important later is:
**V.8.2.11. Corollary.** Let \( a, b, M \in \mathbb{R}, a < b, M \geq 0 \). Let \( f \) be a function which is continuous on \([a, b]\) and differentiable on \((a, b)\). If \( |f'(x)| \leq M \) for all \( x \in (a, b) \), then 

\[
|f(x_2) - f(x_1)| \leq M|x_2 - x_1|
\]

for all \( x_1, x_2 \in [a, b] \) (i.e. if \( f' \) is bounded on \((a, b)\), then \( f \) is a Lipschitz function \()\) on \([a, b]\).

**Proof:** Let \( x_1, x_2 \in [a, b], x_1 < x_2 \). Then, applying the MVT to \([x_1, x_2]\), for some \( c \in (x_1, x_2) \) we have

\[
|f(x_2) - f(x_1)| = |f'(c)||x_2 - x_1| \leq M|x_2 - x_1| .
\]

There is also a generalized version whose statement is left to the reader (it is very similar to V.8.4.9.).

**The Intermediate Value Property for Derivatives**

Although derivatives can be quite discontinuous (cf. V.12.), they rather remarkably satisfy the conclusion of the Intermediate Value Theorem.

**V.8.2.12. Definition.** A function \( g \) defined on an interval \( I \) has the Intermediate Value Property, or Darboux Property, if, whenever \( a, b \in I, a < b \), and \( r \) is a number strictly between \( g(a) \) and \( g(b) \), there is a \( c \in (a, b) \) with \( g(c) = r \).

A function which has the Intermediate Value Property is sometimes called Darboux continuous.

Every continuous function has the Intermediate Value Property by V.2.3.1. So do derivatives:

**V.8.2.13. Theorem.** If \( f \) is a differentiable function on an interval \( I \), then \( f' \) has the Intermediate Value Property on \( I \).

**Proof:** Let \( a, b \in I, a < b \), and \( r \) a number strictly between \( f'(a) \) and \( f'(b) \). Set \( g(x) = f(x) - rx \); then \( g \) is differentiable on \( I \) and \( g'(x) = f'(x) - r \) for \( x \in I \).

If \( f'(a) > r > f'(b) \), then \( g'(a) > 0 \) and \( g'(b) < 0 \). Since \( g \) is continuous on \([a, b]\), it has a maximum on this interval at some \( c \in [a, b] \) (V.2.4.1.). The maximum cannot occur at \( a \) or \( b \) since \( g'(a) > 0 \) and \( g'(b) < 0 \) (V.3.6.11.); thus \( c \in (a, b) \), and \( g'(c) = 0 \) by V.3.6.3.. Then \( f'(c) = r \).

The case \( f'(a) < r < f'(b) \) is nearly identical, considering the minimum of \( g \) on \([a, b]\).

**V.8.2.14. Corollary.** If \( f \) is differentiable on an interval \( I \), and \( f'(x) \neq 0 \) for all \( x \in I \), then \( f' \) does not change sign on \( I \), i.e. either \( f'(x) > 0 \) for all \( x \in I \) or \( f'(x) < 0 \) for all \( x \in I \). In particular, \( f \) is either strictly increasing on \( I \) or strictly decreasing on \( I \) (V.8.2.1., V.8.2.2.).

Here is another related approximate continuity property of derivatives:
**V.8.2.15.** **Theorem.** Let \( f \) be differentiable on an open interval \((a, b)\), and \( c \in (a, b) \). Then

\[
\liminf_{x \to c^+} f'(x) \leq f'(c) \leq \limsup_{x \to c^+} f'(x)
\]

\[
\liminf_{x \to c^-} f'(x) \leq f'(c) \leq \limsup_{x \to c^-} f'(x)
\]

In particular, if \( \lim_{x \to c^+} f'(x) \) exists, it equals \( f'(c) \), and similarly for \( \lim_{x \to c^-} f'(x) \).

**Proof:** We prove only the first inequality; the others are virtually identical. If \( f'(c) < \liminf_{x \to c^+} f'(x) \) there is an \( \epsilon > 0 \) and a \( d, c < d \leq b \), such that \( f'(x) \geq f'(c) + \epsilon \) for all \( x \in (c, d) \). Then, by the MVT, for every \( x, y \in (c, d) \), \( x \neq y \), we have

\[
\frac{f(y) - f(x)}{y - x} \geq f'(c) + \epsilon.
\]

Fix \( y \in (c, d) \); we then get

\[
\frac{f(y) - f(c)}{y - c} = \lim_{x \to c^+} \frac{f(y) - f(x)}{y - x} \geq f'(c) + \epsilon
\]

since \( f \) is continuous at \( c \). But then we have

\[
f'(c) = \lim_{y \to c^+} \frac{f(y) - f(c)}{y - c} \geq f'(c) + \epsilon
\]

which is a contradiction.

In fact, every Darboux continuous function has this approximate continuity property (Exercise V.8.6.4.).

See V.9.4.11. for an extension of the last statement. See also V.12.2.5.

**V.8.3.** **Geometric Interpretation of the Second Derivative**

Using the MVT, we can now give careful justification of the interpretation of the second derivative of a function in terms of concavity.

**V.8.3.1.** **Definition.** Let \( f \) be a continuous function on an interval \( I \). Then \( f \) is **concave upward** on \( I \) if, whenever \( a, b, c \in I \) with \( a < c < b \), we have

\[
f(c) < f(a) + \frac{f(b) - f(a)}{b - a}(c - a).
\]

The function \( f \) is **concave downward** on \( I \) if, whenever \( a, b, c \in I \) with \( a < c < b \), we have

\[
f(c) > f(a) + \frac{f(b) - f(a)}{b - a}(c - a).
\]

Geometrically, \( f \) is concave upward on \( I \) if on every closed bounded subinterval of \( I \), the graph of \( f \) on the interior lies strictly below the secant line through the endpoints, and similarly the graph lies strictly above the secant line if \( f \) is concave downwards. “Concave upward” is synonymous with “strictly convex” (cf. XIV.15.1.1.).

596
V.8.3.2. THEOREM. Let \( f \) be continuous on \([a, b]\) and differentiable on \((a, b)\). Then \( f \) is concave upward on \([a, b]\) if and only if \( f' \) is strictly increasing on \((a, b)\), and \( f \) is concave downward on \([a, b]\) if and only if \( f' \) is strictly decreasing on \((a, b)\).

**Proof:** We prove the first statement. Suppose \( f' \) is strictly increasing on \([a, b]\). Let \( L(x) \) be the linear function

\[
L(x) = f(a) + \frac{f(b) - f(a)}{b - a}(x - a)
\]

whose graph is the secant line through \((a, f(a))\) and \((b, f(b))\). Suppose there is an \( x_0 \in (a, b) \) with \( f(x_0) \geq L(x_0) \). Then by the MVT there are \( c_1 \in (a, x_0) \) and \( c_2 \in (x_0, b) \) with

\[
f'(c_1) = \frac{f(x_0) - f(a)}{x_0 - a} \geq \frac{L(x_0) - L(a)}{x_0 - a} = \frac{f(b) - f(a)}{b - a} \geq \frac{f(b) - f(x_0)}{b - x_0} = f'(c_2)
\]

which contradicts that \( f' \) is strictly increasing on \((a, b)\) since \( a < c_1 < c_2 < b \). The converse is a special case of XIV.15.1.16. The proof of the second statement is identical with inequalities reversed.

V.8.3.3. COROLLARY. Let \( f \) be continuous on \([a, b]\) and twice differentiable on \((a, b)\). If \( f''(x) \geq 0 \) for all \( x \in (a, b) \), and is not identically 0 on any subinterval, then \( f \) is concave upward on \([a, b]\). If \( f''(x) \leq 0 \) for all \( x \in (a, b) \), and is not identically 0 on any subinterval, then \( f \) is concave downward on \([a, b]\). In particular, if \( f'' > 0 \) [resp. \( f'' < 0 \)] on an interval \( I \), then \( f \) is concave upward [resp. concave downward] on \( I \).

**Proof:** If \( f'' \geq 0 \) on \((a, b)\) and not 0 on any subinterval, then \( f' \) is strictly increasing on \((a, b)\) (V.8.2.1.), and similarly if \( f'' \leq 0 \).

V.8.3.4. A function which is concave upward need not be differentiable everywhere, for example \( f(x) = |x| + x^2 \) (but it must be differentiable except on a countable set, cf. XIV.15.1.16.). A linear function is twice differentiable, but not concave up or concave down on any interval. And even a nonlinear twice differentiable function need not be either concave upward or concave downward on any interval: consider an antiderivative for the example of \((x)\).

There is a pointwise analog:

V.8.3.5. THEOREM. Let \( I \) be an interval, \( f \) be a function from \( I \) to \( \mathbb{R} \), and \( a \) in the interior of \( I \). Suppose \( f \) is twice differentiable at \( a \) (which implies that \( f' \) exists in a neighborhood of \( a \) and is continuous at \( a \)). Let \( L \) be the linear function whose graph is the tangent line to the graph of \( f \) at \( a \), i.e. \( L(x) = f(a) + f'(a)(x-a) \).

(i) If \( f''(a) > 0 \), then there is an \( \epsilon > 0 \) such that \( f(x) > L(x) \) for all \( x \), \( 0 < |x-a| < \epsilon \).
(ii) If \( f''(a) < 0 \), then there is an \( \epsilon > 0 \) such that \( f(x) < L(x) \) for all \( x \), \( 0 < |x-a| < \epsilon \).

Geometrically, if \( f''(a) > 0 \), the graph of \( f \) near \( a \) lies strictly above the tangent line at \( a \), and strictly below if \( f''(a) < 0 \).
Proof: (i): We have that $f'$ is increasing at $a$ (V.3.6.8.), i.e. there is an $\epsilon > 0$ such that $f'(x) < f'(a)$ if $x \in (a-\epsilon,a)$ and $f'(x) > f'(a)$ if $x \in (a,a+\epsilon)$. If $x \in (a-\epsilon,a)$, then by the MVT there is a $c \in (x,a)$ with

$$\frac{f(x) - f(a)}{x-a} = f'(c) < f'(a) = \frac{L(x) - L(a)}{x-a}$$

and it follows that $f(x) - f(a) > L(x) - L(a) = L(x) - f(a)$ since $x - a < 0$. The argument if $x \in (a,a+\epsilon)$ is essentially identical. The proof of (ii) is the same with inequalities reversed.

A special case is particularly important:

V.8.3.6. Corollary. [Second Derivative Test] Let $I$ be an interval, $f$ be a function from $I$ to $\mathbb{R}$, and $a$ in the interior of $I$. Suppose $f$ is twice differentiable at $a$ (which implies that $f'$ exists in a neighborhood of $a$ and is continuous at $a$).

(i) If $f'(a) = 0$ and $f''(a) > 0$, then $f$ has a strict local minimum at $a$.
(ii) If $f'(a) = 0$ and $f''(a) < 0$, then $f$ has a strict local maximum at $a$.

Proof: The function $L(x)$ is the constant function $f(a)$.

V.8.3.7. This result only goes one way. If $f$ has a relative extremum at $a$, it need not be twice differentiable (or even once differentiable!) at $a$, and even if it is we can have $f''(a) = 0$ (consider $f(x) = x^4$ at 0). See V.10.6.13. for an extension of the second derivative test.

Points of Inflection

A point of inflection of a function is a place where the function changes concavity:

V.8.3.8. Definition. Let $f$ be continuous on an interval $I$, and $c$ an interior point of $I$. Then $f$ has a point of inflection at $c$ if there are $a,b \in I$ with $a < c < b$ such that $f$ is concave upward on $[a,c]$ and concave downward on $[c,b]$, or vice versa.

V.8.3.9. If $f$ is differentiable on $I$, and has a point of inflection at $c \in I$, then by V.8.3.2. and V.8.2.15. $f'$ must have a strict local extremum at $c$. In particular, if $f$ is twice differentiable at $c$, then $f''(c) = 0$. However, the converses are not true: if $f(x) = x^4$, then $f''(0) = 0$, but $f$ does not have a point of inflection at 0, and in fact is concave up on all of $\mathbb{R}$. And if $g$ is an antiderivative for the function $f$ of V.3.10.11., then $g$ is twice differentiable everywhere with $g''(0) = 0$, and $g'$ has a strict local minimum at 0, but $g$ does not have a point of inflection at 0: in fact, $g$ is neither concave up or concave down in any interval with endpoint 0.

V.8.4. Refinements of the Mean Value Theorem

We can give a refinement of V.8.2.1.. We do not obtain this as a consequence of the MVT, but give a direct proof in the spirit of the MVT.
V.8.4.1. **Theorem.** Let $f$ be a continuous function on $[a, b]$, and $A$ a countable subset of $[a, b]$. Suppose $f$ is differentiable on $[a, b] \setminus A$.

(i) If $f'(x) > 0$ for all $x \in [a, b] \setminus A$, then $f$ is strictly increasing on $[a, b]$.

(ii) If $f'(x) \geq 0$ for all $x \in [a, b] \setminus A$, then $f$ is nondecreasing on $[a, b]$.

(iii) If $f'(x) = 0$ for all $x \in [a, b] \setminus A$, then $f$ is constant on $[a, b]$.

Similar statements to (i) and (ii) hold if $f$ is strictly increasing on $[a, b]$, and in fact this may fail (cf. V.8.4.2). Thus, to obtain a more general version of V.8.4.2. in this setting, we would have to add a clumsy set of additional hypotheses, although there are situations where a generalization is possible (e.g. XIV.17.1.17.). We can state part (i) in this setting:

**Proof:** (i): It suffices to show that $f$ is nondecreasing on $[a, b]$, since if $f$ is nondecreasing but not strictly increasing it would be constant on some subinterval, hence have $f' = 0$ on some interval. In fact, it suffices to show that $f(a) \leq f(b)$, since the interval $[a, b]$ can be replaced by any closed subinterval.

So suppose $f(a) > f(b)$. Since $f(A)$ is countable, we can find a number $d \notin f(A)$ with $f(a) > d > f(b)$. Let $B = \{x \in [a, b] : f(x) = d\}$. $B$ is nonempty by the Intermediate Value Theorem. Since $f$ is continuous, $B$ is closed, and thus has a largest element $c$. We have $a < c < b$ since $f(a) > d > f(b)$, and $c \notin A$ since $f(c) \notin f(A)$. So $f$ is differentiable at $c$ and $f'(c) > 0$. Since $f(b) < d$ and $f$ never takes the value $d$ on $(c, b)$, we must have $f(x) < d$ for all $x \in (c, b)$ by the Intermediate Value Theorem. Hence

$$
\lim_{x \to c^+} \frac{f(x) - f(c)}{x - c} \leq 0
$$

contradicting the assumption that $f'(c) > 0$.

(ii): Let $\epsilon > 0$. Apply (i) to $g(x) = f(x) + \epsilon x$ to conclude that $f(a) \leq f(b) + \epsilon(b - a)$. Since $\epsilon$ is arbitrary, $f(a) \leq f(b)$.

(iii): Apply (ii) to $f$ and $-f$.

The differentiability of $f$ on $[a, b] \setminus A$ can be relaxed to the assumption that the upper right Dini derivative of $f$ is positive (nonnegative, zero) on $[a, b] \setminus A$ (the proof of (iii) is a bit more subtle in this case, however; see (i)). Hence a more general statement can be proved with the same argument:

V.8.4.2. **Theorem.** Let $f$ be a continuous function on an interval $[a, b]$, and let $A$ be a countable subset of $[a, b]$. Then

(i) If $D^+ f(x) > 0$ for all $x \in [a, b] \setminus A$, then $f$ is strictly increasing on $[a, b]$.

(ii) If $D^+ f(x) \geq 0$ for all $x \in [a, b] \setminus A$, then $f$ is nondecreasing on $[a, b]$.

(iii) If $D^+ f(x) = 0$ for all $x \in [a, b] \setminus A$, then $f$ is constant on $[a, b]$.

Similar statements to (i) and (ii) hold if $D^+ f(x) < 0$ or $D^+ f(x) \leq 0$ for all $x \in [a, b] \setminus A$.

V.8.4.3. Note that the only property of $A$ needed for the proof of (i) is that $f(A)$ does not contain any interval. However, there is a subtlety in the proof of (ii) (and hence (iii)) if only this assumption is made: if $f(A)$ does not contain any interval, if $A$ is uncountable it is not obvious that $g(A)$ contains no interval if $g(x) = f(x) + \epsilon x$, and in fact this may fail (cf. [vRS82, 21.G]). Thus, to obtain a more general version of V.8.4.2. in this setting, we would have to add a clumsy set of additional hypotheses, although there are situations where a generalization is possible (e.g. XIV.17.1.17.). We can state part (i) in this setting:
V.8.4.4. **Theorem.** Let $f$ be a continuous function on an interval $[a, b]$, and let $A$ be a subset of $[a, b]$ such that $f(A)$ contains no interval. Then

(i) If $D^+ f(x) > 0$ for all $x \in [a, b] \setminus A$, then $f$ is strictly increasing on $[a, b]$.

(ii) If $D^+ f(x) < 0$ for all $x \in [a, b] \setminus A$, then $f$ is strictly decreasing on $[a, b]$.

Perhaps the most general version of V.8.4.2 (ii) which can be stated reasonably simply is:

V.8.4.5. **Theorem.** Let $f$ be a continuous function on an interval $[a, b]$. If $D^+ f(x) \geq 0$ for all $x$ not in a set $A$ of measure $0$, and $B = \{ x \in [a, b] : D^+ f(x) = -\infty \}$ is at most countable, then $f$ is nondecreasing on $[a, b]$.

(Under the hypotheses, the sets $B$, and even $A$, would turn out to be empty, but this need not be assumed. Actually, the result is interesting and useful even in the case $B = \emptyset$.)

**Proof:** Let $g$ be a nondecreasing function on $[a, b]$ with $D_+ g(x) = +\infty$ for all $x \in A$. Fix $\epsilon > 0$ and let $h_{\epsilon} = f + \epsilon g$. Then $D^+ h_{\epsilon}(x) \geq D^+ f(x) \geq 0$ for $x \notin A \cup B$ since $g$ is nondecreasing. If $x \in A \setminus B$, then $D^+ f(x) > -\infty$, so $D^+ h_{\epsilon}(x) = +\infty$ by ($\cdot$). Thus $D^+ h_{\epsilon}(x) \geq 0$ for all $x \notin B$, so $h_{\epsilon}$ is nondecreasing by V.8.4.2 (ii). Since $f = \lim_{\epsilon \to 0} h_{\epsilon}$, $f$ is also nondecreasing.

V.8.4.6. Note that the hypothesis that $B$ be countable cannot be replaced by an assumption that $B$ is a null set: the negative of the Cantor function ($\cdot$) is a counterexample.

Using V.8.4.1., we can obtain generalizations of V.8.2.7. and V.8.2.8.. As explained in V.8.4.3., to obtain a clean statement we must assume the conditions hold except on a countable subset.

V.8.4.7. **Corollary.** Let $a, b, M \in \mathbb{R}$, $a < b$. Let $f$ be a function which is continuous on $[a, b]$. Let $A$ be a countable subset of $[a, b]$. If $D^+ f(x) < M$ for all $x \in [a, b] \setminus A$, then

$$f(x_2) - f(x_1) < M(x_2 - x_1)$$

for all $x_1, x_2 \in [a, b]$, $x_1 < x_2$. The result also holds if $<$ is replaced by $\leq$ throughout.

**Proof:** Apply V.8.4.2. to $h(x) = Mx - f(x)$.

V.8.4.8. **Corollary.** Let $a, b, m \in \mathbb{R}$, $a < b$. Let $f$ be a function which is continuous on $[a, b]$. Let $A$ be a countable subset of $[a, b]$. If $m < D^+ f(x)$ for all $x \in [a, b] \setminus A$, then

$$m(x_2 - x_1) < f(x_2) - f(x_1)$$

for all $x_1, x_2 \in [a, b]$, $x_1 < x_2$. The result also holds if $<$ is replaced by $\leq$ throughout.

**Proof:** Apply V.8.4.2. to $g(x) = f(x) - mx$.
**V.8.4.9.** Corollary. Let \(a, b, m, M \in \mathbb{R}, a < b\). Let \(f\) be a function which is continuous on \([a, b]\). Let \(A\) be a countable subset of \([a, b]\). If \(m < D^+ f(x)\) and \(D_+ f(x) < M\) for all \(x \in [a, b] \setminus A\), then
\[
m(x_2 - x_1) < f(x_2) - f(x_1) < M(x_2 - x_1)
\]
for all \(x_1, x_2 \in [a, b], x_1 < x_2\). The result also holds if \(<\) is replaced by \(\leq\) throughout.

The following special case of V.8.4.2.(iii) is useful:

**V.8.4.10.** Corollary. Let \(f\) and \(g\) be continuous functions on an interval \(I\). If there is a countable subset \(A\) of \(I\) such that \(D_R f(x)\) and \(D_R g(x)\) exist and are equal for all \(x \in I \setminus A\), then \(f\) and \(g\) differ by a constant on \(I\).

**Proof:** Apply V.8.4.2.(iii) to \(f - g\) (on any closed bounded subinterval of \(I\)).

---

**V.8.5. Antiderivatives and Primitives**

Antiderivatives are usually associated with integration, but we can use the results of the previous subsection to obtain antiderivatives for certain well-behaved functions without discussing integration, at least explicitly.

**V.8.5.1.** Definition. Let \(f\) be a function on an interval \(I\). An antiderivative for \(f\) on \(I\) is a function \(F\) on \(I\) which is differentiable on \(I\) and with \(F' = f\) on \(I\).

A primitive for \(f\) on \(I\) is a continuous function \(F\) on \(I\) such that, for some countable subset \(A\) of \(I\), \(F'(x)\) exists and equals \(f(x)\) for all \(x \in I \setminus A\).

**V.8.5.2.** Since a differentiable function on an interval is continuous, every antiderivative for \(f\) on \(I\) is a primitive for \(f\) on \(I\) (with \(A = \emptyset\)). The terms “antiderivative” and “primitive” are often used as synonyms, but we make a slight technical distinction between them which will be useful.

**V.8.5.3.** Antiderivatives and primitives are not unique: a constant can be added to any antiderivative (primitive) to obtain another antiderivative (primitive). By V.8.2.5., this is the only change possible for antiderivatives: any two antiderivatives for a function \(f\) differ by a constant. This is also true for primitives by V.8.4.10.

**Step Functions**

Recall () that a step function on an interval \([a, b]\) corresponding to a partition
\[
\mathcal{P} = \{a = x_0, x_1, \ldots, x_n = b\}
\]
is a function which is constant on \((x_{k-1}, x_k)\) for \(1 \leq k \leq n\).
V.8.5.4. Proposition. Let \( f \) be a step function on \([a, b]\). Then \( f \) has a primitive on \([a, b]\).

Proof: This is quite simple and straightforward, but notationally a bit complicated. The function \( f \) will be “piecewise linear” or “polygonal”. Suppose \( f \) takes the value \( a_k \) on \((x_{k-1}, x_k)\). Define \( f \) as follows:

For \( x_0 \leq x \leq x_1 \), let \( F(x) = a_1(x - x_0) \).

For \( x_1 < x \leq x_2 \), let \( F(x) = a_1(x_1 - x_0) + a_2(x - x_1) \).

For \( x_2 < x \leq x_3 \), let \( F(x) = a_1(x_1 - x_0) + a_2(x_2 - x_1) + a_3(x - x_2) \).

\[ \cdots \]

For \( x_{k-1} < x \leq x_k \), let \( F(x) = \sum_{j=1}^{k-1} a_j(x_j - x_{j-1}) + a_k(x - x_{k-1}) \).

\[ \cdots \]

It is obvious that \( F \) is continuous on \([a, b]\), and that \( F'(x) = f(x) \) for \( x \in [a, b] \setminus \{x_0, \ldots, x_n\} \). ☐

The next theorem is the most important result of this subsection. It will be used for other purposes than the ones of this subsection, such as justifying term-by-term differentiation and integration of infinite series of functions. In many, but not all, applications, the set \( A \) in the statement of the theorem will be the empty set.

V.8.5.5. Theorem. Let \((F_n)\) and \((f_n)\) be sequences of functions on an interval \( I \), and \( A \) a countable subset of \( I \). Suppose

(a) Each \( F_n \) is continuous on \( I \).

(b) For every \( x \in I \setminus A \), each \( F_n \) is differentiable at \( x \) and \( F'_n(x) = f_n(x) \).

(c) The sequence \((f_n)\) converges u.c. on \( I \) to a function \( f \).

(d) There is an \( x_0 \in I \) such that the sequence \((F_n(x_0))\) converges.

Then:

(i) The sequence \((F_n)\) converges u.c. on \( I \) to a (continuous) function \( F \).

(ii) For each \( x \in I \setminus A \), \( F \) is differentiable at \( x \) and \( F'(x) = f(x) \).

Proof: (i): Let \( J \) be a closed bounded subinterval of \( I \). We will show that \((F_n)\) is a uniform Cauchy sequence on \( J \), hence uniformly convergent to a (continuous) limit function \( F \) by \( (\cdot) \). By expanding \( J \), we may assume \( x_0 \in J \).

Let \( \epsilon > 0 \). Choose \( N \) such that for all \( n, m \geq N \),

\[
\sup_{x \in J} |f_n(x) - f_m(x)| < \frac{\epsilon}{2\ell(J)}
\]

602
Now fix for all case where \( V.x.y \), and thus whenever \( 0 < \epsilon < \frac{\epsilon}{2} \). Then, if \( n, m \geq N \) and \( x \in J \), by V.8.4.7. we have, since \((F_n - F_m)' = f_n - f_m \) on \( J \setminus A \),

\[
|F_n(x_0) - F_m(x_0)| < \frac{\epsilon}{2}.
\]

Then, if \( n, m \geq N \) and \( x \in J \), by V.8.4.7. we have, since \((F_n - F_m)' = f_n - f_m \) on \( J \setminus A \),

\[
|F_n(x) - F_m(x)| - |F_n(x_0) - F_m(x_0)| < \frac{\epsilon}{2f(J)} |x - x_0| \leq \frac{\epsilon}{2}
\]

and so

\[
|F_n(x) - F_m(x)| = |[F_n(x) - F_n(x_0)] - [F_m(x) - F_m(x_0)] + [F_n(x_0) - F_m(x_0)]| \\
\leq |[F_n(x) - F_n(x_0)] - [F_m(x) - F_m(x_0)]| + |F_n(x_0) - F_m(x_0)| < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon.
\]

(ii): Let \( J \) be as above, and \( \epsilon > 0 \). There is an \( N \) such that

\[
\sup_{x \in J} |f_n(x) - f(x)| < \frac{\epsilon}{4}
\]

for all \( n \geq N \). Fix \( n \geq N \). For all \( m \geq N \), we have

\[
\sup_{x \in J} |f_n(x) - f_m(x)| < \frac{\epsilon}{2}
\]

and hence by V.8.4.7. we have

\[
|[F_m(y) - F_m(x)] - [F_n(y) - F_n(x)]| = |[F_m(y) - F_n(y)] - [F_m(x) - F_n(x)]| < \frac{\epsilon}{2} |y - x|
\]

for all \( x, y \in J \). Since \( F_m \to F \) uniformly on \( J \), letting \( m \to \infty \) we have

\[
|[F(y) - F(x)] - [F_n(y) - F_n(x)]| \leq \frac{\epsilon}{2} |y - x|
\]

for all \( x, y \in J \).

Now fix \( x \in J \setminus A \). Then there is a \( \delta > 0 \) such that

\[
\left| \frac{F_n(y) - F_n(x)}{y - x} - f_n(x) \right| < \frac{\epsilon}{4}
\]

whenever \( 0 < |y - x| < \delta \). Then, for \( 0 < |y - x| < \delta \), we have

\[
\left| \frac{F(y) - F(x)}{y - x} - f(x) \right| = \left| \frac{F(y) - F(x)}{y - x} - \frac{F_n(y) - F_n(x)}{y - x} + \frac{F_n(y) - F_n(x)}{y - x} - f_n(x) + f_n(x) - f(x) \right| \\
\leq \left| \frac{F(y) - F(x)}{y - x} - \frac{F_n(y) - F_n(x)}{y - x} \right| + \left| \frac{F_n(y) - F_n(x)}{y - x} - f_n(x) \right| + |f_n(x) - f(x)| < \frac{\epsilon}{2} + \frac{\epsilon}{4} + \frac{\epsilon}{4} = \epsilon
\]

and thus \( F'(x) = f(x) \).

\[\Box\]

V.8.5.6. A simpler proof using the Fundamental Theorem of Calculus can be given in the crucial special case where \( A = \emptyset \) and the \( f_n \) are continuous (XIV.2.9.15.).

603
V.8.5.7. **Corollary.** Let \((f_n)\) be a sequence of functions on an interval \(I\), converging u.c. on \(I\) to a function \(f\).

(i) If each \(f_n\) has a primitive on \(I\), then \(f\) has a primitive on \(I\).

(ii) If each \(f_n\) has an antiderivative on \(I\), then \(f\) has an antiderivative on \(I\).

**Proof:** Fix \(x_0 \in I\). By adjusting by a constant, \(f_n\) has a primitive (antiderivative in case (ii)) \(F_n\) on \(I\) with \(F_n(x_0) = 0\). Let \(A_n\) be the set of \(x \in I\) for which \(F'_n(x) = f_n(x)\) does not hold; then \(A_n\) is countable, and \(A_n = \emptyset\) in case (ii). Set \(A = \bigcup_{n=1}^{\infty} A_n\). Then \((f_n), (F_n), A\) satisfy the hypotheses of V.8.5.5.  

V.8.5.8. **Proposition.** Let \(f\) be a continuous function on an interval \(I\). Then there is a sequence \((f_n)\) of step functions on \(I\) converging u.c. to \(f\) on \(I\). If \(A\) is any dense subset of \(I\), the \(f_n\) may be chosen to have discontinuities only in \(A\).

**Proof:** This is an almost immediate consequence of (i). Let \([a_n, b_n]\) be an increasing sequence of closed bounded intervals with union \(I\). Then \(f\) is uniformly continuous on \([a_n, b_n]\). For each \(n\) fix \(\delta_n > 0\) such that \(x, y \in [a_n, b_n], |x - y| < \delta_n\) implies \(|f(x) - f(y)| < \frac{1}{n}\). Then let \(\mathcal{P}_n\) be a partition of \([a_n, b_n]\) with interior points in \(A\) with mesh \(< \delta_n\), and \(t_k\) a point in the \(k\)th subinterval of the partition. Let \(f_n\) be the step function with value \(f(t_k)\) on the \(k\)th subinterval of the partition \(\mathcal{P}_n\) (and, say, left continuous at the points of the partition), and extend \(f_n\) to \(I\) by making it constant to the left and right of \([a_n, b_n]\) if necessary. Then \(f_n \to f\) u.c. on \(I\) (Exercise V.8.6.6.).

V.8.5.9. **Theorem.** Let \(f\) be a continuous function on an interval \(I\). Then \(f\) has an antiderivative on \(I\).

**Proof:** Fix \(x_0 \in I\), and let \(A\) and \(B\) be disjoint countable dense subsets of \(I\) (e.g. \(A = \mathbb{Q} \cap I, B = [\mathbb{Q} + \sqrt{2}] \cap I\)). Then there is a sequence \((f_n)\) of step functions on \(I\) with discontinuities only in \(A\), converging u.c. to \(f\) on \(I\). It follows from V.8.5.5. that \(f\) has a primitive \(F_1\) on \(I\) satisfying \(F'_1(x) = f(x)\) for all \(x \in I \setminus A\) and \(F_1(x_0) = 0\). Similarly, there is a primitive \(F_2\) of \(f\) on \(I\) such that \(F'_2(x) = f(x)\) for all \(x \in I \setminus B\) and \(F_2(x_0) = 0\). By V.8.4.10. (applied using the countable set \(A \cup B\)), \(F_1\) and \(F_2\) differ by a constant. But \(F_1(x_0) = F_2(x_0)\), so \(F_1 = F_2\). Thus \(F'_1(x)\) exists and equals \(f(x)\) for all \(x \in (I \setminus A) \cup (I \setminus B) = I\).

V.8.5.10. We will give another proof of this theorem in XIV.2.9.4. (Deep down, it is really the same proof.)

Another example where a similar argument applies is monotone functions:

V.8.5.11. **Proposition.** Let \(f\) be a monotone function on an interval \(I\). Then there is a sequence \((f_n)\) of step functions on \(I\) converging u.c. to \(f\) on \(I\).
V.8.5.12. Corollary. Let \( f \) be a monotone function on an interval \( I \). Then \( f \) has a primitive on \( I \).

V.8.5.13. It can be shown with a little additional work that if \( f \) is monotone on \( I \) and \( F \) is a primitive of \( f \) on \( I \), then the (countable) set \( A \) of \( x \) for which \( F'(x) = f(x) \) does not hold is exactly the set of discontinuities of \( f \). See V.8.6.7. for a more general result.

V.8.6. Exercises

V.8.6.1. Let \( C \) be a smooth curve from \( p \) to \( q \) in \( \mathbb{R}^2 \) (i.e. with a parametrization \( (g(t), f(t))_{a \leq t \leq b} \) with \( f \) and \( g \) differentiable on \([a, b]\) and \( f' \) and \( g' \) not simultaneously 0). If \( p \neq q \) and \( r \) is a point on \( C \) of maximum distance from the line \( L \) through \( p \) and \( q \) (why does such a point exist?), show that the tangent line to \( C \) at \( r \) is parallel to \( L \).

V.8.6.2. (a) Prove V.8.4.2.(i) and (ii) in the case where the upper right Dini derivative \( D_+ f \) is positive or nonnegative on \([a, b] \setminus A \). Show why (iii) does not immediately follow from (ii) in this case.

(b) Suppose \( D_+ f(x) = 0 \) for all \( x \in [a, b] \setminus A \). Apply (ii) to conclude that \( f \) is nondecreasing on \([a, b] \). Thus the lower right Dini derivative \( D_- f \) satisfies \( D_- f(x) \geq 0 \) for all \( x \in [a, b] \).

(c) In the situation of (b), conclude that \( D_+ f(x) = 0 \) for all \( x \in [a, b] \setminus A \); thus (ii) can be applied to \(-f\) to conclude that \(-f\) is increasing on \([a, b] \). Thus \( f \) is constant on \([a, b]\).

V.8.6.3. Use the Intermediate Value Property for derivatives () to give an alternate proof of ().

V.8.6.4. Let \( g \) be a Darboux continuous function on an open interval \((a, b)\), and \( c \in (a, b) \). Show that

\[
\liminf_{x \to c^+} g(x) \leq g(c) \leq \limsup_{x \to c^+} g(x)
\]

\[
\liminf_{x \to c^-} g(x) \leq g(c) \leq \limsup_{x \to c^-} g(x)
\]

V.8.6.5. Let \( f \) be a continuous function on an open interval \( I \). Set

\[
M^+ = \sup\{D^+ f(x) : x \in I\}
\]

\[
m^+ = \inf\{D^+ f(x) : x \in I\}
\]

\(m^+\) and/or \(M^+\) may be infinite), and let

\[
S = \left\{ \frac{f(y) - f(x)}{y - x} : x, y \in I, x \neq y \right\}
\]

(a) Show that \((m^+, M^+) \subseteq S \subseteq [m^+, M^+]\). To show \((m^+, M^+) \subseteq S\), fix \( \lambda \in (m^+, M^+) \) and let \( g(x) = f(x) - \lambda x \). Then \( g \) has both positive and negative right Dini derivatives on \( I \) and hence cannot be one-to-one by () . For \( S \subseteq [m^+, M^+]\), let \( \lambda \leq m^+ \) and \( \mu \geq M^+ \), and apply V.8.4.2.(ii) to \( f(x) - \lambda x \) and \( \mu x - f(x)\).

(b) Show that \( m^+ \in S \) if and only if \( f \) is linear with slope \( m^+ \) on a subinterval of \( I \), and similarly for \( M^+ \).
(c) Repeat (a) with

\[ M_+ = \sup \{ D_+ f(x) : x \in I \} \]
\[ m_+ = \inf \{ D_+ f(x) : x \in I \} \]

and with \( M^- \), \( m^- \) and \( M_- \), \( m_- \) defined similarly using \( D^- f \) and \( D_- f \). Conclude that

\[ m^+ = m_+ = m^- = m_- \quad \text{and} \quad M^+ = M_+ = M^- = M_- . \]

(d) Use (a) to give an alternate proof of the Darboux property for derivatives. [Show that if \( f \) is differentiable on an open interval \( I \), then \( f'(J) \) is an interval for every open subinterval \( J \) of \( I \).]

\[ \text{V.8.6.6.} \quad \text{Show that if } f \text{ is as in V.8.5.8., and } (f_n) \text{ is the sequence defined in the proof, then } f_n \to f \text{ u.c. on } I. \]

\[ \text{V.8.6.7.} \quad \text{In [?], IX, Book IV, Chapter II, §1.3], a function on an interval } I \text{ is called regulated ("réglée") on } I \text{ if it is a u.c. limit of a sequence of step functions on } I. \text{ Note that every regulated function has a primitive by V.8.5.5. and V.8.5.4.. By V.8.5.8. and V.8.5.11., every continuous function and every monotone function is regulated.}

(a) Show that a function on an interval \( I \) which has left and right limits at every interior point of \( I \) has only countably many discontinuities on \( I \). [Mimic the proof of V.4.2.11..]

(b) Show that a function \( f \) on an interval \( I \) is regulated if and only if it has left and right limits at every interior point of \( I \) and one-sided limits at any endpoints of \( I \) which are in \( I \).

(c) Show that if \( f \) is regulated on \( I \) and \( F \) is a primitive for \( f \) on \( I \), then the (countable) set \( A \) of all \( x \in I \) for which \( F'(x) = f(x) \) does not hold is precisely the set of discontinuities of \( f \).

(d) Show that a regulated function on an interval \( I \) is bounded on every closed bounded subinterval of \( I \). [Step functions are bounded.]

(e) Any (finite) linear combination of regulated functions on an interval \( I \) is regulated. Thus every function of bounded variation () on every closed bounded subinterval of \( I \) is regulated on \( I \). Not every regulated function (indeed, not every continuous function) has bounded variation, even on closed bounded subintervals of \( I \).

See XIV.3.11.4. for more on regulated functions.

\[ \text{V.8.6.8.} \quad \text{(a) Show by direct calculation that every polynomial has an antiderivative on } \mathbb{R}. \]

(b) Use V.8.5.5. and XV.8.1.1. to give an alternate proof of V.8.5.9..

\[ \text{V.8.6.9.} \quad \text{[?], Exercise 7.6.21] (a) Prove the following generalization of Cauchy’s Mean Value Theorem:}

\[ \text{THEOREM. Let } f, g, h \text{ be continuous on } [a, b] \text{ and differentiable on } (a, b). \text{ Then there is a } c \in (a, b) \text{ such that}

\[ 0 = \text{Det} \begin{bmatrix} f(a) & g(a) & h(a) \\ f(b) & g(b) & h(b) \\ f'(c) & g'(c) & h'(c) \end{bmatrix} = f'(c)[g(a)h(b) - g(b)h(a)] - g'(c)[f(a)h(b) - f(b)h(a)] + h'(c)[f(a)g(b) - f(b)g(a)]. \]

606
Cauchy’s MVT is the special case where \( h \) is the constant function 1. [Consider the function

\[
\phi(x) = \det \begin{bmatrix} f(a) & g(a) & h(a) \\ f(b) & g(b) & h(b) \\ f(x) & g(x) & h(x) \end{bmatrix}
\]

and apply Rolle’s Theorem. Recall that a (square) matrix with two identical rows has determinant 0.]

(b) Extend the result to the case \( n > 3 \):

**Theorem.** Let \( n \geq 4 \), and let \( f_1, \ldots, f_n \) be continuous on \([a, b]\) and differentiable on \((a, b)\). Let \( \{d_{ij} : 3 \leq i \leq n-1, 1 \leq j \leq n\} \) be arbitrary constants. Then there is a \( c \in (a, b) \) such that

\[
0 = \det \begin{bmatrix} f_1(a) & f_2(a) & \cdots & f_n(a) \\ f_1(b) & f_2(b) & \cdots & f_n(b) \\ d_{31} & d_{32} & \cdots & d_{3n} \\ \vdots & \vdots & \ddots & \vdots \\ d_{n-1,1} & d_{n-1,2} & \cdots & d_{n-1,n} \\ f'_1(c) & f'_2(c) & \cdots & f'_n(c) \end{bmatrix}.
\]

(c) Here is another version:

**Theorem.** Let \( n \geq 3 \), and let \( \mathcal{P} = \{a = x_1, x_2, \ldots, x_{n-1} = b\} \) be a partition of \([a, b]\) into \( n-2 \) subintervals. Let \( f_1, \ldots, f_n \) be continuous on \([a, b]\) and differentiable on \([a, b] \setminus \mathcal{P}\). Then, for each \( k \leq n-2 \), there is a \( c \in (x_k, x_{k+1}) \) such that

\[
0 = \det \begin{bmatrix} f_1(x_1) & f_2(x_1) & \cdots & f_n(x_1) \\ f_1(x_2) & f_2(x_2) & \cdots & f_n(x_2) \\ \vdots & \vdots & \ddots & \vdots \\ f_1(x_{n-1}) & f_2(x_{n-1}) & \cdots & f_n(x_{n-1}) \\ f'_1(c) & f'_2(c) & \cdots & f'_n(c) \end{bmatrix}.
\]

**V.8.6.10. The Mean Value Inequality.** This problem gives a direct proof of V.8.2.7. (in the case where \( f \) is differentiable on all of \([a, b]\)) by the Method of Successive Bisections ().

(a) Show that to prove V.8.2.7. it suffices to prove V.8.2.1.

(b) Show that to prove V.8.2.1. it suffices to prove the following. [For each \( \epsilon > 0 \) set \( f_\epsilon(x) = f(x) + \epsilon x \). To show that \( f(a) \leq f(b) \), it suffices to show \( f_\epsilon(a) \leq f_\epsilon(b) \) for all \( \epsilon > 0 \).]

**Proposition.** Let \( f \) be differentiable on \([a, b]\). If \( f'(x) > 0 \) for all \( x \in [a, b] \), then \( f(a) \leq f(b) \).

(c) To prove this proposition, set \( I_1 = [a, b] \), and \( c \) the midpoint of \( I_1 \). If \( f(a) > f(b) \), then either \( f(a) > f(c) \) or \( f(c) > f(b) \). Let \( I_2 = [a, c] \) if the first holds and \( I_2 = [c, b] \) otherwise. Repeat the process to obtain a nested sequence \((I_n)\) of intervals, where \( I_n = [a_n, b_n] \) with \( f(a_n) > f(b_n) \) for all \( n \).

(d) Let \( \cap_{n=1}^\infty I_n = \{x\} \). Show that \( f'(x) \leq 0 \), contradicting that \( f'(x) > 0 \).
V.8.6.11. The aim of this problem is to use a purely algebraic argument, along with the Intermediate Value Theorem for polynomials, to prove Rolle’s Theorem for polynomials: between any two real roots of a polynomial $p$ with real coefficients is a root of $p'$.

(a) Let $p(x)$ be a nonzero polynomial with real coefficients, and $a$ and $b$ consecutive real roots of $p$. Write

$$p(x) = (x-a)^r(x-b)^s q(x)$$

where $r, s \in \mathbb{N}$ and $q$ is a polynomial with real coefficients with no roots in $[a,b]$, and which therefore does not change sign on $[a,b]$.

(b) Use the product rule to show that

$$p'(x) = (x-a)^{r-1}(x-b)^{s-1} [r(x-b)q(x) + s(x-a)q(x) + (x-a)(x-b)q'(x)].$$

(c) Show that the polynomial in brackets in (b) takes values of opposite sign at $a$ and $b$.

(d) Apply the Intermediate Value Theorem for polynomials to conclude that $p'$ has a root in $(a,b)$.

No actual differential calculus is needed for this problem, since the derivative of a polynomial can be defined and calculated formally, and the product rule for polynomials proved algebraically from the formal definition of derivative; cf. Exercise V.3.10.9. (Even the Intermediate Value Theorem for polynomials has a purely algebraic proof in real-closed fields; see, for example, [BPR06].) In fact, ROLLE did something like this, and it is unclear whether he even realized he was computing derivatives: he generated the sequence of derivatives of the given polynomial $p$ in a somewhat different (algebraic) way and called them the “cascade of polynomials” in using them to locate the (real) roots of $p$. See the chapter by J. BARROW-GREEN in [RS09].

V.8.6.12. Let $f$ be differentiable on an interval $I$, and suppose $f'(x) > 0$ for all $x \in I$. Use V.3.6.8. and the Max-Min Theorem () to prove that $f$ is strictly increasing on $I$ without using the MVT. [If $x_1, x_2 \in I, x_1 < x_2$, apply the Max-Min Theorem to $[x_1, x_2].$]

V.8.6.13. Let $f$ be continuous on an interval $I$ and $n$-times differentiable on the interior of $I$. Suppose $f$ has $m$ distinct zeroes in $I$. Show by repeated application of Rolle’s Theorem that for $1 \leq k \leq \min(n, m)$, $f^{(k)}$ has at least $m - k$ distinct zeroes in the interior of $I$.

V.8.6.14. (a) Find an elementary closed formula for

$$\int \sqrt{\tan x} \, dx$$

(a computer algebra system is very helpful).

(b) (LIOUVILLE, 1835) Show that

$$\int \sqrt{\sin x} \, dx$$

has no elementary closed formula.
V.9. L’Hôpital’s Rule

L’Hôpital’s Rule is a very useful technique for evaluating limits of indeterminate forms involving quotients. There are a number of variations of the rule, which all fall under the general name “l’Hôpital’s Rule.”

The rule is named for the French nobleman MARQUIS GUILLAUME FRANÇOIS ANTOINE DE L’HÔPITAL (sometimes spelled l’Hospital; his own spelling was apparently Lhospital) and was first published in 1696 in the calculus text _L'Analyse des Infiniment Petits pour l'Intelligence des Lignes Courbes_ (the first actual calculus text!) written by L’HÔPITAL; this name for the rule apparently first appeared in print in [Gou59] in 1902. The rule was actually discovered by JOHANN (or JEAN) BERNOULLI, who had taught calculus to L’HÔPITAL, in 1694; BERNOULLI had a business arrangement with L’HÔPITAL giving L’HÔPITAL, who was himself a respectable mathematician, the right to publish BERNOULLI’s results. (See [?] for the full story.) L’HÔPITAL’s text, which fairly closely followed lecture notes by BERNOULLI, was very influential, and editions remained in print for almost 100 years (a copy is available online at http://www.archive.org/details/infinimentpetits1716lhos00uoft); before this text became available, calculus was known and understood by only a handful of top European mathematicians. L’HÔPITAL, besides being a gifted expositor (he also wrote a text on conic sections which was the standard for that subject throughout the eighteenth century), seems to have been a considerably more pleasant and genial person than BERNOULLI: BERNOULLI, although he was a great mathematician and had a reputation as an inspiring teacher (EULER was his prize pupil), was hypercompetitive and was continually embroiled in bitter disputes with other mathematicians, the most vicious of which were with his own brother JAKOB (who was himself described as “self-willed, obstinate, aggressive, vindictive, beset by feelings of inferiority and yet firmly convinced of his own abilities.”) [Hof71] [Do not confuse the various BERNOULLIS; there were several outstanding mathematicians in this family, extending over at least three generations, but JOHANN and JAKOB (or JACQUES), and JOHANN’s son DANIEL, were the best.]

V.9.1. L’Hôpital’s Rule, Version 1

The first version we give of l’Hôpital’s Rule is an easy consequence of the definition of derivative, and is often not regarded as a form of l’Hôpital’s Rule at all.

V.9.1.1. THEOREM. [L’Hôpital’s Rule, Version 1] Let \( f \) and \( g \) be functions on an interval \( I \), and \( a \) an interior point of \( I \). Suppose

1. \( \lim_{x \to a} f(x) = \lim_{x \to a} g(x) = 0 \).
2. \( f \) and \( g \) are differentiable at \( a \) and \( g'(a) \neq 0 \).

Then \( \lim_{x \to a} \frac{f(x)}{g(x)} \) exists and equals \( \frac{f'(a)}{g'(a)} \).

PROOF: First note that since \( f \) and \( g \) are differentiable at \( a \), they are continuous at \( a \), and thus \( f(a) = \)
\[ \lim_{x \to a} f(x) = 0 \text{ and } g(a) = \lim_{x \to a} g(x) = 0. \]

We have
\[
\frac{f'(a)}{g'(a)} = \lim_{x \to a} \frac{f(x) - f(a)}{x - a} \cdot \lim_{x \to a} \frac{g(x) - g(a)}{x - a}.
\]

Note that \( g(x) = g(x) - g(a) \neq 0 \) in a deleted neighborhood of \( a \) since
\[
g'(a) = \lim_{x \to a} \frac{g(x) - g(a)}{x - a} \neq 0.
\]

So, by (1),
\[
\frac{f'(a)}{g'(a)} = \lim_{x \to a} \frac{f(x) - f(a)}{g(x) - g(a)} = \lim_{x \to a} \frac{f(x) - f(a)}{g(x) - g(a)}.
\]

Version 1 of the rule is adequate for many of the elementary applications.

**Example.** To evaluate
\[ \lim_{x \to 0} \frac{e^x - 1}{\sin x} \]

let \( f(x) = e^x - 1, g(x) = \sin x, a = 0 \). We have \( \lim_{x \to 0} f(x) = \lim_{x \to 0} g(x) = 0, f'(0) = g'(0) = 1 \), so the hypotheses of Version I are satisfied and
\[ \lim_{x \to 0} \frac{e^x - 1}{\sin x} = \frac{f'(0)}{g'(0)} = \frac{1}{1} = 1. \]

(Note that \( g(x) \neq 0 \) on \((-\pi, \pi) \setminus \{0\}\).)

**L’Hôpital’s Rule, Version 2**

There is another version (the commonly stated version) of l’Hôpital’s Rule which is more complicated to prove, but more widely applicable. There are several slight variations of this version, which will collectively be called Version 2 of l’Hôpital’s Rule.

**Theorem.** [L’Hôpital’s Rule, Version 2] Let \( f \) and \( g \) be differentiable functions on an interval \((a, b)\), with \( g' \) nonzero on \((a, b)\). Suppose

(1) \( \lim_{x \to a^+} f(x) = \lim_{x \to a^+} g(x) = 0 \).

(2) \( \lim_{x \to a^+} \frac{f'(x)}{g'(x)} \) exists in either the usual () or extended () sense.
Then \( \lim_{x \to a^+} \frac{f(x)}{g(x)} \) exists (in the same sense) and equals \( \lim_{x \to a^+} \frac{f'(x)}{g'(x)} \).

Note that it is not quite correct to say that if \( f \) and \( g \) are differentiable on \((a, b)\) with \( g' \) nonzero, and \( \lim_{x \to a^+} f(x) = \lim_{x \to a^+} g(x) = 0 \), then
\[
\lim_{x \to a^+} \frac{f(x)}{g(x)} = \lim_{x \to a^+} \frac{f'(x)}{g'(x)};
\]
it can happen that \( \lim_{x \to a^+} \frac{f(x)}{g(x)} \) exists but \( \lim_{x \to a^+} \frac{f'(x)}{g'(x)} \) does not exist (Exercise V.9.4.4), even if \( f \) and \( g \) are \( C^\infty \) and \( g(x) \) and \( g'(x) \) are nonzero for \( x > a \) (Exercise V.9.4.7.).

**Proof:** If necessary, extend \( f \) and \( g \) to be continuous on \([a, b]\) by setting \( f(a) = g(a) = 0 \). If \( x \in (a, b) \), since \( g \) is continuous on \([a, x]\) and differentiable on \((a, x)\), by the Mean Value Theorem () we have
\[
g(x) - g(a) = g'(d)(x - a)
\]
for some \( d \in (a, x) \); since \( g'(d) \neq 0 \), we have \( g(x) = g(x) - g(a) \neq 0 \). Thus \( \frac{f}{g} \) is defined on \((a, b)\).

Set \( L = \lim_{x \to a^+} \frac{f'(x)}{g'(x)} \in \mathbb{R} \cup \{\pm \infty\} \). By the Sequential Criterion (), it suffices to show that if \((x_n)\) is a sequence in \((a, b)\) converging to \( a \), we have \( \lim_{n \to \infty} \frac{f(x_n)}{g(x_n)} = L \). By the Cauchy Mean Value Theorem we have, for each \( n \),
\[
\frac{f(x_n)}{g(x_n)} = \frac{f(x_n) - f(a)}{g(x_n) - g(a)} = \frac{f'(c_n)}{g'(c_n)}
\]
for some \( c_n \in (a, x_n) \). Since \( a < c_n < x_n \) and \( x_n \to a \), we have \( c_n \to a \) by the Squeeze Theorem () and hence
\[
\frac{f(x_n)}{g(x_n)} = \frac{f'(c_n)}{g'(c_n)} \to L
\]
by the Sequential Criterion applied to \( \lim_{x \to a^+} \frac{f(x)}{g'(x)} = L \).

**V.9.2.4.** Actually, the hypothesis that \( g' \) is nonzero on \((a, b)\) is redundant: it is implicit in the existence of the limit \( \lim_{x \to a^+} \frac{f'(x)}{g'(x)} \) that \( \frac{f}{g} \) is defined, i.e. \( g' \neq 0 \), in an open interval \((a, r)\) for some \( r > a \). Thus the hypothesis can be eliminated at the possible price of reducing the \( b \) to a smaller number still strictly larger than \( a \). We have left the requirement in the statement of the theorem as a reminder that this hypothesis must be checked when the theorem is applied (cf. Exercise V.9.4.5..)

Note that the hypothesis that \( g' \neq 0 \) on \((a, b)\) implies that \( g' \) does not change sign on \((a, b)\) (V.8.2.14.).

An essentially identical argument shows:
V.9.2.5. Theorem. [L’Hôpital’s Rule, Version 2b] Let \( f \) and \( g \) be differentiable functions on an interval \((a, b)\), with \( g' \) nonzero on \((a, b)\). Suppose

1. \( \lim_{x \to b^-} f(x) = \lim_{x \to b^-} g(x) = 0 \).

2. \( \lim_{x \to b^-} \frac{f'(x)}{g'(x)} \) exists in either the usual or extended sense.

Then \( \lim_{x \to b^-} \frac{f(x)}{g(x)} \) exists (in the same sense) and equals \( \lim_{x \to b^-} \frac{f'(x)}{g'(x)} \).

Combining the two previous versions together, we get:

V.9.2.6. Theorem. [L’Hôpital’s Rule, Version 2c] Let \( f \) and \( g \) be differentiable functions on a deleted neighborhood \( U \) of \( a \in \mathbb{R} \), with \( g' \) nonzero on \( U \). Suppose

1. \( \lim_{x \to a} f(x) = \lim_{x \to a} g(x) = 0 \).

2. \( \lim_{x \to a} \frac{f'(x)}{g'(x)} \) exists in either the usual or extended sense.

Then \( \lim_{x \to a} \frac{f(x)}{g(x)} \) exists (in the same sense) and equals \( \lim_{x \to a} \frac{f'(x)}{g'(x)} \).

There is also a version for limits at \( \infty \):

V.9.2.7. Theorem. [L’Hôpital’s Rule, Version 2d] Let \( f \) and \( g \) be differentiable functions on an interval \((a, +\infty)\), with \( g' \) nonzero on \((a, +\infty)\). Suppose

1. \( \lim_{x \to +\infty} f(x) = \lim_{x \to +\infty} g(x) = 0 \).

2. \( \lim_{x \to +\infty} \frac{f'(x)}{g'(x)} \) exists in either the usual or extended sense.

Then \( \lim_{x \to +\infty} \frac{f(x)}{g(x)} \) exists (in the same sense) and equals \( \lim_{x \to +\infty} \frac{f'(x)}{g'(x)} \).

A similar statement holds for limits as \( x \to -\infty \) for functions differentiable on an interval \((-\infty, a)\).

Proof: We may assume \( a > 0 \). Set \( L = \lim_{x \to +\infty} \frac{f(x)}{g(x)} \). For \( t \in (0, \frac{1}{a}) \), set \( F(t) = f(1/t) \) and \( G(t) = g(1/t) \). Then \( F \) and \( G \) are differentiable on \((0, \frac{1}{a})\), \( G'(t) = -\frac{1}{t^2}g'(1/t) \neq 0 \), and \( G(t) \neq 0 \). We have

\[
\lim_{t \to 0^+} \frac{F'(t)}{G'(t)} = \lim_{t \to 0^+} \frac{-\frac{1}{t^2}f'(1/t)}{-\frac{1}{t^2}g'(1/t)} = \lim_{t \to 0^+} \frac{f'(1/t)}{g'(1/t)} = \lim_{x \to +\infty} \frac{f'(x)}{g'(x)} = L
\]
and so, by V.9.2.3.,
\[
\lim_{x \to +\infty} \frac{f(x)}{g(x)} = \lim_{t \to 0^+} \frac{F(t)}{G(t)} = L .
\]

L'Hôpital's Rule also applies to indeterminate forms of type \( \frac{\infty}{\infty} \). The statements are essentially the same, but the proof is a little more complicated. In fact, it is unnecessary to assume the limit of the numerator is \( \frac{\infty}{\infty} \) (if \( \lim f(x) \neq 0 \) and \( \lim g(x) = \pm \infty \), it follows automatically that \( \lim f(x) = \pm \infty \); this can also be proved directly from \( \lim f(x)g'(x) \neq 0 \) without applying l'Hôpital's rule, cf. V.9.4.8.).

V.9.2.8. **Theorem.** [L'Hôpital's Rule, Version 2a] Let \( f \) and \( g \) be differentiable functions on an interval \((a, b)\), with \( g' \) nonzero on \((a, b)\). Suppose

1. \( \lim_{x \to a^+} g(x) = \pm \infty \).
2. \( \lim_{x \to a^+} \frac{f'(x)}{g'(x)} \) exists in either the usual or extended sense.

Then \( \lim_{x \to a^+} \frac{f(x)}{g(x)} \) exists (in the same sense) and equals \( \lim_{x \to a^+} \frac{f'(x)}{g'(x)} \).

V.9.2.9. **Theorem.** [L'Hôpital's Rule, Version 2b'] Let \( f \) and \( g \) be differentiable functions on an interval \((a, b)\), with \( g' \) nonzero on \((a, b)\). Suppose

1. \( \lim_{x \to b^-} g(x) = \pm \infty \).
2. \( \lim_{x \to b^-} \frac{f'(x)}{g'(x)} \) exists in either the usual or extended sense.

Then \( \lim_{x \to b^-} \frac{f(x)}{g(x)} \) exists (in the same sense) and equals \( \lim_{x \to b^-} \frac{f'(x)}{g'(x)} \).

V.9.2.10. **Theorem.** [L'Hôpital's Rule, Version 2c'] Let \( f \) and \( g \) be differentiable functions on a deleted neighborhood \( U \) of \( a \in \mathbb{R} \), with \( g' \) nonzero on \( U \). Suppose

1. \( \lim_{x \to a} g(x) = \pm \infty \).
2. \( \lim_{x \to a} \frac{f'(x)}{g'(x)} \) exists in either the usual or extended sense.

Then \( \lim_{x \to a} \frac{f(x)}{g(x)} \) exists (in the same sense) and equals \( \lim_{x \to a} \frac{f'(x)}{g'(x)} \).
V.9.2.11. Theorem. [L'Hôpital's Rule, Version 2d'] Let \( f \) and \( g \) be differentiable functions on an interval \((a, +\infty)\), with \( g' \) nonzero on \((a, +\infty)\). Suppose

1. \( \lim_{x \to +\infty} g(x) = \pm \infty \).
2. \( \lim_{x \to +\infty} \frac{f'(x)}{g'(x)} \) exists in either the usual or extended sense.

Then \( \lim_{x \to +\infty} \frac{f(x)}{g(x)} \) exists (in the same sense) and equals \( \lim_{x \to +\infty} \frac{f'(x)}{g'(x)} \).

A similar statement holds for limits as \( x \to -\infty \) for functions differentiable on an interval \((-\infty, a)\).

Proof: We give the proof of Version 2d' for variety; proofs of the other versions are similar.

We first show that we may assume \( g \neq 0 \) on \((a, \infty)\). We could give an argument using the Mean Value Theorem (cf. Exercise()), but there is a simpler argument: since \( \lim_{x \to +\infty} g(x) = \pm \infty \), there is automatically an interval \((r, +\infty)\) on which \( |g| > 1 \), say. Thus by increasing \( a \) if necessary we may assume that \( g \neq 0 \) on \((a, \infty)\).

Let \( L = \lim_{x \to +\infty} \frac{f'(x)}{g'(x)} \). As before, it suffices to show that if \((x_n)\) is a sequence in \((a, +\infty)\) with \( x_n \to +\infty \), then \( \lim_{n \to \infty} \frac{f(x_n)}{g(x_n)} = L \). We will assume \( L \in \mathbb{R} \); the case \( L = \pm \infty \) is an easy variation. By Cauchy’s Mean Value Theorem, for each \( m \) and \( n \) for which \( x_m \neq x_n \) there is a \( d_{m,n} \) between \( x_m \) and \( x_n \) such that

\[
\frac{f(x_n) - f(x_m)}{g(x_n) - g(x_m)} = \frac{f'(d_{m,n})}{g'(d_{m,n})}.
\]

We then have

\[
\frac{f(x_n)}{g(x_n)} - L = \left[ \frac{f'(d_{m,n})}{g'(d_{m,n})} - L \right] \cdot \frac{g'(d_{m,n})}{g'(d_{m,n})} \frac{g(x_n)}{g'(d_{m,n})} + \frac{f'(d_{m,n})}{g'(d_{m,n})} \frac{g(x_m) - g(x_n)}{g'(d_{m,n})}.
\]

Fix \( \epsilon > 0 \) and let \( R \) such that

\[
\left| \frac{f'(x)}{g'(x)} - L \right| < \frac{\epsilon}{3}
\]

for \( x > R \), and fix \( m_0 \) such that \( x_n > R \) for all \( n \geq m_0 \). Thus, for \( n > m_0 \),

\[
\left| \frac{f'(d_{m_0,n})}{g'(d_{m_0,n})} - L \right| < \frac{\epsilon}{3}.
\]

Set \( M = |L| + \frac{\epsilon}{3} \). Since \( \lim_{x \to +\infty} |g(x)| = +\infty \), choose \( N > m_0 \) such that \( \left| \frac{f(x_{m_0})}{g(x_{m_0})} \right| < \frac{\epsilon}{3} \) and \( \left| \frac{g(x_{m_0})}{g(x_n)} \right| < \frac{\epsilon}{3M} \) for all \( n \geq N \). Then, for \( n \geq N \),

\[
\left| \frac{f(x_n)}{g(x_n)} - L \right| \leq \left| \frac{f'(d_{m_0,n})}{g'(d_{m_0,n})} - L \right| + \left| \frac{f'(d_{m_0,n})}{g'(d_{m_0,n})} \right| \left| \frac{g(x_{m_0})}{g'(d_{m_0,n})} \right| + \left| \frac{f(x_{m_0})}{g(x_{m_0})} \right| < \epsilon.
\]

\( \Box \)
V.9.2.12. In fact, if \( g' \) is never zero and 
\[
\lim_{x \to x_0} \frac{f'(x)}{g'(x)}
\]
exists, then \( \lim_{x \to x_0} \frac{f(x)}{g(x)} \) always exists, but does not necessarily equal \( \lim_{x \to x_0} \frac{f'(x)}{g'(x)} \) unless \( \lim_{x \to x_0} f(x) = \lim_{x \to x_0} g(x) = 0 \) or \( \lim_{x \to x_0} g(x) = \pm \infty \) (Exercise V.9.4.9.; statements apply to any kind of one-sided limits, but not two-sided).

V.9.2.13. Version 2 of l’Hôpital’s Rule (in its various forms) is commonly used even when Version 1 applies. There are also situations where Version 2 can be used although Version 1 does not apply. (The reverse can also happen: there are situations where Version 1 applies but Version 2 does not; cf. Exercise V.9.4.4.)

V.9.3. Applications

V.9.3.1. Examples. (i) As in V.9.1.2., we can apply Version 2c to obtain
\[
\lim_{x \to 0} \frac{e^x - 1}{\sin x} = \lim_{x \to 0} \frac{e^x}{\cos x} = 1 .
\]

(ii) An example of a limit where Version 1 does not apply but Version 2 does is:
\[
\lim_{x \to 0^+} \frac{\sin x}{\sqrt{x}}.
\]

Version 2a says that if
\[
\lim_{x \to 0^+} \frac{\cos x}{\frac{1}{2}x^{-1/2}} = \lim_{x \to 0^+} 2\sqrt{x} \cos x
\]
exists, the first limit also exists and has the same value. But the second limit is 0 by (); thus
\[
\lim_{x \to 0^+} \frac{\sin x}{\sqrt{x}} = 0 .
\]

This limit could have also been evaluated by
\[
\lim_{x \to 0^+} \frac{\sin x}{\sqrt{x}} = \lim_{x \to 0^+} \left[ \sqrt{x} \cdot \frac{\sin x}{x} \right] = 0 \cdot 1 = 0 .
\]

(iii) Besides applications of Versions 2d and 2a’–2d’, which have no Version 1 analogues, the most common situation where Version 2 is necessary (i.e. Version 1 does not apply) is illustrated by the following example. Let \( f(x) = 1 - \cos x, \ g(x) = x^2 \). Then
\[
\lim_{x \to 0} \frac{f(x)}{g(x)} = \lim_{x \to 0} \frac{1 - \cos x}{x^2}
\]
is an indeterminate form of type \( \frac{0}{0} \) to which we might try to apply l’Hôpital’s Rule. If
\[
\lim_{x \to 0} \frac{f'(x)}{g'(x)} = \lim_{x \to 0} \frac{\sin x}{2x}
\]
exists, then Version 2c implies that the first limit exists and has the same value. The second limit is also an indeterminate form of type $0/0$, so we may apply Version 2c again to convert it to

$$\lim_{x \to 0} \frac{f''(x)}{g''(x)} = \lim_{x \to 0} \frac{\cos x}{2}$$

i.e. if this limit exists, then the second limit and thus also the first limit exists and has the same value. But the last limit is not an indeterminate form, and equals $1/2$ by direct evaluation. We usually just abbreviate the whole argument as

$$\lim_{x \to 0} \frac{1 - \cos x}{x^2} = \lim_{x \to 0} \frac{\sin x}{2x} = \lim_{x \to 0} \frac{\cos x}{2} = \frac{1}{2}$$

where the first two steps are justified by “l’Hôpital’s Rule” (specifically, Version 2c); logically, we technically do the second application first and use the result to justify the first application. We could also justify the first step by Version 2c and calculate the second limit directly by Version 1.

(iv) In applying l’Hôpital’s Rule, it must be checked that the hypotheses apply. This pitfall is particularly important to watch for when the Rule is used repeatedly as in (iii). For example, one might argue

$$\lim_{x \to 0} \frac{x^2}{x^2 + \sin x} = \lim_{x \to 0} \frac{2x}{2x + \cos x} = \lim_{x \to 0} \frac{2}{2 - \sin x} = \frac{2}{2} = 1.$$

However, the second limit is not an indeterminate form and the second application of l’Hôpital’s Rule is not justified. The second limit can be evaluated directly to be 0, and thus the first limit is also 0. See Exercise V.9.4.7. for a more subtle example where the hypotheses of l’Hôpital’s Rule are not satisfied.

Sometimes some cleverness is required to successfully use l’Hôpital’s Rule:

**V.9.3.2.** **Example.** Consider

$$\lim_{x \to 0^+} \frac{e^{-1/x}}{x}.$$

The hypotheses of Version 2a are satisfied with $f(x) = e^{-1/x}$ and $g(x) = x$. Thus the limit can be converted to

$$\lim_{x \to 0^+} \frac{e^{-1/x}}{x} = \lim_{x \to 0^+} \frac{e^{-1/x}}{x^2}.$$

But this limit is worse than the one we started with, and repeating l’Hôpital’s Rule will make things successively even worse.

Instead, we can rewrite the limit as

$$\lim_{x \to 0^+} \frac{1/x}{e^{1/x}}$$

and note that Version 2a’ applies to give

$$\lim_{x \to 0^+} \frac{1/x}{e^{1/x}} = \lim_{x \to 0^+} \frac{-1/x^2}{e^{-1/x} x} = \lim_{x \to 0^+} \frac{e^{-1/x}}{x} = 0.$$
We could also make the substitution $u = 1/x$ and use Version 2d' to give

$$
\lim_{x \to 0^+} \frac{1}{e^{1/x}} = \lim_{u \to +\infty} \frac{u}{e^u} = \lim_{u \to +\infty} \frac{1}{e^u} = 0.
$$

Indeterminate forms of other types can often be converted into a form to which l’Hôpital’s rule can be applied, by algebraic manipulation or taking logarithms or exponentials:

V.9.3.3. Examples. (i) $\lim_{x \to +\infty} xe^{-x}$ is an indeterminate form of type $\infty \cdot 0$. It can be converted to $\lim_{x \to +\infty} x$ and evaluated by Version 2d’. Another similar example is in Exercise (d).

(ii) $\lim_{x \to 0^+} \left[ \frac{1}{\sin x} - \frac{1}{x} \right]$ is an indeterminate form of type $\infty - \infty$. It can be converted into a fraction and evaluated by

$$
\lim_{x \to 0^+} \frac{1 - \cos x}{\sin x + x \cos x} = \lim_{x \to 0^+} \frac{\sin x}{2 \cos x - x \sin x} = 0
$$

by two applications of l’Hôpital’s Rule. (For the first application, it must be verified that $h(x) = \sin x + x \cos x$ is nonzero in a deleted neighborhood of 0; this follows from the fact that $h'(0) \neq 0$.)

(iii) $\lim_{x \to 0^+} x^x$ is an indeterminate form of type $0^0$. By taking logarithms we can reduce the problem to computing $\lim_{x \to 0^+} x \log x$, which is 0 (Exercise (d)). Thus

$$
\lim_{x \to 0^+} x^x = \lim_{x \to 0^+} e^{x \log x} = e^0 = 1
$$

by continuity of the exponential function at 0.

(iv) $\lim_{x \to +\infty} \left(1 + \frac{1}{x}\right)^x$ is of the form $1^\infty$. Taking logarithms, we reduce to evaluating $\lim_{x \to +\infty} x \log \left(1 + \frac{1}{x}\right)$. This is of type $\infty \cdot 0$, so we can convert it to

$$
\lim_{x \to +\infty} \frac{\log(1 + 1/x)}{1/x} = \lim_{x \to +\infty} \frac{1 + \frac{1}{x}(-1/x^2)}{1 - 1/x^2} = \lim_{x \to +\infty} \frac{1}{1 + 1/x} = 1
$$

so

$$
\lim_{x \to +\infty} \left(1 + \frac{1}{x}\right)^x = e^1 = e
$$

again by continuity of the exponential function. (This example is somewhat artificial, since direct evaluation of this limit was used in defining $e$ and the exponential function.)
V.9.4. Exercises

V.9.4.1. Express and justify Version 1 of l’Hôpital’s Rule using little-o notation (V.7.) by writing $f(x) = f'(a)(x-a) + o(x-a)$ and $g(x) = g'(a)(x-a) + o(x-a)$.

V.9.4.2. Show that Version 1 and Version 2c of l’Hôpital’s Rule are equivalent in the (common) case where $f$ and $g$ are differentiable in a neighborhood of $a$, $f'$ and $g'$ are continuous at $a$, $f(a) = g(a) = 0$, and $g'(a) \neq 0$.

V.9.4.3. Let $f(x) = x^2$ for $x \in \mathbb{Q}$ and $f(x) = 0$ for $x \not\in \mathbb{Q}$, and let $g(x) = x$ for all $x$. Then Version 1 of l’Hôpital’s Rule applies for $a = 0$. But $f$ is not differentiable, or even continuous, except at 0, so no variant of Version 2 applies.

V.9.4.4. Let $f(x) = x^2 \sin \frac{1}{x}$ for $x \neq 0$, and $f(0) = 0$; and let $g(x) = \sin x$. Then $f$ and $g$ are differentiable everywhere, and $f'(0) = 0$, $g'(0) = 1$.

(a) Version 1 of l’Hôpital’s Rule applies to show that
\[
\lim_{x \to 0} \frac{f(x)}{g(x)} = \lim_{x \to 0} \frac{x^2 \sin \frac{1}{x}}{\sin x} = 0.
\]

(b) $\lim_{x \to 0} f'(x) = \lim_{x \to 0} \left[2x \sin \frac{1}{x} - \frac{2}{x^2 \sin \frac{1}{x}} \right]$ and $\lim_{x \to 0} \frac{f'(x)}{g(x)}$ do not exist. In particular, Version 2 of l’Hôpital’s rule does not apply.

(c) The existence of $\lim_{x \to a} \frac{f(x)}{g(x)}$ does not imply the existence of $\lim_{x \to a} \frac{f'(x)}{g'(x)}$ even for everywhere differentiable $f$ and $g$ with $g' \neq 0$ in a neighborhood of $a$. Thus Version 2 is not more general than Version 1 even for functions which are everywhere differentiable.

(d) There are simpler examples for limits at $\infty$: for example, let $f(x) = x + \sin x$, $g(x) = x$. Then $\lim_{x \to \infty} f(x) = \lim_{x \to \infty} g(x) = +\infty$ and $\lim_{x \to \infty} \frac{f(x)}{g(x)}$ exists and equals 1, but $\lim_{x \to \infty} \frac{f'(x)}{g'(x)}$ does not exist.

V.9.4.5. ([?]; cf. [?]) What is wrong with the following argument?

(a) Let $f(x) = x + \sin x \cos x$. Show that $f'(x) = 2 \cos^2 x$.

(b) Let $g(x) = e^{\sin^2 x} f(x)$. Show that $\lim_{x \to \infty} f(x) = \lim_{x \to \infty} g(x) = +\infty$.

(c) We have
\[
\lim_{x \to \infty} \frac{f'(x)}{g'(x)} = \lim_{x \to \infty} \frac{2 \cos^2 x}{e^{\sin x} [f(x) \cos x + 2 \cos^2 x]} = \lim_{x \to \infty} \frac{2 \cos x}{e^{\sin x} [f(x) + 2 \cos x]} = 0
\]
since the numerator is bounded and the denominator approaches $+\infty$. Thus, by l’Hôpital’s Rule, Version 2d',
\[
\lim_{x \to \infty} \frac{f(x)}{g(x)} = \lim_{x \to \infty} e^{-\sin x} = 0.
\]

But $e^{-1} \leq e^{-\sin x} \leq e$ for all $x$, and $\lim_{x \to \infty} e^{-\sin x}$ does not exist.
V.9.4.6.  
(a) Using l'Hôpital's Rule, prove that, for every $a > 0$ and $r \in \mathbb{R}$,
\[
\lim_{x \to +\infty} e^{ax} x^r = +\infty.
\]
[Prove this by induction for $r \in \mathbb{N}$, and use the Squeeze Theorem for other $r$.]
(b) Using l'Hôpital's Rule, prove that for all $r > 0$,
\[
\lim_{x \to +\infty} \frac{\log x}{x^r} = 0.
\]
(c) Use (b) to give a proof of (a) not requiring induction.
(d) Using l'Hôpital's Rule, show that for all $r > 0$,
\[
\lim_{x \to 0+} x^r \log x = \lim_{x \to 0+} \frac{\log x}{x^{-r}} = 0.
\]
For a proof of (a) not using l'Hôpital's Rule, note that, for every $x$,
\[
e^{ax} = \sum_{k=0}^{\infty} \frac{a^k x^k}{k!}
\]
and all terms are positive if $a > 0$ and $x > 0$, and hence for any $n$ and $m$ we have
\[
e^{ax} > \frac{a^{n+m} x^{n+m}}{(n+m)!}
\]
\[
e^{ax} x^n > \frac{a^{n+m}}{(n+m)!} x^m.
\]

V.9.4.7.  
[?] Let $f(x) = x \sin \left(\frac{1}{x^2}\right) e^{-1/x^2}$ and $g(x) = e^{-1/x^2}$ for $x \neq 0$ and $f(0) = g(0) = 0$.
(a) Show that $f$ and $g$ are $C^\infty$ on $\mathbb{R}$, and that $g(x)$ and $g'(x)$ are nonzero for $x \neq 0$.
(b) Show that $\lim_{x \to 0} \frac{f(x)}{g(x)} = 0$.
(c) Show that $\frac{f'(x)}{g'(x)}$ is unbounded in every neighborhood of 0, and that $\lim_{x \to 0} \frac{f'(x)}{g'(x)}$ does not exist.

V.9.4.8.  
Suppose $f$ and $g$ satisfy the hypotheses Version 2d' of l'Hôpital's Rule. Recall (V.8.2.14.) that $g'$ does not change sign on $(a, +\infty)$.
(a) Suppose $g' > 0$ on $(a, \infty)$. If $\lim_{x \to +\infty} g(x) = +\infty$ (it cannot be $-\infty$!), and $\lim_{x \to +\infty} \frac{f'(x)}{g'(x)}$ exists and equals $L$, $0 < L \leq +\infty$, then there is an $M > 0$ such that $f'(x) > Mg'(x)$ for sufficiently large $x$. Show that this implies $\lim_{x \to +\infty} f(x) = +\infty$ [$f - Mg$ is eventually increasing]. Modify the argument for the case $g' < 0$ on $(a, \infty)$ and/or $-\infty \leq L < 0$.
(b) Modify the argument to apply to Version 2a', and similarly for Version 2b' and 2c'.

619
V.9.4.9.  (a) Suppose $f$ and $g$ are differentiable on $(a, +\infty)$ and $g'$ is never zero, and that $\lim_{x \to +\infty} \frac{f'(x)}{g'(x)}$ exists and is finite. If $\lim_{x \to +\infty} g(x) = \pm \infty$ is false, show that $\lim_{x \to +\infty} g(x)$ and $\lim_{x \to +\infty} f(x)$ exist and are finite, and $\lim_{x \to +\infty} \frac{f(x)}{g(x)}$ exists (possibly in the extended sense). [Note that $g$ must be strictly monotone. For some $M$, $M|g| \pm f$ are eventually increasing.] If $\lim_{x \to +\infty} g(x) \neq 0$, the condition that $\lim_{x \to +\infty} \frac{f'(x)}{g'(x)}$ exists can be relaxed to just a requirement that $\frac{f(x)}{g(x)}$ be bounded.

(b) Show that $\lim_{x \to +\infty} \frac{f(x)}{g(x)}$ is not necessarily the same as $\lim_{x \to +\infty} \frac{f'(x)}{g'(x)}$ (which need not even exist if $\lim_{x \to +\infty} g(x) \neq 0$), by considering
\[ \lim_{x \to +\infty} \frac{1}{\frac{1}{x} - \frac{1}{2}} \quad \text{or} \quad \lim_{x \to +\infty} \frac{1 - \frac{1}{x^2}}{1 - \frac{1}{x}} \quad \text{or} \quad \lim_{x \to +\infty} \frac{1 - \sin \frac{x}{x}}{1 - \frac{1}{x}} \]
or by noting that constants can be added to $f$ and/or $g$ without affecting the hypotheses. In particular, the assumption $\lim_{x \to +\infty} g(x) = \pm \infty$ cannot be eliminated from Version 2d'.

(c) Suppose $f$ and $g$ are differentiable on $(a, +\infty)$ and $g'$ is never zero, and that $\lim_{x \to +\infty} \frac{f'(x)}{g'(x)} = \pm \infty$. If $\lim_{x \to +\infty} g(x) = \pm \infty$ is false, show that $\lim_{x \to +\infty} g(x)$ and $\lim_{x \to +\infty} f(x)$ exist, $\lim_{x \to +\infty} g(x)$ is finite, and $\lim_{x \to +\infty} \frac{f(x)}{g(x)}$ exists (possibly, but not necessarily, in the extended sense).

(d) Obtain versions for $\lim_{x \to -\infty}$ and, for an interval $(a, b)$, for $\lim_{x \to a^+}$ and $\lim_{x \to b^-}$. (There is no good two-sided version.)

V.9.4.10.  Show that hypothesis (1) in Version 2c' can be relaxed to

$$ (1') \lim_{x \to a} |g(x)| = +\infty . $$

(The same change can be made in Versions 2a', 2b', and 2d', but this is not an actual change in these cases by V.8.2.14.)

V.9.4.11.  Let $I$ be an open interval, $c \in I$, and let $f$ be continuous on $I$ and differentiable on $I \setminus \{c\}$. If $\lim_{x \to c} f'(x)$ exists and equals $L \in \mathbb{R}$, show that $f$ is necessarily differentiable at $c$ and that $f'(c) = L$. [Apply l'Hôpital's Rule Version 2c to $\lim_{x \to c} \frac{f(x) - f(c)}{x - c}$.] Give a similar statement for one-sided limits.

Compare with V.8.2.15. and V.12.2.5.

V.9.4.12.  Let $x_0 \in \mathbb{R}$, and $\sum_{k=0}^{\infty} a_k (x - x_0)^k$ and $\sum_{k=0}^{\infty} b_k (x - x_0)^k$ be power series () centered at $x_0$ with positive radius of convergence, defining analytic functions $f$ and $g$ in an open interval around $x_0$. Let $a_m$ be the first nonzero coefficient in the first series, i.e. $a_m \neq 0$ and $a_k = 0$ for $k < m$. Similarly, let $b_n$ be the first nonzero coefficient in the second series.
(a) Use V.15.3.26. and l’Hôpital’s Rule to show that if \( m \geq n \), then
\[
\lim_{x \to x_0} \frac{f(x)}{g(x)} = \frac{a_n}{b_n}
\]
and in particular, the limit always exists (in the usual sense), and is zero if \( m > n \) and nonzero if \( m = n \).

(b) Obtain the same result from basic limit and power series theorems by first dividing \( f \) and \( g \) by a suitable power of \( x - x_0 \), and show additionally that
\[
\lim_{x \to x_0} \frac{f(x)}{g(x)}
\]
does not exist (in the usual sense) if \( m < n \).

(c) Also conclude the result from (), although this argument is less elementary (but shows more).

V.9.4.13. [?, 11.10] Find
\[
\lim_{x \to 0} \frac{\sin(\tan(x)) - \tan(\sin(x))}{\arcsin(\arctan(x)) - \arctan(\arcsin(x))}
\]
[To apply l’Hôpital’s Rule, or Exercise V.9.4.12., try expanding numerator and denominator in Maclaurin series; a computer algebra system can be very helpful.] Does graphing the function near 0 with a computer algebra system help in guessing the answer?

V.9.4.14. [?, 4.4] Let
\[
h(x) = \frac{x}{\sqrt{x^2 + 1}}
\]
and note that \( h(x) > 0 \) for \( x > 0 \). Applying (), (), and l’Hôpital’s Rule Version 2d’ to \( \lim_{x \to +\infty} h(x) \), the only conclusion that can be drawn is that either the limit is 1 or it does not exist. Use another method to determine which is the case.

V.9.4.15. Let \( f \) be a function defined on an open interval around \( a \).

(a) Suppose \( f''(a) \) exists. Show that
\[
\lim_{h \to 0} \frac{f(a + h) - 2f(a) + f(a - h)}{h^2}
\]
exists and equals \( f''(a) \).

(b) Show that the limit in (a) can exist even if \( f''(a) \) does not exist, and even if \( f \) is not continuous at \( a \).
[Consider an odd function with \( a = 0 \).]
V.10. Taylor’s Theorem

Taylor’s Theorem is one of the most important and useful results in calculus. It can be thought of as a higher-order version of differential approximation or of the Mean Value Theorem, and is crucial in representing functions by power series, which will be discussed later. There are many other applications of both theoretical and practical importance.

The statement and a “proof” of Taylor’s Theorem were first published by Brook Taylor in 1715, although the result was previously known to several mathematicians, and apparently first obtained by Gregory about 1670. Taylor’s “proof” fell far short of modern standards of precision and rigor. For an account of the history of the result, see[].

V.10.1. Taylor Polynomials

V.10.1.1. Suppose $f$ is a function which is differentiable to some high order near a number $x_0$. We would like to approximate $f$ near $x_0$ as closely as possible by a polynomial of fixed degree. It makes intuitive sense that the approximating polynomial should duplicate the values of $f$ and its derivatives at $x_0$ as closely as possible, since these values should determine the location and shape of the graph of $f$ near $x_0$. There is a limit to how far this can be done, since if $p$ is a polynomial of degree $n$, then $p^{(k)}$ is identically 0 for $k > n$; so we can only hope to make the derivatives of a degree $n$ polynomial up through the $n$th derivative agree with those of $f$. In differential approximation, which is the case $n = 1$, we have seen that there is a unique polynomial $p_1$ of degree $\leq 1$ (i.e. linear or affine function) with $p_1(x_0) = f(x_0)$ and $p_1'(x_0) = f'(x_0)$, namely $p_1(x) = f(x_0) + f'(x_0)(x - x_0)$, and $p_1$ is indeed the polynomial of degree $\leq 1$ most closely approximating $f$ near $x_0$, in the sense that

$$\lim_{x \to x_0} \frac{f(x) - p_1(x)}{x - x_0} = 0$$

and $p_1$ is the only linear function with this property.

The higher-order case gets its justification from the following result:

V.10.1.2. THEOREM. Let $g$ be a real-valued function on an interval $I$, and $x_0$ an interior point of $I$, and $n \geq 1$. Suppose $g$ is $n$-times differentiable at $x_0$ (this implies that for all $k < n$, $g^{(k)}$ is defined in a neighborhood of $x_0$ and is continuous at $x_0$, and, for $1 \leq r \leq n - 1$, $g^{(n-r-1)}$ is $r$-times differentiable in a neighborhood of $x_0$). Then

$$\lim_{x \to x_0} \frac{g(x)}{(x - x_0)^n}$$

exists if and only if $g^{(k)}(x_0) = 0$ for $0 \leq k < n$. If the limit exists, it equals $\frac{g^{(n)}(x_0)}{n!}$.

V.10.1.3. COROLLARY. Let $g$ be a real-valued function on an interval $I$, and $x_0$ an interior point of $I$, and $n \geq 1$. Suppose $g$ is $n$-times differentiable at $x_0$ (this implies that for all $k < n$, $g^{(k)}$ is defined in a neighborhood of $x_0$ and is continuous at $x_0$, and, for $1 \leq r \leq n - 1$, $g^{(n-r-1)}$ is $r$-times differentiable in a neighborhood of $x_0$). Then

$$\lim_{x \to x_0} \frac{g(x)}{(x - x_0)^n} = 0$$

if and only if $g(x_0) = g'(x_0) = \cdots = g^{(n)}(x_0) = 0$. 

622
Proof: By (complete) induction on \( n \). First suppose \( n = 1 \). By assumption, \( g \) is differentiable at \( x_0 \) and hence continuous at \( x_0 \). If

\[
\lim_{x \to x_0} \frac{g(x)}{x - x_0}
\]

exists, then \( \lim_{x \to x_0} g(x) \) must be 0 since \( \lim_{x \to x_0} (x - x_0) = 0 \). Thus \( g(x_0) = 0 \). And if \( g(x_0) = 0 \), then

\[
\lim_{x \to x_0} \frac{g(x)}{x - x_0} = \lim_{x \to x_0} \frac{g(x) - g(x_0)}{x - x_0}
\]

exists and equals \( g'(x_0) \) by definition.

Now let \( n > 1 \). Assume the result for all \( k \), \( 1 \leq k < n \), and suppose \( g \) is \( n \)-times differentiable at \( x_0 \). Suppose

\[
\lim_{x \to x_0} \frac{g(x)}{(x - x_0)^n}
\]

exists and equals \( L \). Then, if \( 0 \leq k < n \), we have

\[
\lim_{x \to x_0} \frac{g(x)}{(x - x_0)^n} = \left[ \lim_{x \to x_0} \frac{g(x)}{(x - x_0)^{n-k}} \right] \left[ \lim_{x \to x_0} (x - x_0)^{n-k} \right] = L \cdot 0 = 0
\]

and thus by the inductive hypothesis \( g^{(k)}(x_0) = 0 \) (if \( k = 0 \), we obtain \( g(x_0) = 0 \) by continuity of \( g \) at \( x_0 \)). Conversely, if \( g(x_0) = g'(x_0) = \cdots = g^{(n-1)}(x_0) = 0 \), we apply l'Hôpital’s rule Version 2c (V.9.2.6.): if

\[
\lim_{x \to x_0} \frac{g(x)}{n(x - x_0)^{n-1}}
\]

exists and equals \( L \), then

\[
\lim_{x \to x_0} \frac{g(x)}{(x - x_0)^n}
\]

also exists and equals \( L \). But the inductive hypothesis applies to \( g' \) since it is \( (n-1) \)-times differentiable at \( x_0 \) and \( g'(x_0) = (g')'(x_0) = \cdots = (g')^{(n-2)}(x_0) = 0 \), so the first limit exists and

\[
L = \frac{1}{n} \frac{(g')^{(n-1)}(x_0)}{(n-1)!} = \frac{g^{(n)}(x_0)}{n!}.
\]

\( \blacksquare \)

V.10.1.4. In particular, if \( p \) is a polynomial of degree \( \leq n \) and \( f \) is \( n \)-times differentiable at \( x_0 \), then

\[
\lim_{x \to x_0} \frac{f(x) - p(x)}{(x - x_0)^n} = 0
\]

if and only if \( p^{(k)}(x_0) = f^{(k)}(x_0) \) for \( 0 \leq k \leq n \). Such a polynomial (if it exists) is unique, and is the “best \( n \)’th order polynomial approximation” to \( f \) near \( x_0 \).

So the problem is to construct a polynomial of degree \( \leq n \) with specified derivatives at \( x_0 \). This is easily done:
V.10.1.5. Proposition. Let \( p(x) = a_0 + a_1 x + \cdots + a_n x^n \) be a polynomial of degree \( n \). Then, for \( 0 \leq k \leq n, f^{(k)}(0) = k! a_k \).

The proof is a simple calculation. If derivatives at \( x_0 \) instead of 0 are desired, a simple trick does the shift: if
\[
q(x) = p(x - x_0) = a_0 + a_1 (x - x_0) + \cdots + a_n (x - x_0)^n,
\]
then \( q \) is also a polynomial of degree \( \leq n \) and \( q^{(k)}(x_0) = k! a_k \).

V.10.1.6. Thus, if \( f \) is \( n \)-times differentiable at \( x_0 \) and we want a polynomial \( p_n \) of degree \( \leq n \) whose derivatives at \( x_0 \) up to the \( n \)’th are the same as those of \( f \), we may (and must) take
\[
p_n(x) = f(x_0) + f'(x_0)(x - x_0) + \frac{f''(x_0)}{2!} (x - x_0)^2 + \cdots + \frac{f^{(n)}(x_0)}{n!} (x - x_0)^n
\]
This is the \( n \)’th Taylor Polynomial of \( f \) at \( x_0 \) (it will have degree strictly less than \( n \) if \( f^{(n)}(x_0) = 0 \)).

Although our notation does not reflect it, note that \( p_n \) depends not only on \( n \) (and, of course, \( f \)), but also on the choice of \( x_0 \), i.e. the function \( f \) will generally have different \( n \)’th order Taylor polynomials at different points (just as the best linear or affine approximation to \( f \) generally varies from point to point.)

We summarize our work in the next theorem (see V.10.1.2. for the last statement):

V.10.1.7. Theorem. [Taylor’s Theorem] Let \( f \) be defined in a neighborhood of \( x_0 \), and \( n \in \mathbb{N} \). Suppose \( f^{(n)}(x_0) \) exists (this implies that for all \( k < n \), \( f^{(k)} \) is defined in a neighborhood of \( x_0 \) and is continuous at \( x_0 \), and, for \( 1 \leq r \leq n - 1 \), \( f^{(n-r)} \) is \( r \)-times differentiable in a neighborhood of \( x_0 \)). Then the \( n \)’th Taylor polynomial \( p_n \) of \( f \) at \( x_0 \) satisfies
\[
\lim_{x \to x_0} \frac{f(x) - p_n(x)}{(x - x_0)^n} = 0
\]
and \( p_n \) is the unique polynomial of degree \( \leq n \) with this property. If \( f \) is \( (n + 1) \)-times differentiable at \( x_0 \), then
\[
\lim_{x \to x_0} \frac{f(x) - p_n(x)}{(x - x_0)^{n+1}} = \frac{f^{(n+1)}(x_0)}{(n + 1)!}.
\]

Note that if \( n = 1 \), we obtain the differential approximation polynomial \( p_1 \). Thus the Taylor polynomials can be regarded as giving “higher-order differential approximation.”

V.10.1.8. The Taylor polynomials thus give good approximations to \( f \) sufficiently near \( x_0 \); rephrasing the limit characterization, for any \( \epsilon > 0 \) and \( n \in \mathbb{N} \) there is a \( \delta > 0 \) such that
\[
|f(x) - p_n(x)| \leq \epsilon |x - x_0|^n \quad \text{whenever} \quad |x - x_0| < \delta
\]
and thus, for \( x \) close enough to \( x_0 \), the difference between \( f(x) \) and \( p_n(x) \) is small even compared to the very small number \( |x - x_0|^n \).

In general, the \( \delta \) depends on \( x_0 \) and \( n \), as well as on \( f \) and \( \epsilon \). As a result, for a fixed \( x \) near \( x_0 \) but different from \( x_0 \), we should not necessarily expect \( p_n(x) \) to be a good approximation to \( f(x) \) for any particular \( n \), or
even that \( p_n(x) \) becomes a better and better approximation to \( f(x) \) as \( n \) increases, although fortunately this often happens. In fact, to paraphrase [Act90], the Taylor polynomials give a very, very good approximation close enough to \( x_0 \), then get increasingly worse as we move away, and finally (often) explode into complete unusability. These points will be discussed more carefully later.

### V.10.2. Vanishing Order

#### V.10.2.1. Definition. Let \( f \) be a function defined in a deleted neighborhood of \( x_0 \), and let \( \alpha \in [0, \infty) \). Then \( f \) **vanishes to order** \( \alpha \) at \( x_0 \) if

\[
|f(x)| = O(|x - x_0|^{\alpha}) \quad \text{as} \quad x \to x_0,
\]

i.e. there are positive \( K \) and \( \delta \) such that

\[
|f(x)| \leq K|x - x_0|^{\alpha} \quad \text{for} \quad 0 < |x - x_0| < \delta.
\]

We say \( f \) **vanishes to order** \( \alpha^+ \) at \( x_0 \) if

\[
f(x) = o(|x - x_0|^{\alpha}) \quad \text{as} \quad x \to x_0.
\]

If \( f \) vanishes to order \( \alpha^+ \) at \( x_0 \), then it vanishes to order \( \alpha \). If it vanishes to order \( \beta \) for some \( \beta > \alpha \) at \( x_0 \), then it vanishes to order \( \alpha^+ \). A function vanishes to order \( 0^+ \) at \( x_0 \) if and only if it can be extended to be continuous at \( x_0 \) by setting \( f(x_0) = 0 \).

#### V.10.2.2. Examples. (i) The function \( f(x) = |x - x_0|^{\alpha} \) vanishes at \( x_0 \) to order \( \alpha \) but not to order \( \alpha^+ \).

(ii) The function \( f(x) = \frac{|x-x_0|^{\alpha}}{\log|x-x_0|} \) vanishes at \( x_0 \) to order \( \alpha^+ \), but not to order \( \beta \) for any \( \beta > \alpha \).

Taylor’s Theorem can be rephrased (the last statement becomes slightly weaker):

#### V.10.2.3. Theorem. [Taylor’s Theorem] Let \( f \) be \( n \)-times differentiable at \( x_0 \), and let \( p_n \) be the \( n \)’th order Taylor polynomial of \( f \) at \( x_0 \). Then \( f - p_n \) vanishes to order \( n^+ \) at \( x_0 \), and \( p_n \) is the unique polynomial of degree \( \leq n \) with this property. If \( f \) is \((n+1)\)-times differentiable at \( x_0 \), then \( f - p_n \) vanishes to order \( n+1 \) at \( x_0 \).

### V.10.3. Remainder Formulas

#### V.10.3.1. It is convenient to think of the situation in terms of the **remainder function** \( r_n = f - p_n \). Thus

\[
r_n(x) = f(x) - p_n(x) = f(x) - f(x_0) - f'(x_0)(x-x_0) - \cdots - \frac{f^{(n)}(x_0)}{n!}(x-x_0)^n
\]

(like \( p_n \), the function \( r_n \) depends on \( x_0 \) as well as on \( f \) and \( n \)). The approximation in Taylor’s Theorem can be summarized by

\[
r_n(x) = o(|x - x_0|^{\alpha}) \quad \text{as} \quad x \to x_0.
\]

However, for practical applications of Taylor’s approximation, as well as for many theoretical applications, it is important to have specific estimates for the size of \( r_n(x) \). For example, one might expect that for fixed \( x \) near \( x_0 \), \( r_n(x) \to 0 \) as \( n \to \infty \), i.e. that the Taylor polynomials for \( f \) around \( x_0 \) converge to \( f \) pointwise near
for some times differentiable on an interval formula due to Lagrange Remainder Formula can be regarded as a higher-order generalization of the Mean Value Theorem.

There are many formulas known for \( r_n(x) \). The first and still most widely used was found by Joseph Lagrange about 100 years after Taylor’s work (published 1813). Lagrange’s formula and another useful formula due to Cauchy can be derived by the same procedure using the Mean Value Theorem.

Good formulas for the remainder function can only be obtained when \( f \) is \((n+1)\)-times differentiable in a neighborhood of \( x_0 \). Let us assume this, and fix \( x \) in such a neighborhood. For specificity we will assume that \( x > x_0 \), but an essentially identical argument yields the same formulas in the case \( x < x_0 \).

**V.10.3.2.** The key trick is to keep \( x \) fixed in the formula for \( r_n \), and replace \( x_0 \) (which we also regard as fixed) by a variable \( t \). Set

\[
\phi(t) = f(x) - f(t) - f'(t)(x-t) - \cdots - \frac{f^{(n)}(t)}{n!} (x-t)^n - r_n(x) \left( \frac{x-t}{x-x_0} \right)^{n+1}
\]

for \( x_0 \leq t \leq x \). Then \( \phi \) is differentiable on \([x_0,x]\), \( \phi(x_0) = \phi(x) = 0 \), and

\[
\phi'(t) = -f'(t) - [f''(t)(x-t) - f''(t)] - \cdots - \left[ \frac{f^{(n+1)}(t)}{n!} (x-t)^n - \frac{f^{(n)}(t)}{(n-1)!} (x-t)^{n-1} \right] + \frac{r_n(x)}{(x-x_0)^{n+1}} (n+1)(x-t)^{n+1}
\]

\[
= -\frac{f^{(n+1)}(t)}{n!} (x-t)^n + \frac{r_n(x)}{(x-x_0)^{n+1}} (n+1)(x-t)^n.
\]

By Rolle’s Theorem, there is a \( c \in (x_0,x) \) with \( \phi'(c) = 0 \). We then have

\[
r_n(x) = \frac{(x-x_0)^{n+1}}{(n+1)(x-c)^n} \frac{f^{(n+1)}(c)}{n!} (x-c)^n = \frac{f^{(n+1)}(c)}{(n+1)!} (x-x_0)^{n+1}.
\]

So we obtain:

**V.10.3.3.** Theorem. [Taylor’s Theorem With Remainder, Lagrange’s Form] Let \( f \) be \((n+1)\)-times differentiable on an interval \( I \), \( x_0 \in I \), \( p_n \) the \( n \)th Taylor polynomial for \( f \) at \( x_0 \), and \( x \in I \). Then, for some \( c \) between \( x_0 \) and \( x \),

\[
r_n(x) = f(x) - p_n(x) = \frac{f^{(n+1)}(c)}{(n+1)!} (x-x_0)^{n+1}
\]

or, equivalently,

\[
f(x) = f(x_0) + f'(x_0)(x-x_0) + \cdots + \frac{f^{(n)}(x_0)}{n!} (x-x_0)^n + \frac{f^{(n+1)}(c)}{(n+1)!} (x-x_0)^{n+1}.
\]

**V.10.3.4.** The case \( n = 0 \) is just the usual Mean Value Theorem. Thus Taylor’s Theorem with the Lagrange Remainder Formula can be regarded as a higher-order generalization of the Mean Value Theorem.
V.10.3.5. We can obtain another formula for the remainder by a more straightforward variation of the argument: set

$$\psi(t) = f(x) - f(t) - f'(t)(x-t) - \cdots - \frac{f^{(n)}(t)}{n!}(x-t)^n$$

for $x_0 \leq t \leq x$. Then $\psi$ is differentiable on $[x_0, x]$, $\psi(x_0) = r_n(x)$, $\psi(x) = 0$, and

$$\psi'(t) = -f'(t) - [f''(t)(x-t) - f'(t)] - \cdots - \left[ \frac{f^{(n+1)}(t)}{n!} (x-t)^n - \frac{f^{(n)}(t)}{(n-1)!} (x-t)^{n-1} \right]$$

$$= -\frac{f^{(n+1)}(t)}{n!} (x-t)^n.$$

We apply the Mean Value Theorem to $\psi$ to obtain a formula for $r_n(x)$:

V.10.3.6. **Theorem.** Let $f$ be $(n+1)$-times differentiable on an interval $I$, $x_0 \in I$, $p_n$ the $n$’th Taylor polynomial for $f$ at $x_0$, and $x \in I$. Then, for some $c$ between $x_0$ and $x$,

$$r_n(x) = f(x) - p_n(x) = \phi(x_0) - \phi(x) = \phi'(c)(x_0 - x) = \frac{f^{(n+1)}(c)}{n!} (x-c)^n (x-x_0).$$

This formula for the remainder is usually written in a different form. Since $c$ is between $x_0$ and $x$, $c = x_0 + \theta(x-x_0)$ for some $\theta$, $0 < \theta < 1$. Then $x-c = x-x_0 - \theta(x-x_0) = (1-\theta)(x-x_0)$, so

V.10.3.7. **Corollary.** [Taylor’s Theorem With Remainder, Cauchy’s Form] Let $f$ be $(n+1)$-times differentiable on an interval $I$, $x_0 \in I$, $p_n$ the $n$’th Taylor polynomial for $f$ at $x_0$, and $x \in I$. Then, for some $\theta$ between 0 and 1,

$$r_n(x) = f(x) - p_n(x) = \frac{f^{(n+1)}(x_0 + \theta(x-x_0))}{n!} (1-\theta)^n (x-x_0)^{n+1}.$$

V.10.3.8. Note that the $c$ is not necessarily unique, and depends on $n$, as well as on $f$, $x$, and $x_0$, and on which formula (Cauchy or Lagrange) is used. There is usually no reasonable way to explicitly find a $c$ that works in a given example. However, as we will see, mere existence of such a $c$ often gives good error estimates and crucial information about the degree of approximation given by the Taylor polynomials.

V.10.3.9. See V.11.6.7. for a generalization of V.10.3.3. to the case where $f$ is approximated at more than one point.
V.10.4. The Integral Remainder Formula

V.10.4.1. There is another formula for \( r_n \) given by an integral. Let us fix \( f, x_0 \) and \( x \). Let \( J \) be the closed interval from \( x_0 \) to \( x \) (\( x \) may be greater than or less than \( x_0 \)). If \( f \) is differentiable on \( J \) and \( f' \) is Riemann integrable on \( J \), then

\[
f(x) = f(x_0) + \int_{x_0}^{x} f'(t) \, dt .
\]

If \( f'' \) is defined and Riemann integrable on \( J \), do the integral by parts \(^1\) the “wrong way” by letting

\[
F(t) = f'(t), \quad G(t) = -(x - t)
\]

to obtain

\[
f(x) = f(x_0) + f'(x_0)(x - x_0) + \int_{x_0}^{x} f''(t)(x-t) \, dt.
\]

If \( f'''(t) \) exists and is Riemann integrable on \( J \), do this integral again by parts using

\[
F(t) = f''(t), \quad G(t) = -\frac{1}{2}(x-t)^2
\]

and continue in the same fashion \( n \) steps if \( f \) is \((n+1)\)-times differentiable on \( J \) and \( f^{(n+1)} \) is Riemann integrable on \( J \). The formula for \( f(x) \) thus obtained consists of the \( n \)’th Taylor polynomial \( p_n \) for \( f \) at \( x_0 \) plus an integral:

\[
f(x) = f(x_0) + f'(x_0)(x - x_0) + \cdots + \frac{f^{(n)}(x_0)}{n!}(x-x_0)^n + \frac{1}{n!} \int_{x_0}^{x} f^{(n+1)}(t)(x-t)^n \, dt
\]

so we obtain:

V.10.4.2. **Theorem.** [Taylor’s Theorem With Remainder, Integral Form] Let \( f \) be \((n+1)\)-times differentiable on an interval \( I \) and \( x, x_0 \in I \). Suppose \( f^{(n+1)} \) is Riemann integrable on the interval between \( x_0 \) and \( x \). If \( p_n \) is the \( n \)’th Taylor polynomial of \( f \) at \( x_0 \), and \( r_n = f - p_n \), then

\[
r_n(x) = \frac{1}{n!} \int_{x_0}^{x} f^{(n+1)}(t)(x-t)^n \, dt
\]

V.10.4.3. Using more advanced integration, the hypotheses can be slightly relaxed to only require that \( f^{(n)} \) be absolutely continuous on the interval between \( x_0 \) and \( x \) \(^2\), or that \( f^{(n+1)} \) be defined everywhere between \( x_0 \) and \( x \) \(^2\).
V.10.5. Applications

V.10.6. Exercises

V.10.6.1. In V.10.1.3., the hypothesis that \( g^{(n)}(x_0) \) exists is necessary if \( n > 1 \):

(a) Let \( h_n(x) = \begin{cases} x^{n+1} & \text{if } x \in \mathbb{Q} \\ 0 & \text{if } x \notin \mathbb{Q} \end{cases} \). Then \( \lim_{x \to 0} \frac{h_n(x)}{x^n} = 0 \), but \( h_n \) is not even continuous except at 0, so \( h_n', \ldots, h_n^{(n)} \) do not exist at 0 (or anywhere else).

(b) The hypothesis that \( g^{(n)}(x_0) \) exists is automatic if \( n = 1 \): if \( g(x_0) = 0 \) and \( \lim_{x \to 0} \frac{g(x)}{x-x_0} = 0 \), then \( g'(x_0) \) exists and equals 0.

V.10.6.2. Give an alternate direct proof of Theorem V.10.1.2. not using l'Hôpital's Rule.

V.10.6.3. (a) Mimic the proof of V.10.1.2. to prove the following generalization of V.10.1.3.:

Theorem. Let \( g \) be \( n \)-times differentiable in an open interval around \( x_0 \), with \( g^{(n)} \) Hölder continuous () at \( x_0 \) with exponent \( \alpha \) (\( 0 < \alpha < 1 \)) and constant 0, i.e.

\[
\lim_{x \to x_0} \frac{g^{(n)}(x) - g^{(n)}(x_0)}{(x-x_0)^\alpha} = 0 .
\]

Then

\[
\lim_{x \to x_0} \frac{g(x)}{(x-x_0)^{n+\alpha}} = 0
\]

if and only if \( g(x_0) = g'(x_0) = \cdots = g^{(n)}(x_0) = 0 \).

(b) Derive V.10.1.3. as a corollary of the case \( \alpha = 1 \) of (a).

V.10.6.4. Write out the details of the arguments for the Lagrange and Cauchy remainder formulas in the case \( x < x_0 \).

V.10.6.5. The proof of V.10.3.3. is simple, but requires a nonobvious guess of a function to apply Rolle's theorem to. Phrase the proof in an alternate way not requiring a guess:

(a) Using the hypotheses and the notation of the theorem, show that there is an \( M \) such that

\[
f(x) = f(x_0) + f'(x_0)(x-x_0) + \frac{f''(x_0)}{2}(x-x_0)^2 + \cdots + \frac{f^{(n)}(x_0)}{n!}(x-x_0)^n + M(x-x_0)^{n+1} .
\]

(b) For \( x_0 \leq t \leq x \) set

\[
\phi(t) = f(x) - f(t) - f'(t)(x-t) - \frac{f''(t)}{2}(x-t)^2 - \cdots - \frac{f^{(n)}(t)}{n!}(x-t)^n - M(x-t)^{n+1} .
\]

(c) Apply Rolle's Theorem to \( \phi \) on \([x_0, x]\) (check that the hypotheses apply) and deduce Lagrange's form of the remainder. (The \( M \) will have to be calculated in terms of \( r_n(x) \).)

Let $f$ be $(n+1)$-times differentiable on an interval $I$, $x_0 \in I$, $p_n$ the $n$'th Taylor polynomial for $f$ at $x_0$, and $x \in I$. Let $g$ be a differentiable function on $I$ such that $g'(t) \neq 0$ for all $t$ in the open interval between $x_0$ and $x$. Then there is a $c$ between $x_0$ and $x$ for which

$$r_n(x) = -\frac{g(x_0) - g(x)}{g'(c)} \frac{f^{(n+1)}(c)}{n!} (x-c)^n$$

[Set

$$\omega(t) = \frac{\psi(t)}{g(t)}$$

where $\psi$ is as in V.10.3.5., and apply the Cauchy Mean Value Theorem.]

(b) Obtain the Lagrange form of the remainder by taking $g(t) = (x-t)^{n+1}$.

Theorem. [Taylor's Theorem With Remainder, Schlömilch's Form] Let $f$ be $(n+1)$-times differentiable on an interval $I$, $x_0 \in I$, $p_n$ the $n$'th Taylor polynomial for $f$ at $x_0$, and $x \in I$. Fix $m \in \mathbb{N}$, $1 \leq m \leq n+1$. Then, for some $\theta$ between 0 and 1,

$$r_n(x) = f(x) - p_n(x) = \frac{f^{(n+1)}(x_0 + \theta(x-x_0))}{n!m} (1-\theta)^{n+1-m}(x-x_0)^{n+1}.$$

The case $m = 1$ is Cauchy’s form, and $m = n + 1$ is Lagrange’s form. The $\theta$ depends on $f$, $x_0$, $x$, $n$, and $m$.

(a) Prove by complete induction that $\lim_{x \to 0} \frac{f(x)}{x^n} = 0$ for all $n \in \mathbb{N} \cup \{0\}$. [Hint: Use l'Hôpital’s Rule, but not in the most straightforward way.]

(b) Prove by induction that $f^{(n)}(0)$ exists and equals 0 for all $n$. Thus $f$ is $C^\infty$ on all of $\mathbb{R}$. [You will need to use part (a) and the definition of the derivative.]

(c) Find the $n$'th Taylor polynomial $p_n$ for $f$ around 0, and show that $p_n(x)$ does not converge to $f(x)$ for any fixed $x \neq 0$.

Let $f(x) = e^x$, and let $p_n$ be the $n$'th Taylor polynomial for $f$ around 0. Since $f^{(k)}(x) = e^x$ for all $k$, $p_n(x) = 1 + x + \frac{x^2}{2!} + \cdots + \frac{x^n}{n!}$.

(a) Show that for any fixed $x \in \mathbb{R}$, $\lim_{n \to \infty} \frac{x^n}{n!} = 0$. [Consider the ratios of successive terms, and use ()]

(b) What is wrong with the following argument? Fix $x \in \mathbb{R}$. Then by Lagrange’s remainder formula there is a $c$ between 0 and $x$ such that

$$f(x) - p_n(x) = \frac{e^c x^{n+1}}{(n+1)!} x^{n+1}.$$  

Since $\lim_{n \to \infty} e^c x^{n+1} = 0$, $p_n(x) \to f(x)$ as $n \to \infty$.

(c) Modify the argument of (b) to give a valid proof that $p_n(x) \to f(x)$ for any $x \in \mathbb{R}$.
[Extended Second Derivative Test] Let $f$ be defined in a neighborhood of $x_0$, and $n \in \mathbb{N}$, $n \geq 2$. Suppose $f^{(n)}(x_0)$ exists, and that $f'(x_0) = \cdots = f^{(n-1)}(x_0) = 0$ and $f^{(n)}(x_0) \neq 0$. Using Exercise V.10.6.12 (a), show that

(a) If $n$ is even, then $f$ has a strict local extremum at $x_0$, a local minimum if $f^{(n)}(x_0) > 0$ and a local maximum if $f^{(n)}(x_0) < 0$.

(b) If $n$ is odd, then $f$ is increasing or decreasing at $x_0$ in the sense of V.3.6.7., increasing if $f^{(n)}(x_0) > 0$ and decreasing if $f^{(n)}(x_0) < 0$, and $f$ has a point of inflection at $x_0$.  

V.10.6.10. Give an alternate proof of the integral form of the remainder for Taylor’s Theorem not requiring integration by parts, by computing the iterated integral

$$
\int_{x_0}^{x} \int_{x_0}^{x} \cdots \int_{x_0}^{x} f^{(n+1)}(t) \, dt \, dx_1 \cdots dx_n
$$

where $x_1, \ldots, x_n$ are variables ranging over the interval between $x_0$ and $x$, by successive applications of the Fundamental Theorem of Calculus. Note that the first integral is not necessarily a Riemann integral unless $f^{(n+1)}$ is well-behaved between $x_0$ and $x$, but can be interpreted as a Lebesgue integral or an H-K integral in more general cases. The rest of the integrals are always Riemann integrals.

V.10.6.11. Let $f$ be $C^n$ ($0 \leq n < \infty$) on an open interval $I$, and $x_0 \in I$. Suppose there is a sequence $(x_k)$ in $I \setminus \{x_0\}$ with $x_k \to x_0$ and $f(x_k) = 0$ for all $k$. Show that

$$
f(x_0) = f'(x_0) = \cdots = f^{(n)}(x_0) = 0
$$

and hence

$$
\lim_{x \to x_0} \frac{f(x)}{(x-x_0)^n} = 0.
$$

[Apply Rolle’s Theorem to the intervals between $x_k$ and $x_{k+1}$ for each $k$, and iterate.] Show by example that

$$
\lim_{x \to x_0} \frac{f(x)}{(x-x_0)^{n+1}} = 0
$$

do not necessarily hold.

V.10.6.12. Let $f$ be defined in a neighborhood of $x_0$, and $n \in \mathbb{N}$. Suppose $f^{(n)}(x_0)$ exists (this implies that $f^{(n-1)}$ is defined in a neighborhood $U$ of $x_0$ and is continuous at $x_0$).

(a) Show that there is a unique function $g_n$ defined in $U$ and continuous at $x_0$ such that

$$
f(x) = f(x_0) + f'(x_0)(x - x_0) + \cdots + \frac{f^{(n-1)}(x_0)}{(n-1)!} (x-x_0)^{n-1} + (x-x_0)^ng_n(x)
$$

for all $x \in U$. Show that $g_n$ is $(n-1)$-times differentiable in $U \setminus \{x_0\}$.

(b) If $n > 2$, show that $g_n$ is $(n-2)$-times differentiable at $x_0$. [Hint: show that $g_1$ is given by the formula

$$
g_1(x) = \int_0^1 f'(tx + (1-t)x_0) \, dt.
$$

(c) By considering $f(x) = |x|^{n+1}$ for $n$ even, and a similar example for $n$ odd, with $x_0 = 0$, show that $g_n$ need not be more than $(n-2)$-times differentiable at $x_0$, even if $f$ is $C^n$ on $U$ and $C^\infty$ on $U \setminus \{x_0\}$. 

V.10.6.13. [Extended Second Derivative Test] Let $f$ be defined in a neighborhood of $x_0$, and $n \in \mathbb{N}$, $n \geq 2$. Suppose $f^{(n)}(x_0)$ exists, and that $f'(x_0) = \cdots = f^{(n-1)}(x_0) = 0$ and $f^{(n)}(x_0) \neq 0$. Using Exercise V.10.6.12 (a), show that

(a) If $n$ is even, then $f$ has a strict local extremum at $x_0$, a local minimum if $f^{(n)}(x_0) > 0$ and a local maximum if $f^{(n)}(x_0) < 0$.

(b) If $n$ is odd, then $f$ is increasing or decreasing at $x_0$ in the sense of V.3.6.7., increasing if $f^{(n)}(x_0) > 0$ and decreasing if $f^{(n)}(x_0) < 0$, and $f$ has a point of inflection at $x_0$.  

631
V.11. Interpolation and Extrapolation

In this section, we discuss some topics normally treated only in numerical analysis texts but which are very helpful and relevant to understanding Taylor’s Theorem (our exposition is largely based on the nice treatments in [? and http://www.maths.lancs.ac.uk/~jameson/interpol.pdf]). No actual calculus is needed for the basic definitions and formulas, but the analysis is closely related in spirit to differential approximation and Taylor’s theorem (indeed, Taylor obtained his formula as a limiting case of the Gregory-Newton interpolation formula), and results from calculus are needed for error estimates.

The basic problem is as follows. Suppose we have a function \( f \) defined on an interval \( I \), which we presume to be suitably nicely behaved, e.g. differentiable to some high order. We know values of \( f \) at some points \( x_0, \ldots, x_n \) of \( I \) (typically forming a partition of \( I \), but not necessarily), and we want to estimate \( f(x) \) for a general \( x \in I \). This type of approximation is called \textit{interpolation}, especially if \( x \) is in the smallest interval containing \( x_0, \ldots, x_n \); if \( x \) is not in this interval, the approximation is \textit{extrapolation}. (Extrapolation is generally much more difficult and problematic to do with any accuracy.)

One promising way to proceed is to approximate \( f \) by the unique polynomial \( p \) of degree \( n \) whose values at \( x_0, \ldots, x_n \) are the same as \( f \), called the \textit{interpolating polynomial} for \( f \) with respect to \( x_0, \ldots, x_n \).

V.11.1. The Interpolating Polynomial

We first consider the problem of the existence and uniqueness of the interpolating polynomial and how to find it.

V.11.1.1. The most direct approach is a simple exercise in linear algebra. Given distinct \( x_0, \ldots, x_n \) in \( \mathbb{R} \) and real numbers \( b_0, \ldots, b_n \) (not necessarily distinct), we want a polynomial

\[
p(x) = a_0 + a_1 x + \cdots + a_n x^n
\]

with real coefficients, of degree \( \leq n \) (it could have degree less than \( n \) since \( a_n \) could be zero), such that \( p(x_k) = b_k \) for \( 0 \leq k \leq n \). Such a polynomial, if it exists, must be unique: if \( q(x) \) is another such polynomial, then \( p(x) - q(x) \) is a polynomial of degree \( \leq n \) with at least \( n + 1 \) roots (at \( x_0, \ldots, x_n \)), hence must be identically zero.

To show the polynomial exists, we must solve the system

\[
\begin{bmatrix}
1 & x_0 & x_0^2 & \cdots & x_0^n \\
1 & x_1 & x_1^2 & \cdots & x_1^n \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
1 & x_n & x_n^2 & \cdots & x_n^n
\end{bmatrix}
\begin{bmatrix}
a_0 \\
a_1 \\
\vdots \\
a_n
\end{bmatrix}
= 
\begin{bmatrix}
b_0 \\
b_1 \\
\vdots \\
b_n
\end{bmatrix}
\]

for \( \{a_0, \ldots, a_n\} \). The matrix on the left is a \textit{Vandermonde matrix} which is invertible (the determinant is \( \prod_{j<k} (x_k - x_j) \); cf. Exercise V.11.8.1); thus the system has a (unique) solution which can be found by Gaussian elimination. (This works over any \textit{field}.)

V.11.1.2. This procedure for finding \( p \) works fine in principle, but is regarded as a poor method in numerical analysis, since it is computationally inefficient and the system is often ill-conditioned, especially if the \( x_k \) are close together, leading to large roundoff errors.
V.11.1.3. There is another form of the interpolating polynomial which is more computationally efficient. This form is usually attributed to Lagrange and is often called the Lagrange form of the interpolation polynomial although it was originally due to E. Waring in 1779.

Fix distinct real numbers \(x_0, \ldots, x_n\). The polynomial

\[ p_k(x) = \frac{(x-x_0)(x-x_1)\cdots(x-x_{k-1})(x-x_{k+1})\cdots(x-x_n)}{(x_k-x_0)(x_k-x_1)\cdots(x_k-x_{k-1})(x_k-x_{k+1})\cdots(x_k-x_n)} \]

of degree \(n\) has the property that \(p_k(x_j) = \delta_{kj}\) for \(0 \leq j \leq n\). Thus, if \(b_0, \ldots, b_n \in \mathbb{R}\), the polynomial \(p\) of degree \(n\) with \(p(x_k) = b_k\) for all \(k\) is

\[ p(x) = \sum_{k=0}^{n} b_k p_k(x) \, . \]

V.11.1.4. There is an even better form of the interpolating polynomial, the Newton form (V.11.3.2).

V.11.2. Linear Interpolation and Extrapolation

V.11.2.1. If we only know the value of \(f\) at one point \(x_0\) of \(I\), the best estimate we can make of \(f(x)\) for \(x \in I\) is

\[ f(x) = f(x_0) \]

i.e. \(f\) is constant on \(I\) (this is generally a pretty crude estimate, but the best we can do with only one data point, and reasonably accurate for \(x\) near \(x_0\) if \(f\) is continuous). We will use the notation \(f[x_0]\) to denote the number \(f(x_0)\); thus we have the 0’th order approximation

\[ f(x) = f[x] \approx f[x_0] = f(x_0) \, . \]

Denote by \(p_0\) the constant function with value \(f(x_0)\) (we should really write \(p_{x_0}\), but we will think of \(x_0\) as being fixed and adding additional points \(x_1, x_2, \ldots\) successively).

V.11.2.2. If we know the values of \(f\) at two points \(x_0\) and \(x_1\) of \(I\), we can do a little better: we can assume \(f\) is linear, with slope

\[ f[x_0, x_1] := \frac{f(x_1) - f(x_0)}{x_1 - x_0} \]

(i.e. \(f[x_0, x_1]\) is the difference quotient (V.3.1.8), usually called a divided difference in numerical analysis.) We then have the approximation

\[ f(x) \approx f(x_0) + f[x_0, x_1](x - x_0) = f[x_0] + (x - x_0)f[x_0, x_1] \]

for \(x \in I\) and, of course, the exact formula

\[ f(x) = f[x_0] + (x - x_0)f[x_0, x] \]

\((x \neq x_0)\) which is useless for approximation.

V.11.2.3. The linear function

\[ p_{0,1}(x) = f[x_0] + (x - x_0)f[x_0, x_1] \]

is the unique linear function with the same values as \(f\) at \(x_0\) and \(x_1\).
V.11.2.4. Linear interpolation and extrapolation can be written in the equivalent form

\[ f(\lambda x_0 + (1 - \lambda)x_1) \approx \lambda f(x_0) + (1 - \lambda)f(x_1) \]

(interpolation if \(0 < \lambda < 1\), extrapolation if \(\lambda < 0\) or \(\lambda > 1\)).

V.11.3. Higher-Order Interpolation and Extrapolation

V.11.3.1. Now suppose we know the values of \(f\) at \(x_0, x_1, x_2\) (assumed distinct). We want to find the quadratic polynomial \(p_{0,1,2}\) whose values are the same as \(f\) at \(x_0, x_1, x_2\). This can be done as in section V.11.1, but we take a different approach. The polynomial will be of the form

\[ p_{0,1,2}(x) = f[x_0] + (x-x_0)f[x_0, x_1] + K(x-x_0)(x-x_1) \]

for some constant \(K\). A little algebra gives

\[ K = \frac{f(x_0)}{(x_0-x_1)(x_0-x_2)} + \frac{f(x_1)}{(x_1-x_0)(x_1-x_2)} + \frac{f(x_2)}{(x_2-x_0)(x_2-x_1)} = \frac{f[x_1, x_2] - f[x_0, x_1]}{x_2-x_0}. \]

We thus define

\[ f[x_0, x_1, x_2] = \frac{f[x_1, x_2] - f[x_0, x_1]}{x_2-x_0} \]

so we have, for \(x \in I\),

\[ f(x) \approx p_{0,1,2}(x) = f[x_0] + (x-x_0)f[x_0, x_1] + (x-x_0)(x-x_1)f[x_0, x_1, x_2] \]

and the exact formula

\[ f(x) = f[x_0] + (x-x_0)f[x_0, x_1] + (x-x_0)(x-x_1)f[x_0, x_1, x] \]

(the last expression is not defined if \(x = x_0\) or \(x = x_1\), but the last term can be taken to be 0 in these cases, which makes the overall formula valid).

V.11.3.2. Continuing inductively in the same manner, if we have \(n+1\) distinct points \(x_0, \ldots, x_n \in I\), we have

\[ p_{0,1,\ldots,n}(x) = f[x_0]+(x-x_0)f[x_0, x_1]+(x-x_0)(x-x_1)f[x_0, x_1, x_2]+\cdots+(x-x_0)(x-x_1)\cdots(x-x_{n-1})f[x_0, \ldots, x_n] \]

where

\[ f[x_0, \ldots, x_n] = \frac{f(x_0)}{(x_0-x_1)\cdots(x_0-x_n)} + \cdots + \frac{f(x_k)}{(x_k-x_0)(x_k-x_1)\cdots(x_k-x_{k-1})(x_k-x_{k+1})\cdots(x_k-x_n)} + \cdots + \frac{f(x_n)}{(x_n-x_0)\cdots(x_n-x_{n-1})} \]

are called higher-order divided differences. There are many other formulas for these divided differences; see below for some of them.

Thus, for \(x \in I\), we have the \(n\)’th order approximation

\[ f(x) \approx f[x_0]+(x-x_0)f[x_0, x_1]+(x-x_0)(x-x_1)f[x_0, x_1, x_2]+\cdots+(x-x_0)(x-x_1)\cdots(x-x_{n-1})f[x_0, \ldots, x_n] \]

and the exact formula \((x \neq x_0, \ldots, x_{n-1})\)

\[ f(x) = f[x_0]+(x-x_0)f[x_0, x_1]+(x-x_0)(x-x_1)f[x_0, x_1, x_2]+\cdots+(x-x_0)(x-x_1)\cdots(x-x_{n-1})f[x_0, \ldots, x_n, x]. \]
V.11.3.3. Divided differences and the form of the interpolating polynomial in V.11.3.2. are attributed to Newton and called the Newton form, although they were first obtained by James Gregory around 1670, at least in the case of evenly-spaced data points.

V.11.3.4. The Newton form of the interpolating polynomial is regarded as the most generally useful and efficient form for numerical analysis purposes. Not only is it computationally efficient, but it also has the nice property that the coefficients do not have to all be recomputed if an additional data point is added.

Properties of Higher-Order Divided Differences

V.11.3.5. In the divided difference \( f[x_0, \ldots, x_n] \), the numbers \( x_0, \ldots, x_n \) are typically taken in increasing order. However, this is not necessary; in fact, it is obvious from the definition V.11.3.2. that the order in which the \( x_k \) are taken is irrelevant: the numerical value is invariant under any permutation of the \( x_k \).

This can be seen in another way. The number \( f[x_0, \ldots, x_n] \) is the coefficient of \( x^n \) in the interpolating polynomial corresponding to \( \{x_0, \ldots, x_n\} \). Since this polynomial obviously depends only on the set \( \{x_0, \ldots, x_n\} \) and not on the order of the numbers, so does \( f[x_0, \ldots, x_n] \).

V.11.3.6. There is also a recursive formula

\[
f[x_0, \ldots, x_n] = \frac{f[x_1, \ldots, x_n] - f[x_0, \ldots, x_{n-1}]}{x_n - x_0}
\]

which justifies the name “higher-order divided difference” (Exercise V.11.8.2.). There are many variations obtained by combining this formula with permutations of the \( x_k \) (V.11.3.5.).

V.11.4. The Mean Value Theorem for Divided Differences

We now bring some calculus into the picture.

V.11.4.1. The \( n \)'th order divided difference \( f[x_0, \ldots, x_n] \) can be regarded as a function \( f[^n] \) defined on the subset \( I_d^{n+1} \) of \( I^{n+1} \) consisting of points with all coordinates distinct. The set \( I_d^{n+1} \) is a dense open set in \( I^{n+1} \). If \( f \) is continuous on \( I \), this \( n \)'th order divided difference is clearly continuous on \( I_d^{n+1} \). We will eventually extend it to all of \( I^{n+1} \) if \( f \) is sufficiently differentiable on \( I \) (V.11.5.7.).

The most important calculus result about divided differences is the following version of the MVT:

V.11.4.2. Theorem. Let \( f \) be continuous on \([a, b]\) and \( n \)-times differentiable everywhere on \((a, b)\). Let \( x_0, \ldots, x_n \) be \( n + 1 \) distinct points in \([a, b]\). Then there is at least one \( c \in (a, b) \) with

\[
f[x_0, \ldots, x_n] = \frac{f^{(n)}(c)}{n!}.
\]

Proof: The function

\[
g(x) = f(x) - p_{0,1,\ldots,n}(x)
\]

635
has at least \( n+1 \) distinct zeroes in \([a, b]\) (at \( x_0, \ldots, x_n \)). Applying Rolle’s Theorem repeatedly to the intervals between \( x_{k-1} \) and \( x_k \), \( g'(x) \) has at least \( n \) zeroes in \((a, b)\), \( g''(x) \) has at least \( n-1 \) zeroes, \( \ldots \), \( g^{(n)}(x) \) has at least one zero \( c \). But \( p_{0,\ldots,n} \) is a polynomial of degree \( \leq n \) whose degree \( n \) term is

\[
 f[x_0, \ldots, x_n]x^n
\]

so its \( n \)’th derivative is the constant function \( n!f[x_0, \ldots, x_n] \), and thus

\[
 0 = g^{(n)}(c) = f^{(n)}(c) - p_{0,\ldots,n}^{(n)}(c) = f^{(n)}(c) - n!f[x_0, \ldots, x_n].
\]

**V.11.4.3.** Note that the case \( n = 1 \) of this theorem is the usual MVT, so this theorem is a generalization of the MVT. But the MVT, or at least the special case of Rolle’s Theorem, is used in the proof.

**V.11.4.4.** We can use this result to calculate the error in using \( p_{0,\ldots,n}(x) \) to approximate \( f(x) \) for \( x \in I \). Set

\[
 E_n(x) = f(x) - p_{0,\ldots,n}(x)
\]

for \( x \in I \). If \( x \) is not one of \( x_0, \ldots, x_n \), then we have from **V.11.3.2.** that

\[
 E_n(x) = (x - x_0)(x - x_1)\cdots(x - x_n)f[x_0, \ldots, x_n, x]
\]

and combining this with **V.11.4.2.**, we obtain:

**V.11.4.5.** Corollary. Let \( f \) be \((n + 1)\)-times differentiable on \( I \), and \( x_0, \ldots, x_n \) distinct points of \( I \). Then, for any \( x \in I \), there is a \( c \) in the interior of the smallest subinterval of \( I \) containing \( x_0, \ldots, x_n, x \) such that

\[
 E_n(x) = (x - x_0)(x - x_1)\cdots(x - x_n)\frac{f^{(n+1)}(c)}{(n + 1)!}.
\]

**Proof:** If \( x \) is not one of the \( x_k \), the result follows from **V.11.4.2.**, and if \( x \) is one of the \( x_k \) both sides are zero no matter what \( c \) is chosen.

**V.11.5. Repeated Points**

**V.11.5.1.** In defining \( f[x_0, x_1] \), the \( x_0 \) and \( x_1 \) must be distinct. But if (and only if) \( f \) is differentiable at \( x_0 \), we have, for fixed \( x_0 \),

\[
 \lim_{x_1 \to x_0} f[x_0, x_1] = \lim_{x_1 \to x_0} \frac{f(x_1) - f(x_0)}{x_1 - x_0} = f'(x_0)
\]

so we may define

\[
 f[x_0, x_0] = f'(x_0)
\]

if \( f \) is differentiable at \( x_0 \). This definition is especially suitable if \( f \) is strictly differentiable at \( x_0 \) (\( f' \) is continuous at \((x_0, x_0)\)). In particular, if \( f \) is \( C^1 \) on \( I \), then \( f[\cdot, \cdot] \) is continuous on \( I^2 \).
V.11.5.2. We want to extend this to higher-order divided differences. We first consider the case where all the coordinates are the same. Fix $n$, and for $x_0 \in I$ write $x_0 = (x_0, \ldots, x_0) \in I^{n+1}$. If $x = (y_0, \ldots, y_n) \in I^{n+1}$, write $f[x] = f[y_0, \ldots, y_n]$.

V.11.5.3. Proposition. Let $f$ be $n$-times differentiable on $I$, and $x_0 \in I$. If $f^{(n)}$ is continuous at $x_0$, then

$$\lim_{x \to x_0} f[x] = \frac{f^{(n)}(x_0)}{n!}.$$

Proof: Let $\epsilon > 0$. Then there is a $\delta > 0$ such that, for all $y \in I$, $|y - x_0| < \delta$, we have

$$\left| \frac{f^{(n)}(y)}{n!} - \frac{f^{(n)}(x_0)}{n!} \right| < \epsilon.$$

Let $J = I \cap (x_0 - \delta, x_0 + \delta)$. If $x = (y_0, \ldots, y_n) \in J^{n+1}$, then by V.11.4.2. there is a $c_x \in J$ with

$$f[x] = \frac{f^{(n)}(c_x)}{n!}$$

so

$$\left| f[x] - \frac{f^{(n)}(x_0)}{n!} \right| < \epsilon.$$

V.11.5.4. If $f$ is $C^n$ on $I$, we can thus extend the $n$th order divided difference to points with all coordinates the same by setting

$$f[x_0, \ldots, x_0] = \frac{f^{(n)}(x_0)}{n!}$$

for $x_0 \in I$. The extended function is continuous on the subset of $I^{n+1}$ consisting of points whose coordinates are either all the same or all different.

V.11.5.5. We can extend higher-order divided differences to points where some, but not all, coordinates coincide. Rather than trying to state things in maximum generality (cf. V.11.5.13.), we will just assume $f$ is $C^n$ on $I$. The most efficient approach is to prove an integral formula for the higher-order divided differences which is of general interest:

V.11.5.6. Theorem. Let $f$ be $C^n$ on an interval $I$, and $x_0, \ldots, x_n$ distinct points of $I$. Then

$$f[x_0, \ldots, x_n] = \int_0^1 \int_0^{t_1} \cdots \int_0^{t_{n-1}} f^{(n)}(x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_n(x_n - x_{n-1})) \, dt_n \cdots dt_2 dt_1.$$

637
Proof: By induction on $n$. The case $n = 1$ is essentially the Fundamental Theorem of Calculus in slight disguise: to evaluate the integral
$$\int_0^1 f'(x_0 + t(x_1 - x_0)) \, dt$$
for $f \in C^1$, make the substitution
$$u = x_0 + t(x_1 - x_0)$$
$$du = (x_1 - x_0) \, dt$$
to obtain
$$\int_0^1 f'(x_0 + t(x_1 - x_0)) \, dt = \frac{1}{x_1 - x_0} \int_{x_0}^{x_1} f'(u) \, du = \frac{f(x_1) - f(x_0)}{x_1 - x_0}.$$ 
Thus $f[x_0, x_1]$ is the average value of $f'$ over the interval $[x_0, x_1]$ (or $[x_1, x_0]$ if $x_1 < x_0$).

Now suppose the formula holds for $n - 1$. Compute the first integral
$$\int_0^{t_{n-1}} f^{(n)}(x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_n(x_n - x_{n-1})) \, dt_n$$
making the substitution
$$u = x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_n(x_n - x_{n-1})$$
$$du = (x_n - x_{n-1}) \, dt_n$$
so the first integral evaluates to
$$\frac{1}{x_n - x_{n-1}} [f^{(n-1)}(x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_n(x_n - x_{n-1}))]_0^{t_{n-1}}$$
$$= \frac{1}{x_n - x_{n-1}} [f^{(n-1)}(x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_{n-1}(x_{n-1} - x_{n-2}) + t_n(x_n - x_{n-1})) - f^{(n-1)}(x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_{n-1}(x_{n-1} - x_{n-2}))]
\quad - f^{(n-1)}(x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_{n-1}(x_{n-1} - x_{n-2}))]
\quad - f^{(n-1)}(x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_{n-1}(x_{n-1} - x_{n-2}))]
\quad = \frac{1}{x_n - x_{n-1}} [f^{(n-1)}(x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_{n-1}(x_{n-1} - x_{n-2})) - f^{(n-1)}(x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_{n-1}(x_{n-1} - x_{n-2}))]
\quad - f^{(n-1)}(x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_{n-1}(x_{n-1} - x_{n-2}))]
\quad = \frac{1}{x_n - x_{n-1}} [f^{(n-1)}(x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_{n-1}(x_{n-1} - x_{n-2})) - f^{(n-1)}(x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_{n-1}(x_{n-1} - x_{n-2}))]
\quad - f^{(n-1)}(x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_{n-1}(x_{n-1} - x_{n-2}))]
\quad = \frac{1}{x_n - x_{n-1}} [f[x_0, x_1] - f[x_0, x_{n-2}, x_n] - f[x_0, x_{n-2}, x_{n-1}]) = f[x_0, \ldots, x_n]
\quad = \frac{1}{x_n - x_{n-1}} (f[x_0, \ldots, x_{n-2}, x_n] - f[x_0, \ldots, x_{n-2}, x_{n-1}]) = f[x_0, \ldots, x_n]
\quad = \frac{1}{x_n - x_{n-1}} (f[x_0, \ldots, x_{n-2}, x_n] - f[x_0, \ldots, x_{n-2}, x_{n-1}]) = f[x_0, \ldots, x_n]"
V.11.5.7. The formula in V.11.5.6. makes perfect sense even if \( x_0, \ldots, x_n \) are not distinct, and clearly gives a continuous function of \((x_0, \ldots, x_n)\) on \( I^{n+1} \). We denote this extended function also by \( f[x_0, \ldots, x_n] \). The extended function agrees with the extension given in V.11.5.4. in the case all the coordinates are equal. Thus we obtain

\[ f[x_0, \ldots, x_n] \]

V.11.5.8. Corollary. If \( f \) is \( C^n \) on an interval \( I \), then \( f[\cdot, \ldots, \cdot] \) \((n+1\) arguments), extended as above to points with repeated coordinates, is continuous on \( I^{n+1} \).

V.11.5.9. If \( f \) is \( C^n \) on \([a, b]\), then the conclusion of Theorem V.11.4.2. holds also (with \( c \in [a, b] \)) if not all the \( x_k \) are distinct, as can be seen by a straightforward limiting argument using V.11.5.8. and the Bolzano-Weierstrass Theorem \((\cdot)\). In particular, if \( f \) is \( C^n \), then for any \( x_0 \) and any \([a, b]\) containing \( x_0 \) there is a \( c \in [a, b] \) for which \( f[x_0, \ldots, x_0] = \frac{f^{(n)}(c)}{m!} \). Taking the limit as \( a, b \to x_0 \), we obtain an alternate proof of V.11.5.3.\

To extend \( f[x_0, \ldots, x_n] \) to points with some repetitions in somewhat greater generality, we use the following result, which is proved inductively using V.11.5.8. and the recursion formula for divided differences with distinct entries:

V.11.5.10. Theorem. Let \( f \) be a function on an interval \( I \), \( J_0, \ldots, J_r \) disjoint subintervals of \( I \), and \( m_0, \ldots, m_r \in \mathbb{N} \). Suppose \( f \) is \( C^{m_k-1} \) on \( J_k \) for each \( k \). Then

\[ f[x_0(0), \ldots, x_R(0, m_0-1), x_1(1,0), \ldots, x_1(1,m_1-1), \ldots, x_R(r, m_r-1)] \]

extends to a continuous function on \( J_0^{m_0} \times \cdots \times J_r^{m_r} \).

V.11.5.11. We can obtain an explicit formula for \( f[x_0, \ldots, x_n] \) when the points are not all distinct. Since the function values are independent of the order of the coordinates on a dense set, by continuity this holds everywhere. Thus to evaluate the function we may put the entries in increasing order, with the repeated coordinates grouped together. We write \( x_0, \ldots, x_r \) for the distinct values, and suppose \( x_k \) occurs \( m_k \) times, so \( m_0 + \cdots + m_r = n + 1 \).

V.11.5.12. Theorem. Suppose \( f \) is \( C^n \) on \( I \). Then \( f[x_0, \ldots, x_r] \) is \( C^{n-r} \) on \( I_d^{r+1} \), and

\[ f[x_0, \ldots, x_0, x_1, \ldots, x_1, \ldots, x_r] = \frac{1}{(m_0 - 1)!(m_1 - 1)! \cdots (m_r - 1)!} \frac{\partial^{n-r}}{\partial x_0^{m_0-1} \partial x_1^{m_1-1} \cdots \partial x_r^{m_r-1}} (f[x_0, \ldots, x_r]) \]

where \( x_k \) occurs \( m_k \) times on the left and once on the right.

V.11.5.13. Actually, for this formula to hold and define \( f[x_0, \ldots, x_0, x_1, \ldots, x_1, \ldots, x_r] \) continuously at \( (x_0, \ldots, x_0, x_1, \ldots, x_1, \ldots, x_r) \), it suffices that \( f \) be \( C^{m_k-1} \) in an interval around \( x_k \) for each \( k \) (although the \( C^{n-r} \) statement does not hold in general). See [\( ? \), p. 72-73] for an outline of the proof. Note that the formula agrees with the previous cases where \( r = n \) (all \( m_k = 1 \)) or \( r = 0 \) (\( m_0 = n + 1 \)).

639
V.11.6. Osculating Polynomials

V.11.6.1. We want to extend the notion of interpolating polynomial to the case where the points \( x_0, \ldots, x_n \) are not all distinct. The first thing we must decide is what this should mean: if \( x_0 \) is repeated \( m \) times, how should the approximating polynomial \( p \) agree with \( f \) at \( x_0 \)?

The approximation should be of “order \( m \)” in the sense that \( f - p \) should have a zero of “order \( m \)” at \( x_0 \). The broadest sense in which this can be interpreted is to demand that

\[
f(x) - p(x) = o(|x - x_0|^{m-1})
\]
as \( x \to x_0 \) in \( I \). By V.10.1.3., if \( f \) is \( (m - 1) \)-times differentiable at \( x_0 \), this will happen if and only if

\[
p(x_0) = f(x_0), \quad p'(x_0) = f'(x_0), \ldots, p^{(m-1)}(x_0) = f^{(m-1)}(x_0).
\]

So, if \( f \) is differentiable to high enough order, we need to find a polynomial with specified values and derivatives up to a certain level at each of the points. This is possible because of the following extension of V.11.1.1.:

V.11.6.2. Theorem. Let \( n \in \mathbb{N}, x_0, \ldots, x_r \) distinct real numbers, \( m_0, \ldots, m_r \in \mathbb{N} \) with \( m_0 + \cdots + m_r = n + 1 \) (so necessarily \( r \leq n \)), and

\[
b_0^{(0)}, b_0^{(1)}, \ldots, b_0^{(m_0-1)}, b_1^{(0)}, \ldots, b_r^{(m_r-1)}
\]
real numbers (not necessarily distinct). Then there is a unique polynomial \( p \) with real coefficients, of degree \( \leq n \), for which \( p^{(j)}(x_k) = b_k^{(j)} \) for \( 0 \leq k \leq r, 0 \leq j \leq m_k - 1 \).

Proof: To find

\[
p(x) = a_0 + a_1 x + \cdots + a_n x^n
\]
we need to solve the system

\[
\begin{bmatrix}
1 & x_0 & x_0^2 & \cdots & x_0^n \\
0 & 1 & 2x_0 & \cdots & nx_0^{n-1} \\
0 & 0 & 2 & \cdots & n(n-1)x_0^{n-2} \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
1 & x_1 & x_1^2 & \cdots & x_1^n \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & 0 & \cdots & n(n-1) \cdots (n-m_r+2)x_r^{n-m_r+1}
\end{bmatrix}
\begin{bmatrix}
a_0 \\
a_1 \\
\vdots \\
a_n
\end{bmatrix}
= \begin{bmatrix}
b_0^{(0)} \\
b_0^{(1)} \\
\vdots \\
b_r^{(m_r-1)}
\end{bmatrix}
\]

where there are \( m_k \) rows for each \( x_k \). It can be shown (Exercise V.11.8.1.) that the matrix on the left is invertible if the \( x_k \) are distinct, so the system has a unique solution. 

V.11.6.3. Corollary. Let \( f \) be a function on an interval \( I \). Let \( n \in \mathbb{N}, x_0, \ldots, x_r \) distinct numbers in \( I \), and \( m_0, \ldots, m_r \in \mathbb{N} \) with \( m_0 + \cdots + m_r = n + 1 \) (so necessarily \( r \leq n \)). Suppose \( f \) is \( (m_k - 1) \)-times differentiable at \( x_k \) for each \( k \). Then there is a unique polynomial \( p \) of degree \( \leq n \), with real coefficients, such that \( p^{(j)}(x_k) = f^{(j)}(x_k) \) for \( 0 \leq k \leq r, 0 \leq j \leq m_k - 1 \).
V.11.6.4. Definition. The polynomial $p$ is called the osculating polynomial of $f$ with respect to $(x_0, \ldots, x_r; m_0, \ldots, m_r)$.

V.11.6.5. The osculating polynomial generalizes both the interpolating polynomial (the case $r = n$ and all $m_k = 1$) and the Taylor polynomial (the case $r = 0$, $m_0 = n + 1$). If $f$ is sufficiently differentiable, the osculating polynomial is a limiting case of interpolation polynomials for distinct points approaching the repeated points (this is essentially how TAYLOR found the Taylor polynomials).

V.11.6.6. In fact, there is a formula for the osculating polynomial using the extended definitions of higher-order divided differences which is just an extension of the Newton form of the interpolation polynomial:

$$p(x) = f[x_0] + (x - x_0)f[x_0, x_0] + \cdots + (x - x_0)^{m_0 - 1}f[x_0, \ldots, x_0] + (x - x_0)^{m_0}f[x_0, \ldots, x_0, x_1]$$

$$+ (x - x_0)^{m_0}(x - x_1)f[x_0, \ldots, x_0, x_1, x_1] + \cdots + (x - x_0)^{m_0}(x - x_1)^m(x - x_r)^{m - 1}f[x_0, \ldots, x_0, x_1, \ldots, x_r]$$

where $x_{k+1}$ starts appearing when $x_k$ has been repeated $m_k$ times. There is also an exact formula

$$f(x) = f[x_0] + (x - x_0)f[x_0, x_0] + \cdots + (x - x_0)^{m_0 - 1}f[x_0, \ldots, x_0] + (x - x_0)^{m_0}f[x_0, \ldots, x_0, x_1]$$

$$+ (x - x_0)^{m_0}(x - x_1)f[x_0, \ldots, x_0, x_1, x_1] + \cdots + (x - x_0)^{m_0}(x - x_1)^m(x - x_r)^{m - 1}f[x_0, \ldots, x_0, x_1, \ldots, x_r, x]$$

where $x_k$ is repeated $m_k$ times, which is valid for $x \neq x_0, \ldots, x_r$, and even also for $x = x_k$ if $f$ is $m_k$-times differentiable at $x_k$.

We thus get a formula for the error from approximation by the osculating polynomial: if $E(x) = f(x) - p(x)$, we have

$$E(x) = (x - x_0)^{m_0}(x - x_1)^m \cdots (x - x_r)^{m_r}f[x_0, \ldots, x_0, x_1, \ldots, x_r, x]$$

and, combining this with V.11.5.9., we obtain:

V.11.6.7. Corollary. Let $f$ be $(n+1)$-times differentiable on $I$, $x_0, \ldots, x_r$ distinct points of $I$, and $m_0, \ldots, m_r \in \mathbb{N}$ with $m_0 + \cdots + m_r = n + 1$ (so necessarily $r \leq n$). Let $p$ be the osculating polynomial of $f$ with respect to $(x_0, \ldots, x_r; m_0, \ldots, m_r)$. Then, for any $x \in I$, there is a $c$ in the smallest subinterval of $I$ containing $x_0, \ldots, x_r, x$ such that

$$f(x) - p(x) = (x - x_0)^{m_0}(x - x_1)^m \cdots (x - x_r)^{m_r}f^{(n+1)}(c) \frac{f^{(n+1)}(c)}{(n + 1)!}.$$  

Note that both V.11.4.5. and the Lagrange form of the error in Taylor’s Theorem (V.10.3.3.) are special cases.

V.11.6.8. An osculating polynomial where all $m_k$ are 2 ($n$ is then necessarily odd) is called a Hermite polynomial, and approximation by such a polynomial is called Hermite interpolation. (Approximation with general $m_k \geq 2$ is also sometimes called Hermite interpolation.)
V.11.6.9. In practical approximation problems, it can happen, although it is somewhat unusual, that one has data allowing approximation of an unknown function by an osculating polynomial, especially a Hermite polynomial. Such an approximation, when possible, will generally (but not always) be more accurate than approximation by the interpolation polynomial for the same data points.

V.11.7. How Good are the Approximations?

It is beyond the scope of this book to give a comprehensive discussion of the accuracy (not to mention the efficiency) of the various ways to approximate functions by polynomials. But we will briefly survey some of the aspects of accuracy in this section. Almost any book on numerical analysis contains a much more thorough treatment. The article [http://people.maths.ox.ac.uk/trefethen/mythspaper.pdf](http://people.maths.ox.ac.uk/trefethen/mythspaper.pdf) has some important observations about polynomial approximation. See also [?].

Approximation With Evenly-Spaced Nodes

V.11.7.1. If $I = [a,b]$, the most obvious choice of $x_0, \ldots, x_n$ is as a partition of $I$ into $n$ subintervals of equal length $h = \frac{b-a}{n}$, i.e. $x_k = x_0 + kh$. In this case, the denominators in the recursive formula (V.11.3.6.) for the divided differences are all equal to $h$, so we may instead consider just the ordinary differences

$$\Delta f(x_j) = f(x_{j+1}) - f(x_j)$$

$$\Delta^{k+1} f(x_j) = \Delta^k f(x_{j+1}) - \Delta^k f(x_j)$$

(these are usually called forward differences), giving the formula (easily proved by induction)

$$f[x_0, \ldots, x_k] = \frac{1}{k! h^k} \Delta^k f(x_0).$$

We also use the notation

$$\pi_k(t) = t(t-1) \cdots (t-k+1)$$

for $k \geq 1$ (we may set $\pi_0(t) = 1$; $\pi_k$ is called the $k$’th factorial polynomial). The Newton formula for the interpolation polynomial then becomes, for $0 \leq t \leq n$,

$$p_{0,\ldots,n}(x_0 + th) = f(x_0) + \sum_{k=1}^n \frac{\pi_k(t)}{k!} \Delta^k f(x_0) = \sum_{k=0}^n \frac{\pi_k(t)}{k!} \Delta^k f(x_0)$$

if we set $\Delta^0 f(x_0) = f(x_0)$. This is the Gregory-Newton interpolation formula. We may further rewrite this using the generalized binomial coefficient

$$\binom{t}{k} = \frac{\pi_k(t)}{k!}$$

(cf. V.17.7.1.), so

$$p_{0,\ldots,n}(x_0 + th) = \sum_{k=0}^n \binom{t}{k} \Delta^k f(x_0).$$

We may get similar formulas for backward differences or centered differences; see books on numerical analysis for details.
If \( f \) is continuous on \([a, b]\) and \((n + 1)\)-times differentiable on \((a, b)\), we get a corresponding formula for the error term for \(0 \leq t \leq n\):

\[
E_n(x_0 + th) = \pi_n(t) h^{n+1} \frac{f^{(n+1)}(c)}{(n+1)!}
\]

for some \(c \in (a, b)\).

We also get a formula for the Lagrange form of the interpolation formula using evenly-spaced nodes. Using the same notation as above, we have

\[
p_{0, \ldots, n}(x_0 + th) = \frac{\pi_n(t)}{n!} \sum_{k=0}^{n} (-1)^{n-k} \binom{n}{k} \frac{f(x_k)}{t - k}.
\]

The Runge Phenomenon

Suppose \( f \) is a function on \([a, b]\). One might expect that as \( n \to \infty \), the interpolation polynomials \( p_{0, \ldots, n} \) for \( f \) corresponding to a subdivision of \([a, b]\) into \( n \) subintervals of equal length should converge to \( f \) pointwise or even uniformly on \([a, b]\) if \( f \) is sufficiently smooth. But this fails dramatically in general, even if \( f \) is analytic. This phenomenon was found by C. Runge in 1901, although related work had previously been done by C. Meray.

Runge’s classic example is the innocent-looking function

\[
g(x) = \frac{1}{x^2 + 1}
\]

on the interval \([-5, 5]\), or equivalently by rescaling

\[
f(x) = \frac{1}{25x^2 + 1}
\]

on \([-1, 1]\). These functions are real-analytic on all of \(\mathbb{R}\), and complex-analytic on \(\mathbb{C}\) except for two poles. Figure V.10 (from http://www.math.utk.edu/~ccollins/M471/runge.jpg) shows some approximants of small order, which suggest there is an approximation problem near the ends of the interval.

In fact, the approximants for \( g \) converge pointwise for

\[
|x| < x_c \approx 3.63
\]

and u.c. on \((-x_c, x_c)\), but diverge pointwise for \(x_c < |x| < 5\). The demonstration http://demonstrations.wolfram.com/RungePhenomenon shows just how wildly the approximations diverge near the endpoints.

It should not be too surprising that there are problems near the endpoints, since interpolation near the endpoints is almost extrapolation, for which one would expect problems. In fact, the polynomial \( \pi_n \) has large values near the ends of the interval \([0, n]\), so the error in V.11.7.2. might tend to blow up (and often does) toward the ends of the interval as \( n \) increases.
V.11.7.8. The real “explanation” of why approximation fails in this example is that the poles of the function in \( \mathbb{C} \) are too close to the interval of approximation (cf. Exercise V.11.8.10.). A detailed discussion can be found in [?], (), ()..

Chebyshev Nodes

V.11.7.10. It would appear that one gets a better approximation using nodes which are not evenly spaced, but are more concentrated near the endpoints. This is true in reasonable cases. We will work on the interval \([-1,1]\) for simplicity; other intervals can be handled via an affine transformation.

V.11.7.11. If \( f \) is smooth, the error in approximating by \( p_{0,\ldots,n} \) for \( \{x_0,\ldots,x_n\} \) is given by

\[
(x - x_0)(x - x_1) \cdots (x - x_n) \frac{f^{(n+1)}(c)}{(n+1)!}
\]

for some \( c \in (-1,1) \). To try to minimize this, we can choose the \( x_k \) so that the polynomial

\[
q(x) = (x - x_0)(x - x_1) \cdots (x - x_n)
\]

is uniformly as small as possible on \([-1,1]\). CHEBYSHEV showed that the minimum occurs when

\[
x_k = \cos \left( \frac{2k + 1}{2(n+1)} \pi \right).
\]
These are called the Chebyshev nodes (note that they do not form a partition of \([-1, 1]\); the endpoints are not nodes). If the \(x_k\) are the Chebyshev nodes, the maximum value of \(q(x)\) is \(2^{-n}\), so the error in the approximation can be bounded:

\[
|f(x) - p_0,\ldots,n(x)| \leq \frac{1}{2^n(n+1)!} \sup_{-1 < c < 1} |f^{(n+1)}(c)|
\]

for \(x \in [-1, 1]\).

**V.11.7.12.** In fact, the Chebyshev approximations converge uniformly to \(f\) if \(f\) is Hölder continuous, and in particular if \(f\) is \(C^1\) or even Lipschitz (the minimal requirement to insure convergence is somewhat weaker than Hölder continuity; cf. ())). They converge rapidly if \(f\) is differentiable to high order. There are, however, examples of continuous \(f\) where the Chebyshev approximations do not converge even pointwise. In fact, for any scheme of choosing interpolation points an example of a continuous \(f\) can be concocted for which the scheme does not converge (Faber’s theorem).

**Extrapolation**

**V.11.7.13.** Because the polynomial

\[
q(x) = (x - x_0)(x - x_1) \cdots (x - x_n)
\]

grows rapidly outside the smallest interval containing \(x_0, \ldots, x_n\), the error estimate from V.11.4.5. or V.11.6.6. quickly blows up outside this interval. In fact, extrapolation using an interpolating or osculating polynomial is not generally too accurate outside the interval of nodes.

**V.11.7.14.** Using a Taylor polynomial for \(f\) at \(x_0\) to approximate \(f(x)\) for \(x \neq x_0\) is really always extrapolation, so it is not surprising that the Taylor polynomials do not always give good approximations to \(f(x)\) for a fixed \(x \neq x_0\). It is actually more surprising (from the interpolation-extrapolation point of view) that they really do give good approximations in so many important cases.

**Other Types of Approximation**

**V.11.7.15.** The Chebyshev polynomials are not usually the best uniform approximants to a smooth function \(f\). It can be shown that for any \(f\) which is continuous on \([a, b]\), there is a unique polynomial \(p\) of degree \(\leq n\) which approximates \(f\) uniformly most closely on \([-1, 1]\) (minimax approximation), i.e. for which \(\|f - p\|_{\infty}\) is minimum [existence of a minimizing polynomial is a simple compactness argument, but uniqueness is not so obvious since \(\| \cdot \|_{\infty}\) is not strictly convex], and \(p\) is an interpolation polynomial for \(f\) for some choice of \(x_0, \ldots, x_n\) (Chebyshev’s equioscillation theorem, cf. Exercise V.11.8.9.). But there is no reasonable procedure for finding the best \(x_0, \ldots, x_n\) in general, even if \(f\) is smooth, although there is an iterative procedure (the Remez algorithm) which converges rapidly in good cases. In reasonable cases, the Chebyshev polynomials come close to realizing the minimum. See [May06] for a nice discussion of Chebyshev’s equioscillation theorem with illustrative applets.

**V.11.7.16.** Another way of uniformly approximating a continuous \(f\) is by Bernstein polynomials (XV.8.1.2.). These are not interpolation polynomials and converge uniformly to \(f\) relatively slowly even if \(f\) is smooth, but they are guaranteed to converge uniformly to \(f\) for any continuous \(f\).
V.11.7.17. One can also try for approximation of \( f \) in other norms besides the uniform norm. One alternative which can be efficiently computed is using the 2-norm (least-square approximation). See (x).

V.11.7.18. One can also use other functions besides polynomials to approximate, e.g. rational functions or trigonometric functions. There is an extensive theory of such approximations, discussed in numerical analysis texts.

V.11.8. Exercises

V.11.8.1. (a) Verify the formula for the determinant of the Vandermonde matrix (V.11.1.1). [Regard \( x_0, \ldots, x_n \) successively as variables. The determinant is a polynomial in these variables which vanishes when \( x_k = x_j \) for \( j \neq k \), so \( x_k - x_j \) is a factor.]

(b) Similarly compute the determinant of the matrix in the proof of V.11.6.2. and show it is nonzero. [Experiments with small-size examples using a computer algebra system can be helpful in guessing the correct formula.]

(c) Give an alternate proof that the system of V.11.6.2. (and the special case V.11.1.1.) always has a unique solution \([\text{a solution without computing determinants, as follows. First show that the homogeneous system (all } b_k^{(j)} = 0) \text{ has a unique solution [a solution } q \text{ is a polynomial of degree } \leq n \text{ with at least } n + 1 \text{ roots, counted with multiplicity]. This implies that the matrix is invertible, so the system is uniquely solvable for any } b_k^{(j)} \text{'s.}}\]

V.11.8.2. (a) Verify the formula for \( K \) in V.11.3.1. and the formula in V.11.3.2. [Use that \( f(x_0) + (x - x_0)f(x_1) + (x - x_0)(x - x_1)f(x_0, x_1, x_2) + \cdots + (x - x_0)(x - x_1) \cdots (x - x_{n-1})f(x_0, \ldots, x_n) \)

(b) Verify the recursive formula for \( f[x_0, \ldots, x_n] \) in V.11.3.6. [Show that \( f[x_0, \ldots, x_n, x] = \sum_{k=0}^{n} f[x_k, x] \prod_{j \neq k} (x_k - x_j) \).]

V.11.8.3. Suppose \( f \) is \( C^r \) on an interval \( I \) \((r \geq 1)\), and \( x_0 \in I \). Set 

\[
g(x) = \begin{cases} 
 f[x_0, x] & \text{if } x \neq x_0 \\
 f'(x_0) & \text{if } x = x_0 
\end{cases}
\]

Show that \( g \) is \( C^{r-1} \) on \( I \).

V.11.8.4. (a) Suppose \( f \) is a function on an interval \( I \), and \( x_0, \ldots, x_n \) are distinct points of \( I \). Show that, for \( x \in I \), \( x \) not equal to any \( x_k \),

\[
f[x_0, \ldots, x_n, x] = \sum_{k=0}^{n} f[x_k, x] \prod_{j \neq k} (x_k - x_j) .
\]

(b) Suppose \( f \) is \( C^r \) on \( I \) \((r \geq 1)\). Set 

\[
g(x) = f[x_0, \ldots, x_n, x] = \sum_{k=0}^{n} f[x_k, x] \prod_{j \neq k} (x_k - x_j) 
\]

where \( f[x_k, x] \) is extended to \( x = x_k \) as in V.11.8.3.. Show that \( g \) is \( C^{r-1} \) on \( I \).
V.11.8.5. Write out the details of the proof of V.11.5.10. and V.11.5.13..

V.11.8.6. Show that the formula in V.11.6.6. gives the osculating polynomial.

V.11.8.7. Derive the formula for $p_0, \ldots, p_n$ in V.11.7.1. from V.11.3.2., and the Lagrange form in V.11.7.3. from V.11.1.3..

V.11.8.8. For $n \geq 0$, define

$$T_{n+1}(x) = (x-x_0)(x-x_1)\cdots(x-x_n)$$

where $x_0, \ldots, x_n$ are the Chebyshev nodes (V.11.7.11.). $T_{n+1}$ is called the $(n+1)$’st monic Chebyshev polynomial of the first kind. (References differ on whether to multiply by a conventional factor of $2^n$, which is why we use the term “monic Chebyshev polynomial.” We will not discuss Chebyshev polynomials of other kinds.)

(a) Show that

$$T_n(x) = 2^{-n+1} \cos(n \cos^{-1} x)$$

for $n \geq 1$ and $-1 \leq x \leq 1$. (This formula can also be used to define $T_n$ for $n = 0$.)

(b) Show that $\max_{|x| \leq 1} |T_n(x)| = 2^{-n+1}$, and that the maximum occurs precisely at the $n+1$ points $\cos \frac{k}{n}$, $0 \leq k \leq n$.

(c) Show that $T_n$ ($n \geq 1$) has the smallest uniform norm of all monic polynomials of degree $\leq n$, with real coefficients, with $n$ roots in $[-1,1]$ counted with multiplicity.

(d) Prove the recurrence formula $T_{n+1}(x) = xT_n(x) - \frac{1}{2}T_{n-1}(x)$ for $n \geq 1$.

(e) Show that $T_n$ is a solution to the differential equation

$$(1-x^2)y'' = xy' - n^2 y.$$ 

The Chebyshev polynomials also arise in least-squares approximation.

V.11.8.9. Let $f$ be a continuous function on a closed bounded interval $[a,b]$, and $n \in \mathbb{N}$.

(a) Prove using the Heine-Borel theorem that there is a polynomial $p$ of degree $\leq n$ for which $\|f-p\|_\infty$ is minimum among all polynomials of degree $\leq n$.

(b) If $p$ is a polynomial of degree $\leq n$ and there are $n+2$ distinct points $y_0, \ldots, y_{n+1}$ in $[a,b]$ (in increasing order) such that

$$f(y_k) - p(y_k) = \pm \|f-p\|_\infty$$

with alternating signs, then $\|f-p\|_\infty$ is minimum among all polynomials of degree $\leq n$. [If $q$ is a polynomial of degree $\leq n$ with $\|f-q\|_\infty < \|f-p\|_\infty$, then $q(y_k)$ is alternately greater than and less than $p(y_k)$. Thus $p-q$ is a nonzero polynomial of degree $\leq n$ with at least $n+1$ roots by the Intermediate Value Theorem.]
(c) Chebyshev’s Equioscillation Theorem states the converse to (b): a polynomial $p$ for which $\|f - p\|_\infty$ is minimum among all polynomials of degree $\leq n$ has the equioscillation property of (b).

(d) Show that the result of (c) implies that the polynomial of degree $\leq n$ of minimum uniform distance from $f$ is unique. [If $p$ and $q$ minimize distance from $f$, then so does $\phi = \frac{1}{2}(p + q)$, and thus $\phi$ has the equioscillation property.]

(e) Show by the Intermediate Value Theorem that the closest approximant $p$ is an interpolation polynomial for $f$ with nodes $x_0, \ldots, x_n$ with $y_k < x_k < y_{k+1}$ for all $k$.

V.11.8.10. Let $f(x) = \frac{1}{x^2 + 1}$. Sketch the graphs of the Taylor polynomials of $f$ around 0. On what interval do they converge to $f$? What is the radius of convergence of the Taylor series of $f$ around 0? What about the Taylor series around a general $x_0 \in \mathbb{R}$? Justify this geometrically by considering $f$ as an analytic function with poles on $\mathbb{C}$. This suggests some connection between complex poles and the Runge phenomenon; one would expect interpolating polynomials to approximate somewhat better over an interval than Taylor polynomials, but perhaps not to an unlimited extent.
V.12. How Discontinuous Can a Derivative Be?

If \( f \) is a differentiable function (on an interval, or all of \( \mathbb{R} \)), what can be said about the properties of the function \( f' \)?

V.12.1. Continuity and Measurability of Derivatives

V.12.1.1. Example. If \( f \) is differentiable, the function \( f' \) need not itself be differentiable everywhere. For perhaps the simplest example, let
\[
f(x) = \begin{cases} 
  x^2 & \text{if } x \geq 0 \\
  -x^2 & \text{if } x < 0 
\end{cases}.
\]

Then we have
\[
f'(x) = \begin{cases} 
  2x & \text{if } x \geq 0 \\
  -2x & \text{if } x < 0 
\end{cases}.
\]

(It must be shown directly from the definition of derivative that \( f'(0) \) exists and equals 0.) Thus \( f \) is differentiable everywhere, but \( f' \) is not differentiable at 0.

V.12.1.2. In this example, \( f' \) is continuous. In fact, every continuous function occurs as the derivative of a differentiable function: if \( g \) is continuous on an interval \( I \), and \( x_0 \in I \), for \( x \in I \) define
\[
f(x) = \int_{x_0}^{x} g(t) \, dt.
\]

Then, by the Fundamental Theorem of Calculus, \( f'(x) = g(x) \).

However, a derivative need not even be continuous:

V.12.1.3. Example. Let \( f(x) = x^2 \sin \frac{1}{x} \) for \( x \neq 0 \), and \( f(0) = 0 \). Then, for \( x \neq 0 \),
\[
f'(x) = 2x \sin \frac{1}{x} - \cos \frac{1}{x}.
\]

It can be checked from the definition (Exercise) that \( f'(0) \) exists and equals 0. Thus \( f \) is differentiable everywhere, but \( f' \) is not continuous at 0 since \( \lim_{x \to 0} f'(x) \) does not exist.

In this example, although \( f' \) is not continuous, it is bounded on bounded intervals, and measurable, hence Lebesgue integrable on any bounded interval, and \( f \) can be recovered from \( f' \) by
\[
f(x) = \int_0^x f'(t) \, dt
\]
where the integral is a Lebesgue integral. (In fact, since \( f' \) is bounded and continuous except at one point, it is Riemann integrable on any bounded interval, so the integral can even be taken to be a Riemann integral in this case.)

But \( f' \) need not be even locally Lebesgue integrable:
**V.12.1.4.** Example. Let $f(x) = x^2 \sin \frac{1}{x}$ for $x \neq 0$, and $f(0) = 0$. Then, for $x \neq 0$, 

$$f'(x) = 2x \sin \frac{1}{x^2} - \frac{2}{x} \cos \frac{1}{x^2}.$$ 

It can again be checked from the definition (Exercise ()) that $f'(0)$ exists and equals 0, so $f$ is differentiable, but $f'$ is unbounded and not Lebesgue integrable in any neighborhood of 0.

**V.12.1.5.** However, if $f$ is any differentiable function, then $f'$ is always locally H-K integrable to $f()$. In fact, the function $f'$ of V.12.1.4. is one of the standard examples of a function which is H-K integrable but not Lebesgue integrable.

**V.12.1.6.** The above examples of derivatives are continuous except at one point. A differentiable function can be easily constructed whose derivative has a dense set of discontinuities (Exercise V.12.3.2.). Much more extreme examples can be constructed; see Exercise V.12.3.3. for an example of a differentiable function whose derivative is discontinuous almost everywhere. One of the most extreme examples is Example () of Katznelson and Stromberg ([KS74]; cf. [vRS82, 13.2]):

**V.12.1.7.** Example. There is a differentiable function $f$ with the following properties:

(i) $|f'(x)| \leq 1$ for all $x$.

(ii) Each of the following sets is dense in $\mathbb{R}$:

- $A = \{x : f'(x) > 0\}$
- $B = \{x : f'(x) = 0\}$
- $C = \{x : f'(x) < 0\}$

(iii) $f$ is not monotone on any interval.

In fact, “many” differentiable functions satisfy (ii) and (iii) (XI.12.5.7., XI.12.5.8.). It follows from (ii) that the discontinuities of $f'$ are dense; in fact, $f'$ must be discontinuous wherever it is nonzero.

By (), $f'$ is not Riemann integrable on any interval, hence $f'$ is not continuous a.e. on any interval (). In fact, the sets $A$ and $C$ both have positive Lebesgue measure.

But the next result, combined with (), shows that the derivative of a differentiable function cannot be “too discontinuous.”

**V.12.1.8.** Proposition. If $f$ is differentiable, then $f'$ is of Baire Class 1 (), and in particular must be Lebesgue measurable, and continuous except on a meager set (which may, however, have positive Lebesgue measure (V.12.1.7., V.12.3.3.)).

**Proof:** Define

$$g_n(x) = \frac{f\left(x + \frac{1}{n}\right) - f(x)}{1/n} = n \left[f\left(x + \frac{1}{n}\right) - f(x)\right].$$

(The definition may need slight modification if working on a closed interval; see Exercise V.12.3.1.). Then each $g_n$ is continuous, and $g_n \to f'$ pointwise. \(\Box\)
V.12.2. Other Properties of Derivatives

V.12.2.1. Derivatives have another property characteristic of continuous functions: they have the Intermediate Value Property, or Darboux Property, i.e. they satisfy the conclusion of the Intermediate Value Theorem (V.8.2.13.).

V.12.2.2. So which functions are derivatives, i.e. if $g$ is a function on an interval $I$, when is there a differentiable function $f$ on $I$ with $f' = g$? This is a difficult question, and no reasonable necessary and sufficient conditions are known. It is sufficient that $g$ be continuous, but not necessary. And it is necessary that $g$ be a Baire Class 1 function with the Intermediate Value Property, but this is not sufficient either:

V.12.2.3. Example. Let $g_t(x) = 2x \sin \frac{1}{x} - \cos \frac{1}{x}$ for $x \neq 0$, and $g_t(0) = t$ (cf. V.12.1.3.). Then $g_t$ is Baire Class 1 for any $t$, and has the Intermediate Value Property if $-1 \leq t \leq 1$. But $g_t$ is a derivative if and only if $t = 0$. (The only differentiable function $f$ with $f(0) = 0$ for which $f'$ could be $g_t$ is $f(x) = x^2 \sin \frac{1}{x}$; the derivative of this $f$ is $g_0$.)

V.12.2.4. A derivative must also be H-K integrable over every closed bounded subinterval of $I$, which is a quite mild restriction, although not automatic for a Baire Class 1 function with the Intermediate Value Property (e.g. the function $g(x) = \frac{1}{x} \sin^2 \frac{1}{x}$, $g(0) = 0$.)

V.12.2.5. One can give one necessary and sufficient condition: we must have that

$$\lim_{h \to 0^+} \frac{1}{h} \int_{x_0}^{x_0+h} g(t) dt \quad \text{and} \quad \lim_{h \to 0^+} \frac{1}{h} \int_{x_0-h}^{x_0} g(t) dt$$

must both exist and be equal, for every $x_0$, and the value of $g$ at $x_0$ must be equal to this common value, i.e. for every $x_0$, the value of $g$ at $x_0$ must be approximately equal to the average value of $g$ over short intervals to the left and right of $x_0$. However, this condition is not a useful one to check in most cases. Compare with V.8.2.15. and V.9.4.11..

V.12.2.6. Example. Let $g(t) = 1$ for $t > 0$ except for thin “spikes” down to 0 around 1/n, and $g(-t) = -g(t)$ for $t > 0$. (See Fig. 651.) Then $g$ is bounded, continuous except at 0 (hence Riemann-integrable over every interval), but $\frac{1}{h} \int_0^h g(t) dt$ is approximately 1 and $\frac{1}{h} \int_{-h}^0 g(t) dt$ is approximately $-1$ if the spikes are thin enough. So $g$ is not a derivative no matter how $g(0)$ is defined, i.e. $g$ is not equal a.e. to the derivative of an everywhere differentiable function. If $-1 \leq g(0) \leq 1$, then $g$ has the Intermediate Value Property.

See the article [] for more information on which functions are derivatives.

V.12.3. Exercises

V.12.3.1. Let $f$ be a differentiable function on a closed bounded interval $[a, b]$. Find a sequence of continuous functions on $[a, b]$ converging pointwise to $f'$. [Modify the functions $g_n$ in the proof of V.12.1.8. on $[b - \frac{1}{n}, b]$.]
V.12.3.2.  Let $\phi(x) = x^2 \sin \left( \frac{x}{2} \right)$ for $x \neq 0$ and $\phi(0) = 0$. Then $\phi$ is differentiable everywhere (\).

(a) Show that $|\phi(x)| \leq 1$ and $|\phi'(x)| \leq 3$ for $x \in [-1, 1]$.

(b) Let $(q_k)$ be an enumeration of the rationals in $[0, 1]$, and for each $k$ set $f_k(x) = 2^{-k} \phi(x - q_k)$. Then $f_k$ is differentiable everywhere, $|f_k(x)| \leq \frac{1}{2^k}$ and $|f'(x)| \leq \frac{1}{2^k}$ for $x \in [0, 1]$.

(c) Show that $f_k(x)$ is differentiable everywhere.

(d) Show that $f_k(x)$ is differentiable everywhere.

V.12.3.3.  [vRS82, 14.3–14.5] If $I = [a, b]$ is a closed bounded interval, let $g_I$ be the function with graph as in Figure (\), with $L_I = \frac{b-a}{4}$.

(a) Let $f_I$ be an antiderivative of $g_I$ with $f_I(a) = 0$. Show that $f(b) = 0$ and $0 \leq f(x) \leq L_I^2$ for all $x \in [a, b]$.

(b) Let $K$ be a Cantor set of positive measure in $[0, 1]$, and $(I_n)$ an enumeration of the closures of the open intervals in $[0, 1] \setminus K$. Let $f$ be the function on $[0, 1]$ which is 0 on $K$ and $f_{I_n}$ on $I_n$, and similarly $g$ the function which is 0 on $K$ and $g_{I_n}$ on $I_n$. Show that $f$ is differentiable on $[0, 1]$ and $f' = g$. [It is only necessary to show that $f'(a) = 0$ for $a \in K$. If $f(x) \neq 0$, then $x \in I_n$ for some $n$, so

$$\left| \frac{f(x) - f(a)}{x - a} \right| = \frac{f_{I_n}(x)}{|x - a|} \leq \frac{L_{I_n}^2}{|x - a|} \leq |x - a|$$

since $|x - a| \geq L_{I_n}$.]

(c) Show that for $a \in K$, $\limsup_{x \to a} g(x) = 1$, so $g$ is discontinuous at each point of $K$, i.e. $f'$ is discontinuous on a set of positive measure.

(d) Show that for $a \in K$, $\liminf_{x \to a} g(x) = 0$, so $g$ is lower semicontinuous.

(e) Let $K_n$ be a Cantor set in $[0, 1]$ of measure $1 - \frac{1}{n}$, and $h_n$ the $g$ constructed as above for $K_n$. Set $h = \sum_{n=1}^{\infty} 2^{-n} h_n$. Then $h$ has an antiderivative $\phi$ on $[0, 1]$ (\).

(f) Since each $h_n$ is lower semicontinuous, $h$ is discontinuous wherever one of the $h_n$ is discontinuous (\). Thus $h$ is discontinuous at all points of $\cup K_n$, i.e. $\phi'$ is discontinuous a.e.

V.12.3.4.  [vRS82, 14.J] Let $g$ be a Darboux continuous function on an interval $I$ which is of Baire Class 1 (e.g. $g = f'$ for a differentiable function $f$ on $I$). Show that the graph of $g$ is connected.
When is a function $f$ from $\mathbb{R}$ (or $[a,b]$) to $\mathbb{R}$ the derivative of an everywhere differentiable function? Necessary conditions:

(1) $f$ is Baire class 1, i.e. a pointwise limit of a sequence of continuous functions [if $f = F'$, set $f_n(t) = n[F(t + 1/n) - F(t)]$; then $f_n$ is continuous and $f_n \to f$.] This implies:

   (a) $f$ is Lebesgue measurable.

   (b) $f$ is continuous except on a set of first category [\cite{?}].

(2) $f$ is Henstock-Kurzweil integrable on every bounded interval [\cite{?}].

(3) $f$ has the Intermediate Value Property.

These properties are not sufficient:

**Examples.**

(i) Let $f(t) = \sin(1/t)$ for $t \neq 0$. For any $\alpha$, $-1 \leq \alpha \leq 1$, define $f(0) = \alpha$. Then $f$ has the above properties, but is a derivative if and only if $\alpha = 0$.

(ii) Let $f(t) = 1$ for $t > 0$ except for thin “spikes” down to 0 around $1/n$, and $f(-t) = -f(t)$ for $t > 0$, $f(0) = 0$. Then $f$ has the above properties, is bounded, continuous except at 0, but not equal a.e. to the derivative of an everywhere differentiable function.
V.13. The Gamma Function

The Gamma function, while not as well known as trigonometric, exponential, and logarithm functions, is of comparable importance in both theoretical and applied mathematics, and notably in probability and statistics. In this section, we will only develop the most basic aspects of the theory of this function.

The origin of the Gamma function was an attempt to find an analytic expression for the factorial function and extend its definition from \( \mathbb{N} \) to \( \mathbb{R} \). Euler found both infinite product and improper integral formulas for \( n! \), both of which also make sense for nonintegral \( n \):

\[
n! = \prod_{k=1}^{\infty} \left( 1 + \frac{1}{k} \right)^n = \int_0^1 (-\log s)^n \, ds .
\]

V.13.1. Definition of the Gamma Function

Legendre (1811) used the integral expression of Euler, modified by the substitution \( t = -\log s \), to give the first formal definition of the Gamma function:

V.13.1.5. Definition. If \( x > 0 \), define

\[
\Gamma(x) = \int_0^\infty t^{x-1} e^{-t} \, dt .
\]

Note that Legendre’s definition, for unknown reasons, has a shift of 1 in the argument, so that \( \Gamma(n) = (n-1)! \) for \( n \in \mathbb{N} \). It has remained the convention in mathematics to this day to include this shift, although it has dubious practical merit.

V.13.1.6. Proposition. The improper Riemann integral \( \int_0^\infty t^{x-1} e^{-t} \, dt \) converges for \( x > 0 \) (and only for \( x > 0 \)).

Proof: The integrand is continuous and positive on \((0, \infty)\), hence the Riemann integral over any closed bounded subinterval is defined. The integral \( \int_0^\infty \) converges if and only if \( I_1 = \int_0^1 \) and \( I_2 = \int_1^\infty \) both converge. For \( I_1 \), note that \( t^{x-1} e^{-t} < t^{x-1} \) for \( 0 < t \leq 1 \), and \( \int_0^1 t^{x-1} \, dt \) converges for \( x > 0 \). (For the parenthetical assertion, \( t^{x-1} e^{-t} \geq e^{-1} t^{x-1} \) for \( 0 < t \leq 1 \), and \( \int_0^1 t^{x-1} \, dt \) diverges for \( x \leq 0 \).)

For \( I_2 \), note that, for any \( x \in \mathbb{R} \),

\[
\lim_{t \to +\infty} \frac{t^{x-1}}{e^{t/2}} = 0
\]

by (), and hence \( t^{x-1} e^{-t} < e^{-t/2} \) for all sufficiently large \( t \). Since \( \int_1^\infty e^{-t/2} \, dt \) converges, so does \( I_2 \) for any \( x \in \mathbb{R} \).

The next result gives a crucial factorial-like recurrence property of the Gamma function.
V.13.7. PROPOSITION. If \( x > 0 \), then \( \Gamma(x + 1) = x\Gamma(x) \).

PROOF: Let \( 0 < a < b < \infty \). Compute the integral \( \int_{a}^{b} t^{x} e^{-t} dt \) by parts:

\[
\int_{a}^{b} t^{x} e^{-t} dt = \left[ -t^{x} e^{-t} \right]_{a}^{b} - \int_{a}^{b} x t^{x-1} (-e^{-t}) dt
\]

\[
= -a^{x} e^{-a} + b^{x} e^{-b} + x \int_{a}^{b} t^{x-1} e^{-t} dt .
\]

As \( a \to 0 \) and \( b \to +\infty \), the original integral approaches \( \Gamma(x + 1) \) and the final expression approaches \( x\Gamma(x) \).

V.13.8. COROLLARY. If \( n \in \mathbb{N} \cup \{0\} \), then \( \Gamma(n + 1) = n! \). [Recall that \( 0! = 1 \) by definition.]

PROOF: This is an easy proof by induction using the recurrence formula and the direct computation

\[
\Gamma(1) = \int_{0}^{\infty} e^{-t} dt = \lim_{b \to +\infty} \int_{0}^{b} e^{-t} dt = \lim_{b \to +\infty} [-e^{-t}]_{0}^{b} = \lim_{b \to +\infty} [-e^{-b} + 1] = 1 = 0! .
\]

So the Gamma function extends the (shifted) factorial function to \((0, \infty)\). This extension has the desired analytic property:

V.13.9. THEOREM. The Gamma function is real analytic (and in particular \( C^{\infty} \)) on \((0, \infty)\), and

\[
\Gamma^{(n)}(x) = \int_{0}^{\infty} t^{x-1} e^{-t} (\log t)^{n} dt .
\]

This is a special case of the general result concerning differentiation under the integral sign. It is routine to show that the integral giving \( \Gamma^{(n)}(x) \) converges for \( x > 0 \), and this follows anyway from the general theory.

V.13.10. NOT MANY VALUES OF \( \Gamma(x) \) FOR NONINTEGER \( x \) CAN BE COMPUTED EXACTLY (OF COURSE, MODERN COMPUTERS CAN EASILY CALCULATE VALUES TO GREAT NUMERICAL ACCURACY). ONE IMPORTANT VALUE WHICH CAN BE COMPUTED IS

\[
\Gamma \left( \frac{1}{2} \right) = \sqrt{\pi} .
\]
V.13.2. Log-Convexity and a Characterization of the Gamma Function

V.13.2.11. The Gamma function is far from the only function on \((0, \infty)\) extending the (shifted) factorial: an extension can be defined arbitrarily for nonintegers. \(\Gamma\) is not even the only real-analytic function extending the factorial: if \(f\) is any real-analytic function vanishing at the positive integers, e.g. \(f(x) = \sin \pi x\), then \(\Gamma + f\) is an extension.

Satisfying the functional equation \(g(x + 1) = xg(x)\) for all \(x > 0\) is only slightly more difficult to achieve. In fact, if a function \(g\) is defined arbitrarily on \((0, 1)\), set \(g(1) = 1\) and extend \(g\) by repeatedly applying the functional equation. It is not even hard to find another real-analytic extension satisfying the functional equation, e.g. \(g(x) = \Gamma(x)(1 + \sin 2\pi x)\) \((1 + \sin 2\pi x\) can be replaced by any periodic real-analytic function \(f\) with period 1 and \(f(1) = 1\).

V.13.2.12. However, \(\Gamma\) seems to be the “simplest” and/or “most natural” extension, due to the multitude of formulas for it and its appearance in many contexts. Many leading mathematicians over almost a 200-year period tried to make this precise with a natural characterization, with varied success. The best characterization (to date) was obtained in 1922 by H. Bohr and J. Mollerup using the notion of log-convexity.

V.13.2.13. It is immediate from V.13.1.9. that \(\Gamma''(x) > 0\) for \(x \in (0, \infty)\), and thus that \(\Gamma\) is a convex function on \((0, \infty)\). But more is true.

V.13.2.14. **Definition.** If \(I\) is an interval, a function \(g : I \to (0, \infty)\) is log-convex on \(I\) if \(\log g\) is convex on \(I\).

V.13.2.15. Alternatively, a positive function \(g\) on an interval \(I\) is log-convex on \(I\) if, for all \(a, b \in I\), \(0 \leq \lambda \leq 1\),

\[
g(\lambda a + (1 - \lambda)b) \leq g(a)^\lambda g(b)^{1 - \lambda}.
\]

The right-hand side is a sort of weighted geometric mean of \(g(a)\) and \(g(b)\). If \(g\) is continuous, then by (\() \) \(g\) is log-convex if and only if, for every \(a, b \in I\),

\[
g \left( \frac{a + b}{2} \right) \leq \sqrt{g(a)g(b)}.
\]

V.13.2.16. **Proposition.** A log-convex function is convex.

**Proof:** Let \(g\) be log-convex on \(I\), and let \(a, b \in I\), and \(0 \leq \lambda \leq 1\). Since the log function is concave, we have

\[
\log(\lambda g(a) + (1 - \lambda)g(b)) \geq \lambda \log g(a) + (1 - \lambda) \log g(b).
\]

On the other hand, since \(g\) is log-convex, we have

\[
\log g(\lambda a + (1 - \lambda)b) \leq \lambda \log g(a) + (1 - \lambda) \log g(b).
\]

Combining these, we get

\[
\log g(\lambda a + (1 - \lambda)b) \leq \log(\lambda g(a) + (1 - \lambda)g(b))
\]

and it follows that \(g(\lambda a + (1 - \lambda)b) \leq \lambda g(a) + (1 - \lambda)g(b)\) since the log function is increasing. \(\diamond\)
V.13.2.17. The converse is false. \( g(x) = x^2 \) is convex on \( (0, \infty) \), but not log-convex on any subinterval. In fact, an increasing log-convex function on an interval \( (a, \infty) \) must grow at least exponentially as \( x \to +\infty \).

V.13.2.18. Since a sum of convex functions is convex, it is obvious that a product of log-convex functions is log-convex. It is also clear that a positive scalar multiple of a log-convex function is log-convex. It is less obvious, but true, that a sum of log-convex functions is log-convex (XIV.15.5.7.).

V.13.2.19. Lemma. Let \( a_1, a_2, b_1, b_2, c_1, c_2 \) be positive real numbers. If \( a_1c_1 - b_1^2 \geq 0 \) and \( a_2c_2 - b_2^2 \geq 0 \), then

\[
(a_1 + a_2)(c_1 + c_2) - (b_1 + b_2)^2 \geq 0.
\]

Proof: If \( a, b, c \) are positive real numbers, then the polynomial \( f(x) = ax^2 + 2bx + c \) takes only nonnegative real values (for \( x \) real) if and only if \( ac - b^2 \geq 0 \). By assumption, the polynomials \( f_1(x) = a_1x^2 + 2b_1x + c_1 \) and \( f_2(x) = a_2x^2 + 2b_2x + c_2 \) take only nonnegative real values, and hence

\[
f_1(x) + f_2(x) = (a_1 + a_2)x^2 + 2(b_1 + b_2)x + (c_1 + c_2)
\]

also takes only nonnegative real values.

V.13.2.20. Proposition. A sum of log-convex functions on an interval \( I \) is log-convex on \( I \).

Proof: Since log-convex functions are continuous, by XIV.15.5.2. it suffices to show that if \( f \) and \( g \) are log-convex on \( I \) and \( x, y \in I \), then

\[
\left[ f \left( \frac{x+y}{2} \right) + g \left( \frac{x+y}{2} \right) \right]^2 \leq (f(x) + g(x))(f(y) + g(y))
\]

Apply XIV.15.5.6. with \( a_1 = f(x), a_2 = g(x), b_1 = f \left( \frac{x+y}{2} \right), b_2 = g \left( \frac{x+y}{2} \right), c_1 = f(y), c_2 = g(y) \).

V.13.2.21. The conclusion of XIV.15.5.7. extends to arbitrary finite sums. Since a positive pointwise limit of log-convex functions is obviously log-convex, it also extends to a positive pointwise limit of finite sums of log-convex functions, e.g. a pointwise-convergent infinite series. By approximating the integrals by Riemann sums, we also obtain:

V.13.2.22. Proposition. Let \( f \) be a function on \( I \times [a,b] \) for some interval \( I \) and \( a, b \in \mathbb{R}, a < b \). If \( f(x, t) \) is log-convex on \( I \) for each fixed \( t \), and \( f(x, t) \) is continuous on \( [a, b] \) for each fixed \( x \), then

\[
g(x) = \int_a^b f(x, t) \, dt
\]

is log-convex on \( I \).

Proof: Let \( n \in \mathbb{N} \) and \( h = \frac{b-a}{n} \). Then \( g_n(x) = h(f(x, a) + f(x, a+h) + \cdots + f(x, a+(n-1)h) \) is log-convex, and \( g_n \to g \) pointwise. Since \( f \) is strictly positive, it is obvious that \( g \) is also strictly positive.

This result extends to improper integrals:
V.13.2.23. **Corollary.** Let \( f \) be a function on \( I \times (a, b) \) for some interval \( I \) and \( a, b \in [-\infty, \infty], \ a < b. \) If \( f(x, t) \) is log-convex on \( I \) for each fixed \( t, f(x, t) \) is continuous on \( (a, b) \) for each fixed \( x, \) and the improper Riemann integral \( \int_a^b f(x, t) \, dt \) converges for all \( x \in I, \) then

\[ g(x) = \int_a^b f(x, t) \, dt \]

is log-convex on \( I. \)

**Proof:** Let \( (a_n) \) be a decreasing sequence with \( a_n \to a, \) \( (b_n) \) an increasing sequence with \( b_n \to b, \) \( a_n < b_n \) for all \( n. \) Set

\[ g_n(x) = \int_{a_n}^{b_n} f(x, t) \, dt. \]

Then \( g_n \) is log-convex on \( I \) for all \( n \) by XIV.15.5.9., and \( g_n \to g \) pointwise on \( I. \) It is also clear that \( g \) is strictly positive.

The next theorem is the main result of this section. Our proof is adapted from the Planet Math website http://planetmath.org/?op=getobj&from=objects&id=3808.

V.13.2.24. **Theorem.** The Gamma function is log-convex on \( (0, \infty). \)

**Proof:** We have that \( \Gamma(x) \in (0, \infty) \) for \( x > 0. \) Let \( a, b > 0 \) and \( 0 \leq \lambda \leq 1. \)

\[ \log \Gamma(\lambda a + (1 - \lambda)b) = \log \int_0^\infty e^{-t} t^{\lambda a + (1 - \lambda)b - 1} \, dt = \log \int_0^\infty (e^{-t} t^{a - 1})^\lambda (e^{-t} t^{b - 1})^{1 - \lambda} \, dt. \]

Apply Hölder’s inequality \( ( ) \) with \( p = \frac{1}{\lambda} \) and \( q = \frac{1}{1 - \lambda} \) to obtain

\[ \log \int_0^\infty (e^{-t} t^{a - 1})^\lambda (e^{-t} t^{b - 1})^{1 - \lambda} \, dt \leq \log \left( \left( \int_0^\infty e^{-t} t^{a - 1} \, dt \right)^\lambda \left( \int_0^\infty e^{-t} t^{b - 1} \, dt \right)^{1 - \lambda} \right) \]

\[ = \lambda \log \Gamma(a) + (1 - \lambda) \log \Gamma(b). \]

Theorem. [Bohr-Mollerup] The Gamma function is the unique function \( g \) on \( (0, \infty) \) which is log-convex and satisfies \( g(1) = 1 \) and \( g(x + 1) = xg(x) \) for all \( x > 0. \)

**Proof:** Since \( \Gamma \) satisfies the conditions, we need only prove uniqueness. In fact, it suffices to show that the conditions uniquely determine a function on \( (0, 1), \) since the rest of the values are then uniquely determined by the recurrence formula.

So let \( g \) be a function satisfying the conditions, \( 0 < x < 1, \) and \( n \in \mathbb{N}. \) Using \( n + x = (1 - x)n + x(n + 1), \) we have

\[ g(n + x) \leq g(n)^{1-x} g(n + 1)^x = g(n)^{1-x} g(n)^x n^x = (n - 1)! n^x. \]
Similarly, \( n + 1 = x(n + x) + (1 - x)(n + 1 + x) \), so \( n! \leq g(n + x)(n + x)^{1-x} \).

Combining these two we get

\[
n!(n + x)^{x-1} \leq g(n + x) \leq (n - 1)!n^x
\]

and by using the recurrence relation to obtain \( g(n + x) = x(x + 1)(x + 2) \cdots (x + n - 1) \),

\[
a_n := \frac{n!(n + x)^{x-1}}{x(x + 1) \cdots (x + n - 1)} \leq g(x) \leq \frac{(n - 1)!n^x}{x(x + 1) \cdots (x + n - 1)} =: b_n .
\]

These inequalities hold for every positive integer \( n \). We have

\[
\lim_{n \to \infty} \frac{b_n}{a_n} = \lim_{n \to \infty} \left( \frac{n}{n + x} \right)^{x-1} = 1
\]

so

\[
1 \leq \frac{g(x)}{a_n} \leq \frac{b_n}{a_n} \to 1
\]

and thus \( g(x) = \lim_{n \to \infty} a_n \), so \( g \) is uniquely determined.

As a corollary of the proof, we get a formula for the unique solution, which must be \( \Gamma \). This formula is due to Gauss, and is equivalent to Euler’s infinite product formula from the introduction to the section.

\textbf{V.13.2.26. Corollary.} For \( 0 < x \leq 1 \)

\[
\Gamma(x) = \lim_{n \to \infty} \frac{n!n^x}{x(x + 1) \cdots (x + n)} .
\]

\textbf{V.13.3. Miscellaneous Additional Results}

We give only a few additional sample results about the Gamma function. More are pursued in the Exercises.

\textbf{V.13.3.27.} The integral definition of \( \Gamma(x) \) makes sense if \( x \) is a complex number with positive real part, and defines a complex analytic function on the right half of the complex plane. This function can be analytically continued to the entire complex plane, with simple poles at the nonpositive integers. In fact, Gauss’s formula (V.13.2.26) holds for any complex number \( x \) which is not a nonpositive integer. It turns out that this complex \( \Gamma \) has no zeros, so the reciprocal is an entire function.

\textbf{V.13.3.28.} Unlike the trigonometric, exponential, and logarithm functions, the Gamma function does not satisfy any \textit{algebraic differential equation} (roughly, a differential equation whose coefficient functions are algebraic functions). This theorem was proved by Hölder in 1887. In particular, there is no formula for the derivative or antiderivative of the Gamma function in terms of standard functions, including the Gamma function itself.
There is an almost bewildering array of other formulas, identities, and applications related to the Gamma function. There are entire books (e.g. [Art64]) written on the subject. See [Dav59] for a good survey of the history and importance of this function. In Davis’s words, “[E]ach generation has found something of interest about the gamma function. Perhaps the next generation will also.”
V.13.4. Stirling’s Formula

In this section, we establish an important and useful approximation to the factorial and gamma functions, attributed to James Stirling (1730), but primarily due to A. de Moivre.

V.13.4.1. Theorem. [Stirling’s Formula] For any \( n \in \mathbb{N} \), we have

\[
\sqrt{2\pi n} \, n^n e^{-n} < n! < \sqrt{2\pi n} \, n^n e^{-n} e^{\frac{1}{12n}}.
\]

In particular,

\[
\lim_{n \to \infty} \frac{n!}{\sqrt{2\pi n} \, n^n e^{-n}} = 1.
\]

More generally,

\[
\lim_{x \to +\infty} \frac{\Gamma(x)}{\sqrt{\frac{2\pi}{x} x^x e^{-x}}} = 1.
\]

Informally, we have the approximation

\[
n! \approx \sqrt{2\pi n} \, n^n e^{-n} = \sqrt{2\pi n} \left( \frac{n}{e} \right)^n
\]

\[
\Gamma(x) \approx \sqrt{\frac{2\pi}{x} x^x e^{-x}} = \sqrt{\frac{2\pi}{x} \left( \frac{x}{e} \right)^x}
\]

for \( n \in \mathbb{N}, x > 0 \). The theorem gives precise error estimates. Better error estimates can be obtained by making more careful estimates along the way in the proof; see Exercise ()

V.13.4.2. Stirling’s formula can be written as

\[
n \log n - n + \frac{1}{2} \log(2\pi n) < \log(n!) < n \log n - n + \frac{1}{2} \log(2\pi n) + \frac{1}{12n}.
\]

A crude version of this formula can be obtained by approximating

\[
\log(n!) = \sum_{k=1}^{n} \log k = \sum_{k=2}^{n} \log k
\]

by integrals. We have

\[
\int_{1}^{n} \log x \, dx < \log(n!)
\]

\[
< \int_{2}^{n+1} \log x \, dx = (n + 1) \log(n + 1) - (n + 1) - (2 \log 2 - 2) = n \log(n + 1) - n + \log(n + 1) + (1 - 2 \log 2).
\]

This gives

\[
e \left( \frac{n}{e} \right)^n = n^n e^{-n+1} < n! < \frac{e}{4} (n+1)^{n+1} e^{-n} = \frac{e(n+1)}{4} \left( \frac{n+1}{e} \right)^n.
\]
Better approximations can be made using the Euler-Maclaurin formula to compute the difference between 
\( \log(n!) \) and \( \int_1^n \log x \, dx \), and the theorem can be proved this way. See ( ).

We will proceed differently. The proof we give consists of a sequence of calculations, some of which yield other formulas of interest.

V.13.4.3. Recall that if \( |x| < 1 \), we have

\[ \log(1 + x) = \sum_{k=1}^{\infty} \frac{(-1)^{k+1}}{k} x^k. \]

Thus, we have, for \( |x| < 1 \), combining terms and using some reindexing,

\[
\log \left( \frac{1 + x}{1 - x} \right) = \log(1 + x) - \log(1 - x) = \sum_{k=1}^{\infty} \frac{(-1)^{k+1}}{k} x^k - \sum_{k=1}^{\infty} \frac{(-1)^{k+1}}{k} (-x)^k
= \sum_{k=1}^{\infty} \frac{(-1)^{k+1}}{k} x^k + \sum_{k=1}^{\infty} -\frac{1}{k} x^k = \sum_{k=0}^{\infty} \frac{2}{2k + 1} x^{2k+1} = \frac{2x}{2k + 1} x^{2k+1}.
\]

This is in itself a useful formula.

V.13.4.4. Now set \( x = \frac{1}{2n+1} \) for \( n \in \mathbb{N} \). Then \( \frac{1+x}{1-x} = \frac{n+1}{n} = 1 + \frac{1}{n} \), so we obtain

\[
\left( n + \frac{1}{2} \right) \log \left( 1 + \frac{1}{n} \right) = \sum_{k=0}^{\infty} \frac{1}{2k + 1} \left( \frac{n+1}{n} \right)^{2k}.
\]

Therefore

\[
\left( n + \frac{1}{2} \right) \log \left( 1 + \frac{1}{n} \right) < 1 + \frac{1}{3} \sum_{k=1}^{\infty} \frac{1}{(2n+1)^{2k}}
\]

and the last sum is a geometric series with sum

\[
\frac{1}{1 - \left( \frac{1}{2n+1} \right)^2} = \frac{1}{(2n+1)^2 - 1} = \frac{1}{4n(n+1)}
\]

so we obtain the estimates

\[
1 < \left( n + \frac{1}{2} \right) \log \left( 1 + \frac{1}{n} \right) < 1 + \frac{1}{12n(n+1)}
\]

\[
e < \left( 1 + \frac{1}{n} \right)^{n+\frac{1}{2}} < e^{\frac{1}{12n(n+1)}}
\]

\[
1 < \frac{1}{e} \left( 1 + \frac{1}{n} \right)^{n+\frac{1}{2}} < e^{\frac{1}{12n(n+1)}}
\]

for \( n \in \mathbb{N} \).
V.13.4.5. Now set \( a_n = n!e^{-n}n^{-\frac{1}{2}} \), \( y_n = e^{-\frac{1}{12n}} \).

We have
\[
1 < \frac{a_n}{a_{n+1}} = \frac{1}{e} \left(1 + \frac{1}{n}\right)^{n+\frac{1}{2}} < e^{\frac{1}{12(n+1)}} = \frac{y_{n+1}}{y_n}.
\]

Thus the sequence \((a_n)\) is nonnegative and decreasing, hence converges to a limit \( a \). The sequence \((a_ny_n)\) is increasing, and since \( y_n \to 1 \), \( a_ny_n \to a \), and \( a_ny_n < a < a_n \) for all \( n \). Thus
\[
a < a_n < ae^{\frac{1}{12n}}
\]
for all \( n \). Since
\[
n! = a_n\sqrt{n}n^ne^{-n}
\]
we obtain that
\[
a\sqrt{n}n^ne^{-n} < n! < a\sqrt{n}n^ne^{-n}e^{\frac{1}{12n}}
\]
for \( n \in \mathbb{N} \). (This version is due to DE MOIVRE.)

V.13.4.6. It remains to show that \( a = \sqrt{2\pi} \) (this was STIRLING’s contribution to the formula).

V.13.4.7. To obtain the formula for the Gamma function, note that
\[
\lim_{n \to \infty} \frac{n\Gamma(n)}{\sqrt{2\pi n}n^ne^{-n}} = \lim_{n \to \infty} \frac{n!}{\sqrt{2\pi n}n^ne^{-n}} = 1
\]
\[
\lim_{n \to \infty} \frac{\Gamma(n)}{\sqrt{\frac{2\pi}{n}}n^ne^{-n}} = 1.
\]

To transition to the limit as \( x \to +\infty \) through positive real numbers, use XIV.15.7.10. and log convexity of the Gamma function:

The proof using the Euler-Maclaurin formula works directly for the Gamma function for \( x > 0 \) (and even for complex numbers away from the negative real axis). See, for example, [Str81, p. 468].

V.13.4.8. There is a more precise series giving an approximation to the factorial and the gamma function:
\[
n! \approx \sqrt{2\pi n}n^ne^{-n}\left[1 + \frac{1}{12n} + \frac{1}{288n^2} - \frac{139}{51840n^3} - \frac{571}{2488320n^4} + \ldots\right]
\]
\[
\Gamma(x) \approx \sqrt{\frac{2\pi}{x}}x^xe^{-x}\left[1 + \frac{1}{12x} + \frac{1}{288x^2} - \frac{139}{51840x^3} - \frac{571}{2488320x^4} + \ldots\right]
\]

(the coefficients have a closed formula which is complicated; see e.g. http://mathworld.wolfram.com/StirlingsSeries.html.)

This is an asymptotic expansion () and not a convergent series: for fixed \( n \) or \( x \) adding more terms eventually gives a worse approximation. The relative error after taking finitely many terms is always smaller than the next term.

663
V.13.4.9. By approximating the terms in the asymptotic expansion, we obtain a better asymptotic formula for $n!$:

$$n! \approx \sqrt{\pi(n/e)^n} \left(2n + \frac{1}{3}\right)^{n}.$$ 

This approximation is due to R. W. Gosper.

V.13.4.10. Another numerically efficient approximation, due to G. Nemes [?], is

$$\Gamma(x) \approx \sqrt{\frac{2\pi}{x}} \left[ \frac{1}{e} \left( x + \frac{1}{12x - \frac{1}{10x}} \right) \right]^x.$$ 

V.13.5. Exercises
V.14. The Volume of the Unit Ball in $\mathbb{R}^n$

Throughout this section, we will use the Euclidean norm
\[
\| (x_1, \ldots, x_n) \| = \sqrt{x_1^2 + \cdots + x_n^2}.
\]

Recall that the closed unit ball and unit sphere in $\mathbb{R}^n$ are
\[
B^n = \{ x \in \mathbb{R}^n : \| x \| \leq 1 \}
\]
\[
S^{n-1} = \{ x \in \mathbb{R}^n : \| x \| = 1 \}.
\]

Our objective in this section is to compute the Lebesgue measure $\beta_n = \lambda^n(B^n)$ of the unit ball in $\mathbb{R}^n$. These numbers will be needed for a number of purposes, such as the development of Hausdorff measure, and are intimately tied up with the measure theory of hypersurfaces and other subsets of Euclidean space (such as the $(n-1)$-dimensional “hypersurface area” of $S^{n-1}$).

V.14.0.1. We can compute $\beta_n$ for small values of $n$ by elementary or calculus methods:

We have $\beta_1 = \lambda([-1,1]) = 2$.

We have that $\beta_2$ is the area of the unit disk in $\mathbb{R}^2$. This can be computed as in (1) or (1) to obtain $\beta_2 = \pi$.

Using spherical coordinates (1), we may obtain $\beta_3 = \frac{4}{3} \pi$.

Actually, $\beta_n$ can be calculated for any $n$ just using calculus, either directly (Exercise V.14.4.1.) or using “hyperspherical” coordinates (Exercise V.14.4.2.). However, the formula obtained in this way becomes increasingly complicated for large $n$. (Try to guess the right formula!)

Instead, we will use some machinery from measure theory to rather painlessly compute a simple formula for $\beta_n$. This argument is adapted from [Fol99, 2.7].

V.14.1. Radial Borel Sets and Functions

Fix an $n$. We will examine radially symmetric sets in $\mathbb{R}^n$.

V.14.1.2. Definition. A subset $S$ of $\mathbb{R}^n$ is radially symmetric if $x \in S$, $\| y \| = \| x \|$ imply $y \in S$.

$B^n$ and $S^{n-1}$ are radially symmetric sets in $\mathbb{R}^n$. A set is radially symmetric if and only if it is a union of spheres of various radii around the origin.

V.14.1.3. If $A \subseteq [0, \infty)$, the symmetrization of $A$ in $\mathbb{R}^n$ is
\[
s_n(A) = \{ x \in \mathbb{R}^n : \| x \| \in A \}.
\]

It is clear that $s_n(A)$ is radially symmetric. Conversely, identify $[0, \infty)$ with the ray
\[
R_+^{(n)} = \{ (t, 0, \ldots, 0) : t \in [0, \infty) \} \subseteq \mathbb{R}^n.
\]

If $S \subseteq \mathbb{R}^n$ is radially symmetric, set $A = S \cap R_+^{(n)}$; then $S = s_n(A)$. 665
V.14.1.4. If $A$ is a subset of $[0, \infty)$, then $s_n(A) = f^{-1}(A)$, where $f : \mathbb{R}^n \to \mathbb{R}$ is the norm function $f(x) = \|x\|$. Since $f$ is continuous, if $B \subseteq [0, \infty)$ is a Borel set, then $s_n(B)$ is a Borel set in $\mathbb{R}^n$. Conversely, if $S$ is a radially symmetric Borel set in $\mathbb{R}^n$, then $B = S \cap R_+^{(n)}$ is a Borel set in $[0, \infty)$ with $S = s_n(B)$.

V.14.1.5. Definition. A radial Borel set is a radially symmetric Borel subset of $\mathbb{R}^n$. Let $R^{(n)}$ be the set of all radial Borel sets in $\mathbb{R}^n$.

The next proposition is obvious, since the collection of radially symmetric subsets of $\mathbb{R}^n$ is closed under unions, intersections, and complements.

V.14.1.6. Proposition. $R^{(n)}$ is a sub-$\sigma$-algebra of $B^{(n)}$.

V.14.1.7. Definition. A function $f : \mathbb{R}^n \to \mathbb{R}$ is radially symmetric if $\|x\| = \|y\|$ implies $f(x) = f(y)$. If $g : [0, \infty) \to \mathbb{R}$, the symmetrization $s_n(g)$ is defined by $[s_n(g)](x) = g(\|x\|)$. Then $s_n(g)$ is radially symmetric, and every radially symmetric function is of this form.

V.14.1.8. Proposition. (i) A function $f : \mathbb{R}^n \to \mathbb{R}$ is $R^{(n)}$-measurable if and only if it is Borel measurable and radially symmetric.

(ii) If $g : [0, \infty) \to \mathbb{R}$, then $s_n(g)$ is $R^{(n)}$-measurable if and only if $g$ is Borel measurable.

Proof: If $f$ is $R^{(n)}$-measurable, then $f$ is Borel measurable since $R^{(n)} \subseteq B^{(n)}$, and $\{x : f(x) = \alpha\} \in R^{(n)}$ for any $\alpha \in \mathbb{R}$, so $f$ is radially symmetric. The converse and (ii) are obvious from the fact that $R^{(n)}$ consists precisely of the radially symmetric Borel sets, the symmetrizations of Borel sets in $[0, \infty)$.

The main result of this subsection is:

V.14.1.9. Theorem. Let $g$ be a nonnegative Borel measurable function on $[0, \infty)$. Then

$$\int_{\mathbb{R}^n} s_n(g) d\lambda^{(n)} = n \beta_n \int_0^\infty r^{n-1} g(r) d\lambda(r).$$

Proof: We first prove the result for “annuli.” Let $S = s_n((a, b])$, where $0 \leq a < b < \infty$. Then $S$ is a set-theoretic difference of two closed balls around the origin, so by the scaling invariance of $\lambda^{(n)}$ we have

$$\int_{\mathbb{R}^n} \chi_S d\lambda^{(n)} = \lambda^{(n)}(S) = \beta_n(b^n - a^n) = n \beta_n \int_0^\infty r^{n-1} \chi_{(a, b]}(r) d\lambda(r).$$

Now let $S$ be the collection of all subsets of $\mathbb{R}^n$ of the form $s_n((a, b])$ as above. Then $S$ is a semialgebra, and the $\sigma$-algebra generated by $S$ is $R^{(n)}$. Let $\mu$ be the measure on $(\mathbb{R}^n, R^{(n)})$ given by

$$\mu(s_n(B)) = n \beta_n \int_B r^{n-1} d\lambda(r).$$
Since we have shown that $\mu|_S = \lambda^{(n)}|_S$, we have $\mu = \lambda^{(n)}|_{\mathbb{R}^n}$ by (1). Thus the formula in the theorem holds for radially symmetric characteristic functions, and hence for radially symmetric simple functions by linearity.

Finally, let $(f_k)$ be an increasing sequence of nonnegative simple functions on $[0, \infty)$ converging pointwise to $g$. Then $(s_n(f_k))$ is an increasing sequence of radially symmetric simple functions increasing pointwise to $s_n(g)$, so by two applications of the Monotone Convergence Theorem we get

$$\int_{\mathbb{R}^n} s_n(g) \, d\lambda^{(n)} = \lim_{k \to \infty} \int_{\mathbb{R}^n} s_n(f_k) \, d\lambda^{(n)} = \lim_{k \to \infty} n\beta_n \int_0^\infty r^{n-1} f_k(r) \, d\lambda(r) = n\beta_n \int_0^\infty r^{n-1} g(r) \, d\lambda(r) .$$

The proof of this theorem is somewhat simpler and more elementary if $g$ is continuous, since the second step can be bypassed by using an improper Riemann integral on the right side. This is actually the only case we will use in the calculation of $\beta_n$.

**V.14.2. Calculation of $\beta_n$**

**V.14.2.10.** The trick we will use to calculate $\beta_n$ is to consider the function $f_n : \mathbb{R}^n \to \mathbb{R}$ given for $x = (x_1, \ldots, x_n)$ by

$$f_n(x) = e^{-\|x\|^2} = e^{-x_1^2} \cdots e^{-x_n^2} = e^{-x_1^2} e^{-x_2^2} \cdots e^{-x_n^2} .$$

This function is nonnegative, continuous, and radially symmetric, and is also a product of functions of each coordinate separately; moreover, the integrals can be computed in two separate ways.

**V.14.2.11.** On the one hand, from V.14.1.9. we have

$$I_n := \int_{\mathbb{R}^n} f_n \, d\lambda^{(n)} = n\beta_n \int_0^\infty r^{n-1} e^{-r^2} \, dr$$

(the last integral may be regarded as an improper Riemann integral).

**V.14.2.12.** On the other hand, since $f_n(x_1, \ldots, x_n) = f_1(x_1)f_1(x_2) \cdots f_1(x_n)$, by Tonelli’s theorem (the vector calculus version () suffices) we have

$$I_n = \int_{\mathbb{R}^n} f_n \, d\lambda^{(n)} = \int_{\mathbb{R}} f_1(x_1) \left[ \int_{\mathbb{R}} f_1(x_2) \left[ \cdots \left[ \int_{\mathbb{R}} f_1(x_n) \, d\lambda(x_n) \right] \cdots \right] \, d\lambda(x_2) \right] \, \lambda(x_1)$$

$$= \left[ \int_{\mathbb{R}} f_1(x) \, d\lambda(x) \right]^n = (I_1)^n .$$

**V.14.2.13.** The integral which can be computed by elementary means is $I_2$. Since $\beta_2 = \pi$ (V.14.0.1.), we have

$$I_2 = 2\pi \int_0^\infty r e^{-r^2} \, dr = 2\pi \lim_{b \to \infty} \left[ -\frac{1}{2} e^{-r^2} \right]_0^b = \pi$$

and so $I_1 = \sqrt{\pi}$. 667
So we have
\[(I_1)^n = \pi^{n/2} = I_n = n\beta_n \int_0^\infty r^{n-1}e^{-r^2} \, dr.\]

Making the substitution \(u = r^2\), we have
\[\pi^{n/2} = \frac{n\beta_n}{2} \int_0^\infty u^{\frac{n-2}{2}}e^{-u} \, du = \frac{n\beta_n}{2} \Gamma\left(\frac{n}{2}\right)\]
where \(\Gamma\) is the Gamma function. Solving for \(\beta_n\) and using \(\Gamma\left(\frac{n}{2} + 1\right) = \frac{\pi}{2} \Gamma\left(\frac{n}{2}\right)\), we get the final result:

V.14.2.15. **Theorem.**

\[\beta_n = \frac{\pi^{n/2}}{\Gamma\left(\frac{n}{2} + 1\right)}.\]

So if \(n = 2m\) is even, we have \(\beta_n = \frac{\pi^m}{m!}\).

V.14.2.16. Using \(\beta_1 = 2\), we can obtain \(\Gamma\left(\frac{3}{2}\right) = \frac{\sqrt{\pi}}{2} = \frac{1}{2} \Gamma\left(\frac{1}{2}\right)\), so \(\Gamma\left(\frac{1}{2}\right) = \sqrt{\pi}\). Thus, if \(n = 2m + 1\) is odd, we have
\[\Gamma\left(\frac{n}{2} + 1\right) = \frac{1}{2} \cdot \frac{3}{2} \cdot \frac{5}{2} \cdots \frac{n}{2} \sqrt{\pi} = \frac{1 \cdot 3 \cdot 5 \cdots n}{2^{m+1}} \sqrt{\pi}\]
so we obtain
\[\beta_n = \frac{2^{m+1} \pi^m}{1 \cdot 3 \cdot 5 \cdots n}.\]

V.14.2.17. Thus \(\beta_4 = \frac{\pi^2}{2\pi}, \beta_5 = \frac{8\pi^2}{15}\pi\), etc. Note that each time \(n\) increases by 2, one more factor of \(\pi\) appears. The power of \(\pi\) that occurs in the final formulas is always an integer.

V.14.2.18. We can also define \(\beta_s\) for any \(s \in [0, \infty)\) by the formula
\[\beta_s = \frac{\pi^{s/2}}{\Gamma\left(\frac{s}{2} + 1\right)}.\]

This is the theoretical \(s\)-dimensional “measure of the closed unit ball in \(\mathbb{R}^s\).” This definition will be used in the construction of Hausdorff measure.

V.14.3. Surface Area of a Sphere
V.14.3.19. The arguments of this section can be taken much farther. Fix \(n\). We can define “spherical coordinates” \((\rho, \Theta)\) in \(\mathbb{R}^n \setminus \{0\}\) by setting
\[\rho(x) = \|x\|, \quad \Theta(x) = \frac{x}{\|x\|}.\]

Then \(\rho(x) \in (0, \infty)\) and \(\Theta(x) \in S^{n-1}\), and \(\Phi = (\rho, \Theta)\) is a homeomorphism from \(\mathbb{R}^n \setminus \{0\}\) to \((0, \infty) \times S^{n-1}\); the inverse function \(\Phi^{-1}\) is given by \(\Phi^{-1}(r, x) = rx\). Since these functions are homeomorphisms, they send Borel sets to Borel sets.
\textbf{V.14.3.20.} We can also transfer Lebesgue measure $\lambda^{(n)}$ to the product space $(0, \infty) \times S^{n-1}$ via $\Phi$; call the image measure $\mu$. Thus, if $E$ is a Borel subset of $(0, \infty) \times S^{n-1}$, we have $\mu(E) = \lambda^{(n)}(\Phi^{-1}(E))$. Theorem V.14.1.9. can be rephrased to say that if $A$ is a Borel subset of $(0, \infty)$, then

$$
\mu(A \times S^{n-1}) = n\beta_n \int_A r^{n-1} \, d\lambda(r).
$$

Define a measure $\nu$ on $(0, \infty)$ by $\nu(A) = \int_A r^{n-1} \, d\lambda(r)$. We will show that there is a finite Borel measure $\sigma$ on $S^{n-1}$, with $\sigma(S^{n-1}) = n\beta_n$, such that $\mu = \nu \times \sigma$.

\textbf{V.14.3.21.} If $B$ is a Borel subset of $S^{n-1}$ (in either the abstract sense regarding $S^{n-1}$ as a topological space, or a subset of $S^{n-1}$ which is a Borel set in $\mathbb{R}^n$; since $S^{n-1}$ is a closed, hence Borel, subset of $\mathbb{R}^{n-1}$, the two notions are equivalent), then $\Phi^{-1}((0, 1] \times B)$ is a Borel subset of $\mathbb{R}^n$. Define

$$
\sigma(B) = n\lambda^{(n)}((0, 1] \times B).
$$

It is almost immediate that $\sigma$ is a Borel measure on $S^{n-1}$. The main result is:

\textbf{V.14.3.22.} \textbf{THEOREM.} The measures $\mu$ and $\nu \times \sigma$ coincide on the Borel sets in $(0, \infty) \times S^{n-1}$.

\textbf{PROOF:} In a manner almost identical to the proof of V.14.1.9., for a fixed $B$ we have $\mu(A \times B) = \nu(A)\sigma(B)$ for every Borel subset $A$ of $(0, \infty)$ (first show this for $A = (a, b]$ by homogeneity, and then bootstrap to all Borel sets). Thus, if $A$ is the $\sigma$-algebra of Borel sets in $(0, \infty)$ and $\mathcal{B}$ the Borel sets in $S^{n-1}$, we have $\mu = \nu \times \sigma$ on $A \times \mathcal{B}$. So by () $\mu$ and $\nu \times \sigma$ agree on $A \otimes \mathcal{B}$, which is the $\sigma$-algebra of Borel sets in $(0, \infty) \times S^{n-1}$. \&

\textbf{V.14.3.23.} The measure $\sigma$ is called the \textit{surface measure} of $S^{n-1}$. In the cases $n = 2$ and $n = 3$ this surface measure represents arc length and surface area respectively. This measure can be defined in several other ways: it is the restriction of $(n-1)$-dimensional Hausdorff measure () on $\mathbb{R}^n$ to $S^{n-1}$, it is the Riemannian measure on $S^{n-1}$ as a smooth submanifold of $\mathbb{R}^n ()$, and it can be defined via a parametrization ()

\textbf{V.14.3.24.} The total surface measure $\sigma(S^{n-1})$ is just $n\beta_n$. Thus $\sigma(S^1) = 2\pi$, the circumference of the unit circle, and $\sigma(S^2) = 4\pi$, the surface area of the unit sphere in $\mathbb{R}^3$. By scaling, the surface measure of the sphere of radius $r$ in $\mathbb{R}^n$ is $r^{n-1}\sigma(S^{n-1})$. This is the derivative of the function $V(r) = \beta_n r^n$ giving the Lebesgue measure of a ball in $\mathbb{R}^n$ of radius $r$. An interpretation of this is: if $S_h$ is the spherical shell of inside radius 1 and outside radius $1 + h$ in $\mathbb{R}^n$, we have:

$$
\sigma(S^{n-1}) = \lim_{h \to 0} \frac{\lambda^{(n)}(S_h)}{h}.
$$

A similar formula holds for any Borel subset of $S^{n-1}$. 

669
V.14.4.  Exercises

V.14.4.1.  Let $n \geq 2$. Use iterated integration to compute $\beta_n$ as follows.

(a) Write $\beta_n = \int_{x_1^2 + \cdots + x_n^2 \leq 1} 1 \, d(x_1, \ldots, x_n) = \int_{-1}^{1} \left[ \int_{x_1^2 + \cdots + x_n^2 \leq 1 - x_1^2} 1 \, d(x_2, \ldots, x_n) \right] \, dx_1$.

(b) The quantity in brackets is the $(n-1)$-dimensional measure of a ball of radius $\sqrt{1 - x_1^2}$ in $\mathbb{R}^{n-1}$. By scaling invariance, this integral equals $\beta_{n-1}(1 - x_1^2)^{\frac{n-1}{2}}$.

(c) Obtain a recurrence formula

$$\beta_n = \beta_{n-1} \int_{-1}^{1} (1 - x^2)^{\frac{n-1}{2}} \, dx = 2\beta_{n-1} \int_{0}^{1} (1 - x^2)^{\frac{n-1}{2}} \, dx.$$

(d) Make the change of variables $x = \cos \theta$ to convert the recurrence formula to

$$\beta_n = \beta_{n-1} \int_{0}^{\pi} \sin^n \theta \, d\theta = 2\beta_{n-1} \int_{0}^{\pi/2} \sin^n \theta \, d\theta.$$

(e) Evaluate the integral using (c) and obtain the formula of V.14.2.15. using $\beta_1 = 2$.

V.14.4.2.  Let $n \geq 3$. Compute the $n$-dimensional Lebesgue measure of the ball $B_e^{(n)}$ of radius $r$ around the origin in $\mathbb{R}^n$ as follows.

(a) Introduce “hyperspherical” coordinates $(\rho, \theta_1, \ldots, \theta_{n-1})$ in $\mathbb{R}^n$, where

$$x_1 = \rho \cos \theta_1$$

$$x_2 = \rho \sin \theta_1 \cos \theta_2$$

$$x_{n-1} = \rho \sin \theta_1 \cdots \sin \theta_{n-2} \cos \theta_{n-1}$$

$$x_n = \rho \sin \theta_1 \cdots \sin \theta_{n-2} \sin \theta_{n-1}$$

(for $n = 3$, the usual spherical coordinates $(\rho, \phi, \theta)$ have $\theta_1 = \phi$, $\theta_2 = \theta$, and the coordinates come out in the order $(z, x, y)$).

(b) Show that the $n$-dimensional volume $\lambda^{(n)}(B_e^{(n)})$ is given by

$$\int_{0}^{r} \int_{0}^{\pi} \cdots \int_{0}^{\pi} \rho^{n-1} \sin^{n-2} \theta_1 \sin^{n-3} \theta_2 \cdots \sin \theta_{n-2} \, d\theta_1 \, d\theta_2 \cdots d\theta_{n-1} \, d\rho$$

$$= \left( \int_{0}^{r} \rho^{n-1} \, d\rho \right) \left( \int_{0}^{\pi} d\theta_{n-1} \right) \prod_{k=1}^{n-2} \left( \int_{0}^{\pi} \sin^k \theta_{n-k-1} \, d\theta_{n-k-1} \right)$$

$$= \frac{2\pi}{n} r^n \prod_{k=1}^{n-2} \left( \int_{0}^{\pi} \sin^k \theta \, d\theta \right).$$

(This formula also holds with a simplified argument if $n = 2$ if the last product is taken to be the “empty product” 1.)
(c) Conclude that if \( n \geq 2 \), then
\[
\beta_n = \frac{2\pi}{n} \prod_{k=1}^{n-2} \left( \int_0^\pi \sin^k \theta \, d\theta \right)
\]
(with the last product equal to 1 if \( n = 2 \)). Show that this formula coincides with the formula of V.14.2.15. (cf. ()).

**V.14.4.3.**

(a) Find for which \( n \in \mathbb{N} \) we have \( \beta_n \) maximum.
(b) Find for which \( s \in [0, \infty) \) we have \( \beta_s \) maximum.
(c) Show that \( \lim_{s \to \infty} \beta_s = 0 \).

**V.14.4.4.** [BB92] Show that
\[
\left( 10^{-5} \sum_{-\infty}^{\infty} e^{-\frac{n^2}{10^{10}}} \right)^2
\]
agrees with \( \pi \) to at least 42 billion decimal places, but the numbers are not equal. Which is larger? [Show that
\[
\pi = \left( 10^{-5} \int_{-\infty}^{\infty} e^{-\frac{x^2}{10^{10}}} \, dx \right)^2
\]
(cf. V.14.2.13.).]
V.15. Infinite Series of Functions

V.15.1. Infinite Series of Functions

Term-by-Term Differentiation

V.15.1.1. It is important to understand that even a uniformly convergent infinite series of differentiable functions cannot be differentiated term-by-term in general. For a simple example, the infinite series

\[ \sum_{k=1}^{\infty} 2^{-k} \sin 2^k x \]

converges uniformly on \( \mathbb{R} \) to a (continuous) function \( f \). But the series of term-by-term derivatives

\[ \sum_{k=1}^{\infty} \cos 2^k x \]

do not even converge pointwise at 0 or most other points. (In fact, \( f \) is not even differentiable at most places.) See I.5.1.13. for a heuristic explanation.

We do have the following series version of V.8.5.5.:

V.15.1.2. Theorem. Let \( (F_n) \) and \( (f_n) \) be sequences of functions on an interval \( I \), and \( A \) a countable subset of \( I \). Suppose

(a) Each \( F_n \) is continuous on \( I \).

(b) For every \( x \in I \setminus A \), each \( F_n \) is differentiable at \( x \) and \( F'_n(x) = f_n(x) \).

(c) The series \( \sum_{n=1}^{\infty} f_n \) converges u.c. on \( I \) to a function \( f \).

(d) There is an \( x_0 \in I \) such that the series \( \sum_{n=1}^{\infty} F_n(x_0) \) converges.

Then:

(i) The series \( \sum_{n=1}^{\infty} F_n \) converges u.c. on \( I \) to a (continuous) function \( F \).

(ii) For each \( x \in I \setminus A \), \( F \) is differentiable at \( x \) and \( F'(x) = f(x) \).

As usual, the proof is just an application of V.8.5.5. to the sequence of partial sums.

V.15.1.3. The important special case where \( A = \emptyset \) and each \( f_n \) is continuous follows from XIV.2.9.15.
V.15.2. Exercises

V.15.2.1. (a) Prove the sophomore’s dream:

\[ \int_0^1 x^{-x} \, dx = \int_0^1 \frac{1}{x^x} \, dx = \sum_{k=1}^{\infty} \frac{1}{k^k} \quad \text{and} \quad \int_0^1 x^x \, dx = \sum_{k=1}^{\infty} \frac{(-1)^{k+1}}{k^k} . \]

[Write \( x^x = e^{x \log x} \), expand in an infinite series using the Maclaurin series for \( e^x \), and integrate term-by-term.]

The name “sophomore’s dream” was coined in [BBG04].

(b) Another sophomore’s dream:

\[ \int_0^\infty \frac{x}{x^3 + 1} \, dx = \int_0^\infty \frac{1}{x^3 + 1} \, dx . \]

V.15.2.2. Does the iterated integral

\[ \int_0^8 \int_0^{\sqrt{1-z}} 4y \, dy \, dx \]

exist? If so, what is its value? Interpret the integral geometrically.
V.15.3. Power Series

Power series are probably the most important kinds of infinite series of functions (although trigonometric series are also very important). A great many of the most important functions can be represented as power series, and power series have some special properties which make them relatively easy to use and work with.

V.15.3.1. Definition. Let $x_0$ be a real number. A (real) power series centered at $x_0$ is an expression of the form

$$\sum_{k=0}^{\infty} a_k (x - x_0)^k$$

where the $a_k$ are real numbers. Complex power series can be defined similarly: if $z_0$ is a complex number, a complex power series centered at $z_0$ is an expression of the form

$$\sum_{k=0}^{\infty} a_k (z - z_0)^k$$

where the $a_k$ are complex numbers.

While we will (except in Chapter X) generally only consider real power series, the theory of power series is most naturally done for complex power series as part of complex analysis, and there are places in the real theory where the complex point of view is very helpful. Any real power series can, of course, be regarded as a complex power series by replacing $x$ by $z$.

V.15.3.2. A power series is regarded as an infinite series of functions. It is conventional when working with power series to regard $(x - x_0)^0 = 1$ no matter how $x - x_0$ is interpreted; thus the $k = 0$ term of the power series is just the constant function $a_0$. The same convention holds for complex power series.

V.15.3.3. A power series is, at first, only a formal expression, but it can be regarded as defining a function $f$ of $x$, whose domain is the set of all $x$ for which the series converges. Because of our convention, $x_0$ is always in the domain of the defined function $f$, with $f(x_0) = a_0$. It can happen that the domain of $f$ consists only of $\{x_0\}$ (such power series are not very interesting as functions).

The most important basic property of power series is V.15.3.5., which says that the domain of the defined function is an interval, or degenerate interval, centered at $x_0$.

V.15.3.4. Definition. Let $\sum_{k=0}^{\infty} a_k (x - x_0)^k$ be a power series, and define

$$L = \limsup_{k \to \infty} |a_k|^{1/k} = \limsup_{k \to \infty} \sqrt[k]{|a_k|}$$

and let $R = \frac{1}{L}$ if $0 < L < +\infty$, $R = 0$ if $L = +\infty$, and $R = +\infty$ if $L = 0$. $R$ is called the radius of convergence of the power series.

An identical definition can be made for complex power series. Note that the radius of convergence of a power series depends only on the coefficients $a_k$, not on the center $x_0$, of the power series. The slower the coefficients grow in size, or the faster they approach zero, the larger the radius of convergence.

The term “radius of convergence” is justified by the next result:
V.15.3.5. **Theorem.** Let $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ be a power series, with radius of convergence $R$. Then

(i) If $x \in \mathbb{R}$ and $|x-x_0| < R$, then the series $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ converges absolutely.

(ii) If $x \in \mathbb{R}$ and $|x-x_0| > R$, then the series $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ diverges.

(iii) If $r \in \mathbb{R}$ and $0 < r < R$, then the series $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ converges uniformly on the interval $[x_0-r, x_0+r]$.

(Of course, (i) and (iii) are vacuous if $R = 0$ and (ii) is vacuous if $R = +\infty$.)

**Proof:** In cases (i) and (ii), apply the Root Test to the series $\sum_{k=0}^{\infty} |a_k(x-x_0)^k|$. We have

\[
\limsup_{k \to \infty} |a_k(x-x_0)^k|^{1/k} = |x-x_0| \limsup_{k \to \infty} |a_k|^{1/k} = \frac{|x-x_0|}{R}
\]

(it is $+\infty$ if $x \neq x_0$ and $R = 0$, and 0 if $R = +\infty$ or $x = x_0$). Thus the series converges absolutely if $|x-x_0| < R$ or $x = x_0$ and diverges since the terms do not go to zero if $|x-x_0| > R$.

For (iii), use the Weierstrass $M$-test. Set $M_k = |a_k|r^k$. Then $|a_k(x-x_0)^k| \leq M_k$ for all $k$ and for all $x$, $|x-x_0| \leq r$. We have

\[
\limsup_{k \to \infty} M_k^{1/k} = r \limsup_{k \to \infty} |a_k|^{1/k} = \frac{r}{R} < 1
\]

if $0 < R < \infty$, and $\limsup_{k \to \infty} M_k^{1/k} = 0$ if $R = +\infty$. Thus $\sum_{k=0}^{\infty} M_k$ converges by the Root Test. $\Box$

The statement and proof of the theorem work identically for complex power series.

V.15.3.6. **Corollary.** Let $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ be a power series, with radius of convergence $R > 0$. Then the series converges u.c. on the open interval $(x_0 - R, x_0 + R)$, and the sum is continuous on this interval.

**Proof:** If $[a, b] \subseteq (x_0 - R, x_0 + R)$, then $[a, b] \subseteq [x_0 - r, x_0 + r]$ for some $r < R$. Continuity of the sum follows from (i). $\Box$

The sum is actually far more than just continuous on this open interval.

V.15.3.7. Thus the set on which a power series centered at $x_0$ converges is an interval centered at $x_0$, possibly of length zero, i.e. the degenerate interval $\{x_0\}$, or of infinite length, i.e. all of $\mathbb{R}$, possibly including one or both endpoints, called the *interval of convergence* of the power series. (If $0 < R < \infty$, the theorem has nothing to say about behavior at the points where $x-x_0 = \pm R$, the endpoints of the interval of convergence; endpoint behavior will be discussed below.) Similarly, the set on which a complex power series centered at $z_0$ converges is a disk in $\mathbb{C}$ centered at $z_0$, possibly degenerate or all of $\mathbb{C}$, and possibly including some or all points on the boundary circle of the disk.

675
V.15.3.8. The radius of convergence of a power series \( \sum_{k=0}^{\infty} a_k (x - x_0)^k \) can always be computed as

\[
R = \frac{1}{\limsup |a_k|^{1/k}}
\]

(with the usual conventions if the lim sup is 0 or \(+\infty\)), but it is not always easy to evaluate this expression. Sometimes the radius of convergence can be computed more simply by the following:

**V.15.3.9. Proposition.** Let \( \sum_{k=0}^{\infty} a_k (x - x_0)^k \) be a power series, with all \( a_k \) nonzero. If

\[
\lim_{k \to \infty} \left| \frac{a_k}{a_{k+1}} \right|
\]

exists (in the usual or extended sense), it equals the radius of convergence of the power series.

**Proof:** Let \( S \) be this limit. Apply the Ratio Test (\()\) to show that \( \sum_{k=0}^{\infty} a_k (x - x_0)^k \) converges absolutely if \( |x - x_0| < S \) and diverges if \( |x - x_0| > S \). Thus \( S \) must be exactly the radius of convergence. 🙌

Note that in the limit of V.15.3.9., the \( a_k \) and \( a_{k+1} \) are reversed from the way they appear in the Ratio Test (\()\).

Another convenient characterization of the radius of convergence is the following:

**V.15.3.10. Proposition.** Let \( \sum_{k=0}^{\infty} a_k (x - x_0)^k \) be a power series. The power series has radius of convergence \( R > 0 \) if and only if, for all \( r, 0 < r < R \), there is a constant \( M \) such that \( |a_k| \leq \frac{M}{r} \) for all \( k \), and there is no such \( M \) if \( r > R \).

**Proof:** Suppose the series has radius of convergence \( R > 0 \), and \( 0 < r < R \). Then

\[
\limsup |a_k|^{1/k} < \frac{1}{r}
\]

so there is a \( k_0 \) such that \( |a_k| < \frac{1}{r} \) for all \( k \geq k_0 \). There is an \( M \geq 1 \) such that \( |a_k| \leq \frac{M}{r} \) for \( 0 \leq k < k_0 \). This \( M \) works for all \( k \).

Conversely, if the condition holds for all \( r \) with \( 0 < r < R \) and no \( r > R \), we have, for each such \( r \) with \( 0 < r < R \),

\[
\limsup |a_k|^{1/k} \leq \limsup \frac{M^{1/k}}{r} = \frac{1}{r}
\]

for some constant \( M \), so the radius of convergence \( R' \) is \( \geq R \). If \( R' > R \), choose \( r \) so that \( R < r < R' \); then the condition holds for \( r \) by the first half of the proof, a contradiction. 🙌
V.15.3.11. Examples. (i) Let $c \in \mathbb{R}$, $c \neq 0$. The power series $\sum_{k=0}^{\infty} c^k (x - x_0)^k$ has radius of convergence $\frac{1}{|c|}$, and interval of convergence $\left( x_0 - \frac{1}{|c|}, x_0 + \frac{1}{|c|} \right)$.

(ii) The power series $\sum_{k=0}^{\infty} \frac{1}{k!} (x - x_0)^k$ has radius of convergence $+\infty$ and interval of convergence $\mathbb{R}$.

(iii) The power series $\sum_{k=0}^{\infty} k! (x - x_0)^k$ has radius of convergence 0 and (degenerate) interval of convergence $\{x_0\}$.

V.15.3.12. The convergence behavior of an infinite series does not depend on $x_0$, and if $x_0$ is changed, leaving the $a_k$ the same, the function defined is simply changed by a translation. In particular, if $f$ is the function defined by $\sum_{k=0}^{\infty} a_k x^k$ on its interval of convergence $I$, then the function defined by $\sum_{k=0}^{\infty} a_k (x - x_0)^k$ is simply the function $g(x) = f(x - x_0)$ on $x_0 + I$. Thus in analyzing behavior of functions defined by power series, we generally may (and often will) take $x_0 = 0$ to simplify notation.

Endpoint Behavior

Almost any kind of behavior can occur at endpoints of the interval of convergence, as the following examples show.

V.15.3.13. Examples. (i) The power series $\sum_{k=0}^{\infty} x^k$ has radius of convergence 1. The series diverges if $x = \pm 1$ since the terms do not go to zero, so the interval of convergence is $(-1, 1)$.

(ii) The power series $\sum_{k=1}^{\infty} \frac{1}{k} x^k$ (a power series with constant term 0) has radius of convergence 1. The series diverges if $x = 1$ (harmonic series), but converges conditionally if $x = -1$, so the interval of convergence is $[-1, 1)$. The power series $\sum_{k=1}^{\infty} \frac{(-1)^k}{k} x^k$ has interval of convergence $(-1, 1]$.

(iii) The power series $\sum_{k=1}^{\infty} \frac{1}{k^2} x^k$ has radius of convergence 1. The series converges absolutely if $x = \pm 1$, so the interval of convergence is $[-1, 1]$.

(iv) The series $\sum_{k=1}^{\infty} \frac{(-1)^k}{k} x^{2k}$ (this is a power series with odd coefficients 0) has radius of convergence 1. The series converges conditionally if $x = \pm 1$, so the interval of convergence is $[-1, 1]$. 

677
V.15.3.14. If a power series converges absolutely at one endpoint, it converges absolutely at the other endpoint too, since the absolute series \( \sum_{k=0}^{\infty} |a_k(x-x_0)^k| \) is the same at both endpoints. This is the only restriction on endpoint behavior for real infinite series.

V.15.3.15. Convergence behavior of a complex series on the boundary circle of the disk of convergence is much more subtle. The series can diverge everywhere on this circle (e.g. \( \sum_{k=0}^{\infty} (z-z_0)^k \)) or it can converge absolutely at all points of the circle (e.g. \( \sum_{k=1}^{\infty} \frac{1}{k^2} (z-z_0)^k \)), or it can converge conditionally on some subset \( S \) of the boundary circle. But \( S \) cannot be an arbitrary subset of the circle (it must be an \( F_\alpha \delta \) ), and not even all of these occur; see [Kör83]. The study of boundary behavior of analytic functions is a big topic in complex analysis, with important applications.

We will primarily be interested in using power series on open intervals. But we note one important result about the behavior of a power series near an endpoint or boundary point where it converges:

V.15.3.16. Theorem. [Abel’s Theorem] Let \( \sum_{k=0}^{\infty} a_k(x-x_0)^k \) be a power series. If \([a,b]\) is a closed bounded interval contained in the interval of convergence of the series, then the series converges uniformly on \([a,b]\). (In other words, the series converges u.c. on its entire interval of convergence.)

If \([a,b]\) is contained in the interior of the interval of convergence, the result follows immediately from V.15.3.6., so Abel’s Theorem only gives additional information in the case where \([a,b]\) contains one or both endpoints of the interval of convergence, and this is the case it is designed for.

V.15.3.17. Corollary. Let \( \sum_{k=0}^{\infty} a_k(x-x_0)^k \) be a power series, with interval of convergence \( I \). Then the function on \( I \) defined by the series is continuous on \( I \), including at any endpoints of \( I \).

Proof: Combine V.15.3.16. with ()..

V.15.3.18. Abel’s Theorem also has a complex version, which we do not state precisely. But even the real version is enough to almost immediately show that if \( \sum_{k=0}^{\infty} a_k(z-z_0)^k \) is a complex power series, and it converges at some \( z_1 \) on the boundary circle of the disk of convergence, then the value at \( z_1 \) is the radial limit of the value at \( z \) as \( z \to z_1 \) along the ray from \( z_0 \) to \( z_1 \). See Exercise ()

We now give the proof of Abel’s Theorem.

Proof: By applying V.15.3.6. to expand the interval if necessary, we may assume \( a \leq x_0 \leq b \). We prove that the series converges uniformly on \([x_0,b]\); the proof that it converges uniformly on \([a,x_0]\) is essentially identical.
Let $\epsilon > 0$. Since $\sum_{k=1}^{\infty} a_k (b - x_0)^k$ converges, by (1) there is an $N$ such that

$$\left| \sum_{k=n+1}^{n+m} a_k (b - x_0)^k \right| < \epsilon$$

whenever $n \geq N$ and $m \in \mathbb{N}$. If $x \in [x_0, b]$, set

$$c_k = \left( \frac{x - x_0}{b - x_0} \right)^k.$$ 

Then by Abel’s Partial Summation Formula (IV.2.7.5.) with $r = n$ we have, for any $n \geq N$ and $m \in \mathbb{N}$,

$$\sum_{k=n+1}^{n+m} a_k (x - x_0)^k = \sum_{k=n+1}^{n+m} c_k a_k (b - x_0)^k = \sum_{k=n+1}^{n+m} (c_k - c_{k+1}) s_{k,n} + c_{n+m+1} s_{n+m,n}$$

where $s_{k,n} = \sum_{j=n+1}^{k} a_j (b - x_0)^j$. Since $|s_{k,n}| < \epsilon$ for all $k \geq n$, and $0 \leq c_{k+1} \leq c_k \leq 1$ for all $k$, we have

$$\left| \sum_{k=n+1}^{n+m} a_k (x - x_0)^k \right| \leq \sum_{k=n+1}^{n+m} (c_k - c_{k+1}) |s_{k,n}| + c_{n+m+1} |s_{n+m,n}|$$

$$\leq \epsilon \left[ \sum_{k=n+1}^{n+m} (c_k - c_{k+1}) + c_{n+m+1} \right] = (c_{n+1} - c_{n+m+1}) \epsilon \leq \epsilon$$

and so the series converges uniformly on $[x_0, b]$.

Term-by-Term Integration

Because of the u.c. convergence of a power series on its interval of convergence $I$, we can apply (1) to integrate a power series term-by-term on any closed bounded interval contained in $I$:

**V.15.3.19. Corollary.** Let $\sum_{k=0}^{\infty} c_k (x - x_0)^k$ be a power series with interval of convergence $I$, and $[a, b]$ a closed bounded subinterval of $I$. Then the function $f$ defined by the power series is integrable on $[a, b]$, and

$$\int_{a}^{b} f(x) \, dx = \int_{a}^{b} \left[ \sum_{k=0}^{\infty} c_k (x - x_0)^k \right] \, dx = \sum_{k=0}^{\infty} \left[ \int_{a}^{b} c_k (x - x_0)^k \, dx \right]$$

$$= \sum_{k=0}^{\infty} c_k \left[ (b - x_0)^{k+1} - (a - x_0)^{k+1} \right] = \sum_{k=0}^{\infty} \frac{c_k}{k+1} (b - x_0)^{k+1} - \sum_{k=0}^{\infty} \frac{c_k}{k+1} (a - x_0)^{k+1}$$. 

679
In particular, the series on the last line converge. This result is a consequence of V.15.3.6. if \([a, b]\) is contained in the open interval of convergence, but requires Abel’s Theorem if \(a\) or \(b\) is an endpoint of the interval of convergence. If \([a, b]\) is contained in the open interval of convergence, the series in the last expression will automatically converge absolutely by comparison to the power series evaluated at \(a\) and \(b\) (which converge absolutely by V.15.3.5.(i)). If \(a\) or \(b\) is an endpoint of the interval of convergence, the original series evaluated at \(a\) or \(b\) may not converge absolutely, but the next result shows that the integrated series still converge in this case.

V.15.3.20. **Proposition.** Let \(\sum_{k=0}^{\infty} a_k(x-x_0)^k\) be a power series. If this power series converges for \(x = x_1\), then the integrated series \(\sum_{k=0}^{\infty} \frac{a_k}{k+1} (x-x_0)^{k+1}\) also converges for \(x = x_1\).

**Proof:** Apply Abel’s Test (IV.2.7.7.) with \(c_k = \frac{x_1-x_0}{k+1}\).

Term-by-Term Differentiation

Term-by-term differentiation of a power series is a dicier matter. One of the beautiful and crucial properties of power series is that they can in fact be differentiated term-by-term, in contrast to more general series of functions.

The key fact making this possible is the next result. Note that if \(\sum_{k=0}^{\infty} a_k(x-x_0)^k\) is a power series, the series \(\sum_{k=1}^{\infty} k a_k(x-x_0)^{k-1}\) of term-by-term derivatives is also a power series.

V.15.3.21. **Proposition.** Let \(\sum_{k=0}^{\infty} a_k(x-x_0)^k\) be a power series, with radius of convergence \(R\). Then the radius of convergence of the series \(\sum_{k=1}^{\infty} k a_k(x-x_0)^{k-1}\) of term-by-term derivatives is also exactly \(R\).

**Proof:** First note that the series \(\sum_{k=1}^{\infty} k a_k(x-x_0)^{k-1}\) and \(\sum_{k=1}^{\infty} k a_k(x-x_0)^k\) converge for exactly the same \(x\)’s: both converge for \(x = x_0\), and for \(x \neq x_0\) each series is a constant scalar multiple of the other. Thus it suffices to show that the radius of convergence \(R’\) of the series \(\sum_{k=1}^{\infty} k a_k(x-x_0)^{k}\) is equal to \(R\).

Let \(L = \limsup_{k \to \infty} |a_k|^{1/k}\). Then \(R = \frac{1}{L}\) (with the usual conventions if \(L\) is 0 or \(\infty\). Similarly, \(R’ = \frac{1}{L’}\), where \(L’ = \limsup_{k \to \infty} |ka_k|^{1/k}\). So it suffices to show that \(L’ = L\). But \(\lim_{k \to \infty} k^{1/k} = 1\) (1), so by (1)

\[
L’ = \limsup_{k \to \infty} |ka_k|^{1/k} = \left(\lim_{k \to \infty} k^{1/k}\right) \left(\limsup_{k \to \infty} |a_k|^{1/k}\right) = 1 \cdot L = L.
\]
This result and proof are also valid for complex power series.

**V.15.3.22.** Note that this result does not say that the *interval* of convergence of the derived series is the same as the interval of convergence of the original series; in fact, endpoint behavior can be different. In examples V.15.3.13 (ii)-(iv), the interval of convergence of the derived series is strictly smaller than that of the original series; it cannot be larger (cf. V.15.3.20.).

We now apply () to get the main result:

**V.15.3.23.** **Theorem.** Let \( \sum_{k=0}^{\infty} a_k (x-x_0)^k \) be a power series, with radius of convergence \( R > 0 \). Then the function \( f \) defined by the power series is differentiable on \( (x_0 - R, x_0 + R) \), and

\[
  f'(x) = \sum_{k=1}^{\infty} k a_k (x-x_0)^{k-1}
\]

for all \( x \in (x_0 - R, x_0 + R) \).

**V.15.3.24.** But why stop there? The power series representing \( f' \) can also be differentiated term-by-term, and the theorem applies to show that \( f' \) is also differentiable on \( (x_0 - R, x_0 + R) \), i.e. \( f \) has a second derivative on this interval given by taking term-by-term derivatives twice. This argument can be iterated arbitrarily many times. Thus we obtain:

**V.15.3.25.** **Corollary.** Let \( \sum_{k=0}^{\infty} a_k (x-x_0)^k \) be a power series, with radius of convergence \( R > 0 \). Then the function \( f \) defined by the power series is \( C^\infty \) on \( (x_0 - R, x_0 + R) \), and

\[
  f^{(n)}(x) = \sum_{k=n}^{\infty} k(k-1) \cdots (k-n+1) a_k (x-x_0)^{k-n} = \sum_{k=n}^{\infty} \frac{k!}{(k-n)!} a_k (x-x_0)^{k-n}
\]

for every \( n \) and every \( x \in (x_0 - R, x_0 + R) \).

Note that V.15.3.23. and hence V.15.3.26. apply also on any open subinterval of the interval of convergence. Thus we can rephrase:

**V.15.3.26.** **Corollary.** Let \( \sum_{k=0}^{\infty} a_k (x-x_0)^k \) be a power series which converges to a function \( f \) on an open interval \( I \). Then \( f \) is \( C^\infty \) on \( I \), and

\[
  f^{(n)}(x) = \sum_{k=n}^{\infty} k(k-1) \cdots (k-n+1) a_k (x-x_0)^{k-n} = \sum_{k=n}^{\infty} \frac{k!}{(k-n)!} a_k (x-x_0)^{k-n} = \sum_{k=0}^{\infty} \frac{(k+n)!}{k!} a_{k+n} (x-x_0)^{k+n}
\]

for every \( n \) and every \( x \in I \) (in particular, this series converges for all \( n \) and all \( x \in I \)).
Uniqueness of Power Series Representations

V.15.3.27. V.15.3.26. has another important consequence: if \( \sum_{k=0}^{\infty} a_k (x - x_0)^k \) is a power series with positive radius of convergence, then the coefficients \( a_k \) can be recovered from the function \( f \) defined by the power series. We have that \( f \) is infinitely differentiable in an interval around \( x_0 \), and \( f^{(n)}(x_0) \) is given by the \( n \)’th derived power series. In particular, \( f^{(n)}(x_0) \) is the constant term of the \( n \)’th derived power series, which is \( n! a_n \). Thus we obtain:

V.15.3.28. Corollary. Let \( \sum_{k=0}^{\infty} a_k (x - x_0)^k \) be a power series with positive radius of convergence, and \( f \) the function defined by the series on its open interval of convergence. Then

\[
a_n = \frac{f^{(n)}(x_0)}{n!}
\]

for each \( n \). In particular, the given power series is the only possible power series centered at \( x_0 \) that can represent \( f \) on an open interval containing \( x_0 \). Thus a function can be represented near \( x_0 \) by at most one power series centered at \( x_0 \).

V.15.3.29. Definition. Let \( f \) be \( C^\infty \) on an interval around \( x_0 \in \mathbb{R} \). The Taylor series for \( f \) around \( x_0 \) is the infinite series

\[
\sum_{k=0}^{\infty} \frac{f^{(k)}(x_0)}{k!} (x - x_0)^k.
\]

Note that the partial sums of the Taylor series for \( f \) around \( x_0 \) are exactly the Taylor polynomials (V.10.1.6.) of \( f \) around \( x_0 \). The corollary can be rephrased:

V.15.3.30. Corollary. Let \( f \) be \( C^\infty \) on an interval around \( x_0 \in \mathbb{R} \). Then the only power series centered at \( x_0 \) which can converge to \( f \) in any open neighborhood of \( x_0 \) is the Taylor series for \( f \) around \( x_0 \).

V.15.3.31. Note two important things about the corollary:

(i) The result only applies to power series centered at \( x_0 \). It does not imply that \( f \) cannot be represented near \( x_0 \) by a different power series centered at some \( x_1 \neq x_0 \). In fact, if \( f \) can be represented in some interval by a power series centered at \( x_0 \), there will be such a power series centered at any \( x_1 \) sufficiently close to \( x_0 \).

(ii) The result says nothing about whether a function defined near \( x_0 \) can in fact be represented by a power series centered at \( x_0 \), only that if it can, the series is unique and is the Taylor series for \( f \) around \( x_0 \). An obvious necessary condition for \( f \) to be representable is that it be \( C^\infty \) in an interval around \( x_0 \), but this is far from sufficient. The question of which functions can be represented by power series is a substantial one which will be discussed in the next section.
V.16. Analytic Functions

Functions which can be locally represented by their Taylor series, called analytic functions, are particularly well-behaved. It turns out that most standard functions, and many of the functions naturally encountered in mathematics, are analytic.

V.16.1. Definitions and Basic Properties

V.16.1.1. Definition. (i) Let \( U \) be an open set in \( \mathbb{R} \). A function \( f : U \rightarrow \mathbb{R} \) is real analytic on \( U \) if for every \( x_0 \in U \), \( f \) is represented in some neighborhood of \( x_0 \) by a (real) power series centered at \( x_0 \).

(ii) Let \( V \) be an open set in \( \mathbb{C} \). A function \( f : V \rightarrow \mathbb{C} \) is complex analytic on \( V \) if for every \( z_0 \in V \), \( f \) is represented in some neighborhood of \( z_0 \) by a complex power series centered at \( z_0 \).

In mathematics it is most common to use the term analytic to mean “complex analytic.” However, in this book, except in Chapter X, it will normally mean “real analytic” or occasionally “real or complex analytic.”

V.16.1.2. Some remarks on the definition:

(i) The phrase “represented in some neighborhood of \( x_0 \) by a (real) power series centered at \( x_0 \)” means that there is some \( \epsilon > 0 \) and some (real) power series centered at \( x_0 \) which converges to \( f(x) \) for all \( x \in (x_0 - \epsilon, x_0 + \epsilon) \). The meaning in (ii) is analogous.

(ii) If \( f \) is analytic (in either the real or complex sense), then \( f \) is \( C^1 \) and the (unique) power series centered at \( x_0 \) representing \( f \) in a neighborhood of \( x_0 \) is the Taylor series of \( f \) around \( x_0 \) (V.15.3.29.).

(iii) Since the partial sums of the Taylor series for \( f \) around \( x_0 \) are the Taylor polynomials (V.10.1.6.) of \( f \) around \( x_0 \), \( f \) is analytic on \( U \) if and only if, for each \( x_0 \in U \), the Taylor polynomials for \( f \) around \( x_0 \) converge to \( f \) in a neighborhood of \( x_0 \), i.e. the remainder terms \( r_n \) converge to zero on a neighborhood of \( x_0 \) (cf. V.10.1.8.).

(iv) It is important to note that if \( f \) is analytic on \( U \) and \( x_0 \in U \), then the Taylor series of \( f \) around \( x_0 \) does not converge to \( f \) on all of \( U \) in general; it only converges to \( f \) in some open interval around \( x_0 \). Thus the property of being analytic on \( U \) is strictly a local property. If \( f : U \rightarrow \mathbb{R} \) is a function, and for every \( x \in U \) there is a neighborhood of \( x \) in \( U \) on which \( f \) is analytic, then \( f \) is analytic on \( U \). In particular, if \( f \) is analytic on every open subinterval of \( U \), then \( f \) is analytic on \( U \); thus for convenience we often just work with open intervals when dealing with analytic functions.

A similar comment applies in the complex analytic case. See ().

V.16.1.3. One of the important theorems of complex analysis is a strong form of the converse to V.16.1.2.(ii): if \( V \) is an open subset of \( \mathbb{C} \) and \( f : V \rightarrow \mathbb{C} \) is differentiable in the complex sense at every point of \( V \), then \( f \) is complex analytic on \( V \). There is nothing resembling an analog of this result for real analytic functions, and this is one of the most fundamental differences in nature between real analysis and complex analysis. More specifically:

If \( f \) is differentiable on \( I \), then \( f' \) need not even be continuous on \( I \) (), much less differentiable. In particular, a differentiable real function is “usually” not even \( C^1 \), much less \( C^\infty \).

Even most \( C^\infty \) functions are not real analytic; see section () for details.

V.16.1.4. Notation: The set of real analytic functions on an open set \( U \) is denoted \( C^\infty(U) \).
V.16.1.5. Examples. (i) Let \( f \) be a polynomial of degree \( n \). Then, for any \( x_0 \in \mathbb{R} \), by Taylor’s Theorem the \( n \)th order Taylor polynomial for \( f \) around \( x_0 \) is \( f \) itself, i.e. the Taylor series for \( f \) around \( x_0 \) (which has only finitely many nonzero terms) represents \( f \) on all of \( \mathbb{R} \). Thus \( f \) is analytic on \( \mathbb{R} \).

(ii) Let \( f(x) = \sin x \). Then \( f \) is \( C^\infty \) on \( \mathbb{R} \), and \(|f^{(k)}(x)| \leq 1\) for all \( k \) and \( x \). Fix \( x_0 \in \mathbb{R} \), and let \( p_n \) be the \( n \)th order Taylor polynomial for \( f \) around \( x_0 \), and \( r_n = f - p_n \). Then, for any \( x \in \mathbb{R} \), we have

\[
 r_n(x) = \frac{f^{(n+1)}(c)}{(n+1)!}(x - x_0)^{n+1}
\]

for some \( c \) between \( x_0 \) and \( x \), and thus

\[
 |r_n(x)| \leq \frac{|x - x_0|^{n+1}}{(n+1)!} \to 0
\]

as \( n \to \infty \), so the Taylor series for \( f \) around \( x_0 \) converges to \( f(x) \) for all \( x \) and \( f \) is analytic on \( \mathbb{R} \). An identical argument shows that \( g(x) = \cos x \) is analytic on \( \mathbb{R} \).

(iii) Let \( f(x) = e^x \). Then \( f \) is \( C^\infty \) on \( \mathbb{R} \), and \( f^{(k)}(x) = e^x \) for all \( k \) and \( x \). Fix \( x_0 \in \mathbb{R} \) and \( s > 0 \), and let \( m = e^{x_0 + s} \). Then \( |f^{(k)}(x)| < m \) if \( |x - x_0| < s \). Let \( p_n \) be the \( n \)th order Taylor polynomial for \( f \) around \( x_0 \), and \( r_n = f - p_n \). Then, for any \( x \) with \( |x - x_0| < s \), we have

\[
 r_n(x) = \frac{f^{(n+1)}(c)}{(n+1)!}(x - x_0)^{n+1}
\]

for some \( c \) between \( x_0 \) and \( x \), and thus

\[
 |r_n(x)| \leq \frac{m|x - x_0|^{n+1}}{(n+1)!} \to 0
\]

as \( n \to \infty \), so the Taylor series for \( f \) around \( x_0 \) converges to \( f(x) \) for all \( x \), \( |x - x_0| < s \). Since \( s \) is arbitrary, the Taylor series converges to \( f(x) \) for all \( x \in \mathbb{R} \). Thus \( f \) is analytic on \( \mathbb{R} \).

Analyticity of Functions Defined by Power Series

The definition of an analytic function is hard to check directly: to show that \( f \) is analytic on \( U \), one must show for every \( x_0 \in U \) that the Taylor series for \( f \) around \( x_0 \) converges to \( f \) in an interval around \( x_0 \), an (uncountably) infinite number of conditions since there is a different Taylor series at each point. The following theorem is one of the most important facts about analytic functions, and saves an enormous amount of work in checking that specific functions are analytic since only one \( x_0 \) must be considered.

V.16.1.6. Theorem. Let \( \sum_{k=0}^{\infty} a_k(x - x_0)^k \) be a power series with radius of convergence \( R > 0 \), and let \( f \) be the function defined on \( I = (x_0 - R, x_0 + R) \) defined by the power series. Then \( f \) is analytic on \( I \).

In fact, the following more precise result holds:
\textbf{V.16.1.7. Theorem.} Let \( \sum_{k=0}^{\infty} a_k (x - x_0)^k \) be a power series with radius of convergence \( R > 0 \), and let \( f \) be the function defined on \( I = (x_0 - R, x_0 + R) \) defined by the power series. Let \( x_1 \in I \), and set \( S = R - |x_1 - x_0| \). Then the Taylor series for \( f \) around \( x_1 \) has radius of convergence at least \( S \) and converges to \( f \) on \( (x_1 - S, x_1 + S) \).

See Figure ( ). Note that \( f \) is \( C^\infty \) on \( I \), so the Taylor series for \( f \) around \( x_1 \) is defined.

To prove these theorems, we first need a lemma which will also be used later.

\textbf{V.16.1.8. Lemma.} Let \( \sum_{k=0}^{\infty} a_k (x - x_0)^k \) be a power series with radius of convergence \( R > 0 \), and let \( f \) be the function defined on \( I = (x_0 - R, x_0 + R) \) defined by the power series. Fix \( r, 0 < r < R \), and \( s, 0 < s < R - r \). Then there is a constant \( m \) such that
\[
|f^{(k)}(x)| \leq \frac{m \cdot k!}{s^k}
\]
for all \( k \geq 0 \) and all \( x \) with \( |x - x_0| \leq r \).

\textbf{Proof:} First note that the power series \( \sum_{j=0}^{\infty} x^j \) converges to \( f(x) = \frac{1}{1-x} \) on \((-1, 1)\), and thus the \( k \)'th derived series
\[
\sum_{j=k}^{\infty} j(j-1)\cdots(j-k)x^{j-k}
\]
converges on \((-1, 1)\) to \( f^{(k)}(x) = \frac{k!}{(1-x)^{k+1}} \) for any \( k \).

Let \( r \) and \( s \) be as in the statement. Since \( r + s < R \), by () there is an \( M \) such that \( |a_k| \leq \frac{M}{(r+s)^k} \) for all \( k \). If \( |x - x_0| \leq r \), then we have, for any \( k \),
\[
f^{(k)}(x) = \sum_{j=k}^{\infty} j(j-1)\cdots(j-k)a_j(x-x_0)^{j-k}
\]
\[
|f^{(k)}(x)| \leq \sum_{j=k}^{\infty} j(j-1)\cdots(j-k) \frac{M}{(r+s)^j} \frac{1}{r^j} = \frac{M}{(r+s)^k} \sum_{j=k}^{\infty} j(j-1)\cdots(j-k) \left( \frac{r}{r+s} \right)^{j-k}
\]
\[
= \frac{M}{(r+s)^k} \frac{k!}{(1-\frac{r}{r+s})^{k+1}} = \frac{M}{(r+s)^k} \frac{k!(r+s)^{k+1}}{s^{k+1}} = \frac{m \cdot k!}{s^k}
\]
where \( m = \frac{M(r+s)}{s} \).

We now give the proof of Theorem V.16.1.6. and most of Theorem V.16.1.7.
Proof: Let $\sum_{k=0}^{\infty} b_k(x-x_1)^k$ be the Taylor series for $f$ around $x_1$. We will show that for every $r$, $|x_1-x_0| < r < R$, and $s$, $0 < s < R-r$, this Taylor series has radius of convergence at least $s$ and converges to $f(x)$ whenever $|x-x_1| < \min(s, r-|x_1-x_0|)$. This will show that this Taylor series has radius of convergence at least $S$ and that it converges to $f$ in a neighborhood of $x_1$; it follows that $f$ is analytic on $I$.

Fix such an $r$ and $s$. By Lemma V.16.1.8, there is an $m$ such that $|f^{(k)}(x)| \leq \frac{m}{s^k}$ for all $k \geq 0$ whenever $|x-x_0| \leq r$. In particular, we have

$$|b_k| = \frac{|f^{(k)}(x_1)|}{k!} \leq \frac{m}{s^k}$$

for all $k$, so the radius of convergence of $\sum_{k=0}^{\infty} b_k(x-x_1)^k$ is

$$\limsup_{k \to \infty} \frac{1}{|b_k|^{1/k}} \geq \frac{1}{\limsup_{k \to \infty} \left(\frac{m}{s^k}\right)^{1/k}} = s.$$

Since $s$ can be made arbitrarily close to $S$ by choosing $r$ close enough to $|x_1-x_0|$, the radius of convergence is at least $S$.

Let $g$ be the function on $J = (x_1 - S, x_1 + S)$ defined by $\sum_{k=0}^{\infty} b_k(x-x_1)^k$, and let

$$g_n(x) = \sum_{k=0}^{n} b_k(x-x_1)^k$$

for $n \in \mathbb{N}$. Then $g_n \to g$ on $J$. Set $\phi_n = f - g_n$. Then $\phi_n$ is $C^\infty$ on $I$, $\phi_n^{(k)}(x_1) = 0$ for $0 \leq k \leq n$, and $\phi_n^{(k)} = f^{(k)}$ on $I$ for $k > n$ since $g_n$ is a polynomial of degree $\leq n$.

Set $t = \min(s, r-|x_1-x_0|)$, and let $x$ satisfy $|x-x_1| < t$. By the Lagrange Remainder Formula (), we have

$$\phi_n(x) = \frac{\phi_n^{(n+1)}(c_n)}{(n+1)!}(x-x_1)^{n+1} = \frac{f^{(n+1)}(c_n)}{(n+1)!}(x-x_1)^{n+1}$$

for some $c_n$ between $x_1$ and $x$; since $|c_n-x_0| \leq r$ we have

$$|\phi_n(x)| \leq \frac{m}{s^{n+1}}|x-x_1|^{n+1} = m \left(\frac{|x-x_1|}{s}\right)^{n+1}.$$ 

Since $|x-x_1| < s$, $\phi_n(x) \to 0$, $g_n(x) \to f(x)$, and thus $f = g$ on $(x_1-t, x_1+t)$.

\[ \Diamond \]

V.16.1.9. We have now proved V.16.1.6., and all that remains to finish the proof of V.16.1.7. is to show that $f = g$ on all of $J$. We have that $f$ and $g$ are both analytic on $J$ by V.16.1.6., and $f = g$ on a neighborhood of $x_1$. The conclusion then follows by an application of V.16.2.2..

V.16.1.10. An analogous theorem holds for complex analytic functions: if $f$ is defined by a complex power series around $z_0$ on an open disk $D$ of radius $R > 0$, $z_1 \in D$, and $S = R - |z_1 - z_0|$, then the Taylor series for $f$ around $z_1$ has radius of convergence at least $S$ and converges to $f$ on the open disk of radius $S$ around $z_1$. This can be proved by an identical proof to the one above, but there is a simpler proof using other theorems of complex analysis.
Growth of Derivatives of Analytic Functions

We can obtain a closely related characterization of analytic functions: they are exactly the $C^\infty$ functions whose derivatives “do not grow too rapidly” locally. Precisely:

**V.16.1.11. Theorem.** Let $f$ be a real-valued function on an open set $U$ in $\mathbb{R}$. Then $f$ is analytic on $U$ if and only if $f$ is $C^\infty$ on $U$ and, for each $x_0 \in U$, there is an open interval $J$ containing $x_0$ and natural numbers $m$ and $n$ such that

$$|f^{(k)}(x)| \leq m \cdot k! \cdot n^k$$

for all $k \geq 0$ and all $x \in J$.

**Proof:** Suppose $f$ is analytic on $U$ and $x_0 \in U$. Then the Taylor series for $f$ around $x_0$ has positive radius of convergence $R$, and there is an $r$, $0 < r < R$, such that this Taylor series represents $f$ on $J = (x_0 - r, x_0 + r)$. Fix $s$ with $0 < S < R - r$. Then by Lemma V.16.1.8., there is an $m$ such that, for any $k \geq 0$ and $x \in J$, $|f^{(k)}(x)| \leq \frac{m \cdot k!}{s^k}$. We may assume $m \in \mathbb{N}$, and we may take $n$ any natural number $\geq \frac{1}{s}$.

Conversely, suppose $f$ is $C^\infty$ on $U$ and the growth condition is satisfied. Fix $x_0 \in U$, and let $\sum_{k=0}^{\infty} a_k (x - x_0)^k$ be the Taylor series of $f$ around $x_0$. Let $J$, $m$, and $n$ be as in the statement, and set $s = \frac{1}{n}$. Then there is an $r$, $0 < r < s$, such that $(x_0 - r, x_0 + r) \subseteq J$. For each $k$, let $p_k$ be the $k$'th Taylor polynomial for $f$ around $x_0$, and $r_k = f - p_k$ the $k$'th remainder. If $|x - x_0| < r$, then we have

$$r_k(x) = \frac{f^{(k+1)}(c_k)}{(k+1)!} (x - x_0)^{k+1}$$

for some $c_k$ between $x_0$ and $x$; since $c_k \in (x_0 - r, x_0 + r)$ we have

$$|r_k(x)| \leq m \cdot n^{k+1} r^{k+1} = m \left( \frac{r}{s} \right)^{k+1} \to 0$$

as $k \to \infty$; thus the Taylor series for $f$ around $x_0$ converges to $f$ on $(x_0 - r, x_0 + r)$ and $f$ is analytic on $U$. \(\blacksquare\)

**V.16.2. Rigidity of Analytic Functions**

One of the remarkable properties of an analytic function $f$ on an open interval $I$ is that the values of $f$ on a small part of $I$ (e.g. a small subinterval of $I$) completely determine the values of $f$ on all of $I$. In particular, if an analytic function $f$ on an interval $I$ is identically 0 on a small subinterval of $I$, then $f$ is identically 0 on all of $I$, and in fact the zeroes of a nonzero analytic function are (relatively) isolated in $I$.

**V.16.2.1. Theorem.** Let $f$ and $g$ be analytic on an open interval $I$, and $(x_n)$ a sequence of distinct points in $I$ converging to $x_0 \in I$. If $f(x_n) = g(x_n)$ for all $n$, then $f(x) = g(x)$ for all $x \in I$. 

687
**V.16.2.2.** Corollary. Let $f$ and $g$ be analytic on an open interval $I$, and $J$ a (nondegenerate) subinterval of $I$. If $f(x) = g(x)$ for all $x \in J$, then $f(x) = g(x)$ for all $x \in I$.

**V.16.2.3.** Corollary. Let $f$ be analytic and not identically 0 on an open interval $I$. Then the zeros of $f$ in $I$ are isolated in $I$: if $x_0 \in I$ and $f(x_0) = 0$, then there is a deleted neighborhood $U$ of $x_0$ in $I$ such that $f(x) \neq 0$ for all $x \in U$.

**V.16.2.4.** Caution: Two analytic functions on an interval $I$ can agree at a sequence of points in $I$ without being identical, so long as the sequence has no cluster points in $I$. For example, $f(x) = \sin x$ takes the same values as the constant function 0 at $n\pi$ for all $n$. The sequence where $f$ and $g$ agree can even have a limit which is not in $I$: $f(x) = \sin \left( \frac{x}{2} \right)$ is analytic on $(0, +\infty)$ and agrees with the constant function 0 at a sequence of points $\left( \frac{1}{n\pi} \right)$ converging to 0.

To prove Theorem V.16.2.1., we need a lemma which is of independent interest:

**V.16.2.5.** Lemma. Let $f$ be $C^\infty$ on an open interval $I$, and $(x_n)$ a sequence of distinct points in $I$ converging to $x_0 \in I$. If $f(x_n) = 0$ for all $n$, then $f^{(k)}(x_0) = 0$ for all $k$.

**Proof:** We have $f(x_0) = \lim_{n \to \infty} f(x_n) = 0$ by continuity, and

$$f'(x_0) = \lim_{n \to \infty} \frac{f(x_n) - f(x_0)}{x_n - x_0} = 0.$$  

Suppose $f(x_0) = f'(x_0) = \cdots = f^{(k-1)}(x_0) = 0$ and $f^{(k)}(x_0) \neq 0$, and set $a = \frac{f^{(k)}(x_0)}{k!}$. Then by Taylor’s Theorem () we have

$$f(x) = a(x - x_0)^k + o((x - x_0)^k)$$

for all $x \in I$. Thus there is a $\delta > 0$ such that

$$|f(x) - a(x - x_0)^k| < \frac{|a|}{2}|x - x_0|^k$$

whenever $0 < |x - x_0| < \delta$. But there is an $n$ with $0 < |x_n - x_0| < \delta$, a contradiction. Thus there is no such $k$.  

See V.10.6.11. for an alternate argument. We now give the proof of Theorem V.16.2.1.

**Proof:** First suppose $g$ is identically 0, i.e. $f(x_n) = 0$ for all $n$. Then by V.16.2.5. the Taylor series for $f$ around $x_0$ is identically 0, i.e. $f$ is identically 0 in a neighborhood of $x_0$ in $I$. Let $E$ be the set of all $x \in I$ such that $f$ is identically 0 in a neighborhood of $x$ in $I$. Then $E$ is nonempty since $x_0 \in E$, and it is obviously open in $I$. If $c \in I$ is in the closure of $E$, another application of V.16.2.5. shows that $f^{(k)}(c) = 0$ for all $k$, and hence $f$ is identically 0 in a neighborhood of $c$ in $I$, i.e. $c \in E$. Thus $E$ is relatively closed in $I$. Since $I$ is connected, $E = I$.

Now consider the case of general $g$. We have that $f - g$ is analytic on $I$ and vanishes at each $x_n$, so $f - g$ is identically 0 on $I$.  

688
V.16.2.6. There are (nonanalytic) $C^\infty$ functions on $I$ satisfying the hypotheses of Lemma V.16.2.5., which are not identically zero (V.17.2.2.). Thus $C^\infty$ functions do not generally have the same rigidity properties as analytic functions. In fact, the difference is dramatic; see V.17.2.9.

There are many important consequences of V.16.2.1., for example:

V.16.2.7. Corollary. Let $f$ be an analytic function on an open interval $I$, and $x_0 \in I$. Let $J$ be the interval of convergence of the Taylor series for $f$ around $x_0$. Then the Taylor series for $f$ around $x_0$ represents $f$ on all of $I \cap J$, and $f$ extends uniquely to an analytic function on $I \cup J^o$.

Proof: Let $g$ be the function defined on $J$ by the Taylor series for $f$ around $x_0$. Then $g$ is analytic on $J^o$. The functions $f$ and $g$ are analytic on $I \cap J^o$, and agree in a neighborhood of $x_0$ by V.16.1.7., so they agree on all of $I \cap J^o$ by V.16.2.2.. If $x$ is an endpoint of $J$ contained in $I$, then $x$ is in the closure of $I \cap J^0$ and both $f$ and $g$ are continuous at $x$ (V.15.3.17.), so $f(x) = g(x)$.

For the last statement, define $h(x) = f(x)$ if $x \in I$ and $h(x) = g(x)$ if $x \in J^o$. Then $h$ is well defined by the first part of the proof, and is obviously analytic on $I \cup J^o$. Since $I \cup J^o$ is an interval, and any extension of $f$ to $I \cup J^o$ agrees with $f$ on $I$, uniqueness follows from V.16.2.2.

V.16.2.8. Example. Note that the interval $I$ cannot be replaced by an open set $U$ in this result: let $U = \mathbb{R} \setminus \{0\}$, and let $f(x) = 0$ for $x < 0$ and $f(x) = 1$ for $x > 0$. Then $f$ is analytic on $U$, but V.16.2.7. fails for any $x_0 \in U$.

V.16.2.9. The exact complex analog of V.16.2.1. holds, with essentially identical proof: if $f$ and $g$ are complex analytic on a connected open set $V$, $(z_n)$ is a sequence in $V$ converging to $z_0 \in V$, and $f(z_n) = g(z_n)$ for all $n$, then $f(z) = g(z)$ for all $z \in V$. V.16.2.7. also extends to the complex case, with “interval” replaced by “disk.” (There are topological obstructions to extending this result to connected open sets in $\mathbb{C}$, even simply connected open sets, but it does extend to convex open sets.)

This is needed to prove the following important fact:

V.16.2.10. Theorem. Let $f$ be a real analytic function on an open set $U$ in $\mathbb{R}$. Then there is an open set $V$ in $\mathbb{C}$ with $V \cap \mathbb{R} = U$, and a complex analytic function $g$ on $V$, such that $g|U = f$.

Proof: For each $x_0 \in U$, the Taylor series for $f$ around $x_0$, regarded as a complex power series, defines a complex analytic function $g_{x_0}$ on an open disk in $\mathbb{C}$ centered at $x_0$ whose intersection with the real axis is contained in $U$, and on which $g_{x_0}$ agrees with $f$. It is only necessary to show that these functions agree on the overlaps of their domains; then $g$ can be defined on the union of these disks. But any two of these functions agree on the part of the overlap of their domain disks contained in $U$ (which is an open interval in $\mathbb{R}$), and the overlap is connected, so they agree on the entire overlap.
V.16.3. Combinations of Analytic Functions

In this section, we show that all usual ways of manufacturing new functions out of old preserve analyticity. Specifically:

(i) Linear combinations of analytic functions are analytic.

(ii) Derivatives and antiderivatives of analytic functions are analytic (V.15.3.20., V.15.3.23.).

(iii) Products of analytic functions are analytic.

(iv) Quotients of analytic functions are analytic if the denominator is nonzero.

(v) Compositions of analytic functions are analytic.

(vi) Inverse functions of analytic functions with nonzero derivatives are analytic.

These results, among other things, provide a large supply of standard analytic functions. The direct proofs range from very easy (i) to easy consequences of previous results ((ii)–(iii)) to moderately involved ((iv)–(v)) to quite difficult (vi). The “easy” way to prove (iii)–(vi) is to use V.16.2.10. and theorems from complex analysis, but we will describe direct proofs not using complex analysis.

Linear Combinations of Analytic Functions

V.16.3.1. Proposition. Let \( f \) and \( g \) be analytic on an open set \( U \), and \( \alpha \) a scalar. Then \( f + g \) and \( \alpha f \) are analytic on \( U \).

Proof: The conclusions are immediate consequences of IV.2.1.16. and IV.2.1.18. respectively (plus the observation that linear combinations of power series centered at the same place are also power series). ☐

Unordered Power Series

V.16.3.2. Definition. An unordered power series is an unordered sum (IV.2.9.2.)

\[
\sum_{j \in J} a_j X^{n_j}
\]

where \( J \) is an index set, \( a_j \) is a scalar, \( X \) is an indeterminate symbol, and \( n_j \in \mathbb{N} \cup \{0\} \) for each \( j \). (Thus we may have unordered real power series or unordered complex power series).

The differences between an unordered power series and an ordinary formal power series are:

(i) The order of the terms is not specified.

(ii) There may be many terms, even infinitely many, with the same power of \( X \).
An unordered power series \( \sum_{j \in J} a_j x^{n_j} \) with coefficients in \( \mathbb{F} (= \mathbb{R} \) or \( \mathbb{C} \)) defines a function by setting
\[
f(x) = \sum_{j \in J} a_j x^{n_j}
\]
whose domain is the set of \( x \) for which the unordered sum converges (i.e. converges absolutely by IV.2.9.9.). The domain may be empty (we adhere to the convention that \( x^0 = 1 \) even if \( x = 0 \)). We may more generally fix an \( x_0 \) and consider the function
\[
f(x) = \sum_{j \in J} a_j (x - x_0)^{n_j}.
\]

While the index set \( J \) can in principle be uncountable, if it is not countable, or at least if \( \{ j : a_j \neq 0 \} \) is uncountable (terms with \( a_j = 0 \) can be effectively ignored in the sum), the unordered sum cannot converge for any \( x \neq 0 \) by IV.2.9.6.. Thus in examining such series expansions of functions there is no essential loss of generality in considering only countable index sets. So from now on we will restrict to the case where \( J \) is countable.

We can formally rearrange an unordered power series into an ordinary power series. To do this, for each \( k \in \mathbb{N} \cup \{0\} \) set \( J_k = \{ j : n_j = k \} \) (i.e. the set of indices for which the power of \( X \) in the term is \( k \)). We can then form the ordinary infinite series
\[
\sum_{k=0}^{\infty} \left( \sum_{j \in J_k} a_j \right) x^k
\]
provided the unordered sum \( \sum_{j \in J_k} a_j \) converges for each \( k \). This power series is called the standard revision of the unordered power series.

**Theorem.** Let
\[
\sum_{j \in J} a_j X^{n_j}
\]
be an unordered power series, and \( x_0 \) a scalar. Suppose the unordered sum
\[
\sum_{j \in J} a_j (x_1 - x_0)^{n_j}
\]
converges for some \( x_1 \neq x_0 \). Then
(i) The unordered sum
\[
f(x) = \sum_{j \in J} a_j (x - x_0)^{n_j}
\]
converges for all \( x, |x - x_0| \leq |x_1 - x_0| \).
(ii) The unordered sum
\[ \sum_{j \in J_k} a_j \]
converges for each \( k \).

(iii) The standard revision
\[
\sum_{k=0}^{\infty} \left[ \left( \sum_{j \in J_k} a_j \right) (x-x_0)^k \right]
\]
of the unordered power series converges absolutely to \( f(x) \) for all \( x, |x-x_0| \leq |x_1-x_0| \). (In particular, this power series has radius of convergence at least \( |x_1-x_0| \).)

(If \( x_1 = x_0 \), (i) and (iii) still hold, and (ii) holds for \( k = 0 \), but the result has little content in this case.)

\textbf{Proof:} By IV.2.9.9.,
\[
\sum_{j \in J} |a_j(x_1-x_0)^{n_j}| 
\]
converges, and thus for \( |x-x_0| \leq |x_1-x_0| \) the unordered sum
\[
\sum_{j \in J} |a_j(x-x_0)^{n_j}|
\]
converges by comparison, hence \( \sum_{j \in J} a_j(x-x_0)^{n_j} \) converges. (Technically we should convert the unordered sums to ordinary infinite series by taking the terms in some order; the order is irrelevant.) Also, for any \( k \), the unordered sum
\[
\sum_{j \in J_k} |a_j(x_1-x_0)^{n_j}| = |(x_1-x_0)^k| \sum_{j \in J_k} |a_j|
\]
converges since it is a subsum of a convergent nonnegative unordered sum. Thus, since \( x_1 \neq x_0 \),
\[
\sum_{j \in J_k} a_j
\]
converges for each \( k \). Finally, for any \( x \) with \( |x-x_0| \leq |x_1-x_0| \) the standard revision
\[
\sum_{k=0}^{\infty} \left[ \left( \sum_{j \in J_k} a_j \right) (x-x_0)^k \right]
\]
(with the terms from each \( J_k \) ordered in some arbitrary way) is a drastic revision (IV.2.10.14.) of the unordered sum
\[
f(x) = \sum_{j \in J} a_j(x-x_0)^{n_j}
\]
(with terms ordered in some way). Since the unordered sum converges (absolutely), the standard revision converges to the same sum by IV.2.10.16..
V.16.3.7. Conversely, any ordinary power series can be regarded as an unordered power series. The unordered power series converges exactly whenever the original power series converges absolutely, i.e. either on the interval (or disk) of convergence or the open interval (or disk) of convergence of the power series.

V.16.3.8. Corollary. Let
\[ \sum_{j \in J} a_j X^j \]
be an unordered power series. If the unordered series
\[ \sum_{j \in J} a_j x^j \]
converges for some \( x \neq 0 \), then for any \( x_0 \) the function
\[ f(x) = \sum_{j \in J} a_j(x - x_0)^j \]
is analytic on an interval (or disk) around \( x_0 \). The Taylor series for \( f \) around \( x_0 \) is the standard revision of the unordered power series.

V.16.3.9. This result can be used to justify many formal manipulations with power series. The rough general principle is:

If \( f \) and \( g \) are functions defined by infinite summations, and the summations can be formally manipulated into the same sum, and the summations converge absolutely in an appropriate sense, then the functions are equal.

We give several specific examples below (V.16.3.12.).

Products of Analytic Functions

V.16.3.10. Theorem. Let \( f \) and \( g \) be analytic functions on an open set \( U \). Then \( fg \) is analytic on \( U \).

Proof: Fix \( x_0 \in U \), and let
\[ f(x) = \sum_{k=0}^{\infty} a_k(x - x_0)^k \quad \text{and} \quad g(x) = \sum_{k=0}^{\infty} b_k(x - x_0)^k \]
be the Taylor series for \( f \) and \( g \), converging to \( f \) and \( g \) on \( \{ x : |x - x_0| < R \} \subseteq U \). If \( |x - x_0| < R \), then the above series converge absolutely, so the product series
\[ \sum_{n=0}^{\infty} \left( \sum_{k=0}^{n} a_k b_{n-k} \right)(x - x_0)^k \]
converges (absolutely) to \( f(x)g(x) \) by IV.2.11.8.
V.16.3.11. It can be readily checked by repeated applications of the Product Rule that if \( f \) and \( g \) are infinitely differentiable at \( x_0 \), then so is \( fg \), and that the Taylor series for \( fg \) around \( x_0 \) is the product of the Taylor series for \( f \) and \( g \) around \( x_0 \) (i.e. the Taylor series for \( fg \) around \( x_0 \) is the standard revision of the unordered power series obtained by multiplying the two Taylor series termwise). This observation is not needed for the proof of V.16.3.10., but it and V.16.3.10. give additional motivation for why the definition (IV.2.11.5.) of the product of two infinite series is the “right” one.

Compositions of Analytic Functions

V.16.3.12. Theorem. Let \( f \) be analytic on an open set \( U \), \( g \) analytic on an open set \( V \), and \( f(U) \subseteq V \). Then \( g \circ f \) is analytic on \( U \).

Proof: We may proceed formally as follows, ignoring convergence questions for the moment. Let \( x_0 \in U \), and \( y_0 = f(x_0) \in V \). Let

\[
f(x) = \sum_{k=0}^{\infty} a_k(x-x_0)^k \quad \text{and} \quad g(y) = \sum_{k=0}^{\infty} b_k(y-y_0)^k
\]

be the Taylor series for \( f \) around \( x_0 \) and for \( g \) around \( y_0 \). Then we can expand

\[
g(f(x)) = \sum_{k=0}^{\infty} b_k(f(x)-y_0)^k = \sum_{k=0}^{\infty} b_k \left( \sum_{j=1}^{\infty} a_j(x-x_0)^j \right)^k.
\]

If we expand the \( k \)'th power series

\[
\left( \sum_{j=1}^{\infty} a_j(x-x_0)^j \right)^k
\]

into a product series

\[
\sum_{n=0}^{\infty} c_{kn}(x-x_0)^n
\]

for each \( k \) (cf. IV.2.11.11.), we have a drastic revision

\[
\sum_{k=0}^{\infty} b_k \left( \sum_{n=1}^{\infty} c_{kn}(x-x_0)^n \right)
\]

of an unordered power series

\[
\sum_{(n,k)} b_k c_{kn}(x-x_0)^n.
\]

The drastic revision V.1 converges to \( g(f(x)) \) if \( x \) is sufficiently close to \( x_0 \); so if the unordered series V.2 converges for some \( x \neq x_0 \), we can conclude from V.16.3.8. that its sum (which is \( g \circ f \) by IV.2.10.16.) is analytic on a neighborhood of \( x_0 \). Since \( x_0 \in U \) is arbitrary, the result follows.

The two power series

\[
\sum_{k=1}^{\infty} |a_k|x^k \quad \text{and} \quad \sum_{k=0}^{\infty} |b_k|y^k
\]

694
have a positive radius of convergence, hence define analytic functions $F$ and $G$ near 0. Thus, if $t$ is a sufficiently small positive number, we can write

$$G(F(t)) = \sum_{k=0}^{\infty} |b_k| F(t)^k = \sum_{k=0}^{\infty} |b_k| \left( \sum_{j=1}^{\infty} |a_j| t^j \right)^k$$  \hspace{1cm} (V.3)

where all the series converge (absolutely). Expanding the $k$’th power series

$$\left( \sum_{j=1}^{\infty} |a_j| t^j \right)^k = \sum_{n=0}^{\infty} d_{kn} t^n$$

for each $k$ (note that $d_{kn} \geq 0$ for all $k$ and $n$) and converting V.3 to an unordered series

$$\sum_{(n,k)} |b_k| d_{kn} t^n$$

we obtain a convergent nonnegative unordered series which converges to $G(F(t))$. If we compare the series

$$\left( \sum_{j=1}^{\infty} a_j (x-x_0)^j \right)^k = \sum_{n=0}^{\infty} c_{kn} (x-x_0)^n$$

$$\left( \sum_{j=1}^{\infty} |a_j| t^j \right)^k = \sum_{n=0}^{\infty} d_{kn} t^n$$

we obtain easily from the triangle inequality that $|c_{kn}| \leq d_{kn}$ for all $k$ and $n$. Thus the unordered series

$$\sum_{(n,k)} b_k c_{kn} t^n$$

converges absolutely by comparison, which was what needed to be shown to complete the proof (taking $x = x_0 + t$).

\vspace{1cm}

**V.16.3.13. Remarks.** Here are some remarks about the theorem and its proof.

(i) In most of the proof we work with $\sum_{k=1}^{\infty} a_k (x-x_0)^k$, not $\sum_{k=0}^{\infty} a_k (x-x_0)^k$. This is because we necessarily have $a_0 = f(x_0) = y_0$ and we are working with $f(x) - y_0$.

(ii) The $k$’th power sum

$$\left( \sum_{j=1}^{\infty} a_j (x-x_0)^j \right)^k$$
when converted into the product series
\[
\sum_{n=0}^{\infty} c_{kn}(x-x_0)^n
\]
has summation starting at \(k\), i.e. \(c_{kn} = 0\) for \(n < k\). Thus the standard revision of the unordered series
\[
\sum_{(n,k)} b_k c_{kn}(x-x_0)^n
\]
representing \(g \circ f\) is an ordinary revision, not a drastic revision:
\[
\sum_{n=0}^{\infty} \left[ \left( \sum_{k=0}^{n} b_k c_{kn} \right) (x-x_0)^n \right] \quad \text{(V.4)}
\]
which must be the Taylor series for \(g \circ f\) around \(x_0\).

(iii) If \(f\) is \(C^\infty\) on \(U\), \(g\) is \(C^\infty\) on \(V\), and \(f(U) \subseteq V\), then \(g \circ f\) is \(C^\infty\) on \(U\) by the Chain Rule. If \(x_0 \in U\) and the Taylor series for \(g \circ f\) around \(x_0\) is calculated using Faà di Bruno’s formula (V.3.7.8.), the same power series as in V.4 is obtained, as can be verified by unpleasant direct calculation. In fact, the derivation of this Taylor series in the proof of V.16.3.12. is a good way to derive (but not prove!) Faà di Bruno’s formula.

Quotients of Analytic Functions

The next result is an immediate corollary of V.16.3.12., since \(g(x) = \frac{1}{x}\) is analytic on \(\{x : x \neq 0\}\):

V.16.3.14. Corollary. Let \(f\) be analytic on an open set \(U\), with \(f(x) \neq 0\) for all \(x \in U\). Then \(\frac{1}{f}\) is analytic on \(U\).

Combining this with V.16.3.10., we obtain:

V.16.3.15. Theorem. Let \(f\) and \(g\) be analytic on an open set \(U\), with \(g(x) \neq 0\) for all \(x \in U\). Then \(\frac{f}{g}\) is analytic on \(U\).

Bernstein’s Theorem

We prove a theorem obtained by S. Bernstein in 1912, which is at least interesting if not too useful. (Bernstein only stated (ii), but the more precise statements of (i) and (iii) follow easily from his proof.)

V.16.3.16. Theorem. Let \(I = (a, b)\) be an open interval in \(\mathbb{R}\) (where \(a \in \mathbb{R} \cup \{-\infty\}\) and \(b \in \mathbb{R} \cup \{+\infty\}\)), and let \(f\) be a \(C^\infty\) function on \(I\). If \(f^{(k)}(x) \geq 0\) for all \(k \geq 0\) and all \(x \in I\), then:

(i) If \(x_0 \in I\) and \(R = b - x_0\) \((R = +\infty\) if \(b = +\infty\)), then the Taylor series for \(f\) around \(x_0\) converges to \(f(x)\) for all \(x \in I\) with \(|x - x_0| < R\). (In particular, the radius of convergence of this Taylor series is at least \(R\).)

696
(ii) $f$ is analytic on $I$.

(iii) If $\ell = b - a$ ($\ell = +\infty$ if $b = +\infty$ or $a = -\infty$), then $f$ extends uniquely to an analytic function on $(a - \ell, b)$ (all of $\mathbb{R}$ if $b = +\infty$).

Note, however, that the extension in (iii) does not necessarily have $f^{(k)}(x) \geq 0$ for all $k$ and $x$: consider $f(x) = x^3$ on $(0, \infty)$.

**Proof:** (i): Fix $x_0 \in I$, and fix $x > x_0$. Let $c \in I$ with $c > x$. Let $p_n$ be the $n$th Taylor polynomial for $f$ around $x_0$. We have $p_n(x) \geq 0$ since all the terms in the Taylor series are nonnegative. By the Integral Form of the Remainder (V.10.4.2.), we have

$$R_n(x) = f(x) - p_n(x) = \frac{1}{n!} \int_{x_0}^{x} f^{(n+1)}(t)(x-t)^n \, dt.$$ 

Using two changes of variable ($u = t - x_0$ and $s = \frac{u}{x-x_0}$), we obtain

$$R_n(x) = \frac{1}{n!} \int_{0}^{x-x_0} f^{(n+1)}(u+x_0)(x-x_0-u)^n \, du = \frac{(x-x_0)^{n+1}}{n!} \int_{0}^{1} f^{(n+1)}((x-x_0)s-x_0)(1-s)^n \, ds$$

and, since $f^{(n+1)}$ is nonnegative and nondecreasing ($f^{(n+2)}$ is also nonnegative), we have

$$0 \leq R_n(x) \leq \left(\frac{x-x_0}{c-x_0}\right)^{n+1} \left(\frac{c-x_0}{x-x_0}\right)^{n+1} \int_{0}^{1} f^{(n+1)}((c-x_0)s+x_0)(1-s)^n \, ds = \left(\frac{x-x_0}{c-x_0}\right)^{n+1} R_n(c).$$

We have $R_n(c) = f(c) - p_n(c) \leq f(c)$ since $p_n(c) \geq 0$, so we have

$$0 \leq R_n(x) \leq \left(\frac{x-x_0}{c-x_0}\right)^{n+1} f(c)$$

and thus $R_n(x) \to 0$ as $n \to \infty$, i.e. the Taylor series for $f$ around $x_0$ converges to $f(x)$.

Now suppose $x \in I$, $x < x_0$, $|x-x_0| < R$. Set $y = x_0 + |x-x_0|$, i.e. $y > x_0$ and $|y-x_0| = |x-x_0|$. By comparison of integrals we have $|R_n(x)| \leq R_n(y)$ since $f^{(n+1)}$ is nondecreasing, so $R_n(x) \to 0$ as $n \to \infty$.

(ii): Immediate from (i).

(iii): If $x_0 > a$ and $R = b - x_0$, then by (i) the Taylor series for $f$ around $x_0$ defines an analytic function on $(x_0-R, x_0+R)$ which agrees with $f$ on $I$. Let $x_0 \to a+$. (All the extensions defined this way must coincide on the intersections of their domains by V.16.2.1., which also gives the uniqueness of the extension.)

**Formal Manipulation of Power Series**

**V.16.3.17.** The results of this section can be used to justify the formal manipulation of power series. For example, suppose we are given analytic functions $f$ and $h$ taking the same value at 0 and we want to find an analytic function $g$ satisfying $g(0) = 0$ and $h = f \circ g$ (we stick to analytic functions around 0 for notational simplicity; more generally, we may take power series centered at other points than 0). Temporarily ignoring questions of convergence, we can proceed formally: write

$$f(x) = \sum_{k=0}^{\infty} a_k x^k$$

$$h(x) = \sum_{k=0}^{\infty} b_k x^k$$

$$g(x) = \sum_{k=0}^{\infty} c_k x^k$$

such that $c_k = \frac{1}{k!} \int_{0}^{x} f^{(k+1)}(t)(x-t)^k \, dt$ for all $k$. Then $g(0) = 0$, $h(x) = f(g(x))$, and $g(x) = \frac{1}{k!} \int_{0}^{x} f^{(k+1)}(t)(x-t)^k \, dt$ for all $k$. By the Integral Form of the Remainder (V.10.4.2.), we have

$$g(x) = \sum_{k=0}^{\infty} \frac{1}{k!} \int_{0}^{x} f^{(k+1)}(t)(x-t)^k \, dt = \sum_{k=0}^{\infty} \frac{1}{k!} \int_{0}^{x} a_k (x-t)^k \, dt = \sum_{k=0}^{\infty} \frac{x^k}{k!} a_k = f(x).$$

Thus $g(x) = f(x)$ for all $x$ in the domain of $f$.
\[ h(x) = \sum_{k=0}^{\infty} c_k x^k \]

with \( a_0 = c_0 \). The unknown function

\[ g(x) = \sum_{k=1}^{\infty} b_k x^k \]

can be “found” by manipulation of the power series:

\[ f(g(x)) = a_0 + a_1(b_1 x + b_2 x^2 + \cdots) + a_2(b_1 x + b_2 x^2 + \cdots)^2 + \cdots \]

We can formally multiply out the last expression to get

\[
(b_1 x + b_2 x^2 + \cdots)^2 = b_1^2 x^2 + 2b_1 b_2 x^3 + \cdots
\]

and similarly for higher powers. Collecting together like powers of \( x \), we get

\[ f(g(x)) = a_0 + a_1 b_1 x + (a_1 b_2 + a_2 b_1^2) x^2 + \cdots \]

and for this to be equal to \( h(x) \), we get the equations

\[
c_0 = a_0 \\
c_1 = a_1 b_1 \\
c_2 = a_1 b_2 + a_2 b_1^2
\]

etc., which must be solved for the \( b_k \). It is easy to see exactly when this can be done recursively, and what the (necessarily unique) solution is when it exists.

To justify the formal manipulations, the theorems of this section can be used. In fact, using (), we can show:

**V.16.3.18. Theorem.** If the system is solvable for the \( b_k \), and if the power series

\[ \sum_{k=1}^{\infty} b_k x^k \]

has a positive radius of convergence, then the function \( g \) defined by the series satisfies \( h = f \circ g \) in a neighborhood of 0. Conversely, if \( g \) is an analytic function in a neighborhood of 0 satisfying \( g(0) = 0 \) and \( h = f \circ g \) in a neighborhood of 0, and

\[ g(x) = \sum_{k=1}^{\infty} b_k x^k \]

is its Taylor series around 0, then the \( b_k \) satisfy the equations. In particular, \( g \) is the unique analytic function with these properties.

**V.16.3.19.** It is a more delicate matter to find or estimate how large a neighborhood of 0 the formula is valid in. In fact, it is valid in the largest open disk around 0 mapped by \( g \) into the open disk of convergence of the Taylor series for \( f \) around 0.
V.17. Smooth Non-Analytic Functions

A striking and important phenomenon is that a smooth ($C^1$) function on an interval $I$ need not be analytic on $I$; in fact, it can be “completely nonanalytic” on $I$. In this section we describe various ways in which a smooth function can be nonanalytic.

This is a topic in which the fairly extensive work over a rather long period of time does not seem to be widely known in the mathematical community (e.g. the author only rather recently became aware of it). It is remarkable how often the basic results and examples (with slight variations) have been rediscovered, reproved, and republished. Only variations of Cauchy’s original example, and Borel’s Theorem, have apparently become standard knowledge among mathematicians. For an extensive survey of the work done in this area, see http://mathforum.org/kb/message.jspa?messageID=387148.

V.17.1. Analyticity at a Point

The definition of an analytic function (V.16.1.1.) only defines analyticity on an open interval in $\mathbb{R}$ (or an open set in $\mathbb{C}$). It is useful to make the following definition of “analyticity at a point.”

V.17.1.1. Definition. Let $I$ be an interval in $\mathbb{R}$, and $x_0 \in I$. A real-valued $C^1$ function $f$ on $I$ is analytic at $x_0$ if the Taylor series of $f$ around $x_0$ converges to $f$ in some relatively open subinterval of $I$ containing $x_0$ (an open interval if $x_0$ is an interior point of $I$). A point where $f$ is not analytic is called a singular point of $f$.

The next result, an immediate corollary of V.16.1.6., is fundamental:

V.17.1.2. Proposition. Let $f \in C^\infty(I)$. The set

$$A_f = \{x_0 \in I : f \text{ is analytic at } x_0\}$$

is relatively open in $I$.

Thus the set of singular points of $f$ is a relatively closed subset of $I$. (It is not yet clear that this set can be nonempty.)

Types of Singular Points

V.17.1.3. If $f$ is $C^\infty$ on $I$ and $x_0 \in I$, there are two potential ways $f$ can fail to be analytic at $x_0$:

(i) The Taylor series of $f$ around $x_0$ has radius of convergence zero. Such a point is sometimes called a divergence point of $f$. In [Zah47], such points are called points of type (P), or (P)-points (for Pringsheim).

(ii) The Taylor series of $f$ around $x_0$ has positive radius of convergence, but does not represent the function on any interval around $x_0$. Such a point is sometimes called a false convergence point of $f$. The name from [Zah47] is point of type (C), or (C)-point (for Cauchy).

V.17.1.4. Thus, if $f$ is $C^\infty$ on $I$, $I$ decomposes as the disjoint union of the set $A_f$ of points where $f$ is analytic, the set $P_f$ of the (P)-points of $f$, and the set $C_f$ of the (C)-points of $f$. $A_f$ is (relatively) open by V.17.1.2., so $P_f \cup C_f$ is (relatively) closed.
V.17.2. (C)-Points and Smooth Partitions

V.17.2.1. The first example of a (C)-point, the best-known example in this subject, was given by Cauchy in 1823.

V.17.2.2. Example. Let
\[
 f(x) = \begin{cases} 
 e^{-1/x^2} & \text{if } x \neq 0 \\
 0 & \text{if } x = 0 
\end{cases}.
\]

Then \( f \) is clearly analytic on \( \mathbb{R} \setminus \{0\} \). On \( \mathbb{R} \setminus \{0\} \), it can easily be shown by induction on \( k \) that \( f^{(k)}(x) \) is a finite sum of terms of the form \( e^{-1/x^2} \) for \( c \in \mathbb{R}, \ m \in \mathbb{N} \cup \{0\} \). Thus, since \( f(0) = 0 \), we have by induction that \( f^{(k)}(0) \) exists and is 0 for all \( k \).

So \( f \) is infinitely differentiable also at 0, thus \( C^\infty \) on \( \mathbb{R} \). The Taylor series at 0 (Maclaurin series) for \( f \) has all terms zero, and thus has infinite radius of convergence. But it does not converge to \( f(x) \) for any \( x \neq 0 \) since \( f(x) > 0 \) for \( x \neq 0 \). Thus 0 is a (C)-point of \( f \) and \( f \) is not analytic at 0. See Figure (). See X.5.2.17.(ii) for an “explanation” of why the function is not analytic at 0.

V.17.2.3. This example is usually presented with an exponent of \(-\frac{1}{x^2}\), but this is just somewhat of a matter of taste. Identical arguments show that each of the following functions has the same properties:
\[
 f_2(x) = \begin{cases} 
 e^{-1/|x|} & \text{if } x \neq 0 \\
 0 & \text{if } x = 0 
\end{cases},
\]
\[
 f_3(x) = \begin{cases} 
 e^{-1/x} & \text{if } x > 0 \\
 0 & \text{if } x \leq 0 
\end{cases},
\]
\[
 f_4(x) = \begin{cases} 
 e^{-1/x^2} & \text{if } x > 0 \\
 0 & \text{if } x \leq 0 
\end{cases},
\]
i.e. each of these is \( C^\infty \) on \( \mathbb{R} \), analytic on \( \mathbb{R} \setminus \{0\} \), and has a (C)-point at 0 where its Taylor series is identically 0. Any of these can be called “Cauchy’s example.” The last two have the interesting property that they are identically zero on the negative real axis. Note that all these examples take values in \([0, 1)\), and are in particular bounded.

Smooth Bump Functions

We can combine translates of these functions to make smooth “bump functions” which are identically zero outside a specified interval:

V.17.2.4. Example. Let \( a, b \in \mathbb{R}, \ a < b \). Define
\[
 g_{a,b}(x) = f_3(x-a)f_3(b-x) = \begin{cases} 
 e^{-\frac{b-a}{x-(b-a)}} & \text{if } a < x < b \\
 0 & \text{if } x \leq a \text{ or } x \geq b 
\end{cases}.
\]

Then \( g \) is \( C^\infty \) on \( \mathbb{R} \), analytic on \( \mathbb{R} \setminus \{a, b\} \), has (C)-points at \( a \) and \( b \) where its Taylor series is identically zero, and is positive on \( (a, b) \) and identically zero on \( \mathbb{R} \setminus (a, b) \). See Figure ().
Smooth Heaviside Functions

V.17.2.5. The function

\[ \phi(x) = \int_a^x g_{a,b}(t) \, dt \]

is \( C^\infty \) on \( \mathbb{R} \), analytic on \( \mathbb{R} \setminus \{a, b\} \), identically 0 for \( x \leq a \), takes a constant positive value for \( x \geq b \), and is strictly increasing on \([a, b]\). A suitable scalar multiple \( h_{a,b} \) has the same properties and is identically 1 for \( x \geq b \). This can be regarded as a smooth version of the Heaviside function \( \chi_{[b, \infty)} \). See Figure ( ).

Smooth Mesa Functions

V.17.2.6. Let \( a < b < c < d \), and let \( f \) be the function

\[ f(x) = h_{a,b}(x)(1 - h_{c,d}(x)) . \]

Then \( f \) is \( C^\infty \) on \( \mathbb{R} \), analytic on \( \mathbb{R} \setminus \{a, b, c, d\} \), identically 0 on \( (-\infty, a] \) and on \([d, +\infty) \), identically 1 on \([b, c] \), strictly increasing on \([a, b] \), and strictly decreasing on \([c, d] \). See Figure ( ).

Smooth Partitions of Unity

Recall the definition of partition of unity ( ). We will show that on \( \mathbb{R} \), smooth partitions of unity exist:

V.17.2.7. Theorem. Let \( \mathcal{U} \) be an open cover of \( \mathbb{R} \). Then there is a countable partition of unity \( \{f_n\} \) subordinate to \( \mathcal{U} \) consisting of \( C^\infty \) functions of compact support.

Proof: This is an easy consequence of ( ). There is a collection \( \mathcal{V} = \{(a_n, b_n) : n \in \mathbb{Z}\} \) of bounded open intervals refining \( \mathcal{U} \) such that \( a_n < b_{n-1} < a_{n+1} < b_n \) for all \( n \). Take \( f_n \) to be the smooth mesa function

\[ f_n = h_{a_n,b_{n-1}}(1 - h_{a_{n+1},b_n}) \]

defined in V.17.2.6. and V.17.2.5.. \( \blacksquare \)

Smooth Functions With Prescribed Zero Sets

V.17.2.8. If \( f \) is a continuous function, then its zero set

\[ Z_f = \{ x : f(x) = 0 \} \]

is always closed. We now show that every closed subset of \( \mathbb{R} \) is the zero set of a smooth function. This is in stark contrast to the situation for analytic functions, where the zero set is either discrete or all of \( \mathbb{R} \) ( ). For a simple example of a \( C^\infty \) function with a nonisolated zero, see Exercise V.17.5.1..
V.17.2.9. **Theorem.** Let $E$ be a closed subset of $\mathbb{R}$. Then there is a nonnegative bounded $C^\infty$ function $\theta$ on $\mathbb{R}$ for which $Z_\theta = E$ and $\theta$ is analytic on $\mathbb{R} \setminus E$.

**Proof:** There is a simple and appealing argument that almost works to prove this result, which can be adapted to give a real proof. The open set $U = \mathbb{R} \setminus E$ is a countable disjoint union of open intervals $I_n$. For each $n$, we can take a smooth bump function $f_n$ which is nonzero exactly on $I_n$ (if $I_n$ is unbounded, take a translation of the $f_3$ of V.17.2.3. or its reflection instead of a bump function). Define $\theta$ to be $f_n$ on $I_n$ and $0$ on $E$. Alternately, define $\theta = \sum_{n=1}^\infty f_n$; the series converges for each $x$ since at most one term is nonzero.

However, there is a problem with this approach. Since the set of endpoints of the $I_n$ is not closed and discrete in general (e.g. consider the case where $E$ is the Cantor set), the sum of the series will not even be continuous in general unless the heights of the bumps are controlled.

We can do this as follows. The complement of $E$ consists of at most a countable number of bounded open intervals $I_n = (a_n, b_n)$, plus possibly one or two unbounded open intervals we will deal with separately at the end of the argument. We may assume there are infinitely many $I_n$ since otherwise a finite sum of bump functions works for $f$. Let $g = g_{0,1}$ be the smooth bump function of V.17.2.4., normalized so that $\max(g(x)) = 1$, and for each $k \geq 0$ let $M_k = \max |g^{(k)}|$. Let $g_n$ be $g$ translated to $I_n$, i.e.

$$g_n(x) = g \left( \frac{x - a_n}{b_n - a_n} \right)$$

for $x \in \mathbb{R}$. Set $f_n = c_ng_n$, where

$$c_n = \min(1, (b_n - a_n)^n) \frac{1}{2^n \max_{0 \leq k \leq n} M_k}.$$ 

Then $f_n$ is $C^\infty$ on $\mathbb{R}$, and $|f_n^{(k)}(x)| \leq 2^{-n}$ for $0 \leq k \leq n$ and all $x \in \mathbb{R}$. Thus

$$\sum_{n=1}^\infty f_n^{(k)}$$

converges uniformly on $\mathbb{R}$ for each $k$. If $\theta = \sum_{n=1}^\infty f_n$, then by V.15.1.2. (the simpler version suffices), $\theta$ is $C^\infty$ on $\mathbb{R}$ and $\theta^{(k)} = \sum_{n=1}^\infty f_n^{(k)}$ for all $k$. The function $\theta$ takes values in $[0, 1]$, and is clearly zero precisely on $E$ and any unbounded intervals in $E^c$. There will be such an unbounded interval if and only if $E$ has a minimum element $a$ and/or a maximal element $b$. If there is such a $b$, adding to $f$ a translated version of Cauchy’s example $f_3$ makes $\theta$ positive on $(b, +\infty)$. A similar correction can be made on $(-\infty, a)$ if $a$ exists. Since, for each $x \in E^c$, $\theta$ is equal to $f_n$ for some $n$ (or a translated Cauchy function) on a neighborhood of $x$, $\theta$ is analytic at $x$. \(\diamondsuit\)

The Smooth Urysohn Lemma

With somewhat more work along the same lines, we can get a smooth version of Urysohn’s Lemma (for $\mathbb{R}$):

V.17.2.10. **Theorem.** [SMOOTH URYSOHN LEMMA FOR $\mathbb{R}$] Let $A$ be a closed subset of $\mathbb{R}$ and $U$ an open set in $\mathbb{R}$ containing $A$. Then there is a $C^\infty$ function $\phi$ from $\mathbb{R}$ to $[0, 1]$ such that $\phi \equiv 1$ on $A$ and $\phi \equiv 0$ on $\mathbb{R} \setminus U$. We may choose $\phi$ so that $\phi^{-1}(\{1\}) = A$ and $\phi^{-1}(\{0\}) = \mathbb{R} \setminus U$. 

702
Alternatively, if $E$ and $F$ are disjoint closed subsets of $\mathbb{R}$, there is a smooth function $\phi : \mathbb{R} \to [0, 1]$ such that $\phi^{-1}(\{1\}) = E$ and $\phi^{-1}(\{0\}) = F$ (set $A = E$ and $U = \mathbb{R} \setminus F$).

**Proof:** We prove the alternative form. Let $E$ and $F$ be disjoint closed subsets of $\mathbb{R}$. Then the open set $V = \mathbb{R} \setminus (E \cup F)$ is a countable disjoint union of open intervals, at most two of which are unbounded. Let $\{(a_i, b_i) : i \in I\}$ be the set of bounded intervals in this union such that $a_i \in E$ and $b_i \in F$, and let $\{(c_j, d_j) : j \in J\}$ be the set of bounded intervals in the collection with $c_j \in F$ and $d_j \in E$. Then $I$ and $J$ are countable. Between any two $a_i$ there must be at least one of the intervals $(c_j, d_j)$, and similarly for the other combinations.

Let $L_E = \{a_i : i \in I\}$, $L_F = \{c_j : j \in J\}$, $R_E = \{d_j : j \in J\}$, $R_F = \{b_i : i \in I\}$. $L_E$ is countable; we claim it is closed and discrete in $\mathbb{R}$. If not, there is a sequence $(a_{i_n})$ in $L_E$ of distinct points converging to some $x \in \mathbb{R}$, and passing to a subsequence we may assume that the sequence is strictly monotone ($\uparrow$). Since each $a_{i_n} \in E$, $x \in E$. If $(a_{i_n})$ is strictly monotone, we also have $b_{i_n} \to x$ since $b_{i_n}$ is between $a_{i_n-1}$ and $a_{i_n+1}$, so $x \in F$, contradicting that $E$ and $F$ are disjoint. Thus $L_E$ is closed and discrete. By similar arguments, $L_F$, $R_E$, $R_F$ are all closed and discrete in $\mathbb{R}$. Thus $L_E \cup L_F \cup R_E \cup R_F$ is also closed and discrete, i.e. there are only finitely many points in any bounded interval.

Thus the endpoints of the intervals can be reindexed $\{(a_k, b_k), (c_k, d_k) : k \in \mathbb{Z}\}$, where

$$a_k < b_k < c_k < d_k < a_{k+1}$$

for all $k$. If $V$ contains an unbounded interval on either side, the indexing on that side will be finite. Define $\phi$ separately on each of the subintervals of $\mathbb{R}$ so defined. On $[b_k, a_{k+1}]$, let $\phi$ be the smooth Heaviside function $h_{c_k,d_k}$ (V.17.2.5), and on $[d_{k-1}, c_k]$ let $\phi$ be $1 - h_{a_k, b_k}$. Note that these definitions coincide on the overlaps of the intervals. If there is an unbounded interval to $+\infty$ in $V$, let $\phi$ be $h_{c_k,d_k}$ on $[b_k, +\infty)$ if $(c_k, d_k)$ is the last bounded interval, and $1 - h_{a_k, b_k}$ on $[d_{k-1}, +\infty)$ if $(a_k, b_k)$ is the last bounded interval; define $\phi$ analogously if $V$ has an unbounded interval to $-\infty$. Since the endpoints of the intervals form a closed discrete set, the $\phi$ so defined is a $C^\infty$ function from $\mathbb{R}$ to $[0, 1]$ which is identically 1 on $E$ and 0 on $F$.

This $\phi$, however, does not necessarily have the property that $\phi^{-1}(\{1\}) = E$ and $\phi^{-1}(\{0\}) = F$. We can obtain this property by a trick. Let $\theta$ be a $C^\infty$ function from $\mathbb{R}$ to $[0, 1]$ such that $\theta = 0$ precisely on $E \cup F$ (V.17.2.9.). Then $\psi_1 = \phi(1 - \theta)$ is a $C^\infty$ function from $\mathbb{R}$ to $[0, 1]$ which is 0 on $F$ and which is 1 precisely on $E$. Similarly, $\psi_2 = 1 - (1 - \phi)(1 - \theta)$ is a $C^\infty$ function from $\mathbb{R}$ to $[0, 1]$ which is 1 on $E$ and 0 precisely on $F$. Then $\psi = \frac{1}{2}(\psi_1 + \psi_2)$ is a $C^\infty$ function from $\mathbb{R}$ to $[0, 1]$ which is 1 precisely on $E$ and 0 precisely on $F$. \hfill \Box

### Multivariable Versions

**V.17.2.11.** There are versions of all these examples and results for real-valued functions on $\mathbb{R}^n$ ( ). The multivariable versions tend to be more complicated, sometimes considerably so, but also more useful.

### V.17.3. (P)-Points and Borel’s Theorem

The first example of a (P)-point was apparently obtained by CELLÈRIER in the early 1860’s, only published posthumously in 1890 (Exercise ( )). The first published example was by DU BOIS-REYMOND in 1876 (Exercise ( )).

Some specific examples of (P)-points will be given in ( ). In this subsection we will be primarily concerned with a striking theorem of E. BOREL from 1895, which provides (P)-points in profusion. The theorem can be stated in two equivalent ways.
**V.17.3.1. Theorem.** Let \((a_k)_{k \geq 0}\) be any sequence of real numbers. Then there is a \(C^\infty\) function on \(\mathbb{R}\) whose Taylor series around 0 (Maclaurin series) is

\[
\sum_{k=0}^{\infty} a_k x^k.
\]

**V.17.3.2. Corollary.** Let \((b_k)_{k \geq 0}\) be any sequence of real numbers. Then there is a \(C^\infty\) function \(f\) on \(\mathbb{R}\) such that \(f^{(k)}(0) = b_k\) for all \(k\).

The two statements are equivalent by setting \(b_k = k!a_k\).

We first give a simple proof from [Mir56] (the same proof works in the multidimensional case ()). Then we will give another argument giving an example with additional analyticity properties.

**Proof:** Fix a smooth mesa function \(g\) such that \(g\) is supported on \((-1, 1)\), and for each \(n\) let \(M_n\) be a bound on \(g^{(n)}\). Note that \(g^{(n)}(0) = 0\) for all \(n > 0\) since \(g\) is constant on an interval around 0. For \(k \geq 0\) define

\[
f_k(x) = a_k x^k g(c_k x)
\]

where \((a_k)\) is the given sequence and \((c_k)\) is a sequence of natural numbers to be chosen later. Then \(f_k\) is \(C^\infty\) on \(\mathbb{R}\), and by the higher product rule () and the chain rule for the \(g\) factors,

\[
f_k^{(n)}(x) = \sum_{m=0}^{n} \binom{n}{m} k(k-1)\cdots(k-n+m+1)a_k c_k^m x^{k-n+m} g^{(m)}(c_k x)
\]

for all \(n\) (the product \(k(k-1)\cdots(k-n+m+1)\) is 1 if \(m = n\)). In particular, we have

\[
f_k^{(k)}(0) = \sum_{m=0}^{k} \binom{k}{m} k(k-1)\cdots(m+1)a_k c_k^m 0^m g^{(m)}(0) = k!a_k = b_k
\]

and \(f_k^{(n)}(0) = 0\) if \(n \neq k\) (for \(n > k\), note that \(f_k^{(n)}\) is identically 0 in a neighborhood of 0). Since \(f_k(x) = 0\) for all \(x\) with \(|x| \geq \frac{1}{c_k}\), we have

\[
|f_k^{(n)}(x)| \leq \sum_{m=0}^{n} \binom{n}{m} k(k-1)\cdots(k-n+m+1)a_k c_k^m c_k^{k+n-m} M_m
\]

\[
\leq \frac{1}{c_k} \sum_{m=0}^{n} \binom{n}{m} k(k-1)\cdots(k-n+m+1)a_k M_m
\]

for \(0 \leq n < k\) and all \(x\), and thus by choosing \(c_k\) sufficiently large we obtain that

\[
|f_k^{(n)}(x)| \leq 2^{-k}
\]
for $0 \leq n < k$ and all $x$. Thus the series
\[
\sum_{k=0}^{\infty} f_k^{(n)}
\]
converges uniformly on $\mathbb{R}$ for every $n \geq 0$ by the $M$-test. So the function
\[
f = \sum_{k=0}^{\infty} f_k
\]
is $C^\infty$ on $\mathbb{R}$ and
\[
f^{(n)} = \sum_{k=0}^{\infty} f_k^{(n)}
\]
for every $n$ by (). In particular, $f^{(n)}(0) = b_n$ for all $n$. 

\[V.17.3.3.\] To obtain an example of a smooth function with a (P)-point, apply the theorem with a sequence $a_k \to +\infty$ rapidly, e.g. $a_k = k!$.

\[V.17.3.4.\] Note that the example constructed in the above proof is analytic except on a countable set; in fact, if $x_0 \neq 0$ and $U$ is an open neighborhood of $x_0$ bounded away from 0, then all but finitely many of the terms in the series are identically zero on $U$. Thus this theorem is strictly a single-point result.

We can in fact improve this result to make $f$ analytic on all of $\mathbb{R} \setminus \{0\}$. This result is due to Besicovitch [Bes24].

\[V.17.3.5.\] **Theorem.** Let $(b_k)$ be an arbitrary sequence of real numbers. Then there is a real-valued function $f$, $C^\infty$ on $[0, +\infty)$ and analytic on $(0, +\infty)$, with $f^{(k)}(0) = b_k$ for all $k$ (these are one-sided derivatives).

**Proof:** [KP02b, Lemma 2.2.4] Define
\[
f_0(x) = \frac{1}{\sqrt{c_0 + x}}
\]
and for each $k \geq 1$, define
\[
f_k(x) = \int_0^x \int_0^{t_{k-1}} \cdots \int_0^{t_1} \frac{1}{\sqrt{c_k + t}} \, dt_1 \cdots dt_{k-1}
\]
where the $c_k$ are positive real numbers which will be chosen later, i.e. $f_k$ is the unique function such that $f_k^{(k)}(x) = \frac{1}{\sqrt{c_k + x}}$ and $f_k^{(n)}(0) = 0$ for $0 \leq n < k$. For each $k$, $f_k$ is $C^\infty$ on $(-c_k, +\infty)$.

Fix $N > 1$. If $0 \leq x \leq N$, we have, for $0 \leq n < k$,
\[
0 \leq f_k^{(n)}(x) \leq \int_0^N \int_0^{t_{k-n-1}} \cdots \int_0^{t_1} \frac{1}{\sqrt{t}} \, dt_1 \cdots dt_{k-n-1} = \frac{N^{k-n-1/2}}{\frac{1}{2} \cdots \frac{2(k-n)-1}{2}} < \frac{2N^{k-n}}{(k-n-1)!}
\]
and so the series
\[
\sum_{k=0}^{\infty} \sigma_k f_k^{(n)}
\]
converges uniformly on \([0, N]\) for every \(n \geq 0\) and any choice of \(\sigma_k = -1, 0, 1\) by the \(M\)-test. Thus, for any such choice of \(\sigma_k\), we have that
\[
f = \sum_{k=0}^{\infty} \sigma_k f_k
\]
is \(C^\infty\) on \([0, \infty)\) and for each \(n\),
\[
f^{(n)} = \sum_{k=0}^{\infty} \sigma_k f_k^{(n)}
\]
by (\(\cdot\)). We also have, for \(\epsilon > 0\),
\[
|f^{(n)}(x)| \leq \sum_{k=0}^{n} \frac{2}{(c_k + \epsilon)^{k+1/2}} + \sum_{k=n+1}^{\infty} \frac{2N^{k-n}}{(k-n-1)!} \leq 2(n+1) \left( \frac{1}{\epsilon} \right)^{n+1} + 2e^N
\]
for \(\epsilon \leq x \leq N\), so by (\(\cdot\)) \(f\) is analytic on \((0, \infty)\).

The above results hold for any choice of \(c_k\) and \(\sigma_k\). We need only show that these can be chosen so that \(f^{(k)}(0) = b_k\) for all \(k\). Since \(f_k^{(n)}(0) = 0\) if \(0 \leq n < k\), we must solve the equations
\[
b_0 = \sigma_0 \frac{1}{c_0^{1/2}}
\]
\[
b_1 = -\frac{1}{2} \sigma_0 \frac{1}{c_0^{1/2}} + \frac{1}{c_1^{1/2}}
\]
\[
b_2 = \frac{1}{2} \cdot 2 \cdot 3 \sigma_0 \frac{1}{c_0^{1/2}} - \frac{1}{2} \sigma_1 \frac{1}{c_1^{1/2}} + \frac{1}{2} \sigma_2 \frac{1}{c_2^{1/2}}
\]
\[
\ldots
\]
We may solve these successively. If \(b_0 = 0\), set \(\sigma_0 = 0\) and \(c_0 = 1\); otherwise, set \(\sigma_0 = \frac{b_0}{|b_0|}\) and \(c_0 = |b_0|^{-2}\). Then set \(\sigma_1\) equal to \(1, -1, 0\) depending whether
\[
b_1 + \frac{1}{2} \sigma_0 \frac{1}{c_0^{3/2}}
\]
is positive, negative, or 0, and then \(c_1\) is determined from the previous choices. This process can clearly be continued indefinitely.

As a corollary, we get a two-sided version which improves Borel’s result:
**V.17.3.6.** Corollary. Let \((b_k)\) be an arbitrary sequence of real numbers. Then there is a real-valued function \(f\), \(C^\infty\) on \(\mathbb{R}\) and analytic on \(\mathbb{R} \setminus \{0\}\), with \(f^{(k)}(0) = b_k\) for all \(k\).

**Proof:** Let \(f\) be as in the Theorem for the sequence \((b_k)\), and \(g\) as in the theorem for the sequence \((-1)^k b_k\). Extend \(f\) to \(\mathbb{R}\) by setting \(f(x) = g(-x)\) for \(x < 0\). The extended \(f\) is \(C^\infty\) at \(0\). 

We now obtain the main result of [Bes24], that the derivatives of a \(C^\infty\) function can be independently specified at two points with the function analytic in between:

**V.17.3.7.** Theorem. Let \((a_k)\) and \((b_k)\) be arbitrary sequences of real numbers. Then there is a real-valued function \(f\), \(C^\infty\) on \(\mathbb{R}\) and analytic on \(\mathbb{R} \setminus \{0, 1\}\), such that \(f^{(k)}(0) = a_k\) and \(f^{(k)}(1) = b_k\) for all \(k\).

**Proof:** Let \(h(x) = h_{0,1}\) be the smooth Heaviside function from V.17.2.5. Let \(g_0\) and \(g_1\) be functions as in V.17.3.6. for the sequences \((a_k)\) and \((b_k)\) respectively; and set

\[
\begin{align*}
f_0(x) &= g_0(x)(1 - h(x)) \\
f_1(x) &= g_1(x - 1)h(x)
\end{align*}
\]

and \(f = f_0 + f_1\). Then \(f_0, f_1, f\) are \(C^\infty\) on \(\mathbb{R}\) and analytic on \(\mathbb{R} \setminus \{0, 1\}\). We have that \(f_0^{(k)}(0) = a_k\) and \(f_0^{(k)}(1) = 0\) for all \(k\), and \(f_1^{(k)}(0) = 0\) and \(f_1^{(k)}(1) = b_k\) for all \(k\). Thus \(f\) is the desired function.

**V.17.4.** Everywhere Nonanalytic Functions

There are smooth functions on an interval \(I\) which are not analytic anywhere. By V.17.1.2., these are precisely the functions \(f\) for which the set \(C_f \cup P_f = I\). Since \(C_f \cup P_f\) is closed in \(I\), to find examples it suffices to find \(f\)'s for which \(C_f\) or \(P_f\) is dense in \(I\). (It turns out that for any such example, \(P_f\) must be dense in \(I\) (V.17.4.10.), but this is often not easy to explicitly verify.)

**V.17.4.1.** There are two standard methods for constructing smooth functions which are not analytic anywhere, both involving infinite series. The first is to take a smooth function \(g\) which is not analytic at one, or a few, points, such as Cauchy’s example, and form a sum of the form

\[
f(x) = \sum_{n=1}^{\infty} c_n g(x - r_n)
\]

where the \(r_n\) form a dense sequence (e.g. an enumeration of \(\mathbb{Q}\)) and \(c_n \to 0\) rapidly, or some variation of this involving translation and scaling of \(g\). This method is called the method of condensation of singularities.

The other method is to consider an infinite sum of the form

\[
\sum_{n=1}^{\infty} c_n \cos(\lambda_n x)
\]

(sin can be used instead of cos) where \(c_n \to 0\) rapidly, \(\lambda_n \to \infty\) rapidly, and there are appropriate relations between the \(c_n\) and \(\lambda_n\). The first example of a function with a dense set of (P)-points was a function of this second kind due to Cellèrier in the 1860’s (Exercise ()). We give a nice example of this sort in V.17.4.3. (Caution: there is an example of this kind on Wikipedia which is not correct.)
so this series therefore has infinite radius of convergence, but represents a nonanalytic function. Thus the graph of $F$ can be extended to be $C^\infty$ on all of $\mathbb{R}$ by setting $F(-t) = F(t)$ or $F(-t) = -F(t)$ (there seems to be no convention). Thus the graph of $F^{(n)}$ is similar to the graph of $F$, stretched vertically by a factor of $2^{2n}$ and compressed horizontally by a factor of $2^n$. See Figure (1) for the graph of $F$.

However, $F$ is not analytic anywhere. For if $t_0 = \frac{k}{2^n}$ is a dyadic rational number, it follows that $2^m t_0 \in \mathbb{Z}$, so $F^{(n)}(t_0) = 0$ for $n > m$. Thus the Taylor series for $F^{(n)}$ around $t_0$ has all terms zero except possibly the constant term. This series therefore has infinite radius of convergence, but represents $F^{(n)}$ only for $t = t_0$ since $F^{(n)}$ is not constant on any interval by (i). So by working backwards, the Taylor series for $F$ around $t_0$ has infinite radius of convergence (it is a polynomial), but represents $F$ only at $t_0$. So every dyadic rational is a (C)-point for $F$, i.e. $F$ has a dense set of (C)-points.
Smooth Functions With Only (P)-Points

The following example of a smooth function with only (P)-points is from [http://mathoverflow.net/questions/43462/existence-of-a-smooth-function-with-nowhere-converging-taylor-series-at-every-poi/81465#81465](http://mathoverflow.net/questions/43462/existence-of-a-smooth-function-with-nowhere-converging-taylor-series-at-every-poi/81465#81465). This is a specific instance of a general class of examples from [SZ55]. The first example of this kind was given by H. Cartan in 1940 [Car40].

**V.17.4.3. Example.** Let

\[
f_n = (n!)^{-3n+2} \cos((n!)^3 x)
\]

which has the following properties:

(i) \(|f_n^{(k)}(x)| \leq \frac{1}{n!}\) for all \(x\) if \(0 \leq k \leq n - 1\).

(ii) \(|f_n^{(n)}(x)|^2 + |f_n^{(n+1)}(x)|^2 \geq (n!)^4\) for all \(x\); hence \(\max(|f_n^{(k)}(x)|, |f_n^{(n+1)}(x)|) \geq \frac{1}{2}(n!)^2\) for all \(x\) (a better constant can be obtained, but this is sufficient for the argument).

We will inductively choose a sequence \((n_m)\) so that, if \(f = \sum_{m=1}^\infty f_{n_m}\), \(f\) is \(C^\infty\) and the Taylor series of \(f\) around any \(x_0\) has radius of convergence zero. We need to insure that at least some of the derivatives of \(f\) increase rapidly in size at every \(x\).

First note that however the \(n_m\) are chosen (strictly increasing), the resulting \(f\) will be \(C^\infty\) and its derivatives will be given by successive term-by-term differentiation. For the \(k\)'th term-by-term derived series is dominated by the series

\[
\sum_{n=1}^\infty (n!)^{-3n+2+3k}
\]

which obviously converges for each \(k\), so the \(k\)'th derived series converges uniformly on \(\mathbb{R}\) by the \(M\)-test, and we can apply \((\cdot)\). Also note that if \(r > k\), we have, for all \(x\),

\[
\sum_{n=r}^\infty |f_n^{(k)}(x)| \leq \sum_{n=r}^\infty \frac{1}{n!}
\]

which is a tail sum for the Maclaurin series for \(e^1\), so by Taylor's Theorem we have, for some \(c < 1\),

\[
\sum_{n=r}^\infty |f_n^{(k)}(x)| \leq \frac{e^c}{r!} < \frac{e}{r!}
\]

Let \(n_1 = 1\). Suppose \(n_1, \ldots, n_r\) have been chosen. Let \(g(x) = \sum_{m=1}^r f_{n_m}(x)\). Then the Maclaurin series for \(g\) converges to \(g\) on all of \(\mathbb{R}\), and \(g\) is periodic, so there is a constant \(C\) such that \(|g^{(k)}(x)| \leq C(k + 1)!\) for all \(k\) and all \(x \in \mathbb{R}\). Choose \(n \geq n_r + 2\) large enough that \(C(n + 2)! < \frac{1}{4}(n!)^2\), and set \(n_{r+1} = n\). This completes the inductive construction of the \(n_m\).

Fix \(r\) and let \(k = n_r\). Set \(g = \sum_{m=1}^{r-1} f_{n_m}\) and \(h = \sum_{m=r+1}^\infty f_{n_m}\). Then \(f = f_k + g + h\). We have

\[
\max(|f^{(k)}(x)|, |f^{(k+1)}(x)|) \geq \max(|f_k^{(k)}(x)|, |f_k^{(k+1)}(x)|) - \max(|g^{(k)}(x)|, |g^{(k+1)}(x)|) - \max(|h^{(k)}(x)|, |h^{(k+1)}(x)|)
\]

709
Proof:
We will prove the result for meager set in is compact (recall that the topology of for any polynomial polynomials are dense in point of $I$).

$\phi_{m;n}$ is closed, suppose $f_n \to f$ in $C^\infty(I)$. For each $n$ there is an $x_n$ such that $|f_n(k)(x_n)| \leq k! \cdot m \cdot n^k$. Passing to a subsequence, we may assume $x_n \to x$ for some $x \in I$ since $I$ is compact (recall that the topology of $C^\infty(I)$ is metrizable). Then $f_n^{(k)}(x_n) \to f^{(k)}(x)$ for all $k$, since $f_n^{(k)} \to f^{(k)}$ uniformly on $I$ for each $k$ (1). Thus

$|f^{(k)}(x)| = \lim_{n \to \infty} |f_n^{(k)}(x_n)| \leq k! \cdot m \cdot n^k$

for all $k$, i.e. $f \in E_{m,n}$.

Now suppose $f \in E_{m,n}$. Then there is an $x_0 \in I$ such that

$\left|\frac{f^{(k)}(x_0)}{k!}\right|^{1/k} \leq m^{1/k}n$
for all $k$, so we have
\[
\limsup_{k \to \infty} \left| \frac{f^{(k)}(x_0)}{k!} \right|^{1/k} \leq n
\]
so the radius of convergence of the Taylor series for $f$ around $x_0$ is at least $\frac{1}{n}$, and $f \notin \mathcal{P}$. Conversely, suppose $f \notin \mathcal{P}$, i.e. there is an $x_0 \in I$ where the Taylor series has positive radius of convergence. Thus there is an $n \in \mathbb{N}$ such that
\[
\limsup_{k \to \infty} \left| \frac{f^{(k)}(x_0)}{k!} \right|^{1/k} < n
\]
so there is a $k_0$ such that
\[
\left| \frac{f^{(k)}(x_0)}{k!} \right|^{1/k} < n
\]
for all $k > k_0$, i.e. $|f^{(k)}(x_0)| < k! \cdot n^k$ for $k \geq k_0$.

Let $m \in \mathbb{N}$, $m \geq \max(|f(x_0)|, |f'(x_0)|, \ldots, |f^{(k_0)}(x_0)|)$. Then $|f^{(k)}(x_0)| < k! \cdot m \cdot n^k$ for all $k$, i.e. $f \in E_{m,n}$.

**Corollary.** Let $I$ be an interval in $\mathbb{R}$. The set of all smooth functions on $I$ which are nowhere analytic is a residual subset of $C^\infty(I)$ with its usual topology. Thus the set of smooth functions which are analytic at at least one point is a meager set in $C^\infty(I)$.

**Can a Smooth Function Have Only (C)-Points?**

**Proposition.** Let $f \in C^\infty(I)$. Then each $E_{m,n}(f)$ is relatively closed in $I$, and $\bigcup_{m,n} E_{m,n}(f) = I \setminus P_f$. Thus $C_f$ is an $F_\sigma$ and $P_f$ is a $G_\delta$.

**Proof:** The proof of the first statement is a simplified form of the argument in the proof of V.17.4.4., and is left to the reader. For the second statement, note that each of the following subsets of $\mathbb{R}$ is both an $F_\sigma$ and a $G_\delta$:

$I$, an interval ($\emptyset$).

$A_f$, a relatively open subset of $I$.

$C_f \cup P_f = I \setminus A_f$, a relatively closed subset of $I$.

$E_{m,n}(f)$, a relatively closed subset of $I$.

So by the first statement $I \setminus P_f$ is an $F_\sigma$, and thus $C_f = (C_f \cup P_f) \cap (I \setminus P_f)$ is an $F_\sigma$, and $P_f = I \setminus (I \setminus P_f)$ is a $G_\delta$.

Each $E_{m,n}(f)$ is contained in $A_f \cup C_f$. The key fact is that interior points of $E_{m,n}(f)$ are in $A_f$: 711
**V.17.4.8.** Proposition. If $x_0$ is an interior point of $E_{m,n}(f)$ for some $(m,n)$, then $f$ is analytic in a neighborhood of $x_0$.

**Proof:** Let $J$ be an open interval around $x_0$ contained in $E_{m,n}(x_0)$, and let $x \in J$ with $|x - x_0| = r < \frac{1}{n}$. If $p_k$ is the $k$'th Taylor polynomial of $f$ around $x_0$, we have, by Taylor’s Theorem,

$$f(x) - p_k(x) = \frac{f^{(k+1)}(c)}{(k+1)!}(x-x_0)^{k+1}$$

for some $c \in J$, and so we have

$$|f(x) - p_k(x)| \leq \frac{(k+1)! \cdot m \cdot n^{k+1}}{(k+1)!}|x-x_0|^{k+1} = m(nr)^{k+1} \to 0$$

and so the Taylor series for $f$ around $x_0$ converges to $f$ on $J \cap (x_0 - \frac{1}{n}, x_0 + \frac{1}{n})$. 

**V.17.4.9.** Theorem. Let $f \in C^\infty(I)$. Then the set $C_f$ is a meager subset of $I$, and in particular has empty interior.

**Proof:** We have that $C_f = \cup_{m,n}[C_f \cap E_{m,n}(f)]$, and by **V.17.4.8.** $C_f \cap E_{m,n}(f)$ is nowhere dense (note that $C_f \cap E_{m,n}(f) = A_{C_f} \cap E_{m,n}(f)$ is relatively closed in $I$).

**V.17.4.10.** Corollary. Let $f \in C^\infty(I)$.

(i) If $P_f = \emptyset$, i.e. if the Taylor series for $f$ around $x_0$ has positive radius of convergence for every $x_0 \in I$, then $f$ is analytic on a dense open subset of $I$.

(ii) If $f$ is not analytic at any point of $I$, then $P_f$ is dense in $I$.

Note that a function satisfying (i) is not necessarily analytic everywhere: Cauchy’s example is a counterexample. But there is a companion result to (i), first stated by Pringsheim in 1893 with a faulty proof and proved by R. Boas in 1935 in the same paper [BJ35] where **V.17.4.9.** was first proved:

**V.17.4.11.** Theorem. Let $f \in C^\infty(I)$. If there is an $r > 0$ such the Taylor series for $f$ around $x_0$ has radius of convergence at least $r$, for every $x_0 \in I$, then $f$ is analytic at every point of $I$ (i.e. analytic on $I$ if $I$ is open).
V.17.4.12. We give only a partial argument; for the full proof see (). Since $P_f$ is empty, it follows from V.17.4.10. that $C_f$ is a nowhere dense relatively closed subset of $I$. We only show that $C_f$ has no isolated points. If $x_0$ is an isolated point of $C_f$, i.e. $f$ is analytic on a deleted open interval $J$ around $x_0$, and $r > 0$ is as in the statement, take $x_1 \in J$ with $x_0 < x_1 < x_0 + r$. The Taylor series for $f$ around $x_1$ defines an analytic function $g$ on $(x_1 - r, x_1 + r)$, and $g$ agrees with $f$ on $(x_0, x_1)$ by V.16.2.2., since they agree on an interval around $x_1$. By continuity of all derivatives of $f$ and $g$, the Taylor series for $g$ around $x_0$ agrees with the Taylor series for $f$ around $x_0$, so the Taylor series for $f$ converges to $f$ on $[x_0, x_1]$ by V.16.2.7. (applied to $g$). A similar argument shows that the Taylor series for $f$ around $x_0$ converges to $f$ on an interval $(x_2, x_0]$ for some $x_2 < x_0$. Thus $f$ is analytic at $x_0$, contradicting that $x_0 \notin C_f$.

This argument does not rule out that $C_f$ could look like a Cantor set. Showing that this is impossible requires a more delicate argument involving application of the Baire Category Theorem to the set $C_f$, which is a locally compact metrizable space.

Zahorski’s Theorem

In 1947 Z. ZAHORSKI [Zah47] gave a complete characterization of which subsets of $I$ occur as $C_f$ and $P_f$ for a smooth function $f$ on an interval $I$. We have shown that these sets have the following properties:

- $C_f$ is a meager $F_\sigma$.
- $P_f$ is a $G_\delta$ disjoint from $C_f$.
- $C_f \cup P_f$ is relatively closed in $I$.

Zahorski’s Theorem asserts that these conditions are sufficient as well as necessary:

V.17.4.13. Theorem. [Zahorski’s Theorem] Let $I$ be an interval in $\mathbb{R}$, and let $C$ and $P$ be subsets of $I$ such that

- $C$ is a meager $F_\sigma$.
- $P$ is a $G_\delta$ disjoint from $C$.
- $C \cup P$ is relatively closed in $I$.

Then there is an $f \in C^\infty(I)$ such that $C_f = C$ and $P_f = P$.

See [SZ55] for a proof which is somewhat simpler than ZAHORSKI’s, but still complicated.

V.17.4.14. Thus, although $C_f$ is always a meager set, it can be large in a measure-theoretic sense. For example, there is a smooth function $f$ on $\mathbb{R}$ for which $P_f$ is the set of Liouville numbers and $C_f$ the complement. This $f$ is not analytic anywhere, and $C_f$ is a set whose complement has Lebesgue measure zero, and in fact Hausdorff dimension zero (III.8.2.37.).

V.17.4.15. There is a multidimensional version of Zahorski’s Theorem [?].
V.17.5. Exercises

V.17.5.1. Let

\[ f(x) = \begin{cases} 
  e^{-1/x^2} \sin \frac{1}{x} & \text{if } x \neq 0 \\
  0 & \text{if } x = 0 
\end{cases}. \]

Show that \( f \) is \( C^\infty \) on all of \( \mathbb{R} \), and has a nonisolated zero at 0.
V.17.6. Exercises

1. Prove a generalization of the Ratio Test for positive series \( \sum_{k=1}^{\infty} a_k \) using \( \limsup_{k \to \infty} \frac{a_{k+1}}{a_k} \) and \( \liminf_{k \to \infty} \frac{a_{k+1}}{a_k} \), i.e. find conditions which allow the proof of (1) to work in greater generality. Note the results of Exercises (1) and (2).

2. Choose an increasing sequence \((k_n)\) such that \( \sum_{k=k_n+1}^{\infty} \frac{1}{k^2} < 4^{-n} \), and for \( k_n < k \leq k_{n+1} \) let \( a_k = \frac{2^n}{k^2} \).
   (a) Show that \( \limsup_{k \to \infty} \frac{a_{k+1}}{a_k} = 2 \) and \( \liminf_{k \to \infty} \frac{a_{k+1}}{a_k} = 1 \).
   (b) Show that \( \sum_{k=1}^{\infty} a_k \) converges.
   (c) Construct a similar convergent positive series \( \sum_{k=1}^{\infty} b_k \) with \( \limsup_{k \to \infty} \frac{b_{k+1}}{b_k} = +\infty \) and \( \liminf_{k \to \infty} \frac{b_{k+1}}{b_k} = 1 \).

3. Choose an increasing sequence \((k_n)\) such that \( \sum_{k=1}^{k_n} \frac{1}{k} > 4^n \), and for \( k_n < k \leq k_{n+1} \) let \( a_k = \frac{2^n}{k} \).
   (a) Show that \( \limsup_{k \to \infty} \frac{a_{k+1}}{a_k} = 1 \) and \( \liminf_{k \to \infty} \frac{a_{k+1}}{a_k} = \frac{1}{2} \).
   (b) Show that \( \sum_{k=1}^{\infty} a_k \) diverges.
   (c) Construct a similar divergent positive series \( \sum_{k=1}^{\infty} b_k \) with \( \limsup_{k \to \infty} \frac{b_{k+1}}{b_k} = 1 \) and \( \liminf_{k \to \infty} \frac{b_{k+1}}{b_k} = 0 \).
V.17.7. The Binomial Theorem

The Binomial Theorem in algebra gives a formula for positive integral powers of a sum of two numbers. The Binomial Theorem can be extended to apply also to negative and nonintegral powers, but the extended version involves infinite series and there are convergence questions which must be addressed.

Recall that the binomial coefficients are defined by the following formula:

V.17.7.1. Definition. If \( n \in \mathbb{N}, 0 \leq k \leq n \), then

\[
\binom{n}{k} = \frac{n!}{k!(n-k)!} = \frac{n(n-1)(n-2) \cdots (n-k+1)}{k!}
\]

V.17.7.2. The last expression makes sense for any \( n \in \mathbb{R} \) if \( k \in \mathbb{N} \), and hence we can define the generalized binomial coefficient

\[
\binom{\alpha}{k} = \frac{\alpha(\alpha-1)(\alpha-2) \cdots (\alpha-k+1)}{k!}
\]

for \( \alpha \in \mathbb{R}, k \in \mathbb{N} \). We set \( \binom{\alpha}{0} = 1 \) for all \( \alpha \) (even \( \alpha = 0 \)). Note that if \( n \in \mathbb{N} \cup \{0\} \), then \( \binom{n}{k} = 0 \) for \( k > n \); but if \( \alpha \notin \mathbb{N} \cup \{0\} \), then \( \binom{\alpha}{k} \neq 0 \) for all \( k \). \( \binom{n}{k} \) is read “\( \alpha \) choose \( k \),” since if \( n \in \mathbb{N} \), \( \binom{n}{k} \) is just the number of ways of choosing \( k \) elements out of an \( n \)-element set.

Here is the standard Binomial Theorem of algebra:

V.17.7.3. Theorem. Let \( x, y \in \mathbb{C}, n \in \mathbb{N} \). Then

\[(x + y)^n = \sum_{k=0}^{n} \binom{n}{k} x^k y^{n-k} \]

(with the convention that \( t^0 = 1 \) for all \( t \), even \( t = 0 \).) The formula actually holds (suitably interpreted) in any commutative ring.

This theorem can easily be proved by induction on \( n \) using the following relation among binomial coefficients, which can be proved by induction on \( k \):

V.17.7.4. Proposition. Let \( \alpha, \beta \in \mathbb{R}, k \in \mathbb{N} \cup \{0\} \). Then

\[
\binom{\alpha + \beta}{k} = \sum_{j=0}^{k} \binom{\alpha}{k-j} \binom{\beta}{j}
\]

In particular, if \( k \in \mathbb{N} \),

\[
\binom{\alpha + 1}{k} = \binom{\alpha}{k} + \binom{\alpha}{k-1}
\]

The fact that the binomial coefficient \( \binom{n}{k} \) is always a natural number if \( n \) and \( k \) are natural numbers with \( k \leq n \) has an interesting consequence in number theory, which is not entirely obvious:
V.17.7.5. Corollary. If \( k \in \mathbb{N} \), then the product of any \( k \) consecutive integers is divisible by \( k! \).

Proof: Let \( n \) be the largest number in the sequence. Then \( n \geq k \), and
\[
\frac{n(n-1)(n-2)\cdots(n-k+1)}{k!} = \binom{n}{k} \in \mathbb{N}.
\]

V.17.7.6. Corollary. Let \( g \) be a polynomial with integer coefficients, and \( k \in \mathbb{N} \). Then all coefficients of the \( k \)'th derivative \( g^{(k)} \) are divisible by \( k! \).

Proof: It suffices to prove this for \( g(x) = x^n \). If \( n \geq k \), then \( g^{(k)}(x) = n(n-1)(n-2)\cdots(n-k+1)x^{n-k} \), and \( g^{(k)} \) is identically 0 if \( k > n \).

This result is also an easy corollary of Taylor’s Theorem.

V.17.7.7. To prove a version of the Binomial Theorem when \( n \) is not a positive integer, we restrict to the case where \( y = 1 \) and regard \( (1 + x)^n \) as a function of \( x \). This is not an essential restriction, since if \( y \neq 0 \) we have \((x+y)^n = y^n \left( \frac{x}{y} + 1 \right)^n \).

Fix \( \alpha \in \mathbb{R} \) and consider the function \( f(x) = (1 + x)^\alpha \). This function is infinitely differentiable on \((-1, \infty)\) and extends to a continuous function on \([-1, \infty)\) if \( \alpha \geq 0 \). For certain special \( \alpha \) it also extends to numbers less than \(-1\).

V.17.7.8. Proposition. For any \( k \in \mathbb{N} \cup \{0\} \),
\[
\frac{f^{(k)}(0)}{k!} = \binom{\alpha}{k}.
\]
Thus the Taylor series for \( f \) around 0 is
\[
\sum_{k=0}^{\infty} \binom{\alpha}{k} x^k.
\]

The proof of the first formula is an easy calculation, and the second formula follows immediately.

V.17.7.9. Theorem. [Binomial Theorem] For any \( \alpha \in \mathbb{R} \), the series
\[
\sum_{k=0}^{\infty} \binom{\alpha}{k} x^k
\]
converges on \((-1, 1)\) to \((1 + x)^\alpha\). If \( \alpha \geq 0 \), the series converges uniformly on \([-1, 1]\) to \((1 + x)^\alpha\).
Proof: The proof has three steps. (i) Show that the series converges on \((-1, 1)\). (ii) Show that the series represents the function on \((-1, 1)\). (iii) If \(\alpha \geq 0\), show the series converges uniformly on \([-1, 1]\). Since the results are obvious when \(\alpha \in \mathbb{N} \cup \{0\}\) (since then the sum is finite), we will assume \(\alpha \notin \mathbb{N} \cup \{0\}\). We set \(a_k = \binom{\alpha}{k}\); then \(a_k > 0\) for all \(k\).

(i) Using the Ratio Test, the radius of convergence of the series is

\[
\lim_{k \to \infty} \frac{a_k}{a_{k+1}} = \lim_{k \to \infty} \frac{k+1}{k-\alpha} = 1
\]

so the series converges for \(|x| < 1\).

(ii) For \(x \in (-1, 1)\), let \(f(x) = \sum_{k=0}^{\infty} \binom{\alpha}{k} x^k\). Then \(f\) is differentiable on \((-1, 1)\), and

\[
f'(x) = \sum_{k=1}^{\infty} k \binom{\alpha}{k} x^{k-1} = \sum_{k=0}^{\infty} (k+1) \binom{\alpha}{k+1} x^k
\]

on \((-1, 1)\). We have

\[
(1+x)f'(x) = \sum_{k=0}^{\infty} \left[(k+1) \binom{\alpha}{k+1} + k \binom{\alpha}{k}\right] x^k.
\]

Since

\[
(k+1) \binom{\alpha}{k+1} + k \binom{\alpha}{k} = \alpha \binom{\alpha-1}{k}
\]

we have

\[
(1+x)f'(x) = \frac{d}{dx} (1+x)^{\alpha} = \alpha (1+x)\alpha-1 f(x) = 0.
\]

Thus \((1+x)^{-\alpha} f(x)\) is constant, so \(f(x) = C(1+x)^\alpha\) for some \(C\). Since \(f(0) = 1\), \(C = 1\).

(iii) Suppose \(\alpha > 0\). We will show that \(\sum_{k=0}^{\infty} a_k\) converges. If \(k > \alpha\), then \(\frac{a_{k+1}}{a_k} = \frac{k-\alpha}{k+1}\), so \((k+1)a_{k+1} = (k-\alpha)a_k, ka_k - (k+1)a_{k+1} = \alpha a_k > 0\). Thus the sequence \((ka_k)\) is nonnegative and decreasing for \(k > \alpha\), and hence \(\lambda = \lim_{k \to \infty} ka_k\) exists. We have

\[
\sum_{k=0}^{\infty} (ka_k - (k+1)a_{k+1}) = -(n+1)a_{n+1} \to -\lambda
\]

so \(\sum_{k=0}^{\infty} (ka_k - (k+1)a_{k+1})\) converges. Since \(a_k = \alpha^{-1}(ka_k - (k+1)a_{k+1})\) for \(k > \alpha\), \(\sum_{k=0}^{\infty} a_k\) converges. Thus, by the Weierstrass M-test, \(\sum_{k=0}^{\infty} \binom{\alpha}{k} x^k\) converges absolutely and uniformly on \([-1, 1]\). Since by (ii) the series represents \((1+x)^\alpha\) on \((-1, 1)\), it represents \((1+x)^\alpha\) on \([-1, 1]\) by continuity.

\(\diamondsuit\)
V.17.8. Exercises

V.17.8.1. (a) Prove the second formula in V.17.7.4. by induction on $k$. [Hint: show using the inductive step that
\[
\binom{\alpha + 1}{k + 1} = \binom{\alpha}{k} \left[ \frac{\alpha - k + 1}{k + 1} \right] + \binom{\alpha - k}{k - 1} \frac{\alpha - k + 1}{k + 1}
\]
and consider three terms by multiplying. Show that the first term is $(\frac{\alpha}{k+1})$ and the last is $\frac{k}{k+1} (\frac{\alpha}{k})$.]

(b) Give a combinatorial argument for this formula if $\alpha \in \mathbb{N}$, interpreting $\binom{n}{k}$ as the number of ways of choosing $k$ elements from an $n$-element set.

(c) Use this formula to prove V.17.7.3. by induction on $n$.

(d) Generalize the argument in (a) to prove the first formula in V.17.7.4.

V.17.8.2. Here is an alternate proof of V.17.7.9. (ii) (this was essentially Cauchy’s original argument). Fix $x$ with $|x| < 1$. Set $F_n(\alpha) = \sum_{k=0}^{\alpha} \binom{\alpha}{k} x^k$.

(a) Mimic the proof of the Ratio test to show that the infinite series $\sum_{k=0}^{\alpha} \binom{\alpha}{k} x^k$ converges absolutely and uniformly on $\mathbb{R}$ to a function $F(\alpha)$, i.e. $F_n(\alpha) \to F(\alpha)$ uniformly in $\alpha$. Thus $F(\alpha)$ is continuous in $\alpha$.

(b) For fixed $\alpha, \beta \in \mathbb{R}$, use the product formula for power series () to show that
\[
F(\alpha)F(\beta) = \sum_{k=0}^{\infty} \left[ \sum_{j=0}^{k} \binom{\alpha}{k-j} \binom{\beta}{j} \right] x^k.
\]

(c) Conclude from V.17.7.4. that $F(\alpha)F(\beta) = F(\alpha + \beta)$.

(d) Apply () to conclude that $F(\alpha) = b^\alpha$ for some $b > 0$. Since $F(1) = 1 + x$, $b = 1 + x$.

V.17.8.3. (a) Show that for any $n \in \mathbb{N}$ and $x \in \mathbb{R}$,
\[
(1 - x)(1 + x + x^2 + \cdots + x^n) = 1 - x^{n+1}.
\]

(b) Show that for all $x \in \mathbb{R}, x \neq -1$,
\[
\frac{1}{1+x} = 1 - x + x^2 - \cdots + (-1)^n x^n + \frac{(-1)^{n+1} x^{n+1}}{1+x}.
\]

(c) Show from (b) that if $|x| < 1$, then the series $\sum_{n=0}^{\infty} (-1)^n x^n$ converges to $\frac{1}{1+x}$. Compare with the Binomial Theorem for $\alpha = -1$.

V.17.8.4. Here is yet another proof of V.17.7.9. (ii), based on the Cauchy Remainder Formula for Taylor’s Theorem (V.10.6.7.).

(a) Fix $x$ with $|x| < 1$. By the Cauchy remainder formula, for any $n$ there is a $\theta = \theta_n$, $0 < \theta < 1$, such that
\[
R_n(x) = (1 + x)^\alpha - \sum_{k=0}^{n} \binom{\alpha}{k} x^k = \frac{f^{(n+1)}(\theta x)}{n!} (1 - \theta)^n x^{n+1}
\]
\[
\begin{align*}
\frac{\alpha(\alpha - 1) \cdots (\alpha - n)(1 + \theta x)^{\alpha - n - 1}}{n!} (1 - \theta)^n x^{n+1} \\
= \left[\frac{(\alpha - 1)(\alpha - 2) \cdots (\alpha - n)}{n!} x^n\right] \left[\alpha x(1 + \theta x)^{\alpha - 1} \left(\frac{1 - \theta}{1 + \theta x}\right)^n\right]
\end{align*}
\]

(b) If \( M = \max((1 + x)^{\alpha - 1}, (1 - x)^{\alpha - 1}) \), the second factor is bounded in absolute value by \( M|\alpha x| \) independent of \( n \) since \( \left|\frac{1 - \theta}{1 + \theta x}\right| < 1 \).

(c) The first factor is \( \binom{\alpha - 1}{n} x^n \) which goes to 0 as \( n \to \infty \) since \( \sum \binom{\alpha - 1}{n} x^n \) converges by V.17.7.9.(i).

(d) Thus \( R_n(x) \to 0 \) as \( n \to \infty \) and the series converges to \( (1 + x)^\alpha \).
Chapter VI

The Topology of \( \mathbb{R} \), \( \mathbb{R}^n \), and Metric Spaces

In this chapter we discuss the basic notions of open and closed sets, closure of a set, interior and boundary of a set, and some of the elementary results about them, beginning with the real numbers, then moving on to \( \mathbb{R}^n \) and general metric spaces. This chapter should be considered a parallel thread to Chapter ( ) on sequences and series; there is much interplay between the two chapters.

The general theory of topology and more detailed results along the lines of this chapter are the subject of Chapter ( ).

VI.1. The Topology of \( \mathbb{R} \)

We begin with the real numbers. Recall the definition of an interval in \( \mathbb{R} \) (III.1.9.12.). The open intervals and the closed intervals are most important for this section. The open intervals are the intervals of the form \((a, b)\), where \( a \in \mathbb{R} \cup \{-\infty\}, \ b \in \mathbb{R} \cup \{+\infty\}, \ \text{and} \ a < b \). The closed intervals are of the form \([a, b]\) with \( a, b \in \mathbb{R}, \ a < b \), or \([a, +\infty), \ (-\infty, b]\), or all of \( \mathbb{R} \). We generalize both open intervals and closed intervals into open sets and closed sets respectively.

VI.1.1. Open and Closed Sets in \( \mathbb{R} \)

VI.1.1.1. Definition. (i) A subset \( U \) of \( \mathbb{R} \) is an open set if, whenever \( x \in U \), there is an open interval \( I \) with \( x \in I \) and \( I \subseteq U \).
(ii) A subset \( E \) of \( \mathbb{R} \) is a closed set if \( E^c = \mathbb{R} \setminus E \) is an open set.

A slight rephrasing of the definition gives:

VI.1.1.2. Proposition. A subset of \( \mathbb{R} \) is an open set if and only if it is a union of open intervals.
VI.1.1.3. An open set is, roughly, a set which locally looks like an open interval. Any open interval is an open set. The empty set vacuously satisfies the definition of open set, hence is also an open set (it is an “empty union” of open intervals). The complement of a closed interval is either one open interval, the disjoint union of two open intervals, or the empty set, hence open; thus a closed interval is a closed set, so the terminology is consistent. The complement of the empty set is $\mathbb{R}$, which is open, so $\emptyset$ is closed as well as open. There are many nonempty closed sets which look nothing like closed intervals; for example, any finite set is closed since its complement is a union of open intervals; similarly $\mathbb{Z}$ is a closed set. There are much more complicated examples; see e.g. $\left(\right)$, $\left(\right)$.

A half-open interval of the form $[a,b)$ for $a < b$ is not an open set since it does not contain an open interval around $a$; similarly, its complement is not open, so $[a,b)$ is not a closed set either. $\mathbb{Q}$ is also neither open nor closed, since every open interval contains both rational and irrational numbers. In fact, “most” subsets of $\mathbb{R}$ are neither open nor closed.

The only subsets of $\mathbb{R}$ which are both open and closed are $\emptyset$ and $\mathbb{R}$ ($\emptyset$).

Here is a useful rephrasing of the definition of open set:

VI.1.1.4. Proposition. Let $U$ be a subset of $\mathbb{R}$. Then $U$ is an open set if and only if, for every $x \in U$, there is an $\epsilon > 0$ such that the open interval $(x-\epsilon, x+\epsilon) = \{y \in \mathbb{R} : |y-x| < \epsilon\}$ is contained in $U$. (The $\epsilon$ can depend on $x$.)

Proof: Any such set is obviously open, since $(x-\epsilon, x+\epsilon)$ is an open interval. Conversely, if $U$ is open and $x \in U$, and $I$ is an open interval with $x \in I$ and $I \subseteq U$, then there is a smaller open interval $J$ centered at $x$ contained in $I$ (and hence in $U$); $J$ will be of the form $(x-\epsilon, x+\epsilon)$ for some $\epsilon > 0$. $\Diamond$

Unions and Intersections

VI.1.1.5. Proposition. (i) An arbitrary union of open sets is open. A finite intersection of open sets is open.

(ii) An arbitrary intersection of closed sets is closed. A finite union of closed sets is closed.

Proof: (i): It is obvious from VI.1.1.2. (or just straight from the definition) that a union of any collection of open sets is open. For a finite intersection, we use VI.1.1.4.. Let $U_1, \ldots, U_n$ be a finite collection of open sets, and $U = U_1 \cap \cdots \cap U_n$. Let $x \in U$. Then $x \in U_j$ for each $j$, so for each $j$ there is an $\epsilon_j > 0$ such that $(x-\epsilon_j, x+\epsilon_j) \subseteq U_j$. Set $\epsilon = \min\{\epsilon_1, \ldots, \epsilon_n\}$. Then $\epsilon > 0$, and $(x-\epsilon, x+\epsilon) \subseteq U$. Since this can be done for any $x \in U$, $U$ is open.

(ii) follows from (i) by taking complements and using de Morgan’s Laws ($\emptyset$).

VI.1.1.6. The intersection of an infinite number of open sets is not open in general. For example, $\cap_{n=1}^{\infty} \left(x - \frac{1}{n}, x + \frac{1}{n}\right) = \{x\}$, which is not open (in fact it is closed). Similarly, an infinite union of closed sets is not closed in general. In fact, every subset of $\mathbb{R}$ is a union of singleton sets, each of which is closed.
VI.1.1.7. **COROLLARY.** Let \( U \) be an open set and \( E \) a closed set. Then \( U \setminus E \) is open and \( E \setminus U \) is closed.

**Proof:** \( U \setminus E = U \cap E^c \) and \( E \setminus U = E \cap U^c \).

#### Neighborhoods and Deleted Neighborhoods

VI.1.1.8. Let \( x \) be a real number. An open interval containing \( x \), or more generally an open set containing \( x \), is often called a *neighborhood*, or open neighborhood, of \( x \). In topology, a neighborhood of \( x \) is generally thought of as a set of points “close to \( x \)”; this is literally true if the neighborhood is something like \((x - \epsilon, x + \epsilon)\) for a small positive \( \epsilon \), but may be somewhat of a stretch for general neighborhoods. Nonetheless, the notion of neighborhood is a useful one, as we will see. An open set is an open neighborhood of each of its points.

Sometimes we use the term “neighborhood” to mean a not necessarily open set: a neighborhood of \( x \) is a set containing an open neighborhood of \( x \). For example, it is sometimes useful to consider closed neighborhoods (e.g. \((0)\)).

VI.1.1.9. It is also often useful to consider deleted neighborhoods of a point. If \( x \in \mathbb{R} \), a deleted neighborhood of \( x \) is a subset of \( \mathbb{R} \) of the form \( U \setminus \{x\} \), where \( U \) is a neighborhood of \( x \). Deleted neighborhoods are usually taken to be open, but not necessarily.

The most commonly used deleted neighborhoods of an \( x \in \mathbb{R} \) are sets of the form

\[
(x - \epsilon, x) \cup (x, x + \epsilon) = \{y \in \mathbb{R} : 0 < |y - x| < \epsilon\}
\]

for some (typically “small”) \( \epsilon > 0 \). Every deleted neighborhood of \( x \) contains a deleted neighborhood of this form.

#### VI.1.2. Limit Points and Closures

There is an alternate way to view closed sets, via the notions of limit points and closures, which we now describe.

VI.1.2.1. **DEFINITION.** Let \( A \) be a subset of \( \mathbb{R} \), and \( x \in \mathbb{R} \). Then \( x \) is a *limit point* of \( A \) if every open neighborhood of \( x \) contains at least one point of \( A \).

The word “open” may be deleted from the definition without effect.

VI.1.2.2. Any point of \( A \) is a limit point of \( A \): if \( x \in A \), then any neighborhood of \( x \) contains at least one point of \( A \), namely \( x \) itself. But the importance of the definition is that there may be real numbers which are not in \( A \) but are limit points of \( A \). For example, \( 0 \notin (0,1) \), but 0 is a limit point of \( (0,1) \) since every neighborhood of 0 contains small positive numbers. For a more dramatic example, every real number is a limit point of \( \mathbb{Q} \), since every nonempty open set in \( \mathbb{R} \) contains rational numbers.

Some authors define “limit point” to mean what is more commonly called an *accumulation point* of \( A \). The number \( x \) is an accumulation point of \( A \) if every neighborhood of \( x \) contains a point of \( A \) other than \( x \), i.e. every deleted neighborhood of \( x \) contains a point of \( A \). Not every element of \( A \) is necessarily an accumulation point of \( A \); those which are not are called *isolated points* of \( A \). We will not need to make much use of the notion of accumulation point; limit points are more important for most purposes.

As with open sets, the notion of limit point can be phrased in terms of \( \epsilon \)'s:
VI.1.2.3. **Proposition.** Let \( A \subseteq \mathbb{R} \), \( x \in \mathbb{R} \). Then \( x \) is a limit point of \( A \) if and only if, for every \( \epsilon > 0 \), there is a \( y \in A \) with \( |x - y| < \epsilon \).

Intuitively, \( x \) is a limit point of \( A \) if and only if there are points of \( A \) arbitrarily close to \( x \).

VI.1.2.4. **Definition.** Let \( A \) be a subset of \( \mathbb{R} \). The **closure** of \( A \) is the set \( \bar{A} \) of all limit points of \( A \).

VI.1.2.5. Since every element of \( A \) is a limit point of \( A \), we have \( A \subseteq \bar{A} \). If \( A \subseteq B \), then it follows immediately from the definition of limit point that every limit point of \( A \) is a limit point of \( B \), so \( \bar{A} \subseteq \bar{B} \).

The term “closure” is justified by the next result.

VI.1.2.6. **Theorem.** Let \( A \) be a subset of \( \mathbb{R} \). Then

(i) \( \bar{A} = \bar{A} \), i.e. every limit point of \( \bar{A} \) is in \( \bar{A} \).

(ii) \( \bar{A} \) is a closed set.

(iii) \( \bar{A} \) is the smallest closed set containing \( A \), i.e. if \( E \) is a closed set containing \( A \), then \( \bar{A} \subseteq E \).

**Proof:** (i): Let \( x \) be a limit point of \( \bar{A} \), and \( U \) an open neighborhood of \( x \). Then there is a \( y \in A \) with \( y \in U \). Then \( y \) is a limit point of \( A \), and \( U \) is a neighborhood of \( y \), so there is a \( z \in A \) with \( z \in U \). This is true for every open neighborhood \( U \) of \( x \), so \( x \) is a limit point of \( A \).

(ii): Let \( x \in (\bar{A})^c \). Then \( x \) is not a limit point of \( A \), so there is an open neighborhood \( U \) of \( x \) containing no points of \( A \). Then \( U \) also cannot contain any limit points of \( A \), for if \( y \in U \) were a limit point of \( A \), then the neighborhood \( U \) of \( y \) would have to contain a point of \( A \). Thus \( U \subseteq (\bar{A})^c \). Since such a \( U \) exists for every \( x \in (\bar{A})^c \), \( (\bar{A})^c \) is open.

(iii): There is a smallest closed set \( F \) containing \( A \), namely the intersection of all closed sets containing \( A \) (cf. VI.1.1.5.; there is at least one closed set containing \( A \), \( \mathbb{R} \) itself). Since \( \bar{A} \) is a closed set containing \( A \) by (ii), we have \( F \subseteq \bar{A} \). To show the opposite inclusion, let \( x \notin F \). Since \( F \) is closed, \( F^c \) is an open neighborhood of \( x \) containing no point of \( A \). Thus \( x \) cannot be a limit point of \( A \).  

724
VI.2. Metric Spaces

Much of what was done in the last section works almost verbatim in the more general setting of metric spaces. Besides Euclidean spaces, there are many other metric spaces which are important in analysis, as well as in other parts of mathematics, so it is quite worthwhile working in this generality.

VI.2.1. Definitions

A metric space is a set \( X \) with a specified numerical distance between any two points, which behaves reasonably like the usual distance between numbers or points in Euclidean space. The distance may be regarded as a function \( \rho : X \times X \to \mathbb{R} \), with \( \rho(x, y) \) denoting the distance between \( x \) and \( y \). Formally:

VI.2.1.1. Definition. A metric on a set \( X \) is a function \( \rho : X \times X \to \mathbb{R} \) satisfying:

(i) \( \rho(x, y) \geq 0 \) for all \( x, y \in X \).

(ii) \( \rho(x, y) = 0 \) if and only if \( x = y \) (definiteness).

(iii) \( \rho(x, y) = \rho(y, x) \) for all \( x, y \in X \) (symmetry).

(iv) \( \rho(x, z) \leq \rho(x, y) + \rho(y, z) \) for all \( x, y, z \in X \) (triangle inequality).

A pair \( (X, \rho) \), where \( X \) is a set and \( \rho \) is a metric on \( X \), is called a metric space. The diameter of a metric space \( (X, \rho) \) is \( \text{diam}(X, \rho) = \sup \{ \rho(x, y) : x, y \in X \} \). The metric \( \rho \) is bounded if \( \text{diam}(X, \rho) \) is finite.

VI.2.1.2. It is customary to call a set \( X \) with a given metric a “space”, and to call elements of \( X \) “points”, even though there may be no geometric picture or interpretation of \( X \) as an actual space in the usual sense. The geometric terminology helps to motivate some aspects of the theory of metric spaces.

VI.2.1.3. Examples.

(i) On \( \mathbb{R} \), the function \( \rho(x, y) = |x - y| \) is a metric. This is called the standard metric on \( \mathbb{R} \), and we will often use this metric on \( \mathbb{R} \) without specific mention.

(ii) On \( \mathbb{R}^n \), the Euclidean distance function

\[
\rho_2(x, y) = \sqrt{(x_1 - y_1)^2 + \cdots + (x_n - y_n)^2}
\]

for \( x = (x_1, \ldots, x_n), y = (y_1, \ldots, y_n) \) in \( \mathbb{R}^n \) is a metric, the standard metric on \( \mathbb{R}^n \).

(iii) There are other important metrics on \( \mathbb{R}^n \). Two of them are:

\[
\rho_1(x, y) = |x_1 - y_1| + \cdots + |x_n - y_n|
\]

\[
\rho_\infty(x, y) = \max(|x_1 - y_1|, \ldots, |x_n - y_n|)
\]

for \( x = (x_1, \ldots, x_n), y = (y_1, \ldots, y_n) \) in \( \mathbb{R}^n \).
(iv) There are important metrics on function spaces analogous to those of (ii) and (iii). For example, let 
\[ C[a, b] \]
be the set of real-valued continuous functions on the interval \([a, b]\), and for \( f, g \in C[a, b] \) define
\[
\rho_2(f, g) = \left[ \int_a^b (f(t) - g(t))^2 \, dt \right]^{1/2}
\]
\[
\rho_1(f, g) = \int_a^b |f(t) - g(t)| \, dt
\]
\[
\rho_\infty(f, g) = \max_{a \leq t \leq b} |f(t) - g(t)|
\]
(It is not obvious that \( \rho_2 \) satisfies the triangle inequality. See Exercise (iv) or (v) for a proof.)

(v) Let \( X \) be a sphere (recall that a sphere in mathematics is a two-dimensional surface, not including the points “inside”). If \( x, y \in X \), let \( \rho(x, y) \) be the arc length of the shortest great circle path between \( x \) and \( y \). (The triangle inequality is not entirely obvious here, but can be proved.) This example has obvious practical applications: it is the appropriate “distance” to consider on the surface of the earth.

(vi) Let \( X \) be any set, \( \rho(x, y) = \begin{cases} 
1 & \text{if } x \neq y \\
0 & \text{if } x = y 
\end{cases} \). Then \( \rho \) is a metric on \( X \), called the \textit{discrete metric}.

(vii) Let \( X \) be the set of all \( n \)-tuples of 0’s and 1’s, and define \( \rho(x, y) \) to be the number of coordinates in which \( x \) and \( y \) differ. This is a metric, called the \textit{Hamming metric}, which is important in coding theory.

In these examples, only the metrics in (v)–(vii) are bounded.
