(d) Is \( \mathcal{P}(\mathbb{R}) \otimes \mathcal{P}(\mathbb{R}) = \mathcal{P}(\mathbb{R}^2) \)? [Unfair question: it cannot be answered in ZFC! The CH, or, more generally, Martin’s Axiom (II.10.5.6.), implies a positive answer, but (if ZFC is consistent) there are models of ZFC where the answer is negative.]

XIII.5.5.2. ([GP10], attributed to von Neumann) Let \( R = \prod_{k=1}^n [a_k, b_k] \) be a closed rectangle in \( \mathbb{R}^n \). Note that \( \lambda(R) \leq \prod_{k=1}^n (b_k - a_k) \) is immediate from the definition. The aim of this problem is to show the opposite inequality.
(a) Suppose \( R_1, \ldots, R_m \) are open rectangles covering \( R \) (note that any cover of \( R \) by open rectangles has a finite subcover). Let \( R_j = \prod_{k=1}^{n} (a_{k}^{(j)}, b_{k}^{(j)}) \). If \( S \subseteq \mathbb{R}^n \), let \( \#(S) \) be the number of points with integer coordinates in \( S \). If \( \alpha > 0 \) is large enough that \( \alpha(b_k - a_k) > 1 \) and \( \alpha(b_{k}^{(j)} - a_{k}^{(j)}) > 1 \) for all \( k \) and \( j \), then

\[
\prod_{k=1}^{n} (\alpha b_k - \alpha a_k - 1) \leq \#(\alpha R) \leq \sum_{j=1}^{m} \#(\alpha R_j) \leq \sum_{j=1}^{m} \prod_{k=1}^{n} (\alpha b_{k}^{(j)} - \alpha a_{k}^{(j)} + 1).
\]

(b) Let \( \alpha \to +\infty \) to conclude that

\[
\prod_{k=1}^{n} (b_k - a_k) \leq \sum_{j=1}^{m} \prod_{k=1}^{n} (b_{k}^{(j)} - a_{k}^{(j)}).
\]

Taking the infimum over all such open covers, conclude that

\[
\prod_{k=1}^{n} (b_k - a_k) \leq \lambda(R).
\]

XIII.5.3. Let \((X, \mathcal{A}, \mu)\) and \((Y, \mathcal{B}, \nu)\) be measure spaces, with completions \((X, \bar{\mathcal{A}}, \bar{\mu})\) and \((Y, \bar{\mathcal{B}}, \bar{\nu})\) respectively, and let \(\iota\) and \(\bar{\iota}\) be the induced premeasures on \(\bar{\mathcal{A}} \times \bar{\mathcal{B}}\) and \(\mathcal{A} \times \mathcal{B}\), i.e. \(\iota(A \times B) = \mu(A)\mu(B)\) for \(A \in \mathcal{A}, B \in \mathcal{B}\) and \(\bar{\iota}(\bar{A} \times \bar{B}) = \bar{\mu}(\bar{A})\bar{\nu}(\bar{B})\) for \(\bar{A} \in \bar{\mathcal{A}}, \bar{B} \in \bar{\mathcal{B}}\). Let \(\theta^*\) and \(\bar{\theta}^*\) be the outer measures on \(X \times Y\) induced by \(\iota\) and \(\bar{\iota}\) respectively.

(a) If \(\bar{A} \in \bar{\mathcal{A}}\) and \(\bar{B} \in \bar{\mathcal{B}}\), show that there are \(A \in \mathcal{A}\) and \(B \in \mathcal{B}\) such that \(\bar{A} \subseteq A, \bar{B} \subseteq B\), and \(\iota(A \times B) = \bar{\iota}(\bar{A} \times \bar{B})\).

(b) Show that \(\bar{\theta}^* = \theta^*\).
XIII.6. Signed and Complex Measures

In this section we examine the theory of measures which are not necessarily nonnegative or even real-valued. It turns out that the theory of such measures can be nicely reduced to the theory of ordinary (nonnegative) measures.

The only insurmountable difficulty comes with trying to make sense of the expression $\infty - \infty$. It will be implicit in our definitions that this possibility will never arise, which will entail that our measures do not take both values $\pm \infty$. In most applications, we will only consider real-valued measures, i.e. ones not taking either value $\pm \infty$. For complex measures we will not be able to satisfactorily allow any type of infinite value.

XIII.6.1. Signed Measures

XIII.6.1.1. Definition. Let $(X, A)$ be a measurable space. A signed measure on $(X, A)$ is a function $\nu : A \to [-\infty, +\infty]$ such that

(i) $\nu(\emptyset) = 0$.

(ii) If $\{A_n\}$ is a sequence of pairwise disjoint sets in $A$, then either

$$\sum_{\nu(A_n) > 0} \nu(A_n) < +\infty \quad \text{or} \quad \sum_{\nu(A_n) < 0} \nu(A_n) > -\infty$$

(so $\sum_n \nu(A_n)$ is well defined), and

$$\nu \left( \bigcup_{n=1}^\infty A_n \right) = \sum_{n=1}^\infty \nu(A_n).$$

The signed measure $\nu$ is finite if $\nu(A) \in \mathbb{R}$ for all $A \in A$.

Note that, as with measures, the countable additivity of (ii) includes finite additivity (taking the remaining sets to be $\emptyset$). In particular, there cannot be disjoint sets $A_1, A_2 \in A$ with $\nu(A_1) = +\infty$ and $\nu(A_2) = -\infty$.

XIII.6.1.2. Examples. (i) Any measure is a signed measure.

(ii) If $\mu_1$ and $\mu_2$ are (ordinary) measures on a measurable space $(X, A)$, at least one of which is finite, then $\mu_1 - \mu_2$ is a well-defined signed measure on $(X, A)$. More generally, any (finite) linear combination of measures, all but at most one of which are finite, is a signed measure. Any (finite) linear combination of finite signed measures is a (finite) signed measure.

(iii) Let $(X, A, \mu)$ be an (ordinary) measure space, and $f \in L^1(X, A, \mu)$. For $A \in A$, let

$$\nu(A) = \int_A f \, d\mu.$$

It is easy to check (cf. (i)) that $\nu$ is a finite signed measure.

A signed measure of the form in (ii) can be regarded as “trivial”, since its structure is completely determined and easy to describe in terms of the properties of $\mu_1$ and $\mu_2$. The main result of this section is that every signed measure is of this form, with the positive and negative pieces supported on disjoint sets:
XIII.6.1.3. Theorem. [Jordan Decomposition Theorem] Let \( \nu \) be a signed measure on a measure space \((X, \mathcal{A})\). Then there are unique measures \( \nu^+ \) and \( \nu^- \) on \((X, \mathcal{A})\), with \( \nu = \nu^+ - \nu^- \) and \( \nu^+ \perp \nu^- \). At least one of \( \nu^+ \) and \( \nu^- \) is a finite measure.

Thus the theory of signed measures turns out to be “trivial.” (However, the proof that the theory is actually trivial is definitely nontrivial!)

It is useful to rephrase this theorem in a somewhat different way. We first make some definitions:

XIII.6.1.4. Definition. Let \( \nu \) be a signed measure on a measurable space \((X, \mathcal{A})\). A set \( P \in \mathcal{A} \) is a positive set for \( \nu \) if \( \nu(A) \geq 0 \) for every \( A \in \mathcal{A}, A \subseteq P \). Similarly, \( N \in \mathcal{A} \) is a negative set for \( \nu \) if \( \nu(A) \leq 0 \) for all \( A \in \mathcal{A}, A \subseteq N \). A set \( E \in \mathcal{A} \) is a null set for \( \nu \) if it is both positive and negative, i.e. \( \nu(A) = 0 \) for all \( A \in \mathcal{A}, A \subseteq E \).

Note that a set \( E \in \mathcal{A} \) with \( \nu(E) = 0 \) is not necessary a null set: such an \( E \) could be a disjoint union \( A \cup B \), where \( \nu(A) > 0 \) and \( \nu(B) = -\nu(A) \). Similarly, an \( E \in \mathcal{A} \) with \( \nu(E) > 0 \) is not necessarily a positive set.

It is obvious that any (measurable) subset of a positive set is positive, and a finite or countable union of positive sets is positive (Exercise ()). The same holds for negative sets and null sets.

XIII.6.1.5. Definition. Let \( \nu \) be a signed measure on a measurable space \((X, \mathcal{A})\). A Hahn decomposition for \( \nu \) is a pair \((P, N)\), where \( P, N \in \mathcal{A}, N = X \setminus P \), \( P \) is positive for \( \nu \), and \( N \) is negative for \( \nu \).

We can then rephrase the Jordan Decomposition Theorem in the following way:

XIII.6.1.6. Theorem. [Hahn Decomposition Theorem] Let \( \nu \) be a signed measure on a measurable space \((X, \mathcal{A})\). Then there is a Hahn decomposition for \( \nu \). If \((P, N)\) and \((P', N')\) are Hahn decompositions for \( \nu \), then \( P \triangle P' \) and \( N \triangle N' \) are null sets for \( \nu \), i.e. the Hahn decomposition of \( \nu \) is unique up to null sets.

XIII.6.1.7. To see that the Hahn Decomposition Theorem is equivalent to the Jordan Decomposition Theorem (we will only need one direction of this equivalence), suppose \((P, N)\) is a Hahn decomposition for \( \nu \). For \( A \in \mathcal{A} \), set \( \nu^+(A) = \nu(A \cap P) \) and \( \nu^-(A) = -\nu(A \cap N) \). Then it is easily checked that \( \nu^+ \) and \( \nu^- \) are measures, \( \nu^+ \perp \nu^- \), and \( \nu = \nu^+ - \nu^- \). These measures do not change if \( P \) and \( N \) are changed by null sets. At least one of \( P \) and \( N \) must have finite measure. Conversely, let \( \nu = \mu_1 - \mu_2 \), where \( \mu_1 \) and \( \mu_2 \) are measures with \( \mu_1 \perp \mu_2 \). Let \( P \in \mathcal{A} \) with \( \mu_2(P) = 0 \) and \( \mu_1(X \setminus P) = 0 \); such a \( P \) is unique up to null sets. Then \((P, X \setminus P)\) is a Hahn decomposition for \( \nu \). Another Hahn decomposition for \( \nu \) not differing from this one by null sets would give a pair \((\nu^+, \nu^-)\) different from \((\mu_1, \mu_2)\).

XIII.6.1.8. Example. Let \((X, \mathcal{A}, \mu)\) be a measure space, and \( f \in L^1(X, \mathcal{A}, \mu) \), and for \( A \in \mathcal{A} \) set \( \nu(A) = \int_A f \, d\mu \) as in XIII.6.1.2. A Hahn decomposition for \( \nu \) is precisely a pair \((P, N)\), where \( N = X \setminus P \), \( f \geq 0 \) a.e. on \( P \), and \( f \leq 0 \) a.e. on \( N \). One Hahn decomposition is given by \( P = \{ x : f(x) \geq 0 \} \) and \( N = \{ x : f(x) < 0 \} \). The Jordan decomposition of \( \nu \) is \( \nu = \nu^+ - \nu^- \), where \( \nu^+(A) = \int_A f_+ \, d\mu \) and \( \nu^-(A) = \int_A f_- \, d\mu \) for \( A \in \mathcal{A} \) and \( f_+ \), \( f_- \) the positive and negative parts of \( f \).
The proof of Theorem XIII.6.1.6. (and therefore Theorem XIII.6.1.3.) will consist of a series of lemmas, all of which would be easy corollaries of the theorem. Our proof is based on [Dos80] [note that the argument of [Dos80] is incomplete as written since it assumes the conclusion of XIII.6.1.14. without comment.]

The first result about signed measures is that a signed measure cannot take both the values $+\infty$ and $-\infty$:

**XIII.6.1.9. Lemma.** Let $\nu$ be a signed measure on $(X, \mathcal{A})$. Then there do not exist $A, B \in \mathcal{A}$ with $\nu(A) = +\infty$ and $\nu(B) = -\infty$.

**Proof:** It follows immediately from XIII.6.1.1(ii) that there do not exist disjoint sets $A_1, A_2 \in \mathcal{A}$ with $\nu(A_1) = +\infty$ and $\nu(A_2) = -\infty$. Suppose $\nu(A) = +\infty$ and $\nu(B) = -\infty$. Then $A \cap B$, $A \setminus B$, and $B \setminus A$ are pairwise disjoint, and:

- At least one of $A \cap B$ and $A \setminus B$ has measure $+\infty$.
- At least one of $A \cap B$ and $B \setminus A$ has measure $-\infty$.

Thus there are disjoint sets with measure $+\infty$ and $-\infty$, a contradiction.

**XIII.6.1.10. Lemma.** Let $\nu$ be a signed measure on $(X, \mathcal{A})$, and $A, B \in \mathcal{A}$ with $B \subseteq A$. If $\nu(A) \in \mathbb{R}$ (i.e. $|\nu(A)| < \infty$), then $\nu(B) \in \mathbb{R}$.

**Proof:** We have $\nu(A) = \nu(B) + \nu(A \setminus B)$, and the sum on the right is well defined. If $\nu(B) = +\infty$, then we cannot have $\nu(A \setminus B) = -\infty$, and hence we would have to have $\nu(A) = +\infty$. The argument if $\nu(B) = -\infty$ is similar.

The next result is an exact analog of (i).

**XIII.6.1.11. Lemma.** Let $\nu$ be a signed measure on a measurable space $(X, \mathcal{A})$.

(i) If $E_1, E_2, \cdots \in \mathcal{A}$ with $E_1 \subseteq E_2 \subseteq \cdots$, then $\lim_{n \to \infty} \nu(E_n)$ exists as an extended real number and equals $\nu(\bigcup_{n=1}^{\infty} E_n)$.

(ii) If $E_1, E_2, \cdots \in \mathcal{A}$ with $E_1 \supseteq E_2 \supseteq \cdots$, and $\nu(E_n) \in \mathbb{R}$ for some $n$, then $\lim_{n \to \infty} \nu(E_n)$ exists as a real number and equals $\nu(\bigcap_{n=1}^{\infty} E_n)$.

**Proof:** (i): Let $A_1 = E_1$ and $A_n = E_n \setminus E_{n-1}$ for $n > 1$. Then the $A_n$ are pairwise disjoint, $E_n = \bigcup_{k=1}^{n} A_k$ for all $n$, $\bigcup_{n=1}^{\infty} A_n = \bigcup_{n=1}^{\infty} E_n$, and the series $\sum_{k=1}^{\infty} \nu(A_k)$ converges to $\nu(\bigcup_{n=1}^{\infty} E_n)$. So

$$\nu\left(\bigcup_{n=1}^{\infty} E_n\right) = \sum_{k=1}^{\infty} \nu(A_k) = \lim_{n \to \infty} \sum_{k=1}^{n} \nu(A_k) = \lim_{n \to \infty} \nu\left(\bigcup_{k=1}^{n} A_k\right) = \lim_{n \to \infty} \nu(E_n).$$

(ii): We may assume $\nu(E_1) \in \mathbb{R}$. Set $E = \bigcap_{n=1}^{\infty} E_n$, $B_n = E_1 \setminus E_n$, and $B = \bigcup_{n=1}^{\infty} B_n = E_1 \setminus E$. Then by (i)

$$\nu(B) = \lim_{n \to \infty} \nu(B_n) = \lim_{n \to \infty} \nu(E_1 \setminus E_n).$$

1464
Thus, since \( \nu(E_1) \in \mathbb{R} \),
\[
\lim_{n \to \infty} \nu(E_1 \setminus E_n) = \lim_{n \to \infty} [\nu(E_1) - \nu(E_n)]
\]
exists and hence \( \lim_{n \to \infty} \nu(E_n) \) exists and equals \( \nu(E_1) - \lim_{n \to \infty} \nu(B_n) \), and we have
\[
\nu(E) = \nu(E_1) - \nu(B) = \nu(E_1) - \lim_{n \to \infty} \nu(B_n) = \lim_{n \to \infty} \nu(E_n).
\]

Furthermore, since \( E \subseteq E_1 \) and \( \nu(E_1) \in \mathbb{R} \), we have \( \nu(E) \in \mathbb{R} \) by XIII.6.1.10..  

**XIII.6.1.12.** Lemma. Let \( \nu \) be a signed measure on a measurable space \((X, \mathcal{A})\) not taking the value \(+\infty\), and let \( \epsilon > 0 \). Then for every \( A \in \mathcal{A} \) there is a set \( A_\epsilon \in \mathcal{A} \) with \( A_\epsilon \subseteq A \), \( \nu(A_\epsilon) \geq \nu(A) \), and \( \nu(B) > -\epsilon \) for all \( B \in \mathcal{A}, \ B \subseteq A_\epsilon \).

**Proof:** Fix \( \epsilon > 0 \) and \( A \in \mathcal{A} \). If \( \nu(A) \leq 0 \), we may take \( A_\epsilon = \emptyset \). Assume \( \nu(A) > 0 \) (in particular, \( \nu(A) \in \mathbb{R} \)). Suppose the conclusion is false. Then there is a \( B_1 \in \mathcal{A}, \ B_1 \subseteq A \), with \( \nu(B_1) \leq -\epsilon \) (otherwise we could take \( A_\epsilon = A \)). Then \( \nu(A \setminus B_1) = \nu(A) - \nu(B_1) \geq \nu(A) + \epsilon \). There is a \( B_2 \in \mathcal{A}, \ B_2 \subseteq (A \setminus B_1) \), with \( \nu(B_2) \leq -\epsilon \) (otherwise we could take \( A_\epsilon = (A \setminus B_1) \)). Proceeding in this way, we generate a sequence \((B_n)\) of pairwise disjoint sets in \( \mathcal{A} \) with \( B_n \subseteq A \) and \( \nu(B_n) \leq -\epsilon \) for all \( n \). If \( B = \bigcup_{n=1}^\infty B_n \), then \( B \in \mathcal{A}, \ B \subseteq A \), and \( \nu(B) = -\infty \), contradicting XIII.6.1.10..  

**XIII.6.1.13.** Lemma. Let \( \nu \) be a signed measure on a measurable space \((X, \mathcal{A})\) not taking the value \(+\infty\). If \( A \in \mathcal{A} \), then \( A \) contains a subset \( P \) with \( P \in \mathcal{A}, \ \nu(P) \geq \nu(A) \), and \( P \) a positive set for \( \nu \).

**Proof:** Let \( A \in \mathcal{A} \). If \( \nu(A) \leq 0 \) (in particular, if \( \nu(A) = -\infty \)), we may take \( P = \emptyset \). Assume \( \nu(A) > 0 \) (in particular, \( \nu(A) \in \mathbb{R} \)). Generate a decreasing sequence \((A_n)\) of subsets of \( A \) by setting \( A_0 = A \) and \( A_{n+1} = (A_n)_{c} \) (XIII.6.1.12) with \( \epsilon = \frac{1}{n+1} \). Set \( P = \bigcap_{n=1}^\infty A_n \). Then \( P \in \mathcal{A}, \ P \subseteq A \), and
\[
\nu(P) = \lim_{n \to \infty} \nu(A_n) \geq \nu(A)
\]
by XIII.6.1.11 (ii) and the fact that \( \nu(A_n) \geq \nu(A) \) for all \( n \). Also, if \( B \in \mathcal{A}, \ B \subseteq P \), then \( B \subseteq A_n \) for each \( n \), and so \( \nu(B) > -\frac{1}{n} \) for all \( n \geq 1 \). Hence \( \nu(B) \geq 0 \). Thus \( P \) is positive for \( \nu \).

We can now prove that a signed measure which does not take an infinite value is actually bounded on that side.

**XIII.6.1.14.** Lemma. Let \( \nu \) be a signed measure on a measurable space \((X, \mathcal{A})\). If \( \nu \) does not take the value \(+\infty\), then \( \{\nu(A) : A \in \mathcal{A}\} \) is bounded above. If \( \nu \) does not take the value \(-\infty\), then \( \{\nu(A) : A \in \mathcal{A}\} \) is bounded below.

**Proof:** We prove only the first statement; the second follows by replacing \( \nu \) by \(-\nu \).

Suppose for each \( n \) there is a set \( A_n \in \mathcal{A} \) with \( \nu(A_n) > n \). By XIII.6.1.13 there is a set \( P_n \in \mathcal{A} \) with \( \nu(P_n) \geq \nu(A_n) > n \) which is positive for \( \nu \). Set \( P = \bigcup_{n=1}^\infty P_n \). Then \( P \in \mathcal{A} \) and is positive for \( \nu \); thus \( \nu(P) \geq \nu(P_n) > n \) for all \( n \), i.e. \( \nu(P) = +\infty \).  

1465
We can now prove Theorem XIII.6.1.6.

Proof: Replacing $\nu$ by $-\nu$ if necessary, we may assume that $\nu$ does not take the value $+\infty$. Let $M = \sup\{\nu(A) : A \in \mathcal{A}\}$. Then $0 \leq M < +\infty$ by XIII.6.1.14. (M $\geq 0$ since $\nu(\emptyset) = 0$). Let $(A_n)$ be a sequence of sets in $\mathcal{A}$ with $\sup_n \nu(A_n) = M$. By XIII.6.1.13., for each $n$ there is a set $P_n \in \mathcal{A}$ with $\nu(P_n) \geq \nu(A_n)$ which is positive for $\nu$. Then $\sup_n \nu(P_n) = M$. Set $P = \bigcup_{n=1}^{\infty} P_n$. Then $P$ is a positive set for $\nu$, and $\nu(P) \geq \nu(P_n)$ for all $n$; thus $\nu(P) = M$. Let $N = X \setminus P$. If $B \in \mathcal{A}$, $B \subseteq N$, then

$$M + \nu(B) = \nu(P \cup B) \leq M$$

and hence $\nu(B) \leq 0$; thus $N$ is a negative set for $\nu$, and $(P, N)$ is a Hahn decomposition for $\nu$.

To show uniqueness, if $(P', N')$ is another Hahn decomposition, let $A$ be a subset of $P \setminus P'$. Then $\nu(A) \geq 0$ since $A \subseteq P$, and $\nu(A) \leq 0$ since $A \subseteq N'$. Hence $P \setminus P'$ is a null set. Similarly, $P' \setminus P$, $N \setminus N'$, and $N' \setminus N$ are null sets.

This completes the proof of XIII.6.1.6.

The proof actually shows the following:

XIII.6.1.15. Corollary. Let $\nu$ be a signed measure on a measurable space $(X, \mathcal{A})$. If $L = \inf\{\nu(A) : A \in \mathcal{A}\}$ and $M = \sup\{\nu(A) : A \in \mathcal{A}\}$, then:

(i) At least one of $L$ and $M$ is finite (note that $L \leq 0$ and $M \geq 0$ since $\nu(\emptyset) = 0$).

(ii) A pair $(P, N)$ of sets in $\mathcal{A}$ is a Hahn decomposition for $\nu$ if and only if $N = X \setminus P$, $\nu(P) = M$, and $\nu(N) = L$.

(iii) There exists at least one pair $(P, N)$ as in (ii).

See [Kön97] for a detailed discussion of signed premeasures and versions of the Carathéodory Extension Theorem.

The Total Variation of a Signed Measure

XIII.6.1.16. Definition. Let $\nu$ be a signed measure on a measurable space $(X, \mathcal{A})$, with Jordan decomposition $\nu = \nu^+ - \nu^-$. The measure $|\nu| = \nu^+ + \nu^-$ is called the total variation measure, or total variation, of $\nu$.

The next proposition is nearly trivial (given our previous results). Part (ii) is preparation for the definition of the total variation of a complex measure (XIII.6.2.6.), which is less trivial. This part is strongly reminiscent of the definition of the total variation of a function (). (This similarity is no accident! See ()).

XIII.6.1.17. Proposition. Let $\nu$ be a signed measure on a measurable space $(X, \mathcal{A})$. If $E \in \mathcal{A}$, then

(i) $|\nu(E)| \leq |\nu|(E)$.

(ii) $|\nu|(E) = \sup(\sum_{n=1}^{\infty} |\nu(E_n)|)$, where the supremum runs over all measurable partitions $\{E_n\}$ of $E$.  

1466
Proof: (i) is obvious. For (ii), let $S$ be the supremum. If $\{E_n\}$ is a measurable partition of $E$, then since $|\nu|$ is a measure,

$$
\sum_{n=1}^{\infty} |\nu(E_n)| \leq \sum_{n=1}^{\infty} |\nu|(E_n) = |\nu| \left( \bigcup_{n=1}^{\infty} E_n \right) = |\nu|(E)
$$

using (i), so $S \leq |\nu|(E)$. On the other hand, if $(P, N)$ is a Hahn decomposition for $\nu$, we have

$$
|\nu|(E) = \nu^+(E) + \nu^-(E) = |\nu(E \cap P)| + |\nu(E \cap N)| \leq S.
$$

An easy consequence of (ii) is:

**XIII.6.1.18. Corollary.** Let $\nu_1$ and $\nu_2$ be signed measures on a measurable space $(X, \mathcal{A})$. Suppose $\nu_1 + \nu_2$ is well defined as a signed measure (i.e. both $\nu_1$ and $\nu_2$ are bounded above or both are bounded below, e.g. if at least one is finite). Then $|\nu_1 + \nu_2| \leq |\nu_1| + |\nu_2|$ (i.e. $|\nu_1 + \nu_2|(E) \leq |\nu_1|(E) + |\nu_2|(E)$ for all $E \in \mathcal{A}$).

Note that there is no simple way to obtain a Hahn decomposition for $\nu_1 + \nu_2$ from Hahn decompositions for $\nu_1$ and $\nu_2$ in general.

**XIII.6.2. Complex Measures**

**XIII.6.2.1. Definition.** If $(X, \mathcal{A})$ is a measurable space, a *complex measure* on $(X, \mathcal{A})$ is a function $\nu : \mathcal{A} \to \mathbb{C}$ such that

(i) $\nu(\emptyset) = 0$.

(ii) If $A_1, A_2, \ldots$ is a sequence of pairwise disjoint sets in $\mathcal{A}$, then $\sum_{n=1}^{\infty} \nu(A_n)$ converges to $\nu(\bigcup_{n=1}^{\infty} A_n)$.

**XIII.6.2.2. Examples.** (i) Any finite signed measure (in particular, any finite measure) is a complex measure.

(ii) If $\nu_1$ and $\nu_2$ are finite signed measures on $(X, \mathcal{A})$, then $\nu = \nu_1 + i\nu_2$ is a complex measure on $(X, \mathcal{A})$. More generally, any (finite) complex linear combination of complex measures on $(X, \mathcal{A})$ is a complex measure on $(X, \mathcal{A})$.

The following converse to (ii) essentially reduces the theory of complex measures to the theory of finite signed measures, and hence to the theory of ordinary finite measures:

**XIII.6.2.3. Proposition.** Let $\nu$ be a complex measure on a measurable space $(X, \mathcal{A})$. For $E \in \mathcal{A}$, define $\nu_{re}(E) = \text{Re}(\nu(E))$ and $\nu_{im}(E) = \text{Im}(\nu(E))$. Then $\nu_{re}$ and $\nu_{im}$ are finite signed measures on $(X, \mathcal{A})$, called the *real* and *imaginary parts* of $\nu$ respectively.

Conversely, if $\nu_1$ and $\nu_2$ are finite signed measures on $(X, \mathcal{A})$, and $\nu = \nu_1 + i\nu_2$, then $\nu_{re} = \nu_1$, $\nu_{im} = \nu_2$.  

1467
XIII.6.2.4. To a complex measure $\nu$ there are thus four canonically associated finite measures $\nu_{re}^+$, $\nu_{re}^-$, $\nu_{im}^+$, and $\nu_{im}^-$. Note, however, that there may be overlap between the supports of $\nu_{re}^+$ and $\nu_{im}^+$, i.e. the measures $|\nu_{re}|$ and $|\nu_{im}|$ may not be mutually singular. Thus there is no analog of a Hahn decomposition of $X$ into “real” and “imaginary” subsets for $\nu$ in general.

XIII.6.2.5. There is a slight difficulty in making a good definition of the total variation of a complex measure. A reasonable approach is to take the measure

$$|\nu_{re}| + |\nu_{im}| = \nu_{re}^+ + \nu_{re}^- + \nu_{im}^+ + \nu_{im}^-$$

but this measure does not have all the desirable properties of a total variation. Instead it is customary to take the following definition:

XIII.6.2.6. **Definition.** Let $\nu$ be a complex measure on a measurable space $(X, A)$. If $E \in A$, define $|\nu|(E) = \sup(\sum_{n=1}^{\infty} |\nu(E_n)|)$, where the supremum runs over all measurable partitions $\{E_n\}$ of $E$.

XIII.6.2.7. **Theorem.** Let $\nu$ be a complex measure on a measurable space $(X, A)$. Then

(i) $|\nu|$ is a measure on $(X, A)$.
(ii) If $E \in A$, then $|\nu(E)| \leq |\nu|(E)$.
(iii) If $E \in A$, then

$$\max(|\nu_{re}(E)|, |\nu_{im}(E)|) \leq |\nu|(E) \leq |\nu_{re}(E)| + |\nu_{im}(E)|.$$ 

In particular, $|\nu|$ is a finite measure, and since

$$\frac{1}{2} \left[ |\nu_{re}(E)| + |\nu_{im}(E)| \right] \leq \max(|\nu_{re}(E)|, |\nu_{im}(E)|)$$

we have

$$\frac{1}{2} \left[ |\nu_{re}(E)| + |\nu_{im}(E)| \right] \leq |\nu|(E) \leq |\nu_{re}(E)| + |\nu_{im}(E)|.$$ 

**Proof:** (ii): This is trivial since $\{E\}$ is a measurable partition of $E$.
(iii): Note that if $x, y \in \mathbb{R}$, then

$$\frac{1}{2} \left[ |x| + |y| \right] \leq \max(|x|, |y|) \leq |x + iy| \leq |x| + |y|$$

(). If $\{E_n\}$ is a measurable partition of $E$, then

$$\max \left( \sum_{n=1}^{\infty} |\nu_{re}(E_n)|, \sum_{n=1}^{\infty} |\nu_{im}(E_n)| \right) \leq \sum_{n=1}^{\infty} \left[ \max(|\nu_{re}(E_n)|, |\nu_{im}(E_n)|) \right]$$

$$\leq \sum_{n=1}^{\infty} |\nu(E_n)| \leq \sum_{n=1}^{\infty} \left[ |\nu_{re}(E_n)| + |\nu_{im}(E_n)| \right] = \sum_{n=1}^{\infty} |\nu_{re}(E_n)| + \sum_{n=1}^{\infty} |\nu_{im}(E_n)|.$$ 

1468
and the result follows by taking the supremum over all measurable partitions of $E$ and applying XIII.6.17 (ii).

In particular, since $|\nu(E)|$ and $|\nu_m|(E)$ are finite, so is $|\nu|(E)$.

(i): It is obvious that $|\nu|(\emptyset) = 0$. Let $\{A_m\}$ be a pairwise disjoint sets in $\mathcal{A}$, and let $A = \cup_{m=1}^{\infty} A_m$. Fix $\epsilon > 0$. Let $\{E_n\}$ be a measurable partition of $A$ with $\sum_{n=1}^{\infty} |\nu(E_n)| > |\nu|(A) - \epsilon$ ($|\nu|(A)$ is finite by (iii)). Set $A_{n,m} = E_n \cap A_m$ for each $n, m$. Then

$$|\nu|(A) - \epsilon \leq \sum_{n=1}^{\infty} |\nu(E_n)| = \sum_{n=1}^{\infty} \sum_{m=1}^{\infty} \nu(A_{n,m}) \leq \sum_{n=1}^{\infty} \sum_{m=1}^{\infty} |\nu|(A_m)$$

(the equality in the last line uses (i)). Since $\epsilon > 0$ is arbitrary, $|\nu|(A) \leq \sum_{m=1}^{\infty} |\nu|(A_m)$. Conversely, if $\epsilon > 0$, for each $m$ let $\{E_{n,m}\}$ be a measurable partition of $A_m$ with

$$\sum_{n=1}^{\infty} |\nu(E_{n,m})| > |\nu|(A_m) - 2^{-m}\epsilon .$$

Then $\{E_{n,m}\}$ is a measurable partition of $A$, so

$$\left(\sum_{m=1}^{\infty} |\nu|(A_m)\right) - \epsilon = \sum_{m=1}^{\infty} |\nu|(A_m) - 2^{-m}\epsilon < \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} |\nu(E_{n,m})| \leq |\nu|(A) .$$

Since $\epsilon > 0$ is arbitrary, $\sum_{m=1}^{\infty} |\nu|(A_m) \leq |\nu|(A)$.

XIII.6.2.8. PROPOSITION. Let $\nu_1$ and $\nu_2$ be complex measures on $(X, \mathcal{A})$, and let $\alpha \in \mathbb{C}$. Then

(i) $|\nu_1 + \nu_2| \leq |\nu_1| + |\nu_2|$ (i.e. $|\nu_1 + \nu_2|(E) \leq |\nu_1|(E) + |\nu_2|(E)$ for all $E \in \mathcal{A}$).

(ii) $|\alpha \nu_1| = |\alpha||\nu_1|$.

XIII.6.3. Integration With Respect to Signed and Complex Measures

There is nothing difficult or complicated about extending integration to the case of signed or complex measures; we need only make the right definitions, which are fairly obvious, guided by the desire to preserve linearity.

The only slight difficulty is deciding what should be meant by an integrable function. But the definition here is fairly obvious too, because of the following fact:

XIII.6.3.1. PROPOSITION. (i) Let $\nu$ be a signed measure on a measurable space $(X, \mathcal{A})$, and $f : X \to \mathbb{R}$ an $\mathcal{A}$-measurable function. Then $f \in L^1(X, \mathcal{A}, |\nu|)$ if and only if $f \in L^1(X, \mathcal{A}, \nu^+)$ and $f \in L^1(X, \mathcal{A}, \nu^-)$.

(ii) Let $\nu$ be a complex measure on a measurable space $(X, \mathcal{A})$, and $f : X \to \mathbb{C}$ an $\mathcal{A}$-measurable function. Then $f \in L^1_c(X, \mathcal{A}, |\nu|)$ if and only if $f \in L^1_c(X, \mathcal{A}, |\nu_+|)$ and $f \in L^1_c(X, \mathcal{A}, |\nu_-|)$.

PROOF: Part (i) is obvious since $\int_X |f| \, d|\nu| = \int_X |f| \, d\nu^+ + \int_X |f| \, d\nu^-$, and (ii) follows easily from the same argument and XIII.6.2.7 (iii).
**XIII.6.3.2.** Definition. Let \( \nu \) be a signed measure or complex measure on a measurable space \((X, \mathcal{A})\), and \( f \) a real- or complex-valued \( \mathcal{A} \)-measurable function. Then \( f \in \mathcal{L}^1(X, \mathcal{A}, \nu) \) if \( f \) is complex-valued and \( |f| \in \mathcal{L}^1(X, \mathcal{A}, |\nu|) \).

We then make the following obvious definition:

**XIII.6.3.3.** Definition. (i) Let \( \nu \) be a signed measure on a measurable space \((X, \mathcal{A})\), and \( f \in \mathcal{L}^1(X, \mathcal{A}, \nu) \) or \( \mathcal{L}^1_{\mathbb{C}}(X, \mathcal{A}, \nu) \). Then

\[
\int_X f \, d\nu = \int_X f \, d\nu^+ - \int_X f \, d\nu^- .
\]

(ii) Let \( \nu \) be a complex measure on a measurable space \((X, \mathcal{A})\), and \( f \in \mathcal{L}^1_{\mathbb{C}}(X, \mathcal{A}, \nu) \). Then

\[
\int_X f \, d\nu = \int_X f \, d\nu_{re} + i \int_X f \, d\nu_{im} .
\]

(iii) If \( A \in \mathcal{A} \), then in either of the above cases \( \int_A f \, d\nu = \int_X f \chi_A \, d\nu \).

**XIII.6.3.4.** The integrals defined in this way have almost all the properties of integrals with respect to ordinary measures; the only obvious exceptions are positivity and monotonicity. It thus only makes sense to integrate \( \mathcal{L}^1 \)-functions, not arbitrary nonnegative measurable functions.

We list the important properties of this extended integral. The proofs are simple applications of the results for nonnegative measures, and are mostly omitted.

**XIII.6.3.5.** Proposition. Let \( \nu \) be a signed or complex measure on a measurable space \((X, \mathcal{A})\). If \( f, g \in \mathcal{L}^1_{\mathbb{C}}(X, \mathcal{A}, \nu) \), then

\[
\int_A (f + g) \, d\nu = \int_A f \, d\nu + \int_A g \, d\nu
\]

for all \( A \in \mathcal{A} \). If \( f \in \mathcal{L}^1_{\mathbb{C}}(X, \mathcal{A}, \nu) \) and \( \alpha \in \mathbb{C} \), then

\[
\int_A \alpha f \, d\nu = \alpha \int_A f \, d\nu
\]

for all \( A \in \mathcal{A} \).

For the proof of the last statement, see Exercise XIII.6.4.2.

**XIII.6.3.6.** If \( \nu \) is a signed or complex measure and \( f \in \mathcal{L}^1(\nu) \), then in general

\[
\left| \int_X f \, d\nu \right| \leq \int |f| \, d\nu
\]

(the right side is not necessarily nonnegative or even real). However, we have:
XIII.6.3.7. PROPOSITION. Let \( \nu \) be a signed or complex measure on a measurable space \((X, \mathcal{A})\), and let \( f \in L^1_{\mathbb{C}}(X, \mathcal{A}, \nu) \). Then
\[
\left| \int_A f \, d\nu \right| \leq \int_A |f| \, d|\nu|
\]
for any \( A \in \mathcal{A} \).

Because of the lack of monotonicity, there are no versions of the Monotone Convergence Theorem or Fatou’s Lemma for signed or complex measures. But the Dominated Convergence Theorem holds with an identical statement:

XIII.6.3.8. THEOREM. [DOMINATED CONVERGENCE THEOREM] Let \( \nu \) be a signed or complex measure on a measurable space \((X, \mathcal{A})\). Let \((f_n)\) be a sequence of functions in \(L^1_{\mathbb{C}}(X, \mathcal{A}, \nu)\) converging pointwise a.e. to a function \( f \). If there is a \( g \in L^1_{\mathbb{C}}(X, \mathcal{A}, \nu) \) with \( |f_n| \leq g \) a.e. for all \( n \), then
\[
\int_X f \, d\nu = \lim_{n \to \infty} \int_X f_n \, d\nu .
\]

There is a version for infinite series. We omit the general statement, but note the following important special case:

XIII.6.3.9. PROPOSITION. Let \( \nu \) be a signed or complex measure on a measurable space \((X, \mathcal{A})\), and let \( f \in L^1_{\mathbb{C}}(X, \mathcal{A}, \nu) \). Let \( \{A_n\} \) be a sequence of pairwise disjoint sets in \( \mathcal{A} \), with \( A = \bigcup_{n=1}^{\infty} A_n \). Then the series
\[
\sum_{n=1}^{\infty} \int_{A_n} f \, d\nu
\]
converges absolutely to \( \int_A f \, d\nu \).

XIII.6.3.10. As a consequence, if \( \nu \) is a complex measure on \((X, \mathcal{A})\), and \( f \in L^1_{\mathbb{C}}(X, \mathcal{A}, \nu) \), and \( \sigma \) is defined on \( \mathcal{A} \) by \( \sigma(A) = \int_A f \, d\nu \), then \( \sigma \) is also a complex measure on \( \mathcal{A} \). In this case, we have that \( |\sigma|(A) = \int_A |f| \, d|\nu| \) (XIV.9.1).

XIII.6.4. Exercises

XIII.6.4.1. (a) Let \((X, \mathcal{A}, \mu)\) be a measure space, and \( f \in L^1_{\mathbb{R}}(X, \mathcal{A}, \mu) \). Define \( \nu(A) = \int_A f \, d\mu \) as in XIII.6.1.2. and XIII.6.1.8. Show that, for all \( A \in \mathcal{A} \), \( |\nu|(A) = \int_A |f| \, d\mu \).

(b) Show the same for \( f \in L^1_{\mathbb{C}}(X, \mathcal{A}, \mu) \). [Hint: for \( n \in \mathbb{N} \) and \( 1 \leq k \leq n \), consider the set
\[
A_{n,k} = \left\{ x \in A : \frac{2\pi(k-1)}{n} \leq \arg(f(x)) < \frac{2\pi k}{n} \right\}.
\]

1471
XIII.6.4.2. (a) Let $\nu$ be a complex measure on a measurable space $(X, \mathcal{A})$, and $f \in L^1_C(X, \mathcal{A}, \nu)$. Show that
\[
\int_A f \, d\nu = \left[ \int_A \text{Re}(f) \, d\nu + i \int_A \text{Im}(f) \, d\nu \right]
\]
for any $A \in \mathcal{A}$.
(b) Show that if $\alpha \in \mathbb{C}$, then
\[
\int_X \alpha f \, d\nu = \alpha \int_X f \, d\nu.
\]

XIII.6.4.3. Let $\nu$ be a signed measure on a measurable space $(X, \mathcal{A})$, and $f \in L^1_{\mathbb{R}}(X, \mathcal{A}, \nu)$. Define a signed measure $\sigma$ by $\sigma(A) = \int_A f \, d\nu$ for $A \in \mathcal{A}$.
(a) Find a Hahn decomposition for $\sigma$, and the Jordan decomposition.
(b) Show that $|\sigma|(A) = \int_A |f| \, d|\nu|$ for $A \in \mathcal{A}$.

XIII.6.4.4. Try to extend the theory of complex measures to include measures of the form $\nu_1 + i\nu_2$, where $\nu_1$ and $\nu_2$ are signed measures, not necessarily finite. Try to give a definition as in XIII.6.1.1. and XIII.6.2.1. which covers this case (clumsy and unnatural, isn’t it?) Discuss the properties which can and cannot be established in this case, and the difficulties and limitations of such a theory.

XIII.6.4.5. A finitely additive signed measure on an algebra can be finite but unbounded, and can fail to have a Hahn decomposition.
(a) Let $\mathcal{A}$ be the algebra of finite/cofinite subsets of $\mathbb{N}$. If $A \in \mathcal{A}$ is finite, let $\nu(A)$ be the number of elements in $A$; if $A$ is cofinite, let $\nu(A) = -n$, where $n$ is the number of elements in $A^c$. Show that $\nu$ is a finitely additive signed measure on $(\mathbb{N}, \mathcal{A})$.
(b) Show that there is no Hahn decomposition for $\nu$. 

1472
XIII.7. Limits of Measures

In this section, we discuss the following question: if \((\mu_i)\) is a sequence (or net) of measures, and \(\mu_i \to \mu\), is \(\mu\) a measure?

XIII.7.1. General Considerations

We must first make sense of what it means to say that \(\mu_i \to \mu\). There is one obvious minimal sense to interpret this:

XIII.7.1.1. Definition. Let \(X\) be a set, \(\mathcal{A}\) a collection of subsets of \(X\), and \(Y\) a topological space. Then a sequence (or net) \((f_i)\) of functions from \(\mathcal{A}\) to \(Y\) converges setwise to the function \(f : \mathcal{A} \to Y\) if \(f_i(A) \to f(A)\) for all \(A \in \mathcal{A}\). In particular, if \((\mu_i)\) is a sequence (or net) of measures on a measurable space \((X, \mathcal{A})\), and \(\mu : \mathcal{A} \to [0, \infty]\), then \(\mu_i \to \mu\) setwise if \(\mu_i(A) \to \mu(A)\) for all \(A \in \mathcal{A}\). Setwise convergence of a sequence (or net) \((\nu_i)\) of complex measures to a function \(\nu : \mathcal{A} \to \mathbb{C}\) is defined in the same way.

In other words: a measure on \((X, \mathcal{A})\) may be thought of as an element of the product space \([0, \infty]^\mathcal{A}\), the set of all functions from \(\mathcal{A}\) to \([0, \infty]\). Then \(\mu_i \to \mu\) setwise if \(\mu_i \to \mu\) in the product topology. Similarly, a complex measure on \((X, \mathcal{A})\) is an element of \(\mathbb{C}^\mathcal{A}\), and setwise convergence is convergence in the product topology.

There are stronger notions of convergence; see, for example, Exercise XIII.7.4.1.

So the basic question is:

XIII.7.1.2. Question. If \((\mu_i)\) is a sequence (or net) of measures (ordinary or complex), and \(\mu_i \to \mu\) setwise, is \(\mu\) is also a measure (or complex measure)?

This question can be rephrased: is the set of measures a closed subset of \([0, \infty]^\mathcal{A}\)? Is the set of complex measures a closed subset of \(\mathbb{C}^\mathcal{A}\)?

The following simple examples show that the answer is no in general.

XIII.7.1.3. Examples. (i) On \((\mathbb{N}, \mathcal{P}(\mathbb{N}))\), let \(\mu_n\) be counting measure on \(\{m : m > n\}\), regarded as a measure on \((\mathbb{N}, \mathcal{P}(\mathbb{N}))\) by setting \(\mu_n(E) = 0\) if \(E \subseteq \{1, \ldots, n\}\). Then each \(\mu_n\) is a \(\sigma\)-finite measure, \((\mu_n(E))\) is decreasing for each \(E\), and \(\mu(E) = \lim_{n \to \infty} \mu_n(E)\) exists for each \(E \subseteq \mathbb{N}\). But \(\mu(E) = 0\) if \(E\) is finite, and \(\mu(\mathbb{N}) = \infty\) (in fact, \(\mu(E) = \infty\) if \(E\) is any infinite set), so \(\mu\) is not a measure.

(ii) Again on \((\mathbb{N}, \mathcal{P}(\mathbb{N}))\), let \(\delta_n\) be the unit point mass at \(n\), i.e. for \(E \subseteq \mathbb{N}\), \(\delta_n(E) = 1\) if \(n \in E\) and \(\delta_n(E) = 0\) if \(n \notin E\). Each \(\delta_n\) gives a point of \(\{0, 1\}^\mathcal{P}(\mathbb{N})\), which is compact in the product topology; thus there is a subnet of the sequence \((\delta_n)\) which converges setwise to a function \(\mu : \mathcal{P}(\mathbb{N}) \to \{0, 1\}\). But \(\mu(E) = 0\) for all finite \(E\), while \(\mu(\mathbb{N}) = 1\), and thus \(\mu\) cannot be a measure.

Example (ii) is rather generic: there are grave difficulties in taking limits of nets of measures which are not sequences. But, rather remarkably, often (i.e. under mild hypotheses) it will turn out that limits of sequences of measures are measures.

A setwise limit of measures is always at least a finitely additive measure:
XIII.7.1.4. Proposition. Let \((X, \mathcal{A})\) be a measurable space. Then the set of finitely additive measures on \((X, \mathcal{A})\) is closed under setwise limits (i.e. is a closed subset of \([0, \infty]^\mathcal{A}\)). The set of finitely additive complex measures is a closed subset of \(\mathbb{C}^\mathcal{A}\).

This is an immediate consequence of ()

So the whole difficulty is with countable additivity.

XIII.7.2. Monotone and Dominated Convergence

The first result is an analog of the Monotone Convergence Theorem:

XIII.7.2.1. Theorem. Let \((\mu_i)\) be a net of measures on a measurable space \((X, \mathcal{A})\). If \((\mu_i(A))\) is increasing for each \(A \in \mathcal{A}\), then

\[
\mu = \lim_{i} \mu_i = \sup_{i} \mu_i \quad \text{(defined by } \mu(A) = \sup_{i} \mu_i(A) \text{ for } A \in \mathcal{A})
\]

is a measure on \((X, \mathcal{A})\).

Proof: We only need to show countable additivity. Suppose \((A_n)\) is a pairwise disjoint sequence in \(\mathcal{A}\), and set \(A = \bigcup_{n=1}^{\infty} A_n\). We have

\[
\sum_{n=1}^{\infty} \mu(A_n) = \sup_{N} \sum_{n=1}^{N} \mu(A_n) = \sup_{N} \left[ \mu \left( \bigcup_{n=1}^{N} A_n \right) \right] \leq \mu(A)
\]

by finite additivity and monotonicity. To show the reverse inequality, first suppose \(\mu(A) < \infty\). Let \(\epsilon > 0\) and choose \(i_0\) such that \(\mu_i(A) > \mu(A) - \epsilon\). Then we have

\[
\mu(A) - \epsilon < \mu_{i_0}(A) = \sum_{n=1}^{\infty} \mu_i(A_n) \leq \sum_{n=1}^{\infty} \mu(A_n).
\]

Since \(\epsilon > 0\) is arbitrary, \(\mu(A) \leq \sum_{n=1}^{\infty} \mu(A_n)\).

Now suppose \(\mu(A) = \infty\). Fix \(M > 0\), and choose \(i_0\) such that \(\mu_{i_0}(A) > M\). We then have

\[
M < \mu_{i_0}(A) = \sum_{n=1}^{\infty} \mu_i(A_n) \leq \sum_{n=1}^{\infty} \mu(A_n),
\]

so \(\sum_{n=1}^{\infty} \mu(A_n) = +\infty\).

This implies that arbitrary sums of measures are measures (finite sums of measures are obviously measures ()).

XIII.7.2.2. Corollary. Let \(\{\mu_i : i \in I\}\) be a set of measures on a measurable space \((X, \mathcal{A})\). For each \(A \in \mathcal{A}\), define

\[
\mu(A) = \sum_{i \in I} \mu_i(A) = \sup \left\{ \sum_{i \in F} \mu_i(A) : F \subseteq I \text{ finite} \right\}.
\]

Then \(\mu\) is a measure on \((X, \mathcal{A})\).

There is also a version of the Dominated Convergence Theorem:
XIII.7.2.3. Theorem. Let $(\nu_i)$ be a net of complex measures on a measurable space $(X, \mathcal{A})$, converging setwise to a function $\nu$. If there is a finite measure $\mu$ such that $|\nu_i| \leq \mu$ for all $i$, then $\nu$ is a complex measure.

(Of course, this theorem applies in the case the $\nu_i$ are ordinary measures uniformly dominated by a finite measure $\mu$.)

In fact, this result holds in greater generality. We make some definitions:

XIII.7.2.4. Definition. Let $(\nu_i)_{i \in I}$ be a net of complex measures on a measurable space $(X, \mathcal{A})$, and $\mu$ a measure on $(X, \mathcal{A})$. Then $(\nu_i)$ is uniformly absolutely continuous with respect to $\mu$ if for every $\epsilon > 0$ there is a $\delta > 0$ and an $i_0 \in I$ such that, for all $A \in \mathcal{A}$ with $\mu(A) < \delta$,

$$|\nu_i(A)| < \epsilon \text{ for all } i \geq i_0.$$ 

The term “uniformly absolutely continuous” is appropriate for this notion, in analogy with the characterization of absolute continuity of measures in ()

Under the hypotheses of XIII.7.2.5., $(\nu_i)$ is uniformly absolutely continuous with respect to $\mu$ (take $\delta = \epsilon$). Thus Theorem XIII.7.2.5. is a special case of the following result:

XIII.7.2.5. Theorem. Let $(\nu_i)$ be a net of complex measures on a measurable space $(X, \mathcal{A})$, converging setwise to a function $\nu : \mathcal{A} \to \mathbb{C}$. If there is a finite measure $\mu$ such that $(\nu_i)$ is uniformly absolutely continuous with respect to $\mu$, then $\nu$ is a complex measure.

We can even go to one step greater generality:

XIII.7.2.6. Definition. Let $(\nu_i)_{i \in I}$ be a net of complex measures on a measurable space $(X, \mathcal{A})$. Then $(\nu_i)$ is uniformly countably additive if, whenever $(A_n)$ is a sequence of pairwise disjoint sets in $\mathcal{A}$ with $A = \bigcup_{n=1}^{\infty} A_n$, and $\epsilon > 0$, there is an $N_0 \in \mathbb{N}$ and an $i_0 \in I$ such that

$$|\nu_i(A) - \nu_i\left(\bigcup_{n=1}^{N} A_n\right)| < \epsilon$$

for all $N \geq N_0$ and $i \geq i_0$.

XIII.7.2.7. Proposition. Let $(\nu_i)_{i \in I}$ be a net of complex measures on a measurable space $(X, \mathcal{A})$. Then $(\nu_i)$ is uniformly countably additive if and only if, whenever $(B_n)$ is a decreasing sequence in $\mathcal{A}$ with $\bigcap_{n=1}^{\infty} B_n = \emptyset$, we have $\lim_{n \to \infty} \nu_i(B_n) = 0$ uniformly in $i$, i.e. for every $\epsilon > 0$ there is an $n_0 \in \mathbb{N}$ and $i_0 \in I$ such that

$$|\nu_i(B_n)| < \epsilon$$

for all $n \geq n_0$ and $i \geq i_0$.

Proof: If $(\nu_i)$ is uniformly countably additive and $(B_n)$ is decreasing with empty intersection, set $A_n = B_n \setminus B_{n+1}$. Conversely, if $(A_n)$ is a pairwise disjoint sequence, let $B_n = \bigcup_{k \geq n} A_k$. ☑
XIII.7.2.8. **Corollary.** Let \((\nu_i)_{i \in I}\) be a net of complex measures on a measurable space \((X, \mathcal{A})\). If \((\nu_i)\) is uniformly countably additive, then whenever \((A_n)\) is a pairwise disjoint sequence in \(\mathcal{A}\) we have 
\[
\lim_{n \to \infty} \nu_i(A_n) = 0 \text{ uniformly in } i.
\]

The converse is also true for a sequence of complex measures, and is a key step in the direct proof of the Nikodým Convergence Theorem (Exercise XIII.7.4.2.).

**Proof:** Set \(B_n = \bigcup_{k=n}^{\infty} A_k\). Then \(\nu_i(B_n) \to 0 \text{ uniformly in } i\), and 
\[
|\nu_i(A_n)| \leq |\nu_i(B_n)| + |\nu_i(B_{n+1})| \text{ for all } n \text{ and } i.
\]

XIII.7.2.9. **Proposition.** Let \((\nu_i)\) be a net of complex measures on a measurable space \((X, \mathcal{A})\). If there is a finite measure \(\mu\) such that \((\nu_i)\) is uniformly absolutely continuous with respect to \(\mu\), then \((\nu_i)\) is uniformly countably additive.

The converse is true for a setwise convergent sequence of complex measures (XIII.7.3.8.).

**Proof:** Use XIII.7.2.7. Let \(\epsilon > 0\), and fix \(\delta_0\) and \(i_0\) as in Definition XIII.7.2.4. Let \((B_n)\) be a decreasing sequence in \(\mathcal{A}\) with \(\cap_{n=1}^{\infty} B_n = \emptyset\). Fix \(n_0\) such that \(\mu(B_n) < \delta\) for all \(n \geq n_0\). Then, for all \(n \geq n_0\) and \(i \geq i_0\), 
\[
|\nu_i(B_n)| < \epsilon.
\]

We then obtain the most general version of the Dominated Convergence Theorem for measures (note that there is no actual domination in this version!)

XIII.7.2.10. **Theorem.** Let \((\nu_i)\) be a net of complex measures on a measurable space \((X, \mathcal{A})\), converging setwise to a function \(\nu : \mathcal{A} \to \mathbb{C}\). If \((\nu_i)\) is uniformly countably additive, then \(\nu\) is a complex measure.

**Proof:** We again need only show countable additivity. Since \(\nu\) is finite-valued, it suffices to show () that if \((B_n)\) is a decreasing sequence in \(\mathcal{A}\) with \(\cap_{n=1}^{\infty} B_n = \emptyset\), we have \(\lim_{n \to \infty} \nu(B_n) = 0\). Let \(\epsilon > 0\), and fix a corresponding \(n_0\) and \(i_0\) as in the definition of uniform countable additivity (XIII.7.2.6.). Then, if \(n \geq n_0\), then \(|\nu_i(B_n)| < \epsilon\) for all \(i \geq i_0\), and thus \(|\nu(A_n)| \leq \epsilon\).

XIII.7.3. **The Nikodým and Vitali-Hahn-Saks Theorems**

We now restrict attention to sequences of measures. There is a circle of results due to NIKODÝM, VITALI, HAHN, and SAKS (there were other contributors too) which say that under certain mild restrictions, the setwise limit of a sequence of complex measures is a complex measure, and that the convergence is “almost uniform.”

These results are closely interconnected, and can be largely deduced from each other; various schemes for proving them are found in the literature. Even the names of the results are not uniform in references; what is called the “Vitali-Hahn-Saks Theorem” in some references is called the “Nikodým Convergence Theorem” in others, reflecting the close connections. We have tried to use names accurately reflecting the actual work of the originators.

The first observation is that a sequence of complex measures is dominated by a single measure:
XIII.7.3.1. PROPOSITION. Let \((\nu_n)\) be a sequence of complex measures on a measurable space \((X, \mathcal{A})\). Then there is a finite measure \(\mu\) on \((X, \mathcal{A})\) such that \(\nu_n \ll \mu\) for all \(n\).

PROOF: We may assume all the \(\nu_n\) are nonzero. For \(A \in \mathcal{A}\), set
\[
\mu(A) = \sum_{n=1}^{\infty} \frac{|\nu_n|(A)}{2^n|\nu_n|(X)}.
\]
By XIII.7.2.2., \(\mu\) is a measure. It is obvious that \(\mu\) is finite and \(\nu_n \ll \mu\) for all \(n\).

The next theorem is the main result of this section. Vitali proved the first version as a special case of his convergence theorem (), and Hahn obtained the result for Lebesgue-Stieltjes measures. The general result is due to Saks. Our proof, also due to Saks (cf. [DS88]), uses the Baire Category Theorem and is strongly reminiscent of the proof of the Uniform Boundedness Theorem ().

XIII.7.3.2. THEOREM. [VITALI-HAHN-SAKS] Let \(\mu\) be a measure, and \((\nu_n)\) a sequence of complex measures, on a measurable space \((X, \mathcal{A})\). If \((\nu_n)\) converges setwise to a function \(\nu: \mathcal{A} \to \mathbb{C}\), and \(\nu_n \ll \mu\) for all \(n\), then \((\nu_n)\) is uniformly absolutely continuous with respect to \(\mu\).

PROOF: Let \(\Sigma(\mu)\) be the metric space of \(\mu\). Then each \(\nu_n\) gives a continuous function from \(\Sigma(\mu)\) to \(\mathbb{C}\), converging pointwise to \(\nu: \Sigma(\mu) \to \mathbb{C}\). Fix \(\epsilon > 0\). For each \(m\) and \(n\), set
\[
E_{m,n} = \{ A \in \mathcal{A} : |\nu_n(A) - \nu_m(A)| \leq \epsilon \}
\]
(considered as a subset of \(\Sigma(\mu)\)) and set \(F_k = \bigcap_{m,n \geq k} E_{m,n}\). Then \(F_k\) is a closed subset of \(\Sigma(\mu)\) for each \(k\), and since \((\nu_n)\) converges pointwise, \(\bigcup_{k=1}^{\infty} F_k = \Sigma(\mu)\). Thus, since \(\Sigma(\mu)\) is complete (), \(F_k\) has a nonempty interior for some \(k\) by the Baire Category Theorem, i.e. there is a \(k\), an \(A \in \mathcal{A}\), and an \(r > 0\) such that
\[
\{ B \in \mathcal{A} : \mu(A \Delta B) < r \} \subseteq F_k.
\]
There is a \(\delta, 0 < \delta < r\), such that \(|\nu_n(B)| < \epsilon\) for \(1 \leq n \leq k\) whenever \(B \in \mathcal{A}\) and \(\mu(B) < \delta\) (). Then, if \(B \in \mathcal{A}, \mu(B) < \delta\), we have that \(A \cup B\) and \(A \setminus B\) are in \(F_k\), so for \(n \geq k\) we have
\[
\nu_n(B) = \nu_k(B) + (\nu_n(B) - \nu_k(B))
\]
\[
= \nu_k(B) + (\nu_n(A \cup B) - \nu_k(A \cup B)) - (\nu_n(A \setminus B) - \nu_k(A \setminus B))
\]
and thus \(|\nu_n(B)| < 3\epsilon\) for all \(n\).

XIII.7.3.3. COROLLARY. [NIKODYM CONVERGENCE THEOREM] Let \((\nu_n)\) be a sequence of complex measures on a measurable space \((X, \mathcal{A})\), converging setwise to a function \(\nu: \mathcal{A} \to \mathbb{C}\). Then \((\nu_n)\) is uniformly countably additive, and \(\nu\) is a complex measure.

PROOF: There is a finite measure \(\mu\) on \(\mathcal{A}\) with \(\nu_n \ll \mu\) for all \(n\) by XIII.7.3.1. Then \((\nu_n)\) is uniformly absolutely continuous with respect to \(\mu\) by XIII.7.3.2., and hence is uniformly countably additive by XIII.7.2.9.. Then \(\nu\) is a measure by XIII.7.2.10..
XIII.7.3.4. The Nikodým Convergence Theorem was proved before the general theorem XIII.7.3.2. was obtained. See [Swa94] for a direct proof of the Nikodým Convergence Theorem using a matrix version (cf. Exercise ()). The Vitali-Hahn-Saks Theorem can then be derived from the Nikodým Convergence Theorem (cf.). There is a direct proof of the Nikodým Convergence Theorem for ordinary (finite) measures not using the Baire Category Theorem; see Exercise XIII.7.4.3.

There are versions of these results for finitely additive measures and for vector measures; see [DU77].

A nice consequence of the Nikodým Convergence Theorem is the following result, which is a close analog of the Uniform Boundedness Principle:

XIII.7.3.5. **Theorem. [Nikodým Boundedness Theorem]** Let \( (\nu_n) \) be a sequence of complex measures on a measurable space \((X, \mathcal{A})\). If \( \{\nu_n(A) : n \in \mathbb{N}\} \) is bounded for each \( A \in \mathcal{A} \), then the \( \nu_n \) are uniformly bounded, i.e. there is an \( M \) such that \( |\nu_n(A)| \leq M \) for all \( n \) and for all \( A \in \mathcal{A} \).

For the proof, we need a lemma:

XIII.7.3.6. **Lemma.** Let \( (\nu_n) \) be a sequence of complex measures on a measurable space \((X, \mathcal{A})\). If \( \{\nu_n(A) : n \in \mathbb{N}\} \) is bounded for each \( A \in \mathcal{A} \), then \( (\nu_n) \) is uniformly bounded if and only if, for every sequence \( (A_n) \) of pairwise disjoint sets in \( \mathcal{A} \), the set \( \{\nu_n(A_n)\} \) is bounded.

**Proof:** The condition is obviously necessary. For sufficiency, suppose \( (\nu_n) \) is not uniformly bounded. Let \( N_0 = \sup_n \{ |\nu_n(X)| \} \). Let \( E_1 \in \mathcal{A} \) with \( |\nu_n(E_1)| > 1 + N_0 \) for some \( n_1 \); then, if \( F_1 = X \setminus E_1 \), \( |\nu_n(F_1)| \geq |\nu_n(E_1)| - |\nu_n(X)| > 1 \). Either \( \{\nu_n(A \cap E_1) : A \in \mathcal{A}, n \in \mathbb{N}\} \) or \( \{\nu_n(A \cap F_1) : A \in \mathcal{A}, n \in \mathbb{N}\} \) is unbounded; set \( B_1 = E_1 \) in the first case, and \( B_1 = F_1 \) in the second case, and let \( A_{n_1} \) be the other (i.e. \( A_{n_1} = X \setminus B_1 \)). Set \( N_1 = \sup_n \{|\nu_n(B_1)|\} \). Let \( E_2 \in \mathcal{A}, E_2 \subseteq B_1 \), with \( |\nu_n(E_2)| > 2 + N_1 \) for some \( n_2 \); we may assume \( n_2 \neq n_1 \) since \( \{\nu_n(A) : A \in \mathcal{A}\} \) is bounded \( \{\nu_n(|X|)\} \). Then, if \( F_2 = B_1 \setminus E_2, |\nu_n(F_2)| > 2 \). Let \( B_2 = E_2 \) if \( \{\nu_n(A \cap E_2) : A \in \mathcal{A}, n \in \mathbb{N}\} \) is unbounded and \( B_2 = F_2 \) if \( \{\nu_n(A \cap F_2) : A \in \mathcal{A}, n \in \mathbb{N}\} \) is unbounded, and set \( A_{n_2} = B_1 \setminus B_2 \). Continue inductively to obtain a sequence \( (n_k) \) in \( \mathbb{N} \) and a pairwise disjoint sequence \( (A_{n_k}) \) in \( \mathcal{A} \) such that \( |\nu_{n_k}(A_{n_k})| > k \). Set \( A_n = \emptyset \) for \( n \) not equal to any \( n_k \).

XIII.7.3.7. **Remark:** The hypothesis that \( (\nu_n) \) be setwise bounded is omitted from the statement of this result in [Swa94, p. 68]. This hypothesis is easily seen to be necessary: let \( X \) be a singleton and \( \nu_n(X) = n \). Also, the proof only requires that \( \mathcal{A} \) be an algebra and that the \( \nu_n \) be finitely additive if the additional hypothesis is added that each \( \nu_n \) is bounded, which is not automatic in this case (Exercise XIII.6.4.5.). (Without this hypothesis, the result fails: let \( \nu_1 \) be a finitely additive signed measure which is finite but not bounded, and \( \nu_n = 0 \) for \( n > 1 \).)

We now prove XIII.7.3.5..

**Proof:** By XIII.7.3.6. and (), it suffices to show that if \( (A_n) \) is a pairwise disjoint sequence in \( \mathcal{A} \) and \( (\alpha_n) \) is a sequence in \( \mathbb{C} \) with \( \alpha_n \to 0 \), that \( \alpha_n \nu_n(A_n) \to 0 \). But \( (\alpha_n \nu_n) \) is a sequence of complex measures on \((X, \mathcal{A})\) converging setwise to the zero measure; hence by XIII.7.3.3. the sequence \( (\alpha_n \nu_n) \) is uniformly countably additive, giving the conclusion from XIII.7.2.8. 

As a related matter, we have the following converse to XIII.7.2.9.:
XIII.7.3.8. Theorem. Let \((\nu_n)\) be a sequence of complex measures on a measurable space \((X, \mathcal{A})\), and \(\mu\) a measure on \((X, \mathcal{A})\) such that \(\nu_n \ll \mu\) for all \(n\). If \((\nu_n)\) is uniformly countably additive, then \((\nu_n)\) is uniformly absolutely continuous with respect to \(\mu\).

**Proof:** If \((\nu_n)\) is not uniformly absolutely continuous with respect to \(\mu\), we will construct a pairwise disjoint sequence \((A_k)\) in \(\mathcal{A}\) and indices \(n_k\) such that \(\nu_{n_k}(A_k)\) does not approach 0, contradicting XIII.7.2.8.

If \((\nu_n)\) is not uniformly absolutely continuous with respect to \(\mu\), there is an \(\epsilon > 0\) such that for all \(\delta > 0\), there is a \(B \in \mathcal{A}\) with \(\mu(B) < \delta\) and \(|\nu_n(B)| \geq \epsilon\) for infinitely many \(n\). Fix such an \(\epsilon\). Choose \(B_1 \in \mathcal{A}\) and \(n_1\) with \(|\nu_{n_1}(B_1)| \geq \epsilon\) and \(\mu(B_1) < 1\). Since \(\nu_{n_1} \ll \mu\), there is a \(\delta_1 > 0\) such that \(|\nu_{n_1}(B)| < \epsilon/2\) whenever \(\mu(B) < \delta_1\). There is a \(B_2 \in \mathcal{A}\) and an \(n_2 > n_1\) such that \(|\nu_{n_2}(B_2)| \geq \epsilon\) and \(\mu(B_2) < \delta_1/2\). Continuing inductively, construct sets \(B_k \in \mathcal{A}\), numbers \(\delta_k\), and a strictly increasing sequence \((n_k)\) of indices, such that, for all \(k\), \(\delta_{k+1} < \delta_k/2\), \(|\nu_{n_k}(B_k)| \geq \epsilon\), \(\mu(B_{k+1}) < \delta_k/2\), and \(|\nu_{n_k}(B)| < \epsilon/2\) whenever \(\mu(B) < \delta_k\).

Set \(C_k = \cup_{n=k+1}^{\infty} B_n\) for each \(k\). Then

\[
\mu(C_k) \leq \sum_{n=k+1}^{\infty} \mu(B_n) < \sum_{n=1}^{\infty} \frac{\delta_k}{2^n} = \delta_k
\]

so that \(|\nu_{n_k}(B_k \cap C_k)| < \epsilon/2\) for each \(k\). Thus, if \(A_k = B_k \setminus C_k\), the \(A_k\) are pairwise disjoint and, for all \(k\),

\[
|\nu_{n_k}(A_k)| \geq |\nu_{n_k}(B_k)| - |\nu_{n_k}(B_k \cap C_k)| > \epsilon - \frac{\epsilon}{2} = \frac{\epsilon}{2}.
\]

\(\Box\)

XIII.7.4. Exercises

XIII.7.4.1. Let \((\nu_n)\) be a sequence of complex measures on a measurable space \((X, \mathcal{A})\) which is a Cauchy sequence with respect to the total variation norm \((\cdot)\). Give a direct proof (not using the Nikodým Convergence Theorem) that \((\nu_n)\) converges setwise to a complex measure.

XIII.7.4.2. (a) Prove the converse of XIII.7.2.8. If \((B_n)\) is a decreasing sequence with \(\cap_{n=1}^{\infty} B_n = \emptyset\) but \(|\nu_n(B_n)| > \delta\) for all \(n\), for some \(\delta\), choose \(n_1\) with \(\nu_1(B_{n_1}) < \delta/2\), and for each \(k\) choose \(n_{k+1}\) with \(\nu_{n_k}(B_{n_{k+1}}) < \delta/2\). If \(A_{n_k} = B_{n_k} \setminus B_{n_{k+1}}\), the \(A_{n_k}\) are pairwise disjoint and \(|\nu_{n_k}(A_{n_k})| > \delta/2\) for all \(k\).

(b) Use (a) and (b) to give a direct proof of XIII.7.3.3. (cf. [Swa94, p. 68]).

XIII.7.4.3. [Doo94, III.10] Give a direct proof that if \((\mu_n)\) is a sequence of finite measures on a measurable space \((X, \mathcal{A})\), converging setwise to a function \(\mu : \mathcal{A} \to [0, \infty)\), then \(\mu\) is a measure (i.e. countably additive), as follows:

(a) Suppose \((B_n)\) is a decreasing sequence in \(\mathcal{A}\) with \(\cap_{n=1}^{\infty} B_n = \emptyset\) but

\[
\lim_{n \to \infty} \mu(B_n) = \epsilon > 0
\]

(why does the limit exist?) Let \(n_1 = m_1 = 1\) and inductively choose \(n_{k+1} > n_k\) and \(m_{k+1} > m_k\) with \(\mu_{n_{k+1}}(B_{m_k}) > \frac{\epsilon}{8}\) and \(\mu_{n_{k+1}}(B_{m_{k+1}}) < \frac{\epsilon}{8}\).

1479
(b) Let $A_k = B_{m_k} \setminus B_{m_{k+1}}$ for each $k$. Show that if $j > k$ is odd, then

$$
\mu_{n_j}(\cup \{A_n : n \text{ even}, n \geq k\}) > \frac{3\epsilon}{4}
$$

and if $j > k$ is even, then

$$
\mu_{n_j}(\cup \{A_n : n \text{ odd}, n \geq k\}) > \frac{3\epsilon}{4}.
$$

(c) Conclude that $\mu(B_{m_k}) \geq \frac{3\epsilon}{2}$ for all $k$, a contradiction.
Chapter XIV

Integration

In this chapter, we will explore the four general approaches to integration: the Riemann integral and the "modern" approaches of Lebesgue, Daniell, and Denjoy-Perron-Henstock-Kurzweil. The idea is to associate to a real- (or complex)-valued function \( f \) defined on a set \( X \), and a subset \( A \) of \( X \), a number \( \mathcal{I}_A(f) \), usually denoted by some version of the notation \( \int_A f \), reflecting the "contribution" of the function \( f \) on the set \( A \).

XIV.1. Introduction

Integration is a basic component of real analysis. The goal of integration is to systematically assign to a real-valued function \( f \) on a set \( X \), and a subset \( A \) of \( X \), a number \( \mathcal{I}_A(f) \) called the integral of \( f \) over \( A \) (the notation \( \int_A f \), or some variation, is usually used; the symbol \( \int \) is called the integral sign), which is usually thought of as a "normalized sum" of the values of \( f \) on the points of the subset \( A \). This number has various interpretations in applied situations as total distance (regarding \( f \) as giving instantaneous velocity), total mass (regarding \( f \) as giving density), etc. Integration in analysis is thus almost always (and always in this book) a generalization or analog of what in elementary calculus is called the "definite integral." (We will also have occasion to consider analogs of the "indefinite integral" of calculus, but these will have different names and will not be called integrals.)

XIV.1.1. Origin of Integration Theories

XIV.1.1.1. All modern theories of integration are in a sense outgrowths of the so-called Riemann integral (actually developed first by Cauchy for continuous functions and generalized by Riemann to also handle moderately discontinuous functions), the type of integration treated in elementary calculus. The Riemann integral was the first reasonably satisfactory theory of integration, and is still by far the theory most widely used in applications.

XIV.1.1.2. For theoretical purposes, Riemann integration has two serious inadequacies:

1. The class of Riemann integrable functions is too small. For a function to be Riemann integrable on an interval, it must be bounded and "almost continuous" (see () for a precise statement). It is particularly useful to be able to integrate certain unbounded functions. This is reasonably, but not entirely, satisfactorily
achieved by using various notions of improper Riemann integrals and principal values. It is also important to be able to integrate over unbounded intervals, which can be done through other types of improper integrals, although not in an entirely satisfactory way. At least for theoretical purposes, it is also important to be able to integrate functions which are too discontinuous to be Riemann integrable, and to be able to integrate functions over subsets of the real numbers more general than intervals or finite unions of intervals (although the practical value of this type of integration is sometimes somewhat overemphasized as an inadequacy of Riemann integration).

2. It is crucial in many settings to have limit and approximation theorems, i.e. to know that under reasonable conditions, if \( f_n \to f \) in some sense, we have \( \mathcal{I}_A(f_n) \to \mathcal{I}_A(f) \). It is quite difficult to establish good theorems of this sort for Riemann integration which are applicable even if we know that the limit function is Riemann integrable (which is often not the case due to the limitations described above). It turns out that to get reasonable convergence theorems, more general integration theories are needed.

XIV.1.1.3. Another limitation of Riemann integration is that it only (directly) works on \( \mathbb{R} \), or on \( \mathbb{R}^n \). It is very important to have integration theories which work on more general spaces, and it turns out that modern approaches give this flexibility with essentially no additional work.

XIV.1.1.4. There are three principal modern approaches to integration, each with many variations. We first discuss the basics of Riemann integration in a form allowing the various generalizations to be made naturally.

XIV.1.1.5. The Riemann integral has gotten somewhat of a bad rap: it is fashionable in some circles to downplay or even ignore Riemann integration in favor of more modern integration theories. There are certainly inadequacies in Riemann integration which must be addressed, and there will be no suggestion here that modern integration theories are not important. However, Riemann integration is far from obsolete! Here are some senses in which Riemann integration (and even pre-Riemann Cauchy integration) is still central:

(i) Although there are versions of the Fundamental Theorem of Calculus for more general types of integration, it is still really a theorem about Riemann (or Cauchy) integration, and most applications are to computing Riemann integrals.

(ii) All numerical integration is based on the Riemann integral.

(iii) Integrals in vector calculus, complex analysis, and differential geometry (e.g. line and surface integrals, contour integrals, integrals of differential forms) are Riemann integrals.

(iv) Many, if not most, integrals arising in physics and engineering are Riemann integrals.

(v) It is often pointed out that one rarely if ever actually computes a Lebesgue (or other modern) integral; the integral is approximated by a Riemann integral which is computed either by the Fundamental Theorem of Calculus or by numerical integration techniques.

Thus it is worthwhile to give a full treatment of the Riemann integral as well as more modern theories.
XIV.1.2. The Cauchy Integral for Continuous Functions

XIV.1.2.1. Actually, we will begin with a sort of “pre-Riemann integral,” due to Cauchy, in which there seems to be only one natural approach, which is fairly simple: the case of integrating a continuous function on a closed bounded interval. All theories of integration essentially reduce to the same thing in this case. Actually this case, although quite special, is by far the most important one in a practical sense – most integrals encountered in practice are of this form, or slight variations of it which can be treated on an ad hoc basis. In fact, although the integral in this form was not given a rigorous approach until Cauchy’s work, it had been used by mathematicians dating back at least to Archimedes in ancient Greece; the fundamental and brilliant insight of both Newton and Leibniz which got the whole subject of calculus off the ground was the inverse relation between integration and differentiation.

XIV.1.2.2. The integral is intended to denote the “area” of the region under the graph and above the x-axis, between the lines \( x = a \) and \( x = b \) (Figure XIV.1). To obtain an integral with good properties, the parts of the region below the axis, where the function is negative, must be interpreted as “negative area”; such regions are shown in tan. The integral thus denotes a “signed area.”

\[
\begin{align*}
&y = f(x) \\
&a & b
\end{align*}
\]

Figure XIV.1: The Integral of a Continuous Function

XIV.1.2.3. Suppose \( f \) is a continuous real-valued function on a closed bounded interval \( J = [a, b] \). Write \( \ell(J) = b - a \) for the length of \( J \). We want to define the integral \( \mathcal{L}_J(f) \) of \( f \) over \( J \). There are three fundamental properties the integral ought to have:
(i) If \( f \leq g \) on \( J \), then \( \mathcal{I}_J(f) \leq \mathcal{I}_J(g) \).

(ii) If \( f \) takes the constant value \( c \) on \( J \), then \( \mathcal{I}_J(f) = c \cdot \ell(J) = c(b-a) \).

(iii) If \( J \) is partitioned into nonoverlapping intervals \( J_1, \ldots, J_n \) (“nonoverlapping” means the subintervals only have endpoints in common), then

\[
\mathcal{I}_J(f) = \sum_{k=1}^{n} \mathcal{I}_{J_k}(f) .
\]

These three properties are enough to completely characterize the integral in this case, and to suggest an explicit method of defining and calculating its value.

**XIV.1.2.4.** The continuity of \( f \) means that if \( P = \{J_1, \ldots, J_n\} \) is a sufficiently fine partition of \( J \) into nonoverlapping subintervals, then \( f \) is almost constant on each \( J_k \); thus, if \( t_k \) is any number (tag) in \( J_k \), we must have

\[
\mathcal{I}_J(f) \approx \sum_{k=1}^{n} f(t_k)\ell(J_k)
\]

(such a sum is called a *Riemann sum* for \( \mathcal{I}_J(f) \), although they were introduced by Cauchy, and Riemann did not even make extensive use of them) with the approximation becoming better and better as the partition becomes finer no matter how the \( t_k \) are chosen (within \( J_k \)). See Figure XIV.2.

**XIV.1.2.5.** This can be described more carefully in a slightly different way (this was in effect Riemann’s general approach, although he phrased things somewhat differently; this formulation was explicitly introduced by Darboux after Riemann’s death): if \( m_k \) and \( M_k \) are the infimum and supremum of \( f \) on \( J_k \) (in this case actually the minimum and maximum on \( J_k \) respectively), and \( \omega(f, J_k) = M_k - m_k \) is the oscillation of \( f \) over \( J_k \), then we define the upper and lower estimates \( \overline{\mathcal{I}}(f, P) \) and \( \underline{\mathcal{I}}(f, P) \) by

\[
\overline{\mathcal{I}}(f, P) = \sum_{k=1}^{n} M_k\ell(J_k) \quad \text{and} \quad \underline{\mathcal{I}}(f, P) = \sum_{k=1}^{n} m_k\ell(J_k)
\]

and we have that

\[
\underline{\mathcal{I}}(f, P) \leq \mathcal{I}_J(f) \leq \overline{\mathcal{I}}(f, P)
\]

and

\[
\overline{\mathcal{I}}(f, P) - \underline{\mathcal{I}}(f, P) = \sum_{k=1}^{n} \omega(f, J_k)\ell(J_k) .
\]

(See Figures XIV.3 and XIV.4.) As the partition \( P \) becomes finer, we have that the \( \underline{\mathcal{I}}(f, P) \) increase, the \( \overline{\mathcal{I}}(f, P) \) decrease, and the \( \omega(f, J_k) \) approach 0, so the upper and lower estimates approach the same limiting value (there are of course some technicalities to check here), which is the only reasonable value for \( \mathcal{I}_J(f) \). We also have

\[
\underline{\mathcal{I}}(f, P) \leq \sum_{k=1}^{n} f(x_k)\ell(J_k) \leq \overline{\mathcal{I}}(f, P)
\]

1484
For any Riemann sum, so we have

\[ I_J(f) - \frac{1}{n} \sum_{k=1}^{n} f(x_k) \ell(J_k) \leq T(f, P) - I(f, P) = \sum_{k=1}^{n} \omega(f, J_k) \ell(J_k) \]

for any Riemann sum, and thus the Riemann sums converge to \( I_J(f) \) as the partitions become arbitrarily fine (in the sense that the mesh of the partition, defined as the maximum of the lengths of the \( J_k \), goes to 0).

**XIV.1.2.6.** Before the rigour introduced in the nineteenth century, and informally still to this day, instead of an actual (finite) partition of \( J \) one would think of “partitioning” the interval \( J \) into an infinite number of subintervals of “infinitesimal” length \( dx \) (Figure XIV.5). Then on the infinitesimal interval containing the number \( x \), the function value would differ only infinitesimally from the number \( f(x) \), so the integral over this infinitesimal subinterval would be \( f(x) \cdot dx \) (up to a “second-order infinitesimal”). The total integral would then be the “sum” of these. This approach was taken by Leibniz, who developed the standard notation used for the integral even today: he denoted this “sum” \( S \), and wrote

\[ I_J(f) = S_a^b f(x) \, dx \]

He actually used a “long \( S \)” and almost immediately elongated it further to the familiar integral sign \( \int \). (Summation notation using \( \sum \) was introduced by Euler, and did not exist in Leibniz’s time.)

1485
XIV.1.3. The Riemann Integral

XIV.1.3.1. Cauchy’s approach works in somewhat greater generality, as developed by Riemann. In order to have the upper and lower estimates converge together, we do not actually have to have the oscillations $\omega(f, J_k)$ approach zero as the partitions become fine; we need only that the sum (“weighted local oscillation”)

$$\sum_{k=1}^{n} \omega(f, J_k) \ell(J_k)$$

becomes small, which only requires that the oscillation $\omega(f, J_k)$ be small for “most” $k$. See Figures XIV.6 and XIV.7. If $f$ has isolated discontinuities, the weighted local oscillation is still small for fine partitions (Figure XIV.8).

XIV.1.3.2. Thus, if $f$ is bounded, and continuous except at finitely many points (or, more generally, except on a set of Lebesgue measure 0), the Cauchy approach works perfectly well, either via the weighted local oscillation idea or via Riemann sums. (If $f$ is unbounded, the weighted local oscillation approach does not make sense, and it is also easily seen that the Riemann sum approach cannot work either, at least the way we have done it using the mesh of the partitions.) The functions for which the approach works are called Riemann-integrable functions on $J$; it turns out that they are precisely the bounded functions which are continuous “almost everywhere” (except on a set of Lebesgue measure 0).
XIV.1.4. The Lebesgue Approach

XIV.1.4.1. The first and most widely used modern approach began with Lebesgue’s work in the early twentieth century. Lebesgue’s idea was to consider more general partitions of the interval $J$ on which the integral is to be defined, where the subsets $A_k$ are not necessarily subintervals but can be more complicated, but where as in the Cauchy approach the function is almost constant on each $A_k$. The integral $\int_J (f)_{P}$ is then approximated by a sum over the sets in the partition, where the term corresponding to $A_k$ is the almost constant value of $f$ on $A_k$ times the “size” of $A_k$.

XIV.1.4.2. It is easy to find such sets $A_k$ for any bounded function. (For motivational purposes, we will consider only bounded functions, although the actual development of the theory outlined below works equally well for unbounded functions and even extended real-valued functions.) In fact, it is not important that the domain of the function be an interval or even a set of real numbers; we can consider a bounded function $f$ from any set $X$ to $\mathbb{R}$ (bounded just means the range is a bounded subset of $\mathbb{R}$). Suppose $|f(x)| \leq M$ for all $x \in X$. Then, for any natural number $n$, we set

$$A_k = \left\{ x \in X : \frac{k-1}{n} < f(x) \leq \frac{k}{n} \right\}$$

for integers $k$ with $|k| \leq nM$. This is a finite partition of $X$ into pairwise disjoint subsets, and $\omega(f, A_k) \leq \frac{1}{n}$.
XIV.1.4.3. We need one more ingredient, though: a “size” for each $A_k$. The reasonable way to do this is to require the $A_k$ to be measurable sets for a measure $\mu$ on $X$; then $\mu(A_k)$ can be taken to be the “size” of $A_k$, and we get an approximation

$$I_X(f, \mu) \approx \sum_{k} \frac{k}{n} \mu(A_k)$$

(the notation reflects the fact that the integral is with respect to the measure $\mu$) which should become exact in the limit as $n \to \infty$. The restriction on $f$ is then that the sets $A_k$ must be $\mu$-measurable for any choices of $n$ and $k$; such an $f$ is called a $\mu$-measurable function. In most applications, including Lebesgue measure on $\mathbb{R}$, $\mu$-measurability is a very mild restriction on $f$ and is satisfied by any function which can be explicitly described. (There is an additional technicality: the sum may not be well defined if $\mu(A_k)$ is infinite for both positive and negative $k$’s. This technicality forces a slightly different approach to the actual integral.)

XIV.1.4.4. So in this approach, one begins with a measure space (LEBESGUE at first only considered Lebesgue measure on $\mathbb{R}$, but the general theory is nearly identical). As mentioned, for technical reasons, we will not proceed exactly as above, but the motivational description is an accurate reflection of the essence of the process.

XIV.1.4.5. If $\mu$ is a measure on a set $X$, we build up the integral corresponding to $\mu$ in stages. We first consider indicator functions (often called characteristic functions, but this term also has other uses in...

Figure XIV.5: Partition into Rectangles of “Infinitesimal” Width
analysis). If $A \subseteq X$, let $\chi_A$ denote the function from $X$ to $\mathbb{R}$ defined by

\begin{align*}
\chi_A(x) &= \begin{cases} 
1 & \text{if } x \in A \\
0 & \text{if } x \notin A
\end{cases}.
\end{align*}

This $\chi_A$ is called the \textit{indicator function} of the set $A$. It is reasonable to define the integral of $\chi_A$ to be the measure $\mu(A)$ of the set $A$ (provided, of course, that $A$ is a $\mu$-measurable set, or equivalently that $\chi_A$ is a $\mu$-measurable function).

\textbf{XIV.1.4.6.} Next, we consider \textit{simple functions}, finite nonnegative linear combinations of indicator functions of $\mu$-measurable sets. Such a function has a representation

\begin{equation}
 s = \sum_{k=1}^{n} a_k \chi_{A_k}
\end{equation}

where the $A_k$ are $\mu$-measurable sets and the $a_k$ are nonnegative real numbers. These are precisely the nonnegative $\mu$-measurable functions taking only finitely many values. It then makes sense to define the integral by

\begin{equation}
\mathcal{I}_X(s, \mu) = \sum_{k=1}^{n} a_k \mu(A_k)
\end{equation}

and indeed this is the only possible definition to obtain a linear integral. (There is a technicallity here: it must be shown that this number is well defined by $s$, since the representation $s = \sum a_k \chi_{A_k}$ is not unique.)
XIV.1.4.7. If $f$ is a nonnegative $\mu$-measurable function, we then define

$$\mathcal{I}_X(f, \mu) = \sup \{ \mathcal{I}_X(s, \mu) : s \text{ simple}, 0 \leq s \leq f \} .$$

This definition even makes sense for extended real-valued functions. Even if $f$ is real-valued, $\mathcal{I}_X(f, \mu)$ can equal $+\infty$. We say a nonnegative function $f$ is $\mu$-integrable if $f$ is $\mu$-measurable and $\mathcal{I}_X(f, \mu) < \infty$.

XIV.1.4.8. Finally, if $f$ is a real-valued $\mu$-measurable function, and there are nonnegative $\mu$-integrable functions $g$ and $h$ with $f = g - h$, we say $f$ is $\mu$-integrable and set

$$\mathcal{I}_X(f, \mu) = \mathcal{I}_X(g, \mu) - \mathcal{I}_X(h, \mu)$$

(it must be shown that this is well defined by $f$ independent of the choices of $g$ and $h$).

XIV.1.4.9. We can extend the notion of integration over the whole measure space $X$ to integration over any $\mu$-measurable set $A$ by setting

$$\mathcal{I}_A(f, \mu) = \mathcal{I}_X(f \chi_A, \mu)$$

where $f \chi_A$ is the function which is equal to $f$ on $A$ and is identically zero outside $A$; this definition even makes sense if $f$ is only defined on the subset $A$. 

1490
XIV.1.4.10. It turns out that this integral $I_X$ has all the nice properties one would expect, and almost all one might hope for, in an integral. In the case where $\mu$ is Lebesgue measure $\lambda$ on $\mathbb{R}$, this integral extends the Riemann integral in the sense that any Riemann-integrable function $f$ on a closed bounded interval $J$ is Lebesgue-integrable ($\lambda$-integrable) on $J$ and the the Riemann integral $I_J(f)$ of $f$ over $J$ agrees with the Lebesgue integral $L_J(f, \lambda)$ of $f$ over $J$. But many more functions are Lebesgue integrable than are Riemann-integrable, including many unbounded functions.

XIV.1.4.11. The Lebesgue approach to integration on a general measure space is also very important. For example, if $(\Omega, \mathcal{E}, P)$ is a probability space, a $P$-measurable real-valued function $X$ on $\Omega$ is called a random variable, and if $X$ is nonnegative or $P$-integrable, its integral is called the expected value of the random variable $X$.

XIV.1.4.12. There are a couple of drawbacks to the Lebesgue approach, however. In order to define the Lebesgue integral on $\mathbb{R}$, Lebesgue measure must first be constructed, which is a moderately complicated task. The Lebesgue integral on a general measure space is somewhat simpler, but preliminaries are not completely avoided: besides the simple basics of the theory of measure spaces from ( ), one needs to know about measurable functions, where the details ( ) are somewhat more challenging.

XIV.1.4.13. The other drawback of Lebesgue integration from a certain point of view is that it is an “absolute” theory of integration: if $f$ is measurable, then $f$ is integrable if and only if $|f|$ is integrable.
Roughly, this means that both the positive and negative parts of $f$ are not too large. There are situations where the improper Riemann integral of a function $f$ taking both positive and negative values is defined, yet $f$ is not Lebesgue integrable. On the other hand, the “absolute” property is what makes Lebesgue integration well-behaved; it is a sort of analog of absolute convergence of infinite series, which forces all sorts of nice behavior which does not carry over to conditionally convergent series. (The connection between integration and infinite series is much more than just an analog; the theory of infinite series can be interpreted as a special case of the theory of measure and integration – see ( ).)

XIV.1.5. The Daniell Approach

XIV.1.5.1. Either measure or integration can be regarded as the primitive notion, and the other one can be derived from it. We have seen how integration can be derived from measure via the Lebesgue approach. In Euclidean space, there is a more direct approach simply consisting of increasing dimension by one: if $f$ is a nonnegative real-valued function on a subset $E$ of $\mathbb{R}^n$, the integral $\int_E f \, d\lambda^{(n)}$ is simply the $(n+1)$-dimensional Lebesgue measure of the “subgraph”

$$\{(x_1, \ldots, x_n, y) : (x_1, \ldots, x_n) \in E, 0 \leq y \leq f(x_1, \ldots, x_n)\} \subseteq \mathbb{R}^{n+1}$$

(in particular, the integral of a nonnegative measurable function over a subset of $\mathbb{R}$ is just the measure of a corresponding subset of the plane). Conversely, measure can be recovered from integration: the measure of a subset $E$ of $\mathbb{R}^n$ (or of a general measure space) is just the integral of the indicator function $\chi_E$ over $\mathbb{R}^n$.

XIV.1.5.2. Taking integration as the primitive concept and defining measure from it is the approach taken by Daniell. In this approach, we begin with a sufficiently large supply of real-valued functions on a set $X$ for which there is an “integral” defined having reasonable linearity, positivity, and continuity properties. The actual mechanism by which the integral is defined is unimportant; it can even just be an abstract real-valued functional defined on the set of functions. If necessary, the integral is then extended in a systematic way to a larger class of real-valued functions on $X$ including indicator functions of enough subsets of $X$. A measure $\mu$ on $X$ can then be defined by setting $\mu(E)$ for a subset $E$ of $X$ to be the integral of $\chi_E$. A good motivating example (which was Daniell’s own starting point) is to take $X$ to be an interval $[a, b]$ in $\mathbb{R}$, the functions to be the real-valued continuous functions on $[a, b]$, and the integral the Cauchy integral. The measure obtained by the Daniell process is then just Lebesgue measure on $[a, b]$. This turns out to actually be a rather painless way to define Lebesgue measure.

XIV.1.5.3. An important generalization of the motivating example is the Riesz Representation Theorem: if $X$ is a compact Hausdorff space and $\phi$ is a positive linear functional on the set $C(X)$ of real-valued (or complex-valued) continuous functions on $X$, i.e. an assignment of a number $\phi(f)$ to each continuous function $f$ with the properties that

1. $\phi(f + g) = \phi(f) + \phi(g)$ for all $f, g \in C(X)$.
2. $\phi(\alpha f) = \alpha \phi(f)$ for every $f \in C(X)$ and every scalar $\alpha$.
3. $\phi(f) \geq 0$ if $f$ takes only nonnegative real values.

then there is a finite measure $\mu$ on the $\sigma$-algebra of subsets of $X$ generated by the open sets (the Borel sets) such that $\phi(f) = \int_X f \, d\mu$ for all $f$. The measure $\mu$ is constructed by the Daniell process of extending the integral (linear functional) to a larger class of functions including indicator functions of Borel sets.
XIV.1.6.  Direct Generalizations of Riemann Integration

XIV.1.6.1.  A third approach to generalizing Riemann integration is to directly modify the definition of the Riemann integral to obtain a more-inclusive integral on $\mathbb{R}$. This approach was notably used by Denjoy and Perron, and culminated relatively recently (1957) in the so-called Henstock-Kurzweil (H-K) integral, which agrees with the integrals of Denjoy and Perron but has a much better definition.

XIV.1.6.2.  The H-K integral is easier to define than the Lebesgue integral (Lebesgue measure is not needed), and almost as easy as the Riemann integral; and it remedies both shortcomings of the Riemann integral. In fact, it turns out to be almost the same as the Lebesgue integral, and even slightly more general: a nonnegative function is H-K integrable if and only if it is Lebesgue integrable, but a function taking both positive and negative values can be H-K integrable but not Lebesgue integrable if its positive and negative parts are too big but “cancel out” in a suitable way.

XIV.1.6.3.  The H-K integral is defined using the Riemann sum approach. The main difference from Riemann integration is a much more delicate notion of the “fineness” of a partition into subintervals than just its mesh. We will not give a precise description here (see ()), but the fineness of a partition depends not only on the intervals $J_k$ but also on which tags $t_k \in J_k$ are chosen. It is then a somewhat subtle matter to show that arbitrarily fine partitions exist. Once this has been done, the rest of the development formally follows the theory of Riemann integration very closely. But many more functions turn out to be H-K integrable.

XIV.1.6.4.  The H-K integral is nice to work with in many ways. For example, integrals which would naturally be called “improper H-K integrals” turn out to be honest H-K integrals. One of the nicest properties of H-K integration is that the following version of the Fundamental Theorem of Calculus, which fails spectacularly for Riemann integration and even fails for Lebesgue integration, holds for H-K integration:

XIV.1.6.5.  **Theorem.** Let $f$ be a differentiable function on a closed bounded interval $[a, b]$. Then $f'$ is H-K integrable on $[a, b]$ (and hence on any subinterval), and for every $x \in [a, b]$ we have

$$f(x) = f(a) + \int_a^x f'(t) \, dt$$

where the integral is the H-K integral of $f'$ over $[a, x]$.

XIV.1.6.6.  On the other hand, the H-K integral is strictly an extension of Riemann integration on $\mathbb{R}$, and does not generalize the way Lebesgue integration does to other measure spaces. (There is a version of H-K integration on $\mathbb{R}^n$, which is not nearly as satisfactory as on $\mathbb{R}$, but nothing more general.)
XIV.1.7. Oriented and Unoriented Integration

XIV.1.7.1. There are two general kinds of integration: oriented integration and unoriented integration (they are not very different, differing only in sign, but the sign is often crucial in applications). The two types both appear in Riemann integration: if \( I \) is a closed bounded interval \([a, b]\), with \( a < b \), then the integral

\[
\int_a^b f(x) \, dx
\]

of a function \( f \) from \( I \) to \( \mathbb{R} \) can be regarded either as an integral over \( I \) ("unoriented") or as an integral from \( a \) to \( b \) ("oriented"). The expression

\[
\int_b^a f(x) \, dx
\]

appears to be rather artificial and intrinsically meaningless, and the definition

\[
\int_b^a f(x) \, dx = - \int_a^b f(x) \, dx
\]

is seemingly arbitrary, although it is useful in a number of natural contexts, for example making the formula

\[
\int_a^c f(x) \, dx = \int_a^b f(x) \, dx + \int_b^c f(x) \, dx
\]

valid for any \( a, b, c \) no matter what their order (so long as they are all contained in some interval on which \( f \) is integrable). Another important use of this convention is that if \( f \) is continuous on an interval \( I \) and \( x_0 \in I \), not necessarily the left endpoint, then the formula

\[
F(x) = \int_{x_0}^x f(t) \, dt
\]

defines the unique antiderivative of \( f \) on \( I \) satisfying \( F(x_0) = 0 \).

XIV.1.7.2. Integrating from right to left in \( \mathbb{R} \) seems unnatural since there is a natural orientation of \( \mathbb{R} \). However, in Euclidean space there is no natural orientation; there are two equally natural possibilities (choice of a coordinate system specifies one of the two orientations; cf. VI.3.1.1., []). Complicated subsets of \( \mathbb{R}^n \) do not have any obvious intrinsic notion of orientation. Thus in the Lebesgue approach to integration it is natural to use unoriented integration. And when the generalization to abstract measure spaces is made, there is no notion of orientation available at all, so unoriented integration is the only possibility. Thus the theory of integration in measure theory is (almost) exclusively unoriented integration.

XIV.1.7.3. On the other hand, in vector calculus and analysis such integrals as line and surface integrals are important, and in Complex Analysis contour integrals are basic; such integrals incorporate a natural orientation, and the orientation is crucial in many results. In fact, any result relating integration and differentiation along the lines of the Fundamental Theorem of Calculus, e.g. the various versions of Stokes' Theorem, necessarily involves oriented integration, since differentiation itself requires orientation (this is obscured for functions from \( \mathbb{R} \) to \( \mathbb{R} \) since \( \mathbb{R} \) has a natural orientation, but orientations must be chosen to define the derivative of a real-valued function on a one-dimensional Euclidean space or a function between two one-dimensional Euclidean spaces). It turns out that many deep results in geometry and topology involve oriented integration.
XIV.1.7.4. As a general (but not universal) rule, oriented integration is usually done only for smooth objects and is primarily used in geometry, while unoriented integration is done for not necessarily smooth or even continuous objects and is primarily used in analysis. That these statements are not categorically true is partly due to the fact that the boundary between analysis and geometry is quite blurred. We will examine important examples of both types of integration.
XIV.2. The Riemann Integral

We first examine the integral commonly called the Riemann integral. This integral was actually developed informally by Newton and Leibniz (based in part on ideas going back to ancient Greece), and formally developed by Cauchy for continuous functions and expanded and put on a “modern” foundation by Riemann, with important contributions by others, notably Dirichlet and Darboux. See [?] for a detailed historical account of the development of this integral.

It is a curious fact that there is no consensus among mathematicians at the present time about the proper definition of the Riemann integral and of Riemann-integrable functions. Several rather different-looking (but equivalent) definitions can be found in standard references and texts, with other variations given as theorems. While it is pretty easy to see that any two of these definitions give the same value for the integral of any function satisfying both definitions, it is not entirely obvious that they apply to exactly the same functions (i.e. give the same class of integrable functions). We will discuss the various definitions and show that they are actually all equivalent. A normal pedagogical approach would be to pick one definition as the definition, and prove that the others are equivalent characterizations; but the lack of a standard definition makes the several-definition approach more reasonable in this case.

The multitude of definitions can be somewhat of a conceptual obstacle to focusing on the essential nature of the Riemann integral. However, the situation can, and should, be viewed positively: the fact that Riemann-integrability can be viewed in a number of ways is of theoretical importance and an indication that it is a natural concept. And the large supply of equivalent definitions is very useful in practice: in any situation, we are free to use whichever definition is most convenient to work with at the moment.

The various definitions are all precise versions of the following informal definition:

**Definition. (Informal)** Let \( f \) be a real-valued function on a closed bounded interval \( J = [a, b] \). Then \( f \) is Riemann-integrable on \( J \) if the sums
\[
\sum_{k=1}^{n} c_k \ell(J_k)
\]
where \( \{J_1, \ldots, J_n\} \) is a partition of \( J \) into subintervals and \( c_k \) is an approximation to the value of \( f \) on \( J_k \), converge to a limiting value \( L \) as the partition becomes sufficiently fine. The limiting value \( L \) is called the \textit{(Riemann) integral of} \( f \) \textit{over} \( J \), denoted
\[
\int_{a}^{b} f(x) \, dx.
\]

There are, of course, several aspects of this “definition” which must be made precise to have a real definition. It is not entirely clear how to make some parts of the definition precise, particularly the part about the partition becoming “sufficiently fine.” (With the right interpretation of this phrase, the statement actually becomes a definition of the Henstock-Kurzweil integral.)

The integral can be interpreted as the “area” of the region under the graph and above the \( x \)-axis, between the lines \( x = a \) and \( x = b \). Parts of the region below the axis, where the function is negative, are interpreted as “negative area”; such regions are shown in tan. The integral thus denotes a “signed area.”

XIV.2.1. Partitions, Tags, Riemann and Darboux Sums

In this subsection we make a number of definitions and set up the notation we will use for Riemann integration.
**Partitions**

**XIV.2.1.1. Definition.** Let \([a, b]\) be a closed bounded interval in \(\mathbb{R}\). A *partition* of \([a, b]\) is a division of \([a, b]\) into a finite number of subintervals \(\{[x_{k-1}, x_k] : 1 \leq k \leq n\}\) with only endpoints in common. A partition \(\mathcal{P}\) is usually described by its set of endpoints \(\{x_0, x_1, \ldots, x_n\}\), where \(a = x_0 < x_1 < \cdots < x_n = b\). We can also write \(\mathcal{P} = \{J_1, \ldots, J_n\}\), where \(J_k = [x_{k-1}, x_k]\) is the \(k\)’th subinterval. We sometimes write \(\Delta x_k\) for \(\ell(J_k) = x_k - x_{k-1}\), the length of the \(k\)’th subinterval of the partition.

The *norm* or *mesh* of a partition \(\mathcal{P} = \{x_0, x_1, \ldots, x_n\}\) is

\[
\|
\mathcal{P}\| = \max\{x_k - x_{k-1} : 1 \leq k \leq n\}.
\]

If \(\mathcal{P} = \{x_0, \ldots, x_n\}\) and \(\mathcal{Q} = \{x_0', \ldots, x_m'\}\) are partitions of \([a, b]\), we say that \(\mathcal{Q}\) is *finer* than \(\mathcal{P}\), or a *refinement* of \(\mathcal{P}\), if \(\mathcal{P} \subseteq \mathcal{Q}\), i.e. if each \(x_k\) is one of the \(x_j'\), or equivalently if each interval in the partition \(\mathcal{Q}\) is a subinterval of one of the intervals in \(\mathcal{P}\).

A *tag* in an interval \([c, d]\) is a specified number in \([c, d]\). A *tagged partition* is a partition \(\{x_0, x_1, \ldots, x_n\}\) with a specified tag \(t_i\) in \([x_{i-1}, x_i]\) for each \(i\). A tagged partition is usually denoted by

\[
\mathcal{P} = \{x_0, x_1, \ldots, x_n; t_1, \ldots, t_n\}.
\]

The norm or mesh of a partition is a measure of how fine the partition is. There is a more sophisticated and flexible notion of fineness of a partition based on gauges (\().

1497
Note that if $P$ and $Q$ are two partitions of $[a; b]$, neither is a refinement of the other in general. But:

**XIV.2.1.2. Proposition.** Two partitions $P$ and $Q$ of an interval $[a; b]$ have a common refinement.

**Proof:** Just take $P \cup Q$, the partition obtained by using all the endpoints in both partitions. ☑

**Riemann Sums**

**XIV.2.1.3. Definition.** Let $f$ be a real-valued function on an interval $[a, b]$, and let

$$\hat{P} = \{x_0, x_1, \ldots, x_n; t_1, \ldots, t_n\}$$

be a tagged partition of $[a, b]$. The *Riemann sum* for $f$ with respect to $\hat{P}$ is

$$R(f, \hat{P}) = \sum_{k=1}^{n} f(t_k)(x_k - x_{k-1}) = \sum_{k=1}^{n} f(x_k) \Delta x_k .$$

Note that Riemann sums are only defined for tagged partitions, and the numerical value depends on the choice of tags as well as the partition.

1498
Darboux Sums and Oscillation

Two closely related sums which do not depend on tags are the upper and lower Darboux sums:

**XIV.2.1.4. Definition.** Let $f$ be a bounded function on an interval $[a, b]$. If $\mathcal{P} = \{x_0, \ldots, x_n\}$ is a partition of $[a, b]$, for $1 \leq k \leq n$ set

$$M_k = \sup_{x_{k-1} \leq x \leq x_k} f(x) \quad \text{and} \quad m_k = \inf_{x_{k-1} \leq x \leq x_k} f(x).$$

Then the upper and lower Darboux sums for $f$ with respect to $\mathcal{P}$ are

$$\mathcal{S}(f, \mathcal{P}) = \sum_{k=1}^{n} M_k (x_k - x_{k-1}) = \sum_{k=1}^{n} M_k \Delta x_k$$

$$\underline{S}(f, \mathcal{P}) = \sum_{k=1}^{n} m_k (x_k - x_{k-1}) = \sum_{k=1}^{n} m_k \Delta x_k$$

(written $U(f, \mathcal{P})$ and $L(f, \mathcal{P})$ in many references).

The relation between Darboux and Riemann sums is:
XIV.2.1.5. **Proposition.** Let $f$ be a bounded function on an interval $[a, b]$, and let $P$ be a partition of $[a, b]$. Then

(i) If $\hat{P}$ is any tagging of $P$, then
\[
\underline{S}(f, P) \leq R(f, \hat{P}) \leq \overline{S}(f, P).
\]

(ii) For any $\epsilon > 0$ there are taggings $\hat{P}$ and $\bar{P}$ of $P$ such that
\[
R(f, \hat{P}) > \overline{S}(f, P) - \epsilon \quad \text{and} \quad R(f, \bar{P}) < \underline{S}(f, P) + \epsilon.
\]

**Proof:** Part (i) is obvious. For (ii), let $P = \{x_0, \ldots, x_n\}$. For each $k$, choose $t_k \in [x_{k-1}, x_k]$ with
\[
f(t_k) > M_k - \frac{\epsilon}{n \Delta x_k}
\]
and set $\hat{P} = \{x_0, \ldots, x_k; t_1, \ldots, t_k\}$. The construction of $\hat{P}$ is similar.

As the partition $P$ becomes finer, the upper Darboux sums decrease and the lower Darboux sums decrease.
XIV.2.1.6.  **Proposition.** Let \( f \) be a bounded function on an interval \([a, b]\), and \( P \) and \( Q \) partitions of \([a, b]\). If \( Q \) is finer than \( P \), then

\[
\mathcal{L}(f, P) \leq \mathcal{L}(f, Q) \leq \mathcal{U}(f, Q) \leq \mathcal{U}(f, P).
\]

There is no such simple relation for Riemann sums.

**Interior Darboux Sums**

For technical purposes, there is a useful variation on the notion of a Darboux sum:

XIV.2.1.7.  **Definition.** Let \( f \) be a bounded function on an interval \([a, b]\). If \( P = \{x_0, \ldots, x_n\} \) is a partition of \([a, b]\), for \( 1 \leq k \leq n \) set

\[
M^o_k = \sup_{x_{k-1} < x < x_k} f(x) \quad \text{and} \quad m^o_k = \inf_{x_{k-1} < x < x_k} f(x).
\]

Then the **upper and lower interior Darboux sums** for \( f \) with respect to \( P \) are

\[
\mathcal{L}_o(f, P) = \sum_{k=1}^{n} M^o_k (x_k - x_{k-1}) = \sum_{k=1}^{n} M^o_k \Delta x_k
\]

1501
The difference is that $M_k^o$ and $m_k^o$ are the supremum and infimum of $f$ on the interior of the $k$'th subinterval.

XIV.2.1.8. For any $f$ and $P$, we obviously have $m_k \leq m_k^o \leq M_k^o \leq M_k$, so

$$\underline{S}(f, P) \leq \underline{S}_o(f, P) \leq \overline{S}_o(f, P) \leq \overline{S}(f, P).$$

If $f$ is continuous on $[a, b]$, then $M_k^o = M_k$ and $m_k^o = m_k$ for all $k$, so we have equality at the ends, but the interior Darboux sums for step functions often differ from the usual Darboux sums. We will obtain an approximate equivalence between the notions in (\).

**The Metaprinciple**

There is a simple but useful observation about the behavior of Riemann sums, Darboux sums, and interior Darboux sums:

XIV.2.1.9. **Proposition.** Let $f$ be a bounded function on an interval $[a, b]$, $P$ a partition of $[a, b]$, and $\_P$ any tagging of $P$. We have the following relations for any constant $c$:

\[
\begin{align*}
R(f + c, \_P) &= R(f, \_P) + c(b - a) \\
\overline{S}(f + c, P) &= \overline{S}(f, P) + c(b - a) \\
\underline{S}(f + c, P) &= \underline{S}(f, P) + c(b - a) \\
\overline{S}_o(f + c, P) &= \overline{S}_o(f, P) + c(b - a) \\
\underline{S}_o(f + c, P) &= \underline{S}_o(f, P) + c(b - a) \\
R(-f, \_P) &= -R(f, \_P) \\
\overline{S}(-f, P) &= -\overline{S}(f, P) \\
\underline{S}(-f, P) &= -\underline{S}(f, P) \\
\overline{S}_o(-f, P) &= -\overline{S}_o(f, P) \\
\underline{S}_o(-f, P) &= -\underline{S}_o(f, P).
\end{align*}
\]

XIV.2.1.10. Thus, in analyzing and comparing such sums, it suffices to consider nonnegative functions by adding a suitable constant; and results about upper Darboux sums have an exact analog for lower Darboux sums which do not have to be proved separately, but simply follow by taking negations.

**Relation between Darboux Sums and Interior Darboux Sums**

The next result is a good example of the metaprinciple in action.
**XIV.2.1.11.** Proposition. Let $f$ be a bounded function on an interval $[a, b]$, and $\mathcal{P}$ a partition of $[a, b]$. Then for every $\epsilon > 0$ there is a partition $\mathcal{Q}$ of $[a, b]$ such that

$$\mathcal{S}_o(f, \mathcal{P}) - \epsilon \leq \mathcal{S}(f, \mathcal{Q}) \leq \mathcal{S}(f, \mathcal{Q}) \leq \mathcal{S}_o(f, \mathcal{P}) + \epsilon .$$

**Proof:** By the Metaprinciple, we need show there is a $\mathcal{Q}$ giving the last inequality: then by negation, there is a $\mathcal{Q}'$ giving the first inequality, and a common refinement of $\mathcal{Q}$ and $\mathcal{Q}'$ gives both. Furthermore, in finding $\mathcal{Q}$ for the last inequality we may assume that $f$ is nonnegative.

Let $\mathcal{P} = \{x_0, \ldots, x_n\}$. We will obtain $\mathcal{Q}$ by shortening each interval in $\mathcal{P}$ and adding additional small intervals around $x_k$ for each $k$: given $\epsilon > 0$, choose $\delta > 0$ small enough that $\delta < \ell(J_k)/2$ for all $k$, and so that $\delta < \frac{\epsilon}{2M(n+1)}$, where $M$ is a bound for $f$ on $[a, b]$, and let

$$\mathcal{Q} = \{x_0, x_0 + \delta, x_1 - \delta, x_1 + \delta, \ldots, x_n - \delta, x_n\} .$$

Then for each $k$ we have

$$\sup_{x_{k-1} + \delta \leq x \leq x_k - \delta} f(x) \leq M_k^\circ$$

and so by adding up separately over the truncated original intervals and the new intervals we have

$$\mathcal{S}(f, \mathcal{Q}) \leq \sum_{k=1}^{n} M_k^\circ [\ell(J_k) - 2\delta] + \sum_{k=0}^{n} M(2\delta) \leq \mathcal{S}_o(f, \mathcal{P}) + \epsilon .$$

**Oscillation**

The oscillation of a bounded real-valued function on any set can be defined:

**XIV.2.1.12.** Definition. Let $f$ be a real-valued function on a set $X$, and $S \subseteq X$. If $f$ is bounded on $S$, the number

$$\omega(f, S) = \sup_S f - \inf_S f$$

is called the oscillation of $f$ on $S$.

**XIV.2.1.13.** More generally, if $f$ is a function from a set $X$ to a metric space $(Y, \rho)$, and $f$ is bounded on a subset $S$ of $X$, then we can define

$$\omega(f, S) = \sup\{\rho(f(s), f(t)) : s, t \in S\} .$$

If $X$ is a topological space and $x_0 \in X$, then $f$ is continuous at $x_0$ if and only if

$$\lim_{\mathcal{U}} \omega(f, \mathcal{U}) = 0$$

as $\mathcal{U}$ ranges over the directed set of neighborhoods of $x_0$. In particular, if $X \subseteq \mathbb{R}$, then $f : X \to \mathbb{R}$ is continuous at $x_0 \in X$ if and only if

$$\lim_{\epsilon \to 0} \omega(f, (x - \epsilon, x + \epsilon)) = 0 .$$
XIV.2.1.14. The connection with integration is that if $f$ is a bounded function on an interval $[a, b]$, and $\mathcal{P}$ is a partition of $[a, b]$, with $M_k$ and $m_k$ defined as in XIV.2.1.4., then

$$\omega(f, J_k) = M_k - m_k$$

and so we have

$$\overline{S}(f, \mathcal{P}) - \underline{S}(f, \mathcal{P}) = \sum_{k=1}^{n} \omega(f, J_k) \ell(J_k).$$

The last number is called the weighted local oscillation of $f$ with respect to $\mathcal{P}$.

![Figure XIV.14: The Weighted Local Oscillation for a Partition](image)

XIV.2.1.15. The weighted local oscillation does not increase, and typically decreases, as the partition becomes finer (Figure XIV.15).

XIV.2.2. Step Functions and their Integrals

XIV.2.3. Definitions of the Riemann Integral

We will give five definitions of Riemann integrability. All have slight rephrasings which are easily seen to be equivalent to the basic definition. There are other definitions which can be found in the literature, but the ones we give are the “extreme” ones and others can be seen to fit between our definitions.
The basic definitions are in terms of (1) Riemann sums, (2) upper and lower Darboux sums (or oscillation), or (3) approximation above and below by step functions. The other variation is (A) requiring existence of one partition forcing good approximation or (B) requiring good approximation for all sufficiently fine partitions.

**Definition 1**

**XIV.2.3.1.** Definition. [Definition 1A] Let $f$ be a function on a closed bounded interval $J = [a, b]$. Then $f$ is Riemann-integrable on $J$ in sense 1A, with Riemann integral $R \in \mathbb{R}$, if for every $\epsilon > 0$ there is a partition $P = \{x_0, \ldots, x_n\}$ of $J$ such that, for every choice of tags $t_1, \ldots, t_n$ for $P$, we have
\[
\left| R - \sum_{k=1}^{n} f(t_k)(x_k - x_{k-1}) \right| < \epsilon .
\]

**XIV.2.3.2.** Definition. [Definition 1B] Let $f$ be a function on a closed bounded interval $J = [a, b]$. Then $f$ is Riemann-integrable on $J$ in sense 1B, with Riemann integral $R \in \mathbb{R}$, if for every $\epsilon > 0$ there is a $\delta > 0$ such that, for every tagged partition $P = \{x_0, \ldots, x_n; t_1, \ldots, t_n\}$ of $J$ with $\|P\| < \delta$, we have
\[
\left| R - \sum_{k=1}^{n} f(t_k)(x_k - x_{k-1}) \right| < \epsilon .
\]

Figure XIV.15: The Weighted Local Oscillation for a Finer Partition
XIV.2.3.3. Definition. [Definition 2A] Let \( f \) be a bounded function on a closed bounded interval \( J = [a, b] \). Then \( f \) is Riemann-integrable on \( J \) in sense 2A if for every \( \epsilon > 0 \) there is a partition \( P \) of \( J \) such that
\[
\mathfrak{S}(f, P) - \mathfrak{s}(f, P) < \epsilon.
\]

XIV.2.3.4. Definition. [Definition 2B] Let \( f \) be a bounded function on a closed bounded interval \( J = [a, b] \). Then \( f \) is Riemann-integrable on \( J \) in sense 2B if for every \( \epsilon > 0 \) there is a \( \delta > 0 \) such that, for every partition \( P \) of \( J \) with \( ||P|| < \delta \), we have
\[
\mathfrak{S}(f, P) - \mathfrak{s}(f, P) < \epsilon.
\]

Definitions 2A and 2B can be rephrased in terms of “weighted local oscillations”:

XIV.2.3.5. Definition. [Definition 2A’] Let \( f \) be a bounded function on a closed bounded interval \( J = [a, b] \). Then \( f \) is Riemann-integrable on \( J \) in sense 2A’ if for every \( \epsilon > 0 \) there is a partition \( P \) of \( J \) such that
\[
\sum_{k=1}^{n} \omega(f, J_k)\ell(J_k) < \epsilon
\]
where \( J_k \) is the \( k \)’th subinterval of \( P \).

XIV.2.3.6. Definition. [Definition 2B’] Let \( f \) be a bounded function on a closed bounded interval \( J = [a, b] \). Then \( f \) is Riemann-integrable on \( J \) in sense 2B’ if for every \( \epsilon > 0 \) there is a \( \delta > 0 \) such that, for every partition \( P \) of \( J \) with \( ||P|| < \delta \), we have
\[
\sum_{k=1}^{n} \omega(f, J_k)\ell(J_k) < \epsilon
\]
where \( J_k \) is the \( k \)’th subinterval of \( P \).

The fact that Definitions 2A’ and 2B’ are equivalent to 2A and 2B respectively is obvious.

There is a less obvious rephrasing of Definition 2A using interior Darboux sums (XIV.2.1.7) which also turns out to be equivalent and technically useful:

XIV.2.3.7. Definition. [Definition 2A’’] Let \( f \) be a bounded function on a closed bounded interval \( J = [a, b] \). Then \( f \) is Riemann-integrable on \( J \) in sense 2A’’ if for every \( \epsilon > 0 \) there is a partition \( P \) of \( J \) such that
\[
\mathfrak{S}_o(f, P) - \mathfrak{s}_o(f, P) < \epsilon.
\]
XIV.2.3.8. Since for any \( f \) and any partition \( P \) we have
\[
\underline{S}(f, P) \leq \underline{S}_e(f, P) \leq \overline{S}_e(f, P) \leq \overline{S}(f, P)
\]
it follows that if \( f \) is Riemann-integrable in sense 2A, then it is Riemann-integrable in sense 2A”. The converse implication follows easily from XIV.2.1.11., so we have:

XIV.2.3.9. Proposition. Let \( f \) be a bounded function on a closed bounded interval \([a, b]\). Then \( f \) is Riemann-integrable in sense 2A” if and only if \( f \) is Riemann-integrable in sense 2A.

XIV.2.3.10. We could also give an obvious similar version 2B” of 2B. However, although 2B  2B” is obvious, it is difficult to prove directly that 2B”  2B. After the fact it will be seen to be true since we will have 2B”  2A”  2A  2B.

Definition 3

XIV.2.3.11. Definition. [Definition 3A] Let \( f \) be a function on a closed bounded interval \( J = [a, b] \). Then \( f \) is Riemann-integrable on \( J \) in sense 3A if for every \( \epsilon > 0 \) there are step functions \( \phi \) and \( \psi \) on \( J \) such that \( \phi \leq f \leq \psi \) on \( J \) and
\[
\int_a^b (\psi - \phi) = \int_a^b \psi - \int_a^b \phi < \epsilon .
\]

XIV.2.3.12. One could give a corresponding Definition 3B, but the statement is awkward and does not appear in the literature to my knowledge. But there is a commonly used rephrasing of Definition 3A, which is fairly obviously equivalent to 3A. First note that since a step function is bounded, any function satisfying Definition 3A is automatically bounded. Then make the following definition:

XIV.2.3.13. Definition. Let \( f \) be a bounded function on a closed bounded interval \( J = [a, b] \). Define
\[
\int_a^b f(x) \, dx = \sup \left\{ \int_a^b \phi : \phi \text{ step, } \phi \leq f \right\}
\]
\[
\int_a^b f(x) \, dx = \inf \left\{ \int_a^b \psi : \psi \text{ step, } f \leq \psi \right\}.
\]

XIV.2.3.14. Definition. [Definition 3A’] Let \( f \) be a function on a closed bounded interval \( J = [a, b] \). Then \( f \) is Riemann-integrable on \( J \) in sense 3A’ if
\[
\int_a^b f(x) \, dx = \int_a^b f(x) \, dx .
\]
The common value is called the \( \text{Riemann integral of } f \) from \( a \) to \( b \).
XIV.2.3.15. To see that Definitions 3A and 3A’ are equivalent, note first that if \( f \) is any bounded function on \( J \) and \( \phi, \psi \) are step functions with \( \phi \leq f \leq \psi \), then \( \int_a^b \phi \leq \int_a^b f(x) \, dx \leq \int_a^b \psi \), and thus by (\() we have

\[
\int_a^b \phi \leq \int_a^b f(x) \, dx \leq \int_a^b \psi.
\]

Thus, if \( f \) is Riemann integrable in sense 3A, then for any \( \epsilon > 0 \) we have

\[
0 \leq \int_a^b f(x) \, dx - \int_a^b f(x) \, dx < \epsilon
\]

so \( f \) is Riemann integrable in sense 3A’. Conversely, if \( f \) is Riemann integrable in sense 3A’, and \( \epsilon > 0 \), choose step functions \( \phi \) and \( \psi \) on \( J \) with \( \phi \leq f \leq \psi \) and

\[
\int_a^b \phi > \int_a^b f(x) \, dx - \int_a^b \phi \, dx = \frac{\epsilon}{2} \quad \text{and} \quad \int_a^b \psi < \int_a^b f(x) \, dx + \int_a^b \phi \, dx = \frac{\epsilon}{2}.
\]

Then

\[
\int_a^b \psi - \int_a^b \phi < \epsilon
\]

so \( f \) is Riemann integrable in sense 3A.

One useful technical fact is the invariance of all the definitions under adding constants:

XIV.2.3.16. Proposition. Let \( f \) be a function on a closed bounded interval \( J = [a, b] \), let \( c \) be a constant, and \( g = f + c \). If \( f \) is Riemann-integrable in any of the senses, then \( g \) is also Riemann-integrable in the same sense, and the Riemann integral of \( g \) is the Riemann integral of \( f \) plus \( c(b - a) \). Riemann and Darboux sums for \( g \) are also the same as for \( f \), plus \( c(b - a) \).

Using this proposition, the theory of Riemann integration can be reduced to the case of nonnegative functions, since any function which is bounded below can be converted to a nonnegative function by adding a constant.

XIV.2.4. Comparing the Definitions

The main result is:

XIV.2.4.1. Theorem. Let \( f \) be a function on a closed bounded interval \( J = [a, b] \). Then

(i) If \( f \) is Riemann-integrable on \( J \) in sense 1A or 1B, then \( f \) is bounded on \( J \).

(ii) If \( f \) is Riemann-integrable in sense 2A or 2B, there is a unique real number \( I \) such that

\[
\mathcal{S}(f, \mathcal{P}) \leq I \leq \mathcal{S}(f, \mathcal{P})
\]

for every partition \( \mathcal{P} \) of \( J \).
If \( f \) is Riemann-integrable on \( J \) in any of the senses 1A, 1B, 2A, 2B, 2A', 2B', 3A, or 3A', it is Riemann-integrable on \( J \) in all these senses, and the Riemann integral of \( f \) over \( J \) is well defined. In particular, the number \( R \) in definitions 1A and 1B is unique, and coincides with the number \( I \) of (ii) and with \( f_a^b f(x) \, dx \) of 3A'.

**XIV.2.4.2.** A few implications are obvious. If \( f \) is Riemann-integrable in sense 1B, it is clearly Riemann-integrable in sense 1A. Similarly, if \( f \) is Riemann-integrable in sense 2B, it is also Riemann-integrable in sense 2A. And the obvious equivalence of 2A and 2A', and of 2B and 2B', has already been noted, as was the slightly less obvious equivalence between 3A and 3A'.

Thus, to prove (i), it suffices to consider an \( f \) which is Riemann-integrable in sense 1A.

**XIV.2.4.3.** **Lemma.** Suppose \( f \) is Riemann-integrable on \( J \) in sense 1A. Then \( f \) is bounded on \( J \).

**Proof:** Let \( R \) be the Riemann integral of \( f \), and let \( \mathcal{P} = \{J_1, \ldots, J_n\} \) be a partition such that for any choice of tags \( t_k \in J_k \), we have

\[
\left| R - \sum_{k=1}^{n} f(t_k) \ell(J_k) \right| < 1.
\]

If \( f \) is not bounded above, then there is a \( k_0 \) such that \( f \) is not bounded above on \( J_{k_0} \). Let \( t_1, \ldots, t_n \) be a choice of tags, and choose \( s_{k_0} \in J_{k_0} \) with \( f(s_{k_0}) > f(t_{k_0}) + \frac{2}{\ell(J_{k_0})} \). Set \( s_k = t_k \) for \( k \neq k_0 \). We then have

\[
\left| R - \sum_{k=1}^{n} f(t_k) \ell(J_k) \right| < 1
\]

\[
\left| R - \sum_{k=1}^{n} f(s_k) \ell(J_k) \right| < 1
\]

so we have

\[
[f(s_{k_0}) - f(t_{k_0})] \ell(J_{k_0}) = \left| \sum_{k=1}^{n} f(s_k) \ell(J_k) - \sum_{k=1}^{n} f(t_k) \ell(J_k) \right|
\]

\[
\leq \left| \sum_{k=1}^{n} f(s_k) \ell(J_k) \right| + \left| \sum_{k=1}^{n} f(t_k) \ell(J_k) \right| - R < 2
\]

which is a contradiction. The proof that \( f \) is bounded below is almost identical. 

Next we compare definitions 1A and 2A, and 1B and 2B.
XIV.2.4.4. **Lemma.** Suppose $f$ is a bounded function on $J$, and $\mathcal{P} = \{J_1, \ldots, J_n\}$ is a partition of $J$. Then $\underline{S}(f, \mathcal{P})$ and $\overline{S}(f, \mathcal{P})$ are the infimum and supremum, respectively, of the Riemann sums corresponding to all choices of tags for $\mathcal{P}$.

**Proof:** It is clear that if $t_1, \ldots, t_n$ is any choice of tags for $\mathcal{P}$, then

$$\underline{S}(f, \mathcal{P}) \leq \sum_{k=1}^{n} f(t_k)\ell(J_k) \leq \overline{S}(f, \mathcal{P}).$$

Fix $\epsilon > 0$. For each $k$, choose $t_k \in J_k$ with $f(t_k) > M_k - \frac{\epsilon}{\ell(J)}$. Then

$$\sum_{k=1}^{n} f(t_k)\ell(J_k) > \sum_{k=1}^{n} M_k\ell(J_k) - \frac{\epsilon}{\ell(J)}\sum_{k=1}^{n} \ell(J_k) = \overline{S}(f, \mathcal{P}) - \epsilon.$$

The argument for the infimum is almost identical.

XIV.2.4.5. Now let $f$ be a (necessarily bounded) function which is Riemann-integrable on $J$ in sense 1A with Riemann integral $R$, $\epsilon > 0$, and $\mathcal{P} = \{J_1, \ldots, J_k\}$ a partition of $J$ such that

$$\left| R - \frac{1}{n} \sum_{k=1}^{n} f(t_k)\ell(J_k) \right| < \frac{\epsilon}{3},$$

for any choice of tags $t_k \in J_k$. Then

$$\left| R - \overline{S}(f, \mathcal{P}) \right| \leq \frac{\epsilon}{3} \quad \text{and} \quad \left| R - \underline{S}(f, \mathcal{P}) \right| \leq \frac{\epsilon}{3}$$

so we have

$$\overline{S}(f, \mathcal{P}) - \underline{S}(f, \mathcal{P}) \leq |\overline{S}(f, \mathcal{P}) - R| + |R - \underline{S}(f, \mathcal{P})| \leq \frac{2\epsilon}{3} < \epsilon$$

and so $f$ is Riemann-integrable in sense 2A. An almost identical argument shows that if $f$ is Riemann-integrable in sense 1B, then it is also Riemann-integrable in sense 2B.

For the other direction, note that there is no explicitly given value for the Riemann integral in definitions 2A or 2B, or in 2A′ or 2B′ (or in 3A, but there is one in the equivalent definition 3A′.) The essential point of (ii) is to provide a value for the Riemann integral in case 2A or 2B. To prove (ii), we first make an important observation:

XIV.2.4.6. **Lemma.** If $f$ is a bounded function on $J$, and $\mathcal{P}$ and $\mathcal{Q}$ are any partitions of $J$, then

$$\underline{S}(f, \mathcal{P}) \leq \overline{S}(f, \mathcal{Q}).$$

**Proof:** The key is that there is a partition $\mathcal{R}$ which is a refinement of both $\mathcal{P}$ and $\mathcal{Q}$ (XIV.2.1.2.). Then, by XIV.2.1.6.,

$$\underline{S}(f, \mathcal{P}) \leq \underline{S}(f, \mathcal{R}) \leq \overline{S}(f, \mathcal{R}) \leq \overline{S}(f, \mathcal{Q}).$$

We then conclude from () that

1510
XIV.2.4.7. **Corollary.** Let \( f \) be a bounded function on \( J \). Then

\[
\sup_{\mathcal{P}} \{S(f, \mathcal{P})\} \leq \inf_{\mathcal{P}} \{\overline{S}(f, \mathcal{P})\}
\]

where the supremum and infimum are taken over all partitions of \( J \).

XIV.2.4.8. Thus, if \( f \) is Riemann-integrable in sense 2A, then we have

\[
\sup_{\mathcal{P}} \{S(f, \mathcal{P})\} = \inf_{\mathcal{P}} \{\overline{S}(f, \mathcal{P})\}.
\]

Call this number \( I \). Then we have

\[
\int_a^b f(x) \, dx \leq I \leq \overline{S}(f, \mathcal{P})
\]

for any partition \( \mathcal{P} \), and \( I \) is clearly the only number with this property, proving (ii). Also, if \( \epsilon > 0 \) and \( \mathcal{P} = \{J_1, \ldots, J_n\} \) is a partition with \( \overline{S}(f, \mathcal{P}) - S(f, \mathcal{P}) < \epsilon \), then for any choice of tags \( t_1, \ldots, t_n \) with \( t_k \in J_k \) we have

\[
\left| I - \sum_{k=1}^n f(t_k) \ell(J_k) \right| < \epsilon
\]

so \( f \) is Riemann-integrable in sense 1A with Riemann integral \( I \). If \( f \) is Riemann-integrable in sense 2B, it follows almost identically that \( f \) is Riemann-integrable in sense 1B.

XIV.2.4.9. Now let us compare definitions 2A and 3A. Let \( f \) be a bounded function on \( J = [a, b] \), which we may assume to be nonnegative by XIV.2.3.16.. We want to show that

\[
\inf_{\mathcal{P}} \{\overline{S}(f, \mathcal{P})\} = \inf \left\{ \int_a^b \psi : \psi \text{ step, } f \leq \psi \right\}
\]

and similarly for lower estimates. (We have \( \geq \) by the previous argument.) Let \( \psi \) be a step function for which \( f \leq \psi \), and \( \mathcal{P} \) the partition consisting of \( x_0 = a, x_n = b \), and the jump discontinuities \( x_1, \ldots, x_{n-1} \).
of $\psi$ in $(a, b)$. Let $c_k$ be the value of $\psi$ on $(x_{k-1}, x_k)$, and $d_k = f(x_k)$. If $M_k$ is the supremum of $f$ on $J_k = [x_{k-1}, x_k]$, we have $M_k \leq \max(c_k, d_k, d_{k-1})$. So if $d_{k-1}, d_k \leq c_k$ for all $k$, we have

$$\mathcal{I}(f, \mathcal{P}) \leq \int_a^b \psi$$

but this fails if $d_k > c_k$ or $d_{k-1} > c_k$ for some $k$. To get around this problem, use definition $2A''$ instead: we have

$$\mathcal{I}_o(f, \mathcal{P}) \leq \int_a^b \psi$$

for any such $\psi$. We thus get the desired inequality

$$\inf_{\mathcal{P}} \{\mathcal{I}(f, \mathcal{P})\} = \inf_{\mathcal{P}} \{\mathcal{I}_o(f, \mathcal{P})\} \leq \inf \left\{ \int_a^b \psi : \text{step, } f \leq \psi \right\}$$

where the first equality is from XIV.2.11. By a similar argument we obtain

$$\sup_{\mathcal{P}} \{\mathcal{I}(f, \mathcal{P})\} \geq \sup \left\{ \int_a^b \phi : \phi \text{ step, } \phi \leq f \right\}$$

(the opposite inequality follows from the previous argument).

**XIV.2.4.12.** Thus, if $f$ is Riemann-integrable in sense $3A$, it is Riemann-integrable in sense $2A$, and the number $I$ of (ii) is exactly $\int_a^b f(x) \, dx$.

**XIV.2.4.13.** We have now shown that definitions $1A$, $2A$, and $3A$ (hence also $2A'$ and $3A'$) define the same class of Riemann-integrable functions, and the Riemann integrals coincide (using (ii) in case $2A$). We will say that a function Riemann-integrable in any of these senses is Riemann-integrable in sense $A$. Similarly, definitions $1B$ and $2B$ (hence also $2B'$) define the same class of Riemann-integrable functions, with a well-defined Riemann integral, called the functions Riemann-integrable in sense $B$. Also, a function Riemann-integrable in sense $B$ is Riemann-integrable in sense $A$, and the Riemann integrals coincide. Thus, finish the proof of the theorem, we need to show that a function which is Riemann-integrable in sense $A$ is Riemann-integrable in sense $B$. This is the least obvious part of the proof of the theorem.

**XIV.2.4.14.** So suppose $f$ is Riemann-integrable on $J$ in sense $A$, and let $\epsilon > 0$. Let $\mathcal{P} = \{x_0, x_1, \ldots, x_n\}$ be a partition satisfying

$$\mathcal{I}(f, \mathcal{P}) - \mathcal{I}_o(f, \mathcal{P}) < \frac{\epsilon}{2}.$$ 

Let $M$ be a bound for $f$ on $J$, and set $g = f + M$, $h = f - M$. Then $0 \leq g \leq 2M$ and $-2M \leq h \leq 0$. Let $\delta < \frac{\epsilon}{4(n-1)M}$. If $Q = \{I_1, \ldots, I_n\}$ is a partition of $J$ with $\|Q\| < \delta$, then $Q$ might not quite be a refinement of $\mathcal{P}$ since some or all of the $x_k$ might be interior points of intervals of $Q$. But there are at most $n - 1$ of these intervals; let $N_1$ be the set of $r$ such that $I_r$ is one of these, and let $N_2$ be the rest of the indices. Then

$$\mathcal{I}(g, Q) = \sum_{r \in N_1} M_r \ell(I_r) + \sum_{r \in N_2} M_r \ell(I_r)$$

1512
where \( M_r \) is the supremum of \( g \) on \( I_r \). Since for each \( r \in N_2 \) we have that \( I_r \) is contained in one of the \( J_k \), and the supremum of \( g \) over \( I_r \) is less than or equal to the supremum of \( g \) over the corresponding \( J_k \), we have that

\[
\sum_{r \in N_2} M_r \ell(I_r) \leq \mathcal{S}(g, \mathcal{P}) .
\]

Since each \( I_r \) has length \( < \delta \), and \( N_1 \) contains at most \( n - 1 \) indices, we have

\[
\sum_{r \in N_1} M_r \ell(I_r) \leq 2(n - 1)M \delta < \frac{\epsilon}{2}.
\]

Thus we have

\[
\mathcal{S}(g, \mathcal{Q}) < \mathcal{S}(g, \mathcal{P}) + \frac{\epsilon}{2}.
\]

By translation (XIV.2.3.16.), we thus have

\[
\mathcal{S}(f, \mathcal{Q}) < \mathcal{S}(f, \mathcal{P}) + \frac{\epsilon}{2}.
\]

Applying a similar argument to \( h \) using infima, we have

\[
\mathcal{S}(h, \mathcal{Q}) > \mathcal{S}(h, \mathcal{P}) - \frac{\epsilon}{2}
\]

and so by linearity we have

\[
\mathcal{S}(f, \mathcal{Q}) > \mathcal{S}(f, \mathcal{P}) - \frac{\epsilon}{2}.
\]

Combining the two estimates, we get

\[
\mathcal{S}(f, \mathcal{Q}) - \mathcal{S}(f, \mathcal{Q}) < \epsilon
\]

and so \( f \) is Riemann-integrable in sense 2B (i.e. in sense B).

**XIV.2.4.15.** There is one last loose end. We must show that the number \( R \) in Definition 1A is unique. Let \( f \) be Riemann-integrable in sense 1A, and \( R \) a number satisfying Definition 1A. Fix \( \epsilon > 0 \), and let \( \mathcal{P} \) be a partition such that

\[
\left|R - \sum_{k=1}^{n} f(t_k) \ell(J_k)\right| < \epsilon
\]

for any choice of tags. Then by XIV.2.4.4., we have

\[
|R - \mathcal{S}(f, \mathcal{P})| \leq \epsilon
\]

and so, since the number \( I \) of (ii) is between \( \mathcal{S}(f, \mathcal{P}) \) and \( \mathcal{S}(f, \mathcal{P}) \), we have

\[
|R - I| \leq \epsilon.
\]

since \( \epsilon > 0 \) is arbitrary, we have \( R = I \) and \( R \) is uniquely determined.

This completes the proof of XIV.2.4.1.

In light of Theorem XIV.2.4.1., we can make the definitive definition of Riemann-integrability:
XIV.2.4.16. Definition. Let \( f \) be a bounded function on a closed bounded interval \( J = [a, b] \). Then \( f \) is Riemann-integrable on \( J \) if it is Riemann-integrable in any of the senses 1A-B, 2A-B, 2A'-B', or 3A-A'. The Riemann integral of \( f \) over \( J \), or from \( a \) to \( b \), denoted \( \int_a^b f(x) \, dx \), is the number defined in XIV.2.3.14.

XIV.2.5. Integrals of Continuous and Monotone Functions

Let \( \chi_Q \) be the indicator function of \( Q \).

XIV.2.6. Properties of the Riemann Integral

The following result summarizes some of the most important properties of the Riemann integral:

XIV.2.6.1. Theorem. Let \( [a, b] \) be a closed bounded interval in \( \mathbb{R} \), and \( f \) and \( g \) real-valued functions on \( [a, b] \), and \( c \in \mathbb{R} \). Then

(i) (Linearity) If \( f \) and \( g \) are Riemann-integrable on \( [a, b] \), then \( f + g \) and \( cf \) are Riemann-integrable on \( [a, b] \), and

\[
\int_a^b [f(x) + g(x)] \, dx = \int_a^b f(x) \, dx + \int_a^b g(x) \, dx
\]

\[
\int_a^b (cf)(x) \, dx = c \int_a^b f(x) \, dx
\]

(ii) (Monotonicity) If \( f \) and \( g \) are Riemann-integrable on \( [a, b] \), and if \( f(x) \leq g(x) \) for all \( x \in [a, b] \), then

\[
\int_a^b f(x) \, dx \leq \int_a^b g(x) \, dx
\]

(iii) The constant function \( c \) is Riemann-integrable on \( [a, b] \), and

\[
\int_a^b c \, dx = c(b - a)
\]

Proof: For (i), note that for any tagged partition \( \hat{P} \) of \( [a, b] \), we have

\[
\mathcal{R}(f + g, \hat{P}) = \mathcal{R}(f, \hat{P}) + \mathcal{R}(g, \hat{P})
\]

\[
\mathcal{R}(cf, \hat{P}) = c\mathcal{R}(f, \hat{P})
\]

For (ii), if \( f \leq g \), for any tagged partition \( \hat{P} \) of \( [a, b] \) we have

\[
\mathcal{R}(f, \hat{P}) \leq \mathcal{R}(g, \hat{P})
\]

For (iii), for any tagged partition \( \hat{P} \) of \( [a, b] \) we have

\[
\mathcal{R}(c, \hat{P}) = c(b - a)
\]

Apply Definition 1.

The following crude estimate is surprisingly useful:
**XIV.2.6.2.** Corollary. Let $f$ be Riemann-integrable on $[a, b]$. If $m \leq f(x) \leq M$ for all $x \in [a, b]$, then

$$m(b-a) \leq \int_a^b f(x) \, dx \leq M(b-a).$$

In particular, if $|f(x)| \leq M$ for all $x \in [a, b]$, then

$$\left| \int_a^b f(x) \, dx \right| \leq M(b-a).$$

This Corollary can be proved more easily by simply noting that if $\mathcal{P}$ is the partition of $[a, b]$ consisting of one interval, then

$$m(b-a) \leq S(f, \mathcal{P}) \leq \int_a^b f(x) \, dx \leq S(f, \mathcal{P}) \leq M(b-a).$$

Another closely related inequality, an integral version of the Triangle Inequality ($\omega$), is also used regularly:

**XIV.2.6.3.** Corollary. Let $f$ be Riemann-integrable on $[a, b]$. Then $|f|$ is also Riemann-integrable on $[a, b]$, and

$$\left| \int_a^b f(x) \, dx \right| \leq \int_a^b |f(x)| \, dx.$$

**Proof:** We only need to see that $|f|$ is Riemann-integrable. But if $\mathcal{P}$ is any partition of $[a, b]$, then

$$\mathcal{S}(|f|, \mathcal{P}) - \mathcal{S}(|f|, \mathcal{P}) \leq \mathcal{S}(f, \mathcal{P}) - \mathcal{S}(f, \mathcal{P})$$

since $\omega(|f|, I) \leq \omega(f, I)$ for any interval $I$. \(\blacksquare\)

**XIV.2.6.4.** In the context of Figure XIV.9, this is really a triangle inequality: if $A_1$ and $A_3$ are the areas of the two blue regions and $A_2$ the area of the tan region, then $\left| \int_a^b f(x) \, dx \right| = |A_1 - A_2 + A_3|$ and $\int_a^b |f(x)| \, dx = A_1 + A_2 + A_3$.

**Continuity of the Integral**

One must be quite careful about interchanging integrals and limits: the Riemann integral is not continuous for all types of limits. In fact, obtaining good limit theorems was one of the main goals of developing modern integration theories.

There is one simple but important situation where Riemann integration is continuous:
XIV.2.6.5. PROPOSITION. Let \([a, b]\) be a closed bounded interval, and \((f_n)\) a sequence of functions on \([a, b]\) converging uniformly on \([a, b]\) to a function \(f\). If each \(f_n\) is Riemann-integrable on \([a, b]\), then \(f\) is Riemann-integrable on \([a, b]\) and
\[
\int_a^b f_n(x) \, dx \to \int_a^b f(x) \, dx .
\]
(Informally, the integral of a uniform limit is the limit of the integrals.)

PROOF: If we know \(f\) is Riemann-integrable (e.g. if the \(f_n\) are continuous), this follows immediately from XIV.2.6.1., XIV.2.6.2., and XIV.2.6.3.: if \(\epsilon > 0\), choose \(N\) so that \(|f_n(x) - f(x)| < \frac{\epsilon}{b-a}\) for all \(n \geq N\) and all \(x \in [a, b]\); then
\[
\left| \int_a^b f_n(x) \, dx - \int_a^b f(x) \, dx \right| = \left| \int_a^b (f_n(x) - f(x)) \, dx \right| \leq \int_a^b |f_n(x) - f(x)| \, dx \leq \frac{\epsilon}{b-a}(b-a) = \epsilon
\]
for all \(n \geq N\).

The argument that \(f\) is Riemann-integrable is very similar to the proof that a uniform limit of continuous functions is continuous (). Note that if \(|f_n(x) - f(x)| < \epsilon\) for all \(x \in [a, b]\), then for any partition \(P\) we have
\[
|S(f_n, P) - S(f, P)| \leq \epsilon(b-a)
\]
so, if \(\epsilon > 0\), and \(N\) is such that
\[
|f_n(x) - f(x)| < \frac{\epsilon}{3(b-a)}
\]
for all \(n \geq N\) and \(x \in [a, b]\), and \(P\) is a partition such that
\[
S(f_n, P) - S(f, P) < \frac{\epsilon}{3}
\]
we have that
\[
S(f, P) - S(f, P) \leq |S(f, P) - S(f_n, P)| + |S(f_n, P) - S(f, P)| + |S(f_n, P) - S(f_n, P)|
\]
\[
< \frac{\epsilon}{3(b-a)}(b-a) + \frac{\epsilon}{3} + \frac{\epsilon}{3(b-a)}(b-a) = \epsilon .
\]
Since \(\epsilon > 0\) is arbitrary, \(f\) is Riemann-integrable by Definition 2A.

Dense Sets and Integrability

XIV.2.6.6. PROPOSITION. If \(f_1\) and \(f_2\) are Riemann-integrable on \([a, b]\) and agree on a dense subset \(D\), then
\[
\int_a^b f_1(x) \, dx = \int_a^b f_2(x) \, dx .
\]

PROOF: If \(P\) is any partition of \([a, b]\), then Riemann sums for \(f_1\) and \(f_2\) with respect to \(P\) can be chosen with the tags in \(D\), so these Riemann sums coincide.

We can use this fact to give a definition of Riemann-integrability and the Riemann integral for certain functions which are not defined everywhere.
XIV.2.6.7. Definition. Let \( f \) be a real-valued function defined on a dense subset \( D \) of \([a, b]\). Then \( f \) is Riemann-integrable on \([a, b]\) if there is a Riemann-integrable function \( g \) on \([a, b]\) whose restriction to \( D \) is \( f \). The Riemann integral \( \int_a^b f(x) \, dx \) is defined to be \( \int_a^b g(x) \, dx \).

XIV.2.6.8. The Riemann integral of \( f \) is well defined independent of the choice of \( g \) by XIV.2.6.6., and any two choices for \( g \) actually agree almost everywhere (XIV.3.11.1.). An \( f \) which is Riemann-integrable in this extended sense is necessarily bounded.

The simplest situation is when \( f \) is defined except at finitely many points. Such a function can be changed, defined, or left undefined at finitely many points without changing its Riemann-integrability or its Riemann integral:

XIV.2.6.9. Proposition. Let \( f \) be a function defined at all but finitely many points of \([a, b]\). If \( f \) is Riemann-integrable, then any function \( g \) defined on all but finitely many points and agreeing with \( f \) at all but finitely many points is also Riemann-integrable, with

\[
\int_a^b g(x) \, dx = \int_a^b f(x) \, dx.
\]

Proof: If \( P \) is a partition fine enough that it includes all the points where \( f \) or \( g \) is undefined and the points where they have unequal values, we have

\[
\mathcal{S}_o(f, P) = \mathcal{S}_o(g, P) \text{ and } \mathcal{S}_o(f, P) = \mathcal{S}_o(g, P)
\]

and we can apply Definition 2A'.
XIV.2.7.2. The term “null set” is often used as a synonym for “empty set”, but in analysis it is more useful to use the definition we have given. (Note that the empty set is a null set by the analysis definition, but so are many nonempty sets, such as any finite set; in fact finite sets have zero content.)

Any subset of a null set (resp. a set of zero content) is a null set (resp. a set of zero content).

A set with zero content is obviously a null set (since $\emptyset$ is a degenerate interval); the converse is false:

XIV.2.7.3. **Examples.** (i) Any countable set is a null set. [If $A$ is countable, say $A = \{x_n : n \in \mathbb{N}\}$, and $\epsilon > 0$, let $I_k$ be the open interval centered at $x_k$ of length $\frac{\epsilon}{2^k}$.] Thus, for example, $\mathbb{Q}$ is a null set. But $\mathbb{Q}$ does not have zero content since a set with zero content is clearly bounded.

(ii) Even a bounded null set need not have zero content. For example, $A = \mathbb{Q} \cap [0,1]$ is a null set by (i), but if $\{I_1, \ldots, I_n\}$ is a finite set of intervals containing $A$, then $\bigcup_{k=1}^n I_k$ contains all but finitely many points of $[0,1]$. It follows that $\sum_{k=1}^n \ell(I_k) \geq 1$ (this seems obvious, but is actually somewhat tricky to prove; see XIV.2.7.12). This argument can be used to show that a true interval cannot be a null set, but this can be otherwise proved; see XIV.2.7.12. Thus the complement of a null set is dense.

(iii) There are uncountable sets which have measure zero, e.g. the Cantor set $K()$. In fact, $K$ has zero content.

In testing whether a set is a null set or has zero content, it suffices to use open intervals:

XIV.2.7.4. **Proposition.** Let $A$ be a subset of $\mathbb{R}$. Then $A$ is a null set if and only if there is a sequence $(J_k)$ of bounded open intervals with $A \subseteq \bigcup_{k=1}^\infty J_k$ and $\sum_{k=1}^\infty \ell(J_k) < \epsilon$. $A$ has zero content if and only if for every $\epsilon > 0$ there is a finite sequence $(J_k)$ of bounded open intervals with the same properties.

**Proof:** Suppose $A$ has measure zero, and $\epsilon > 0$. There is a sequence $(I_k)$ of bounded intervals such that $A \subseteq \bigcup_{k=1}^\infty I_k$ and $\sum_{k=1}^\infty \ell(I_k) < \epsilon$. For each $k$ let $J_k$ be the open interval with the same midpoint as $I_k$ with $\ell(J_k) = 2\ell(I_k)$; then $I_k \subseteq J_k$, and the $J_k$ work. The same argument works for finitely many intervals in the zero content case. The converse implication is trivial.

The converse implication is trivial.

XIV.2.7.5. **Corollary.** A subset $A$ has zero content if and only if it is bounded and its closure has measure zero. In particular, a closed bounded null set has zero content.

**Proof:** Suppose $A$ has zero content. Then $A$ is bounded. Let $\epsilon > 0$, and let $\{I_1, \ldots, I_n\}$ be a finite set of bounded intervals with $A \subseteq \bigcup_{k=1}^n I_k$ and $\sum_{k=1}^n \ell(I_k) < \epsilon$. Replacing each $I_k$ by its closure if necessary, we may assume each $I_k$ is closed. But then $\bigcup_{k=1}^n I_k$ is closed, so $A \subseteq \bigcup_{k=1}^n I_k$ and $A$ is a null set (in fact, has zero content).

Conversely, suppose $A$ is bounded and $\bar{A}$ is a null set. Fix $\epsilon > 0$, and let $(I_k)$ be a sequence of bounded open intervals such that $A \subseteq \bigcup_{k=1}^\infty I_k$ and $\sum_{k=1}^\infty \ell(I_k) < \epsilon$. The $I_k$ cover $A$, and since $A$ is compact there is a finite subcover, i.e. $A \subseteq \bigcup_{k=1}^n I_k$ for some $n$. Since $\sum_{k=1}^n \ell(I_k) < \epsilon$, it follows that $\bar{A}$, and hence $A$, has zero content.
Unions of Null Sets

A finite union of null sets is a null set, and a finite union of sets of zero content has zero content. For null sets, we have a better result:

**XIV.2.7.6. Proposition.** A countable union of null sets is a null set.

**Proof:** Let \( A_n \) be a null set for each \( n \), and \( A = \bigcup_{n=1}^{\infty} A_n \). Fix \( \epsilon > 0 \). For each \( n \), let \( \{I_{n,k}\} \) be a sequence of bounded intervals such that \( A_n \subseteq \bigcup_{k=1}^{\infty} I_{n,k} \) and \( \sum_{k=1}^{\infty} \ell(I_{n,k}) < \frac{\epsilon}{2^n} \). Then the set \( \{I_{n,k} : n, k \in \mathbb{N}\} \) is a countable set of bounded intervals with \( A \subseteq \bigcup_{n,k} I_{n,k} \) and \( \sum_{n,k} \ell(I_{n,k}) < \epsilon \). Since \( \epsilon > 0 \) is arbitrary, \( A \) is a null set.

**XIV.2.7.7.** This result gives another proof that every countable set is a null set, since it is a countable union of singletons.

It is not true that countable unions of sets of zero content have zero content (e.g. \( \mathbb{Q} \)). Closure of the null sets under countable unions indicates that the notion of null set is a more flexible one than that of a set of zero content. Good behavior under countable unions turns out to be necessary for a good theory of measure and advanced integration.

Almost Everywhere

**XIV.2.7.8.** It is convenient to use the phrase *almost everywhere*, abbreviated a.e., to mean “except on a null set.” Thus, for example, if we say “the functions \( f \) and \( g \) agree almost everywhere,” we mean “the set of all \( x \) for which \( f(x) = g(x) \) does not hold (i.e. one or both of \( f(x) \) and \( g(x) \) is undefined, or both are defined but unequal) has measure zero.”

Nonnegative Riemann-Integrable Functions

Using the language of null sets and almost everywhere, we can give an important fact about nonnegative Riemann-integrable functions:

**XIV.2.7.9. Proposition.** Let \( f \) be a nonnegative function on an interval \([a, b]\). If \( f \) is Riemann-integrable on \([a, b]\) and \( \int_{a}^{b} f(x) \, dx = 0 \), then \( f = 0 \) a.e. on \([a, b]\).

**Proof:** For each \( n \), let

\[
A_n = \left\{ x \in [a, b] : f(x) \geq \frac{1}{n} \right\}.
\]

We will show that each \( A_n \) has zero content, hence is a null set. This will suffice, since then

\[
\{ x \in [a, b] : f(x) \neq 0 \} = \bigcup_{n=1}^{\infty} A_n
\]

will be a null set by XIV.2.7.6.
Fix $n$, and then fix $\epsilon > 0$. Let $\mathcal{P} = \{x_0, \ldots, x_m\}$ be a partition with $\mathcal{S}(f, \mathcal{P}) < \frac{\epsilon}{n}$. Let $K$ be the set of all $k$ such that $A_n \cap [x_{k-1}, x_k]$ is nonempty. Then $A_n \subseteq \bigcup_{k \in K} [x_{k-1}, x_k]$. If $M_k$ is the supremum of $f$ on $[x_{k-1}, x_k]$, we have

$$
\frac{1}{n} \sum_{k \in K} (x_k - x_{k-1}) \leq \sum_{k \in K} M_k (x_k - x_{k-1}) \leq \sum_{k = 1}^m M_k (x_k - x_{k-1}) = \mathcal{S}(f, \mathcal{P}) < \frac{\epsilon}{n}
$$

and so $\sum_{k \in K} (x_k - x_{k-1}) < \epsilon$. Since $\epsilon > 0$ is arbitrary, $A_n$ has zero content.

**XIV.2.7.10.** XIV.2.6.6. gives a strong converse: if $f$ is Riemann-integrable on $[a, b]$ and equal to zero on a dense subset, then $\int_a^b f(x) \, dx = 0$.

One direction of the next proposition is a corollary of the proof of XIV.2.7.9.:

**XIV.2.7.11.** **Proposition.** Let $A$ be a subset of $[a, b]$. Then $A$ has zero content if and only if the indicator function $\chi_A$ is Riemann-integrable on $[a, b]$ and $\int_a^b \chi_A(x) \, dx = 0$.

**XIV.2.7.12.** **Corollary.** No interval is a null set.

**Proof:** First let $[a, b]$ be a closed bounded interval (with $a < b$). If $[a, b]$ is a null set, it has zero content by XIV.2.7.5.. But $\int_a^b \chi_{[a,b]}(x) \, dx = b - a > 0$, so $[a, b]$ does not have zero content by XIV.2.7.11.. Now let $I$ be an arbitrary interval, and let $a, b \in I$, $a < b$. If $I$ is a null set, then its subset $[a, b]$ is also a null set, a contradiction.

Almost the same result as XIV.2.6.9. holds if “finite set” is replaced by “set of zero content,” but boundedness of the modified function is not automatic and must be assumed:

**XIV.2.7.13.** **Proposition.** Let $f$ be a function defined on $[a, b]$ except on a set of zero content. If $f$ is Riemann-integrable, then any bounded function $g$ defined except on a set of zero content and agreeing with $f$ except on a set of zero content is also Riemann-integrable, with

$$
\int_a^b g(x) \, dx = \int_a^b f(x) \, dx.
$$

**Proof:** Let $h$ be a Riemann-integrable function on $[a, b]$ agreeing with $f$ where $f$ is defined. Extend $g$ in any manner to a bounded function defined everywhere on $[a, b]$: we will from now on assume $g$ is defined everywhere.

Let $A$ be a set of zero content such that $f$ and $g$ are defined and equal on $[a, b] \setminus A$, and let $M > 0$ be a bound for both $g$ and $h$ on $[a, b]$. Fix $\epsilon > 0$. Let $\{I_1, \ldots, I_n\}$ be a set of bounded intervals with $A \subseteq \bigcup_{k=1}^n I_k$.
and $\sum_{k=1}^{n} \ell(I_k) < \frac{\epsilon}{4M}$. Let $P$ be a partition of $[a, b]$ such that $\overline{S}_n(h, P) - \underline{S}_n(h, P) < \frac{\epsilon}{4}$ and such that $P$ includes all endpoints of $I_1, \ldots, I_n$ which are in $[a, b]$. Let $M_j$ and $m_j$ be the supremum and infimum of $g$ on $(x_{j-1}, x_j)$.

Let $J$ be the set of all indices $j$ such that $(x_{j-1}, x_j) \subseteq \bigcup_{k=1}^{n} I_k$. Then

$$\overline{S}_n(g, P) - \underline{S}_n(g, P) = \sum_{j=1}^{m} (M_j - m_j)(x_j - x_{j-1})$$

$$= \sum_{j \in J} (M_j - m_j)(x_j - x_{j-1}) + \sum_{j \notin J} (M_j - m_j)(x_j - x_{j-1}) < 2M \frac{\epsilon}{4M} + \frac{\epsilon}{2} = \epsilon.$$ 

Since $\epsilon > 0$ is arbitrary, $g$ is Riemann-integrable on $[a, b]$ by Definition 2A'', and

$$\int_a^b g(x) \, dx = \int_a^b h(x) \, dx.$$ 

\

**XIV.2.8. The Upper and Lower Envelope of a Riemann-Integrable Function**

We continue somewhat in the spirit of XIV.2.3.11., in a sense carrying it to its logical conclusion.

**XIV.2.8.1. Definition.** Let $f$ be a bounded function on an interval $[a, b]$. Define

$$\overline{f} = \sup \{ \phi : [a, b] \to \mathbb{R} : \phi \text{ lower semicontinuous, } \phi \leq f \}$$

$$\underline{f} = \inf \{ \psi : [a, b] \to \mathbb{R} : \psi \text{ upper semicontinuous, } f \leq \psi \}.$$ 

The functions $\overline{f}$ and $\underline{f}$ are called the upper and lower envelopes of $f$ on $[a, b]$.

We have that $\overline{f}$ and $\underline{f}$ are bounded, and $\underline{f} \leq f \leq \overline{f}$. By (4), $\overline{f}$ is upper semicontinuous and $\underline{f}$ is lower semicontinuous.

**XIV.2.8.2. Proposition.** Let $f$ be a bounded function on $[a, b]$, and $\overline{f}$ and $\underline{f}$ its upper and lower envelopes. If $J$ is any open subinterval of $[a, b]$, then

$$\sup_{x \in J} \overline{f}(x) = \sup_{x \in J} f(x) \quad \text{and} \quad \inf_{x \in J} \underline{f}(x) = \inf_{x \in J} f(x).$$ 

**Proof:** It is clear that $\sup_{x \in J} \overline{f}(x) \geq \sup_{x \in J} f(x)$. Conversely, let $M = \sup_{x \in J} f(x)$. Then there is an upper semicontinuous step function $\psi$ on $[a, b]$, which is constant on $J$ and two other subintervals of $[a, b]$, with $\psi = M$ on $J$ and $f \leq \psi$. Thus

$$\sup_{x \in J} \overline{f}(x) \leq \sup_{x \in J} \psi(x) = M = \sup_{x \in J} f(x).$$ 

The argument for $\underline{f}$ is nearly identical.
**XIV.2.8.3.** COROLLARY. Let $f$ be a bounded function on $[a, b]$, and $ar{f}$ and $\underline{f}$ its upper and lower envelopes. For each $x \in [a, b]$, we have

$$\bar{f}(x) = \max\{f(x), \limsup_{y \to x} f(y)\} \quad \text{and} \quad \underline{f}(x) = \min\{f(x), \liminf_{y \to x} f(y)\} .$$

**XIV.2.8.4.** COROLLARY. Let $f$ be a bounded function on $[a, b]$, and $ar{f}$ and $\underline{f}$ its upper and lower envelopes. If $\mathcal{P}$ is any partition of $[a, b]$, then

$$\mathfrak{S}_o(\bar{f}, \mathcal{P}) = \mathfrak{S}_o(f, \mathcal{P}) \quad \text{and} \quad \mathfrak{S}_\delta(f, \mathcal{P}) = \mathfrak{S}_\delta(f, \mathcal{P}) .$$

Thus we have

$$\int_a^b \bar{f}(x) \, dx = \int_a^b f(x) \, dx \quad \text{and} \quad \int_a^b \underline{f}(x) \, dx = \int_a^b f(x) \, dx .$$

Using these results, we can prove the fundamental characterization of Riemann integrability:

**XIV.2.8.5.** THEOREM. Let $f$ be a function on an interval $[a, b]$. Then $f$ is Riemann-integrable on $[a, b]$ if and only if it is bounded, and continuous almost everywhere.

PROOF: We have already shown that a Riemann-integrable function must be bounded. Suppose $f$ is Riemann-integrable on $[a, b]$. Let $\bar{f}$ and $\underline{f}$ be its upper and lower envelopes, and set $g = \bar{f} - \underline{f}$. Then $g \geq 0$. Fix $\epsilon > 0$, and choose a partition $\mathcal{P}$ such that $\mathfrak{S}_o(f, \mathcal{P}) - \mathfrak{S}_\delta(f, \mathcal{P}) < \epsilon$. Then we have

$$\mathfrak{S}_o(g, \mathcal{P}) = \mathfrak{S}_o(\bar{f}, \mathcal{P}) - \mathfrak{S}_\delta(f, \mathcal{P}) = \mathfrak{S}_o(f, \mathcal{P}) - \mathfrak{S}_\delta(f, \mathcal{P}) < \epsilon$$

and, since $g$ is nonnegative and hence $0 \leq \mathfrak{S}_o(g, \mathcal{P}) \leq \mathfrak{S}_o(g, \mathcal{P}) < \epsilon$, we have that $g$ is Riemann-integrable on $[a, b]$ and $\int_a^b g(x) \, dx = 0$. Thus $g = 0$ a.e. (XIV.2.7.9.), i.e. $f = \bar{f} = \underline{f}$ a.e. If $x$ is such that $\bar{f}(x) = f(x) = \underline{f}(x)$, then $f$ is both upper semicontinuous and lower semicontinuous at $x$, hence continuous at $x$. (The conclusion also follows immediately from XIV.2.8.3.)

Conversely, suppose $f$ is bounded and continuous a.e. on $[a, b]$. Let $M > 0$ be a bound for $f$ on $[a, b]$, and $A$ the set of discontinuities of $f$ in $[a, b]$. Fix $\epsilon > 0$. Let $(I_k)$ be a sequence of open intervals with $A \subseteq \bigcup_{k=1}^{\infty} I_k$ and $\sum_{k=1}^{\infty} \ell(I_k) < \frac{\epsilon}{4M}$. For each $x \in [a, b] \setminus A$ there is an open interval $J_x$ around $x$ with $|f(y) - f(z)| < \frac{\epsilon}{2(b-a)}$ for all $y, z \in J_x$, since $f$ is continuous at $x$. The collection $\{I_k : k \in N\} \cup \{J_x : x \in [a, b] \setminus A\}$ is an open cover of $[a, b]$. By compactness, there is a finite subcover, so there is a partition $\mathcal{P} = \{x_0, \ldots, x_n\}$ of $[a, b]$ such that each interval $[x_{j-1}, x_j]$ is contained either in one of the $I_k$ or one of the $J_x$. Let $K$ be the set of $j$ such that $[x_{j-1}, x_j]$ is contained in one of the $I_k$. Then, if $M_j$ and $m_j$ are the supremum and infimum of $f$ on $[x_{j-1}, x_j]$, we have

$$\mathfrak{S}(f, \mathcal{P}) - \mathfrak{S}(f, \mathcal{P}) = \sum_{j=1}^{n} (M_j - m_j)(x_j - x_{j-1})$$

$$= \sum_{j \in K} (M_j - m_j)(x_j - x_{j-1}) + \sum_{j \notin K} (M_j - m_j)(x_j - x_{j-1}) < 2M \frac{\epsilon}{4M} + \frac{\epsilon}{2(b-a)}(b-a) = \epsilon .$$

Since $\epsilon > 0$ is arbitrary, $f$ is Riemann-integrable on $[a, b]$. \(\blacksquare\)
XIV.2.9. Differentiation and the Fundamental Theorem of Calculus

In this section, we establish the fundamental results that integration and differentiation are inverse processes.

XIV.2.9.1. Let \( f \) be a Riemann-integrable function on \([a, b]\). Then, for any \( x \in [a, b] \), \( f \) is Riemann-integrable on \([a, x]\) . For \( a \leq x \leq b \), define

\[
A(x) = \int_a^x f(t) \, dt .
\]

\( A(x) \) is called the cumulative area of \( f \) from \( a \) to \( x \); this can be regarded as a function \( A \) from \([a, b]\) to \( \mathbb{R} \), called the cumulative area function of \( f \) from \( a \) to \( b \). (If \( f \) is nonnegative, \( A(x) \) can be truly regarded as the “area” of the region below the graph of \( f \) and above the \( x \)-axis, between the vertical lines at \( a \) and \( x \). Rigorously, this is backward: the area of this region can be defined to be this integral – see (). For a general \( f \), \( A(x) \) gives the “signed area” under the graph from \( a \) to \( x \), with regions below the \( x \)-axis having negative “area.”)

XIV.2.9.2. Proposition. If \( f \) is a Riemann-integrable function on \([a, b]\), then its cumulative area function is Lipschitz () on \([a, b]\), and hence (uniformly) continuous on \([a, b]\).

Proof: Since \( f \) is Riemann-integrable on \([a, b]\), it is bounded; let \( M \) be a bound for \( |f| \) on \([a, b]\). Then, for every \( x, y \in [a, b] \), \( x < y \), we have

\[
|A(y) - A(x)| = \left| \int_a^y f(t) \, dt - \int_a^x f(t) \, dt \right| = \left| \int_x^y f(t) \, dt \right| \leq \int_x^y |f(t)| \, dt \leq M(y - x)
\]

by () .

The next theorem is the main result of this section and, as the name suggests, one of the most important theorems in elementary analysis:

XIV.2.9.3. Theorem. [Fundamental Theorem of Calculus, Version 1] Let \( f \) be Riemann-integrable on \([a, b]\), and \( A \) its cumulative area function. If \( f \) is continuous at \( x_0 \in [a, b] \), then \( A \) is differentiable at \( x_0 \) and \( A'(x_0) = f(x_0) \).

Before giving the proof of this theorem, we give some simple consequences. The first is the same as V.8.5.9.:

XIV.2.9.4. Corollary. If \( f \) is continuous on \([a, b]\), then there is a function \( F \), unique up to addition of a constant, which is differentiable on \([a, b]\) and for which \( F''(x) = f(x) \) for all \( x \in [a, b] \).

The uniqueness of the antiderivative up to a constant follows immediately from V.8.2.5.:

The next variation gives the common procedure for calculating the value of the integral:
XIV.2.9.5. **Corollary.** If \( f \) is continuous on \([a, b]\), and \( F \) is any antiderivative for \( f \) on \([a, b]\), then
\[
\int_a^b f(x) \, dx = F(b) - F(a) .
\]

**Proof:** Let \( A \) be the cumulative area function of \( f \). Then we have that \( A \) is an antiderivative for \( f \) by XIV.2.9.3., and that
\[
\int_a^b f(x) \, dx = A(b) - A(a) = \int_a^b f(x) \, dx .
\]
and \( A(a) = 0 \). Also, by XIV.2.9.4., there is a constant \( C \) such that \( F(x) = A(x) + C \) for all \( x \in [a, b] \). We then have
\[
F(b) - F(a) = [A(b) + C] - [A(a) + C] = A(b) - A(a) = \int_a^b f(x) \, dx .
\]

XIV.2.9.6. Extensive and detailed applications of this version of the Fundamental Theorem of Calculus to evaluating definite integrals can be found in any Calculus text. Since this is not a Calculus text, we omit discussion of these applications.

XIV.2.9.7. We now give the proof of XIV.2.9.3.

**Proof:** We have, for \( x \in [a, b] \), \( x \neq x_0 \),
\[
A(x) - A(x_0) = \int_a^x f(t) \, dt - \int_a^{x_0} f(t) \, dt = \int_{x_0}^x f(t) \, dt .
\]
We also have
\[
f(x_0) = \frac{1}{x-x_0} \int_{x_0}^x f(x_0) \, dt \]
(since \( f(x_0) \) is just a constant), and so
\[
\frac{A(x) - A(x_0)}{x-x_0} - f(x_0) = \frac{1}{x-x_0} \int_{x_0}^x [f(t) - f(x_0)] \, dt .
\]
Let \( \epsilon > 0 \). Since \( f \) is continuous at \( x_0 \), there is a \( \delta > 0 \) such that, whenever \( x \in [a, b] \) and \( |x-x_0| < \delta \), \( |f(x) - f(x_0)| < \epsilon \). If \( x \in [a, b] \) and \( |x-x_0| < \delta \), then \( |t-x_0| < \delta \) for all \( t \) between \( x_0 \) and \( x \), and hence
\[
\left| \int_{x_0}^x [f(t) - f(x_0)] \, dt \right| < \epsilon |x-x_0|
\]
by (1); so we have
\[
\left| \frac{A(x) - A(x_0)}{x-x_0} - f(x_0) \right| = \frac{1}{|x-x_0|} \left| \int_{x_0}^x [f(t) - f(x_0)] \, dt \right| < \epsilon
\]
1524
and therefore

\[ A'(x_0) = \lim_{x \to x_0} \frac{A(x) - A(x_0)}{x - x_0} = f(x_0) \, . \]

\(\blacksquare\)

**XIV.2.9.8. Examples.** If \( f \) is Riemann-integrable on \([a, b]\), \( A \) is its cumulative area function, and \( f \) is not continuous at \( x_0 \in [a, b] \), then \( A \) may or may not be differentiable at \( x_0 \), and if it is we may or may not have \( A'(x_0) = f(x_0) \):

(i) Let \( f(x) = 0 \) for \( x < 0 \) and \( f(x) = 1 \) for \( x \geq 0 \). Then \( f \) is Riemann-integrable on \([-1, 1]\), and its cumulative area function \( A \) is given by \( A(x) = 0 \) if \(-1 \leq x \leq 0\) and \( A(x) = x \) if \( 0 \leq x \leq 1 \). \( A \) is not differentiable at 0.

(ii) Let \( f(x) = 0 \) for \( x \neq 0 \) and \( f(0) = 1 \). Then \( f \) is Riemann-integrable on \([-1, 1]\), and \( A \) is identically 0. We have that \( A \) is differentiable at 0, but \( A'(0) \neq f(0) \).

(iii) [vRS82, p. 3-4] Let \( f(x) = \sin \left( \frac{1}{x} \right) \) for \( x \neq 0 \) and \( f(0) = 0 \). Then \( f \) is bounded, and continuous except at 0, so \( f \) is Riemann-integrable on \([-1, 1]\) (or any other closed bounded interval). If \( A \) is its cumulative area function, we will show that \( A \) is differentiable at 0 and \( A'(0) = 0 = f(0) \) even though \( f \) is discontinuous at 0. This can be shown directly by brute force, but we can get it more easily indirectly.

We first show that \( f \) has an antiderivative \( F \). Let

\[ G(x) = \begin{cases} x^2 \cos \left( \frac{1}{x} \right) & \text{if } x \neq 0 \\ 0 & \text{if } x = 0 \end{cases} \, . \]

Then \( G \) is differentiable everywhere, and

\[ G'(x) = g(x) = \begin{cases} 2x \cos \left( \frac{1}{x} \right) + \sin \left( \frac{1}{x} \right) & \text{if } x \neq 0 \\ 0 & \text{if } x = 0 \end{cases} = h(x) + f(x) \, , \]

where

\[ h(x) = \begin{cases} 2x \cos \left( \frac{1}{x} \right) & \text{if } x \neq 0 \\ 0 & \text{if } x = 0 \end{cases} \, . \]

Since \( h \) is continuous, it has an antiderivative \( H \) (XIV.2.9.4.). Then \( f = g - h \) also has an antiderivative \( F = G - H \).

We then have that \( A - F \) is continuous everywhere, differentiable everywhere except possibly at 0, and \( (A - F)'(x) = 0 \) for all \( x \neq 0 \). Thus by V.8.4.1.(iii) \( A - F \) is constant, hence differentiable also at 0; so \( A \) is differentiable at 0 and \( A'(0) = F'(0) = 0 = f(0) \).

More dramatic versions of this example exist: see Exercise V.12.3.3.. For a related example, if \( f \) is a Lebesgue integrable function on \([a, b]\) and \( A \) is its cumulative area function (i.e. \( A(x) \) is the Lebesgue integral of \( f \) from \( a \) to \( x \)), then \( A \) is continuous, differentiable almost everywhere, and \( A' = f \) almost everywhere (). Such an \( f \) need not be continuous anywhere and need not be equal almost everywhere to a function which is Riemann integrable on any subinterval ()

**XIV.2.9.9.** Version XIV.2.9.3. of the Fundamental Theorem of Calculus roughly says that the derivative of the integral is the original function. What about the integral of the derivative? One problem is that the derivative of a differentiable function on an interval need not be Riemann-integrable:
XIV.2.9.10. **Examples.** (i) Let \( F \) be the function
\[
F(x) = \begin{cases} 
  x^2 \sin\left(\frac{1}{x^2}\right) & \text{if } x \neq 0 \\
  0 & \text{if } x = 0
\end{cases}.
\]
Then \( F \) is differentiable everywhere, and
\[
F'(x) = f(x) = \begin{cases} 
  2x \sin\left(\frac{1}{x^2}\right) - \frac{2}{x} \cos\left(\frac{1}{x^2}\right) & \text{if } x \neq 0 \\
  0 & \text{if } x = 0
\end{cases}
\]
which is unbounded near 0 and hence not Riemann-integrable in any interval containing 0 (in fact, it is not even Lebesgue integrable in any interval containing 0).

(ii) Let \( F \) be the function of \((\)\). Then \( F \) is differentiable on \([0;1]\), and \( F' = f \) is bounded there. Since \( f \) is 0 on a dense subset of \([0,1]\), the Riemann integral of \( f \) on any subinterval, if it existed, would have to be 0 (XIV.2.6.6.). Since \( F \) is not constant on any subinterval, it follows from XIV.2.9.11. below that \( f \) is not Riemann-integrable on any subinterval. It even turns out that \( f \) is not equal almost everywhere to a Riemann-integrable function \((.)\).

We do, however, have the following theorem, which extends XIV.2.9.5.:  

**XIV.2.9.11. Theorem.** [**Fundamental Theorem of Calculus, Version 2**] Let \( F \) be a function which is continuous on \([a;b]\) and differentiable except possibly at finitely many points, with derivative \( f \). If \( f \) is Riemann-integrable on \([a;b]\), then for all \( x \in [a,b] \) we have
\[
F(x) = F(a) + \int_a^x f(t) \, dt
\]
and so, in particular,
\[
\int_a^b f(t) \, dt = F(b) - F(a) .
\]

**Proof:** It suffices to prove the second statement; the first statement then results from applying the second to the interval \([a,x]\).

Let \( \epsilon > 0 \), and let \( \mathcal{P} = \{a = x_0, x_1, \ldots, x_n = b\} \) be a partition satisfying Definition 1A for this \( \epsilon \), and fine enough that \( \mathcal{P} \) contains all points where \( F \) is not differentiable (such a partition exists by Definition 1B). By the Mean Value Theorem (.), for each \( k \) choose \( t_k \in (x_{k-1},x_k) \) so that
\[
F(x_k) - F(x_{k-1}) = f(t_k)(x_k - x_{k-1}) .
\]
Then, by telescoping, we have
\[
F(b) - F(a) = \sum_{k=1}^n (F(x_k) - F(x_{k-1})) = \sum_{k=1}^n f(t_k)(x_k - x_{k-1})
\]
and so, since the right side is a Riemann sum for \( f \) with respect to \( P \), we have

\[
\left| (F(b) - F(a)) - \int_a^b f(t) \, dt \right| < \epsilon.
\]

Since \( \epsilon > 0 \) is arbitrary, the result follows.

This result generalizes to the case in which \( f \) is only required to be Lebesgue integrable ().

The hypothesis can be relaxed to allow \( F \) to be nondifferentiable at countably many points (if it is continuous ()), but not just differentiable almost everywhere ().

More general versions of the Fundamental Theorem of Calculus will be discussed in (), (), ...

The Average Value of a Function

XIV.2.9.12. Definition. Let \( f \) be Riemann-integrable on \( J = [a;b] \). Then the average value of \( f \) on \( J \) is

\[
\text{av}(f, J) = \frac{1}{b-a} \int_a^b f(x) \, dx.
\]

(Note that this definition also makes sense if \( b < a \), and gives the same value if \( a \) and \( b \) are interchanged.)

It is not hard to motivate this definition as a reasonable version of the average value of a function on an interval, e.g. by considering Riemann sums corresponding to a subdivision of the interval into a large number of subintervals of equal length. One interpretation which is reasonable motivation is that \( \text{av}(f, J) \) is the value of a constant function on \( J \) which has the same integral over \( J \) as \( f \).

XIV.2.9.13. Using this notion of average value, we have an interesting relation between average and instantaneous rates of change. If \( f \) is differentiable on \( [a;b] \) and \( f' \) is Riemann integrable on \( [a;b] \), then by XIV.2.9.11. we have

\[
\frac{1}{b-a} \int_a^b f'(t) \, dt = \frac{f(b) - f(a)}{b-a}
\]

i.e. the average rate of change of \( f \) over \( [a;b] \) (the right-hand side) is equal to the average value of the instantaneous rate of change of \( f \) over \( [a;b] \) (the left-hand side). This can be thought of as a variant of the Mean Value Theorem: If \( f \) is differentiable on \( [a;b] \) and \( f' \) is Riemann integrable on \( [a,b] \), the difference quotient of \( f \) over \( [a,b] \) is the average value of \( f' \) over \( [a,b] \) (the MVT asserts it is the value of \( f' \) at some particular point of \( [a,b] \)).

We then have the following analog of the Mean Value Theorem (actually more than an analog, in light of XIV.2.9.3.).

XIV.2.9.14. Proposition. [Mean Value Theorem for Integrals] Let \( f \) be a continuous function on a closed bounded interval \( J = [a,b] \). Then there is at least one \( c \in (a,b) \) with \( f(c) = \text{av}(f, J) \).
Proof: Let \( m \) and \( M \) be the minimum and maximum of \( f \) on \([a,b]\). Then, if \( \mathcal{P} = \{a,b\} \) is the partition with one subinterval, we have \( \underline{S}(f,\mathcal{P}) = m(b-a) \) and \( \overline{S}(f,\mathcal{P}) = M(b-a) \), so we have

\[
m(b-a) \leq \int_a^b f(x) \, dx \leq M(b-a)
\]

so, dividing through by \( b-a \), we have

\[
m \leq av(f,J) \leq M.
\]

If \( m = M \), then \( f \) is constant on \([a,b]\), and we can take \( c \) to be any number in \((a,b)\). If \( m < M \), we have \( m < av(f,J) < M \) [if \( m = av(f,J) \), set \( g(x) = f(x) - m \); then \( g \geq 0 \) is continuous and \( \int_a^b g(x) \, dx = 0 \), so \( g \) is identically \( 0 \) (), a contradiction. A similar argument using \( h(x) = M - f(x) \) shows that we cannot have \( av(f,J) = M \).] Choose \( x_1, x_2 \in [a,b] \) with \( f(x_1) = m \), \( f(x_2) = M \). Then by the Intermediate Value Theorem () there is a \( c \) in the open interval between \( x_1 \) and \( x_2 \) with \( f(c) = av(f,J) \).

Note that this result can fail if \( f \) is not continuous, e.g. if \( f \) is a step function taking only the values 0 and 1.

Derivatives and Limits

We can use the FTC plus properties of the Riemann integral to give a simpler proof of a crucial special case of V.8.5.5:

XIV.2.9.15. Theorem. Let \((F_n)\) and \((f_n)\) be sequences of functions on an interval \(I\). Suppose

(a) Each \( f_n \) is continuous on \( I \).

(b) Each \( F_n \) is differentiable on \( I \), with \( F_n' = f_n \).

(c) The sequence \((f_n)\) converges u.c. on \( I \) to a function \( f \).

(d) There is an \( x_0 \in I \) such that the sequence \((F_n(x_0))\) converges.

Then:

(i) The sequence \((F_n)\) converges u.c. on \( I \) to a function \( F \).

(ii) \( F \) is differentiable on \( I \) and \( F' = f \).

Proof: Set \( L = \lim_{n \to \infty} F_n(x_0) \). By the FTC2, we have, for each \( n \) and each \( x \in I \),

\[
F_n(x) = F_n(x_0) + \int_{x_0}^x f_n(t) \, dt .
\]

For each fixed \( x \in I \), since \( f_n \to f \) uniformly on the interval between \( x_0 \) and \( x \),

\[
F_n(x) = F_n(x_0) + \int_{x_0}^x f_n(t) \, dt \to L + \int_{x_0}^x f(t) \, dt.
\]
by XIV.2.6.5.; so, if we define, for $x \in I$,

$$F(x) = L + \int_{x_0}^{x} f(t) \, dt$$

we have by the FTC1 that $F$ is differentiable on $I$ and $F' = f$; and $F_n \to F$ pointwise on $I$. It remains to show that $F_n \to F$ u.c. on $I$. Let $[a, b]$ be a closed bounded subinterval of $I$ containing $x_0$. Fix $\epsilon > 0$, and choose $N$ so that $|f_n(x) - f(x)| < \frac{\epsilon}{2(b-a)}$ for all $n \geq N$ and all $x \in [a, b]$, and $|F_n(x_0) - L| < \frac{\epsilon}{2}$ for all $n \geq N$. Then, for $n \geq N$ and $x \in [a, b]$,

$$|F_n(x) - F(x)| \leq |F_n(x_0) - L| + \left| \int_{x_0}^{x} [f_n(t) - f(t)] \, dt \right| \leq |F_n(x_0) - L| + \int_{x_0}^{x} |f_n(t) - f(t)| \, dt$$

$$< \frac{\epsilon}{2} + \frac{\epsilon}{2(b-a)} |x - x_0| \leq \epsilon.$$  

\[ \diamond \]

XIV.2.10. Integration by Substitution and Integration by Parts
XIV.2.11. Improper Riemann Integration

The fact that unbounded functions cannot be Riemann integrable is partially compensated by the various forms of improper Riemann integration.

XIV.2.11.1. Definition. If $f$ is a real-valued function defined on $(a, b]$, and Riemann integrable on $[a + \epsilon, b]$ for every $\epsilon > 0$, then $f$ is improperly Riemann integrable from $a$ to $b$ if

$$\lim_{\epsilon \to 0^+} \left[ \int_{a+\epsilon}^{b} f(x) \, dx \right]$$

exists (in the usual sense, as a real number). We then define the improper Riemann integral to be

$$\int_{a}^{b} f(x) \, dx = \lim_{\epsilon \to 0^+} \left[ \int_{a+\epsilon}^{b} f(x) \, dx \right].$$

If $f$ is nonnegative on $(a, b]$, then

$$\lim_{\epsilon \to 0^+} \left[ \int_{a+\epsilon}^{b} f(x) \, dx \right] = \sup_{\epsilon > 0} \left[ \int_{a+\epsilon}^{b} f(x) \, dx \right]$$

always exists (in the regular or extended sense), and in this case, we define

$$\int_{a}^{b} f(x) \, dx = \lim_{\epsilon \to 0^+} \left[ \int_{a+\epsilon}^{b} f(x) \, dx \right].$$

A nonnegative function is then improperly Riemann integrable from $a$ to $b$ if $\int_{a}^{b} f(x) \, dx < \infty$. 

1530
XIV.2.12. Numerical Integration and Simpson’s Rule

Usually the best way to compute the exact value of a Riemann integral is via the Fundamental Theorem of Calculus. But sometimes integrals are encountered where this approach is not possible or feasible, and to calculate the integral we need to return to the definition and compute the integral directly as a limit.

We know in theory that if a function is Riemann integrable on an interval, then the Riemann sums for the integral converge to the exact integral as the partitions become sufficiently fine. But how can we choose a Riemann sum, or similar sum, which gives the integral to within a specified accuracy, and how do we know how accurate an approximation we get from a given sum? Numerical integration theory is the study of these problems.

Numerical methods for integration are essentially based on Riemann integration, and do not work satisfactorily unless the function being integrated is well-behaved (piecewise-continuous at the least, and usually with some smoothness). Thus numerical integration is really a part of the theory of Riemann integration and not more advanced integration theories. Numerical integration is frequently used in situations where function values can only be calculated easily at certain points, and even then sometimes only to a certain accuracy, or to functions whose values are known only from data sets.

Numerical integration is an important part of the subject of numerical analysis, a part of mathematics (usually regarded as part of “applied mathematics”) which seeks to develop efficient ways to numerically calculate or approximate various important mathematical quantities, e.g. integrals, sums of infinite series, zeroes of functions, eigenvalues and eigenvectors, solutions to differential equations. Much of numerical analysis has a very different character than the type of analysis developed in this book, but the word analysis is appropriately used for this subject since (among other things) analytic techniques are used in determining the accuracy and efficiency of the numerical algorithms developed. We will only scratch the surface of numerical integration here; books such as [Hil87] or [IK94] have a far more thorough treatment.

Quadrature Procedures

XIV.2.12.1. Suppose we have a fixed interval, which we will for simplicity take to be a closed bounded interval \([a, b]\), and we want to have a fixed procedure for estimating integrals

\[
\int_{a}^{b} f(x) \, dx
\]

for continuous functions \(f\). The obvious procedure is to fix points \(x_0, \ldots, x_n\) in \([a, b]\) (which we will always take to be in increasing order). These will typically be a partition of \([a, b]\), but not necessarily, i.e. the endpoints need not be among the \(x_k\). We will then fix real constants \(\alpha_0, \ldots, \alpha_n\), usually positive (a nonnegative procedure, cf. XIV.2.12.4.). The procedure \(Q = Q(x_0, \ldots, x_n; \alpha_0, \ldots, \alpha_n)\) then gives the approximation

\[
\int_{a}^{b} f(x) \, dx \approx Q(f) = \sum_{k=0}^{n} \alpha_k f(x_k) .
\]

XIV.2.12.2. The first obvious property we should have is that the approximation should be exact for constant functions. This translates into the restriction

\[
\sum_{k=0}^{n} \alpha_k = b - a .
\]
XIV.2.12.3. Another more restrictive condition which is natural is that for any continuous $f$,

$$S(f, \mathcal{P}) \leq Q(f) \leq \mathcal{S}(f, \mathcal{P})$$

for some partition $\mathcal{P}$ of $[a,b]$, where $S(f, \mathcal{P})$ and $\mathcal{S}(f, \mathcal{P})$ are the lower and upper Darboux sums. A procedure satisfying this condition is called regular with respect to $\mathcal{P}$. If $Q$ is regular with respect to the partition of $[a,b]$ given by $x_0, \ldots, x_n$ and the endpoints of the interval if not included among the $x_k$, then $Q$ is called regular.

Some quadrature procedures considered in numerical analysis are regular, but many are not, although most are regular with respect to a coarser partition. The condition $\sum \alpha_k = b - a$ insures that all nonnegative procedures are regular with respect to the trivial partition, since any nonnegative procedure is monotone.

XIV.2.12.4. In numerical work, subtraction, or addition of numbers of different magnitudes, can lead to a serious loss of precision; thus the most useful quadrature procedures are ones where the $\alpha_n$ are all the same sign (positive) and approximately the same size, although these restrictions are not necessary in principle.

XIV.2.12.5. Definition. A quadrature procedure, or numerical integration procedure, on an interval $[a,b]$ is a choice of points $x_0, \ldots, x_n \in [a,b]$ and real numbers $\alpha_0, \ldots, \alpha_n$ with $\sum_{k=0}^n \alpha_k = b - a$. For any real-valued function $f$, the application of the procedure $Q = Q(x_0, \ldots, x_n; \alpha_0, \ldots, \alpha_n)$ to $f$ is the sum

$$Q(f) = \sum_{k=0}^n \alpha_k f(x_k).$$

$Q(f)$ is called the approximation to the integral of $f$ over $[a,b]$ by the procedure $Q$.

Definite integration, especially numerical integration, is often called quadrature because of the standard interpretation of integrals as areas.

XIV.2.12.6. We could also consider more general quadrature procedures of the form

$$Q(f) = \sum_{k=0}^n \alpha_k f(x_k) + \sum_{k=0}^n \beta_k f'(x_k) + \sum_{k=0}^n \gamma_k f''(x_k) + \cdots$$

which are sometimes used in numerical analysis (cf. XIV.2.12.19., XIV.2.12.39., XIV.2.12.51.).

XIV.2.12.7. A procedure by this definition must be carefully distinguished from a numerical integration process or scheme, which is a sequence of quadrature procedures converging to the exact integral for all, or at least nicely behaved, functions. For example, the standard procedures like Simpson’s rule begin by partitioning the interval into $n$ subintervals in some specific way. There is thus one procedure for each fixed $n$, and they form a process as $n \to \infty$.

Note that any sequence $(Q_n)$ of quadrature procedures regular with respect to partitions $\mathcal{P}_n$ with $\|\mathcal{P}_n\| \to 0$ as $n \to \infty$ will converge to the exact integral for all continuous functions (in fact for all Riemann-integrable functions), i.e. will form a numerical integration process. However, for practical reasons the rate of convergence is a critical consideration in numerical analysis.
XIV.2.12.8. It is easily checked that any quadrature procedure $Q$ is linear, i.e.

$$Q(cf + g) = cQ(f) + Q(g)$$

for any functions $f, g$ and scalar $c$; a procedure with all $\alpha_k > 0$ is also monotone, i.e. $Q(f) \leq Q(g)$ if $f \leq g$.

XIV.2.12.9. Examples. (i) The simplest quadrature procedures are the left and right estimates for the Riemann integral $\int_a^b$: if $\{x_0, \ldots, x_n\}$ is a partition of $[a, b]$, set $\alpha_k = x_{k+1} - x_k$ for $0 \leq k < n$ and $\alpha_n = 0$. Then the estimate

$$\sum_{k=0}^{n} \alpha_k f(x_k)$$

is the left estimate $L_n$ for the integral of $f$. If we instead take $\alpha_0 = 0$ and $\alpha_k = x_k - x_{k-1}$ for $1 \leq k \leq n$, we get the right estimate $R_n$.

(ii) More generally, if $\{x_0, \ldots, x_n; t_1, \ldots, t_n\}$ is a tagged partition of $[a, b]$, set $\alpha_k = \Delta x_k = x_k - x_{k-1}$ for $1 \leq k \leq n$. Then $Q(t_1, \ldots, t_n; \alpha_1, \ldots, \alpha_n)$ gives the Riemann sum approximation to the integral for this tagged partition:

$$Q(f) = \sum_{k=1}^{n} f(t_k) \Delta x_k .$$

A numerically good procedure is to take the $x_k$ to be evenly spaced and $t_k$ the midpoint of the $k$'th interval. This procedure is called the *midpoint rule* with $n$ intervals, denoted $M_n$. Note that in this procedure the points where the function is evaluated do not form a partition of the interval, i.e. the endpoints are not included.

(iii) Here is a quadrature procedure which is not just a Riemann sum. We average the left and right estimates from (i), normally using $n$ subintervals of equal length $h = \frac{b-a}{n}$. In this case $\alpha_0 = \alpha_n = \frac{h}{2}$ and $\alpha_k = h$ for $1 \leq k \leq n - 1$.

This procedure is called the *trapezoid rule* with $n$ intervals, for the following reason. It is also obtained by approximating the function within each subinterval by a linear (affine) function, so that the integral is approximated by a sum of areas of trapezoids (Figure XIV.16, from http://tutorial.math.lamar.edu/Classes/CalcII/approximatingDefIntegrals.aspx). We call this procedure $T_n$.

An alternate formula for $T_n$ is

$$T_n(f) = \frac{h}{2} \left[ f(x_0) + 2f(x_1) + 2f(x_2) + \cdots + 2f(x_{n-1}) + f(x_n) \right]$$

where $h = \frac{b-a}{n}$ and $x_k = x_0 + kh$ for $0 \leq k \leq n$.

All these quadrature procedures are regular, as is easily verified.

Simpson’s Rule

XIV.2.12.10. If the graph of $f$ is concave up on $[a, b]$, it is clear that the trapezoid estimate is too large and the midpoint estimate is too small, for any fixed $n$, and vice versa if the graph of $f$ is concave down. Thus we would expect the errors to tend to have opposite sign. And experiments with calculable integrals suggest that the absolute error from the midpoint estimate for a given $n$ is typically about half the absolute
error of the trapezoid estimate for the same \( n \) – see XIV.2.12.44. for a precise statement along these lines. (Some unsophisticated references assert or suggest the absolute midpoint error is exactly half the absolute trapezoid error, but in fact it is rarely exactly half, and in some cases is not even approximately half; cf. Exercise XIV.3.11.5.)

**XIV.2.12.11.** These statements suggest that in many cases, twice the midpoint error should largely cancel with the trapezoid error; thus a weighted average of the two should often be much better than either. So we define

\[
S_{2n}(f) = \frac{2}{3}M_n(f) + \frac{1}{3}T_n(f)
\]

which is *Simpson’s rule* with \( 2n \) intervals.

To put Simpson’s rule into the standard form of a quadrature procedure and explain the use of the index \( 2n \), note that in evaluating \( M_n(f) \) and \( T_n(f) \), the function \( f \) must be evaluated at \( 2n + 1 \) points, the \( n + 1 \) points of the partition and the \( n \) midpoints. These points form a partition of the interval \([a, b]\) into \( 2n \) subintervals of equal length.

**XIV.2.12.12.** Changing notation slightly, if \( n \) is an even number and \( \{x_0, \ldots, x_n\} \) is a partition of \([a, b]\) into \( n \) subintervals of equal length \( h = \frac{b-a}{n} \), we have \( \alpha_0 = \alpha_n = \frac{h}{3} \), \( \alpha_k = \frac{2h}{3} \) for \( k \) even, \( 0 < k < n \), and
\[ \alpha_k = \frac{4h}{3} \text{ for } k \text{ odd. Thus} \]
\[ S_n(f) = \frac{h}{3} \left[ f(x_0) + 4f(x_1) + 2f(x_2) + 4f(x_3) + \cdots + 2f(x_{n-2}) + 4f(x_{n-1}) + f(x_n) \right] \]

where \( x_k = x_0 + kh \) for \( 0 \leq k \leq n \).

**XIV.2.12.13.** The Simpson’s rule approximation with \( 2n \) intervals is indeed typically (but not always!) *much* better than the trapezoid or midpoint approximations with \( n \) intervals. The function must, of course, be evaluated at about twice as many points. But \( S_{2n}(f) \) is typically even considerably more accurate than \( T_{2n}(f) \) or \( M_{2n}(f) \). See XIV.2.12.36.–XIV.2.12.52. for an error analysis.

Simpson’s rule \( S_{2n} \) is not a regular quadrature procedure, but it is regular with respect to the partition of \([a, b]\) into \( n \) equal subintervals; hence \( S_{2n}(f) \to \int_a^b f(x) \, dx \) as \( n \to \infty \) for any continuous \( f \) (even every Riemann-integrable \( f \)), as does \( T_n(f) \) and \( M_n(f) \).

**XIV.2.12.14.** There is a quite different way of motivating and arriving at Simpson’s rule; see XIV.2.12.24. and XIV.2.12.26.

**Is There a “Best” Quadrature Procedure?**

**XIV.2.12.15.** We would like to find and use the “best” quadrature procedure. However, it appears obvious that we run into a tradeoff between accuracy and complexity, since it stands to reason (and is “generally” correct) that procedures using more points would tend to be more accurate; thus we should not expect a universal procedure which is “best” in all respects.

But there is a more fundamental sense in which there is no “best” procedure. Given any two quadrature procedures \( Q_1 \) and \( Q_2 \), a continuous function \( f_1 \), even a polynomial, can be constructed such that \( Q_1(f_1) \) is a better approximation to the true integral of \( f_1 \) than \( Q_2(f_1) \), and another continuous function (polynomial) \( f_2 \) such that \( Q_1(f_2) \) is better than \( Q_2(f_2) \). So even beyond questions of complexity of computation there is no universally “best” quadrature procedure.

**XIV.2.12.16.** We will appear to argue that Simpson’s rule is generally the best rule to use for numerical integration, and within the shallow limits of our numerical analysis work here this statement is defensible for many typically encountered integrals, and Simpson’s rule is the most widely used quadrature procedure. However, the reader should be aware that it is much too simplistic to tout Simpson’s rule as the ultimate quadrature procedure; there are many others (e.g. Romberg integration, cf. XIV.2.13.7., or Clenshaw-Curtis Integration, cf. () which are better in certain circumstances. See XIV.2.12.61. for further comments.

**Simple and Composite Quadrature Procedures**

One fairly good measure of the accuracy of a quadrature procedure is how well it approximates the exact integral for polynomials of small order.

**XIV.2.12.17.** Definition. Let \( Q \) be a quadrature procedure on \([a, b] \). Then \( Q \) has *order of precision* \( m \) if
\[
Q(f) = \int_a^b f(x) \, dx
\]
(i.e. $Q$ is exactly correct) whenever $f$ is a polynomial of degree $\leq m$, but not for polynomials of degree $m + 1$.

The term order of precision is standard, but some references use order of exactness which seems more descriptive.

We have built into our definition that a quadrature procedure always has order of precision at least 0.

XIV.2.12.18. A quadrature procedure is simple if it has high order of precision for the number of nodes used. A composite quadrature procedure is one which consists of first dividing the interval $[a, b]$ into a number of smaller intervals and applying a simple quadrature procedure on each subinterval (the simple procedures used on the subintervals are usually, but not always, the same on all subintervals). The order of precision of a composite procedure is at least as great as (usually exactly equal to) the minimum of the order of precision of the simple procedures used on the subintervals. A composite procedure is always regular with respect to the partition into the subintervals on which the simple procedures are applied.

For reasons described in XIV.2.12.4., as well as considerations of efficiency, composite procedures using a simple procedure of lower order on each subinterval are often better in practice than simple procedures of higher order.

Simple quadrature procedures are almost always interpolatory or osculatory:

XIV.2.12.19. Definition. Let $x_0, \ldots, x_n$ be points of $[a, b]$. The interpolatory quadrature procedure on $[a, b]$ for the nodes $x_0, \ldots, x_n$ is the procedure $Q$ defined by

$$Q(f) = \int_a^b p_{0, \ldots, n}(x) \, dx$$

where $p_{0, \ldots, n}$ is the interpolating polynomial of $f$ on $[a, b]$ for these nodes (V.11.1.1.). It follows easily from the Lagrange or Newton form of the interpolating polynomial that an interpolatory quadrature procedure is indeed a quadrature procedure of the form of XIV.2.12.5.

This definition can be extended to the situation where the $x_0, \ldots, x_n$ are not necessarily distinct by using the osculating polynomial (V.11.6.4.): such a quadrature procedure is called osculatory. (An osculatory procedure is of the generalized form of XIV.2.12.6., and can only be used for functions which are sufficiently differentiable.)

XIV.2.12.20. It is immediate that an interpolatory or osculatory quadrature procedure using $n + 1$ nodes has order of precision at least $n$. (Conversely, a quadrature procedure using $n + 1$ nodes of order of precision at least $n$ must by interpolatory or osculatory; but cf. XIV.2.13.6.) If the nodes are well chosen, the order of precision can be greater than $n$ (XIV.2.12.30., XIV.2.12.46.).

XIV.2.12.21. There are thus two general strategies for developing simple quadrature procedures:

(1) First pick nodes $x_0, \ldots, x_n$ in a convenient way, e.g. evenly spaced, and use the interpolatory or osculatory procedure for these nodes.

(2) Fix $n$ and choose the $x_k$ carefully to maximize the order of precision of the corresponding interpolatory or osculatory procedure.
The Newton-Cotes Formulas

**XIV.2.12.22.** We first examine the procedure obtained by choosing a partition of \([a, b]\) into \(n\) subintervals of equal length \(h = \frac{b-a}{n}\), i.e. \(x_k = a + kh\) for \(0 \leq k \leq n\). The corresponding interpolatory procedure is called the Newton-Cotes procedure (or Newton-Cotes formula) of order \(n\), denoted \(NC_n\).

Since an explicit formula for the interpolating polynomial can be obtained, a formula for the procedure \(NC_n\) can be found by integrating this polynomial. The calculation is straightforward but tedious, and we carry it out only for \(n = 1\) and \(n = 2\).

**XIV.2.12.23.** First consider the case \(n = 1\), i.e. \(x_0 = a, x_1 = b\). The interpolating polynomial is

\[ p_{0,1}(x) = f(a) + \frac{f(b) - f(a)}{b-a}(x-a) \]

so we have

\[ NC_1(f) = \int_a^b \left[ f(a) + \frac{f(b) - f(a)}{b-a}(x-a) \right] \, dx \]

\[ = f(a)(b-a) + \frac{1}{2} \frac{f(b) - f(a)}{b-a}(b-a)^2 = \frac{1}{2} [f(a) + f(b)] \]

which is just the trapezoid rule for \(n = 1\), i.e. \(NC_1 = T_1\).

**XIV.2.12.24.** Now consider the case \(n = 2\), i.e. \(x_0 = a, x_1 = \frac{a+b}{2}, x_2 = b\). The interpolating polynomial is

\[ p_{0,1,2}(x) = f(a) + \frac{f(b) - f(a)}{b-a}(x-a) + \frac{f[b, x_1] - f[a, b]}{x_1 - a}(x-a)(x-b) \]

\[ = f(a) + \frac{f(b) - f(a)}{2h}(x-a) + \frac{1}{2h} \left[ \frac{f(b) - f(x_1)}{h} - \frac{f(b) - f(a)}{2h} \right] (x-a)(x-b) \]

\[ = f(a) + \frac{f(b) - f(a)}{2h}(x-a) + \frac{1}{4h^2} [f(b) - 2f(x_1) + f(a)] (x-a)(x-b) \]

so we have

\[ NC_2(f) = \int_a^b \left[ f(a) + \frac{f(b) - f(a)}{2h}(x-a) + \frac{1}{4h^2} [f(b) - 2f(x_1) + f(a)] (x-a)(x-b) \right] \, dx . \]

We have

\[ \int_a^b (x-a)(x-b) \, dx = -\frac{(2h)^3}{6} \]

by making the substitution \(x = a + th\); thus

\[ NC_2(f) = f(a)(2h) + \frac{f(b) - f(a)}{2h} \left( \frac{1}{2} (2h)^2 \right) - \frac{8h^3}{6} \frac{1}{4h^2} [f(b) - 2f(x_1) + f(a)] = \frac{h}{3} [f(a) + 4f(x_1) + f(b)] \]

which is exactly \(S_2(f)\) (XIV.2.12.12.), i.e. \(NC_2\) is exactly the simple Simpson’s rule for \(n = 2\): Simpson’s rule is obtained by approximating the graph of \(f\) by a parabola through the endpoints and midpoint, cf. Figure XIV.17, from http://en.wikipedia.org/wiki/Simpson%27s_rule. (In fact, this is how Simpson came up with the rule in the first place in 1743; the simple Simpson’s rule was previously essentially known to others, including Newton and Kepler, and was apparently first described by Cavalieri in 1639.)
XIV.2.12.25. We list without proof a few more of the Newton-Cotes formulas:

\[ NC_3(f) = \frac{3h}{8} [f(x_0) + 3f(x_1) + 3f(x_2) + f(x_3)] \]

\[ NC_4(f) = \frac{2h}{45} [7f(x_0) + 32f(x_1) + 12f(x_2) + 32f(x_3) + 7f(x_4)] \]

\[ NC_5(f) = \frac{5h}{288} [19f(x_0) + 75f(x_1) + 50f(x_2) + 50f(x_3) + 75f(x_4) + 19f(x_5)] \]

\[ NC_8(f) = \frac{4h}{1417} [989f(x_0) + 5888f(x_1) + 928f(x_2) + 10496f(x_3) - 4540f(x_4) + 10496f(x_5) - 928f(x_6) + 5888f(x_7) + 989f(x_8)] \]

XIV.2.12.26. As \( n \) increases, the coefficients in \( NC_n \) vary more greatly. More problematically, if \( n \geq 8 \) the coefficients are not all positive. Thus, for reasons described in XIV.2.12.4., higher Newton-Cotes formulas are not well suited for numerical work. Composite procedures using Newton-Cotes formulas of smaller degree on the subintervals generally work better numerically.

It turns out that if \( n \) is even, \( NC_n \) generally gives almost as good an approximation as \( NC_{n+1} \) (and sometimes better), for reasons described in XIV.2.12.57. In particular, \( NC_2 \) (simple Simpson’s rule) is generally nearly as good as \( NC_3 \) (Simpson’s three-eighths rule), which requires more arithmetic. (In fact, the
composite Simpson’s rule is generally even better than the composite three-eighths rule for the same overall number of subintervals; cf. Exercise XIV.2.13.4.)

The ordinary Simpson’s rule $S_{2n}$ of XIV.2.12.12. is nothing but the composite procedure consisting of dividing $b - a$ into $n$ subintervals of equal length and then applying the simple Simpson’s rule $S_2$ on each subinterval; for this reason, Simpson’s rule is sometimes called the parabolic rule. In part for the reasons in the last two paragraphs, Simpson’s rule is a popular and generally very good procedure.

**XIV.2.12.27.** As a variation, given $n$ we can divide $[a, b]$ into $n + 2$ subintervals of equal length $h = \frac{b - a}{n + 2}$, and not use the two endpoints but only the $n + 1$ interior points $x_1, \ldots, x_{n+1}$, where $x_k = a + kh$ for $1 \leq k \leq n + 1$. The resulting formulas are the open Newton-Cotes formulas, written $NC^n_0$. The only one of interest to us is $NC^n_0$, which is just the simple midpoint rule $M_1$. We list a couple more:

$$NC^n_1(f) = \frac{3h}{2} [f(x_1) + f(x_2)]$$

$$NC^n_2(f) = \frac{4h}{3} [2f(x_1) - f(x_2) + 2f(x_3)]$$

Already the coefficients in $NC^n_2$ are not all positive. $NC^n_0$ is again of order of precision at least $n$.

**Gaussian Quadrature**

**XIV.2.12.28.** We now change indexing convention slightly, beginning with $k = 1$ instead of $k = 0$. The quadrature formula

$$Q(f) = \sum_{k=1}^{n} \alpha_k f(x_k)$$

has $2n$ unknowns, the coefficients $\alpha_k$ and the nodes $x_k$. If we fix the $x_k$, there is a unique choice of the $\alpha_k$ giving a $Q$ of maximum order of precision, which is necessarily the interpolatory procedure and has order of precision $\geq n - 1$ (these $\alpha_k$ can be found by solving a system of linear equations; the technique is called the method of undetermined coefficients). The Newton-Cotes approach was of this form. We could alternately fix the $\alpha_k$ and find the $x_k$ for which the procedure has maximum order of precision, or we could vary both the $\alpha_k$ and $x_k$, keeping only $n$ fixed.

**XIV.2.12.29.** First consider fixing the $\alpha_k$. For reasons discussed in XIV.2.12.4. (a more detailed analysis justifies this further), a good choice is to take all the $\alpha_k$ equal (to $\frac{h}{n}$). This problem can be solved and gives a procedure of order of precision $\geq n$ only for $n \leq 7$ and $n = 9$; if $n$ is even the order of precision is actually $n + 1$. The case $n = 1$ gives the midpoint rule. If $[a, b] = [-1, 1]$ and $n = 2$, the optimal notes are at $\pm \frac{1}{\sqrt{3}} = 0.577 \cdots$. Tables giving the nodes for other $n$ can be found in [IK94] and other references.

**XIV.2.12.30.** Now consider varying both the $\alpha_k$ and the $x_k$. It can be shown that the maximum order of precision is obtained by taking the nodes to be the roots of the unique (up to constant multiple) polynomial $p_n$ of degree $n$ which is orthogonal to the subspace of polynomials of degree $\leq n - 1$ with respect to the usual real inner product

$$\langle f, g \rangle = \int_a^b f(x)g(x) \, dx$$
If \([a, b] = [-1, 1]\), the \(p_n\) are the Legendre polynomials \(\cdot\); other intervals can be handled via affine transformations. The \(\alpha_k\) are then chosen so the procedure is interpolatory. The resulting procedure is called Gaussian quadrature, or Legendre-Gauss quadrature, with \(n\) nodes, denoted \(G_n\). The procedure \(G_n\) has order \(2n - 1\).

Here are formulas for small \(n > 1\) for the interval \([-1, 1]\) (the case \(n = 1\) is just the midpoint rule):

\[
G_2(f) = f \left( -\frac{1}{\sqrt{3}} \right) + f \left( \frac{1}{\sqrt{3}} \right) = f(-.577350 \cdots) + f(.577350 \cdots)
\]

\[
G_3 = \frac{5}{9} f(-\sqrt{0.6}) + \frac{8}{9} f(0) + \frac{5}{9} f(\sqrt{0.6}) = \frac{1}{9} [5f(-0.774597 \cdots) + 8f(0) + 5f(0.774597 \cdots)]
\]

\[
G_4(f) = (0.347855 \cdots) f(-0.861136 \cdots) + (0.652145 \cdots) f(-0.339981 \cdots) + (0.652145 \cdots) f(0.339981 \cdots) + (0.347855 \cdots) f(0.861136 \cdots)
\]

The coefficients and nodes are algebraic numbers, but irrational in general and must be computed by a numerical procedure; see e.g. http://mathworld.wolfram.com/Legendre-GaussQuadrature.html. There are tables available online for at least up to \(n = 64\).

**XIV.2.12.31.** Advantages of Gaussian quadrature are that it is usually very accurate for modest \(n\) if \(f\) is sufficiently smooth (cf. XIV.2.12.60.), and the coefficients are all positive, although not too close to the same magnitude if \(n\) is large (cf. XIV.2.12.4.). Disadvantages are that it can be difficult to calculate the nodes and coefficients for \(n\) large (although there are tables for reasonable \(n\)), and if the process is repeated for a larger \(n\) all the coefficients and nodes must be recalculated (unlike, say, Simpson’s rule if \(n\) is doubled). A method like this also cannot be easily applied to functions arising from data sets.

**Weight Functions and Chebyshev Quadrature**

**XIV.2.12.32.** It is often important to consider a more general version of quadrature, to estimate integrals of the form

\[
I(f) = \int_{a}^{b} f(x) w(x) \, dx
\]

where \(w\) is a fixed weight function on \([a, b]\). Here \(w\) can be any nonnegative function which is Riemann-integrable or improperly Riemann-integrable (or, more generally, Lebesgue integrable) on \([a, b]\), but in applications \(w\) is usually a simple smooth function. We want a quadrature procedure \(Q\) of the form

\[
Q(f) = \sum_{k=1}^{n} \alpha_k f(x_k)
\]

for constants \(\alpha_k\) and nodes \(x_k\). The basic restriction now is

\[
\sum_{k=1}^{n} \alpha_k = \int_{a}^{b} w(x) \, dx.
\]

Usual quadrature is the special case where \(w\) is the constant function 1.
XIV.2.12.33. Gaussian quadrature works similarly in this setting: the optimal nodes are the roots of the polynomial of degree $n$ which is orthogonal to all polynomials of smaller degree with respect to the real inner product

$$\langle f, g \rangle = \int_a^b f(x)g(x)w(x) \, dx$$

and the weights are then found by the method of undetermined coefficients. This works because of the result of Exercise XIV.2.13.5.

XIV.2.12.34. More generally, a Radon measure $\mu$ can be used on $[a, b]$, and the integrals

$$\int_{[a,b]} f \, d\mu$$

approximated by quadrature procedures as above. The optimal polynomial of degree $n$ is the one orthogonal to the polynomials of smaller degree for the inner product

$$\langle f, g \rangle = \int_{[a,b]} fg \, d\mu .$$

It can be shown using the Krein-Milman theorem that such quadrature procedures must converge for any continuous $f$ as $n \to \infty$. However, this generality is of little or no practical use in numerical analysis.

XIV.2.12.35. A particularly important case is the weight function $w(x) = \frac{1}{\sqrt{1-x^2}}$ on $[-1, 1]$. Making the substitution $x = \cos \theta$, we have

$$\int_{-1}^1 f(x) \, dx = \int_0^\pi f(\cos(\theta)) \, d\theta$$

and the optimal nodes are the Chebyshev nodes. This case is called Chebyshev quadrature.

**Error Analysis of the Trapezoid Rule**

XIV.2.12.36. We begin with an analysis of the accuracy of the simple trapezoid rule

$$T_1(f) = \frac{h}{2}[f(a) + f(b)]$$

where $h = b - a$. The technique in the other error analyses will be similar. We want to calculate the error

$$E_1^T(f) = \int_a^b f(x) \, dx - T_1(f) = \int_a^b [f(x) - p_{0,1}(x)] \, dx = \int_a^b (x - a)(x - b)f[a, b, x] \, dx$$

by (1). Assume $f$ is $C^2$ on $[a, b]$. Then $g(x) = f[a, b, x]$ is continuous on $[a, b]$ (3), and for each $x \in (a, b)$ we can write

$$f[a, b, x] = \frac{f''(\xi(x))}{2}$$

1541
for some $\xi(x) \in (a, b)$ (V.11.5.9.). Since $(x-a)(x-b)$ does not change sign on $[a, b]$, and $f[a, b, x]$ is continuous on $[a, b]$, we can apply the Mean Value Theorem for integrals (1) to obtain
\[
E_T^T(f) = \int_a^b (x-a)(x-b) f[a, b, x] \, dx = f[a, b, c] \int_a^b (x-a)(x-b) \, dx = -\frac{h^3}{6}
\]
for some $c \in (a, b)$, where $\xi = \xi(c) \in (a, b)$. We calculate
\[
\int_a^b (x-a)(x-b) = -\frac{h^3}{6}
\]
(cf. the proof of XIV.2.12.24.), so we get
\[
E_T^T(f) = -\frac{h^3}{12}f''(\xi)
\]
for some $\xi \in (a, b)$.

**XIV.2.12.37.** Now suppose we do the composite trapezoid rule with $n$ subintervals, each of length $h = \frac{b-a}{n}$. Using the previous analysis on each subinterval, we have
\[
E_n^T(f) = -\frac{h^3}{12}f''(\xi_1) - \frac{h^3}{12}f''(\xi_2) - \cdots - \frac{h^3}{12} = -\frac{(b-a)^3}{12n^3} [f''(\xi_1) + \cdots + f''(\xi_n)]
\]
for some $\xi_k \in (x_{k-1}, x_k)$. If $f$ is $C^2$, we can apply the Intermediate Value Theorem to $f''$ to obtain a $\xi \in (a, b)$ with
\[
f''(\xi_1) + \cdots + f''(\xi_n) = nf''(\xi)
\]
so we obtain a simplified form of the error:
\[
E_n^T(f) = -\frac{(b-a)^3}{12n^2}f''(\xi)
\]
for some $\xi \in (a, b)$. If $|f''|$ is bounded by $K$ on $[a, b]$, we have
\[
|E_n^T(f)| \leq \frac{(b-a)^3}{12n^2} K.
\]

**XIV.2.12.38.** Thus, as $n$ increases, the error in the trapezoid rule is $O(n^{-2})$, so decreases fairly rapidly. The error bound at the end of XIV.2.12.37. is actually conservative in many cases: the sum $|f''(\xi_1) + \cdots + f''(\xi_n)|$ is often much less than $n \cdot \max_{[a, b]} |f''|$, especially if $f''$ varies significantly or changes sign on $[a, b]$; in fact,
\[
f''(\xi_1) + \cdots + f''(\xi_n)
\]
is close to $n$ times the average value of $f''$ on $[a, b]$, i.e.
\[
\frac{n f'(b) - f'(a)}{b-a}
\]
for $n$ large. Thus
\[
E_n^T(f) \approx -\frac{(b-a)^2}{12n^2} |f'(b) - f'(a)|
\]
for $n$ large.

1542
XIV.2.12.39. We can thus add a correction term to the trapezoid rule: set

\[ T_n(f) = T_n(f) + \frac{(b-a)^2}{12n^2} [f'(b) - f'(a)]. \]

The error for this quadrature rule is \( o(n^{-2}) \), and \( O(n^{-4}) \) if \( f \) is \( C^4 \). (It is not always practical to compute \( f'(a) \) and \( f'(b) \), e.g. if \( f \) is given only by a data set. There are approximations possible using higher-order differences which can be used as a substitute.)

XIV.2.12.40. If \( f'(a) = f'(b) \), e.g. if \( f \) is periodic and the integration is over an entire period, then the correction term is zero and we have that the error \( E_n^T(f) \) is \( o(n^{-2}) \) if \( f \) is \( C^2 \), and \( O(n^{-4}) \) if \( f \) is \( C^4 \). Thus the trapezoid rule is especially accurate for periodic functions. In fact, using the Euler-Maclaurin formula () it can be shown that if \( f \) is \( C^r \) and periodic with period \( b-a \), then there is a constant \( C_r \) depending only on \( r \) such that

\[ E_n^T(f) = C_r \frac{(b-a)^{r+1}}{n^r} f^{(r)}(\xi) \]

for some \( \xi \in (a,b) \), and thus \( E_n^T(f) = O(n^{-r}) \). See [IK94] for details.

**Error Analysis of the Midpoint Rule**

XIV.2.12.41. Let us examine the error in the simple midpoint rule

\[ M_1(f) = f(x_1)h \]

where \( h = b-a \) and \( x_1 \) is the midpoint of \([a,b]\). The key trick in getting a good error formula is to note that not only is \( M_1 \) the interpolatory quadrature rule for the set \( \{x_1\} \), but, if \( f \) is \( C^1 \), it is also the osculatory quadrature rule for the nodes \( (x_1,x_1) \): the osculating polynomial is \( p(x) = f(x_1) + f'(x_1)(x-x_1) \), and

\[ \int_a^b [f(x_1) + f'(x_1)(x-x_1)] \, dx = f(x_1)(b-a) + \frac{1}{2} f'(x_1)((b-x_1)^2 - (a-x_1)^2) \]

and the second term is zero. Thus the error is

\[ E_1^M(f) = \int_a^b f(x) \, dx - M_1(f) = \int_a^b (x-x_1)^2 f[x_1, x_1, x] \, dx. \]

Assume \( f \) is \( C^2 \) on \([a,b]\). Then \( g(x) = f[x_1, x_1, x] \) is continuous on \([a,b]\) so by the MVT for integrals, there is a \( c \in (a,b) \) such that

\[ \int_a^b (x-x_1)^2 f[x_1, x_1, x] \, dx = f[x_1, x_1, c] \int_a^b (x-x_1)^2 \, dx. \]

We also have by () that

\[ f[x_1, x_1, c] = \frac{f''(\xi)}{2} \]

for some \( \xi \in (a,b) \). We calculate

\[ \int_a^b (x-x_1)^2 \, dx = \frac{1}{3} [(b-x_1)^3 - (a-x_1)^3] = \frac{1}{3} \cdot 2 \left( \frac{h}{2} \right)^3 = \frac{h^3}{12} \]

1543
so we have
\[ E_1^M(f) = \frac{h^3}{24} f''(\xi) \]
for some \( \xi \in (a, b) \).

**XIV.2.12.42.** Now consider the composite midpoint rule with \( n \) subintervals of length \( h = \frac{b-a}{n} \). If \( f \) is \( C^2 \) on \([a, b]\), we have
\[
E_n^M(f) = \frac{h^3}{24} f''(\xi_1) + \cdots + \frac{h^3}{24} f''(\xi_n) = \frac{(b-a)^3}{24n^3} \left[ f''(\xi_1) + \cdots + f''(\xi_n) \right]
\]
for some \( \xi_k \in (x_{k-1}, x_k) \). By the Intermediate Value Theorem there is a \( \xi \in (a, b) \) with \( f''(\xi_1) + \cdots + f''(\xi_n) = nf''(\xi) \), so we get the clean formula
\[
E_n^M(f) = \frac{(b-a)^3}{24n^2} f''(\xi)
\]
for some \( \xi \in (a, b) \). If \( |f''| \) is bounded by \( K \) on \([a, b]\), we get
\[
|E_n^M(f)| \leq \frac{(b-a)^3}{24n^2} K .
\]

**XIV.2.12.43.** As with the trapezoid rule, the absolute error estimate for the midpoint rule is conservative, and we may add a correction term: set
\[
\tilde{M}_n(f) = M_n(f) - \frac{(b-a)^2}{24n^2} [f'(b) - f'(a)] .
\]
This has error \( O(n^{-4}) \) if \( f \) is \( C^4 \). If \( f'(a) = f'(b) \), e.g. if \( f \) is periodic and the integration is over an entire period, then the correction term is zero and we have that the error \( E_n^M(f) \) is \( O(n^{-4}) \) if \( f \) is \( C^4 \). (In the periodic case, the midpoint rule, the trapezoid rule, and the left and right approximations are effectively all the same procedure.)

**XIV.2.12.44.** Comparing XIV.2.12.41. with XIV.2.12.36. and XIV.2.12.42. with XIV.2.12.37., we see that if \( f \) is \( C^2 \), the error in the midpoint rule is indeed approximately of opposite sign and half the absolute value of the error in the trapezoid rule for the same \( n \) (cf. XIV.2.12.10.). The statement is not exactly true since the \( \xi \)'s are not the same in general; but if \( n \) is chosen large enough that \( f'' \) varies little over each subinterval, the \( f''(\xi_k) \)'s are almost equal for each \( k \), so the statement is very nearly true. Thus for such an \( n \) we have that Simpson's rule \( S_{2n} \) is an extremely good approximation to the integral. See XIV.2.12.49..

**XIV.2.12.45.** Another consequence of the error formula (which is pretty obvious just from the definition) is that even though the simple midpoint rule is an interpolatory procedure with only one node, it has order of precision 1, not 0; it gives the exact answer for linear functions, not just constant functions. The simple trapezoid rule also has order of precision 1, as expected since it is an interpolatory procedure with two nodes. The composite procedures also have order of precision 1.
Error Analysis of Simpson’s Rule

**XIV.2.12.46.** Consider the simple Simpson’s rule $S_2$, where $h = \frac{b-a}{3}$. We first observe that $S_2$ actually has order of precision $\geq 3$ instead of the expected 2. To show this, by linearity it suffices to show that $S_2(f) = \int_a^b f(x) \, dx$ for $f(x) = x^3$, which is a simple calculation:

$$S_2(f) = \frac{h}{3} [a^3 + 4x_1^3 + b^3] = \frac{b-a}{6} \left[ a^3 + 4 \left( \frac{a+b}{2} \right)^3 + b^3 \right]$$

$$= \frac{b-a}{6} \left[ a^3 + \frac{1}{2}(a+b)^3 + b^3 \right] = \frac{1}{6} (b-a) \left[ a^3 + \frac{1}{2}a^3 + \frac{3}{2}a^2b + \frac{3}{2}ab^2 + \frac{1}{2}b^3 + b^3 \right]$$

$$= \frac{1}{4} (b-a)(a^3 + a^2b + ab^2 + b^3) = \frac{1}{4} (b^4 - a^4) = \int_a^b x^3 \, dx .$$

(It is easily checked the same way that $S_2$ is not exact on $f(x) = x^4$, so the order of precision of $S_2$ is exactly 3.)

**XIV.2.12.47.** Now suppose $f$ is $C^1$, and let $p$ be the osculating polynomial for $f$ with nodes $x_0, x_1, x_1, x_2$. Then the interpolating polynomial for $p$ for the nodes $x_0, x_1, x_2$ is the same polynomial $q$ as the interpolating polynomial for $f$ with these same nodes. Since $p$ is cubic, we have

$$\int_a^b p(x) \, dx = S_2(p) = \int_a^b q(x) \, dx = S_2(f) .$$

Thus, for $C^1$ functions, $S_2$ is the osculating quadrature procedure with nodes $x_0, x_1, x_1, x_2$.

**XIV.2.12.48.** As a result, if $f$ is $C^1$ we get a formula for the error in $S_2$:

$$E_2^S(f) = \int_a^b [f(x) - p(x)] \, dx = \int_a^b (x-x_0)(x-x_1)^2(x-x_2)f[x_0, x_1, x_1, x_2, x] \, dx .$$

We proceed as before. Suppose $f$ is $C^1$ on $[a, b]$. The function $g(x) = f[x_0, x_1, x_1, x_2, x]$ is continuous on $[a, b]$, and $(x-x_0)(x-x_1)^2(x-x_2)$ does not change sign on $[a, b]$, so by the MVT for integrals we have

$$E_2^S(f) = \int_a^b (x-x_0)(x-x_1)^2(x-x_2)f[x_0, x_1, x_1, x_2, x] \, dx = f[x_0, x_1, x_1, x_2, c] \int_a^b (x-x_0)(x-x_1)^2(x-x_2) \, dx$$

for some $c \in (a, b)$.

Next we calculate

$$\int_a^b (x-a)(x-x_1)^2(x-b) \, dx .$$

Make the substitution $x = x_0 + th$; then

$$\int_a^b (x-a)(x-x_1)^2(x-b) \, dx = h^5 \int_0^2 t(t-1)^2(t-2) \, dt = -\frac{4h^5}{15} .$$

1545
Now suppose $f$ is $C^4$ on $[a, b]$. Then

$$f[x_0, x_1, x_1, x_2, c] = \frac{f^{(4)}(\xi)}{4!}$$

for some $\xi \in (a, b)$. Thus we obtain

$$E_n^S(f) = -\frac{4h^5}{15} \frac{f^{(4)}(\xi)}{24} = -\frac{h^5}{90} f^{(4)}(\xi)$$

for some $\xi \in (a, b)$.

**XIV.2.12.49.** Now consider the composite Simpson's rule with $n$ subintervals of length $h = \frac{b-a}{n}$, where $n = 2m$ is even. If $f$ is $C^4$ on $[a, b]$, we have, applying $S_2$ on each pair of successive intervals,

$$E_n^S(f) = -\frac{h^5}{90} f^{(4)}(\xi_1) - \cdots - \frac{h^5}{90} f^{(4)}(\xi_m) = -\frac{(b-a)^5}{90n^5} [f^{(4)}(\xi_1) + \cdots + f^{(4)}(\xi_m)]$$

for some $\xi_k \in (x_{2k-2}, x_{2k})$. By the Intermediate Value Theorem there is a $\xi \in (a, b)$ with $f^{(4)}(\xi_1) + \cdots + f^{(4)}(\xi_m) = m f^{(4)}(\xi)$, so we get the clean formula

$$E_n^M(f) = -\frac{(b-a)^5}{180n^4} f^{(4)}(\xi)$$

for some $\xi \in (a, b)$. If $|f^{(4)}|$ is bounded by $K$ on $[a, b]$, we get

$$|E_n^S(f)| \leq \frac{(b-a)^5}{180n^4} K .$$

**XIV.2.12.50.** Thus, as $n$ increases, the error in Simpson’s rule is $O(n^{-4})$, so decreases rapidly. The error bound at the end of XIV.2.12.49. is actually conservative in many cases: the sum

$$|f^{(4)}(\xi_1) + \cdots + f^{(4)}(\xi_m)|$$

is often much less than $m \cdot \max_{[a, b]} |f^{(4)}|$, especially if $f^{(4)}$ varies significantly or changes sign on $[a, b]$; in fact,

$$f^{(4)}(\xi_1) + \cdots + f^{(4)}(\xi_m)$$

is close to $m$ times the average value of $f^{(4)}$ on $[a, b]$, i.e.

$$m \frac{f^{(3)}(b) - f^{(3)}(a)}{b - a}$$

for $n$ large. Thus

$$E_n^S(f) \approx -\frac{(b-a)^4}{180n^4} [f^{(3)}(b) - f^{(3)}(a)]$$

for $n$ large. See also XIV.2.12.44.
XIV.2.12.51. We can thus add a correction term to Simpson’s rule: if \( n \) is even, set
\[
\tilde{S}_n(f) = S_n(f) + \frac{(b-a)^4}{180n^4}[f^{(3)}(b) - f^{(3)}(a)] .
\]
The error for this quadrature rule is \( o(n^{-4}) \) if \( f \) is \( C^4 \), and \( O(n^{-6}) \) if \( f \) is \( C^6 \). (It is not always practical to compute \( f^{(3)}(a) \) and \( f^{(3)}(b) \), e.g. if \( f \) is given only by a data set. There are approximations possible using higher-order differences which can be used as a substitute.)

XIV.2.12.52. If \( f^{(3)}(a) = f^{(3)}(b) \), e.g. if \( f \) is periodic and the integration is over an entire period, then the correction term is zero and we have that the error \( E_{n, S}^S(f) \) is \( O(n^{-6}) \) if \( f \) is \( C^6 \). Thus, like the trapezoid rule, Simpson’s rule is especially accurate for periodic functions. But because of XIV.2.12.40., there is little practical reason to use Simpson’s rule instead of the trapezoid rule for periodic functions.

XIV.2.12.53. For functions which are not smooth, the trapezoid rule is actually often a little better than Simpson’s rule for the same number of subintervals. See [CUN02] for a detailed analysis of the errors for both methods for classes of nonsmooth functions.

**Error Analysis for Newton-Cotes Procedures**

XIV.2.12.54. Error formulas for the higher-order Newton-Cotes formulas and open Newton-Cotes formulas can be obtained by essentially the same arguments, although the details are more complicated beyond Simpson’s rule; see e.g. [IK94]. The result is:

XIV.2.12.55. **Theorem.** Let \( f \) be a function on \([a, b]\), and \( n \in \mathbb{N} \). Set \( h = \frac{b-a}{n} \).

(i) Suppose \( n \) is odd and \( f \) is \( C^{n+1} \) on \([a, b]\). Then
\[
E_{n, NC}^C(f) = \int_a^b f(x) \, dx - NC_n(f) = \frac{M_n}{(n+1)!} h^{n+2} f^{(n+1)}(\xi)
\]
for some \( \xi \in (a, b) \), where
\[
M_n = \int_0^n \pi_n(t) \, dt = \int_0^n t(t-1) \cdots (t-n) \, dt < 0 .
\]

(ii) Suppose \( n \) is even and \( f \) is \( C^{n+2} \) on \([a, b]\). Then
\[
E_{n, NC}^C(f) = \int_a^b f(x) \, dx - NC_n(f) = \frac{M_n}{(n+2)!} h^{n+3} f^{(n+2)}(\xi)
\]
for some \( \xi \in (a, b) \), where
\[
M_n = \int_0^n t\pi_n(t) = \int_0^n t^2(t-1) \cdots (t-n) \, dt < 0 .
\]

These formulas are consistent with the cases \( n = 1 \) (trapezoid rule) and \( n = 2 \) (Simpson’s rule) developed in XIV.2.12.36. and XIV.2.12.46.
XIV.2.12.56. **Corollary.** If \( n \) is even, the Newton-Cotes procedure \( NC_n \) has order of precision \( n + 1 \); if \( n \) is odd, \( NC_n \) has order of precision \( n \).

XIV.2.12.57. Thus, if \( n \) is even, The Newton-Cotes procedure \( NC_n \) has essentially the same accuracy as \( NC_{n+1} \) (the accuracy of \( NC_{n+1} \) is roughly better by a constant factor). Thus Newton-Cotes procedures are “better” for even \( n \). The “explanation” is that if \( n \) is even, the procedure \( NC_n \), which is the interpolatory procedure for the evenly spaced nodes \( x_0, \ldots, x_n \), turns out to be also the osculatory procedure for the \( n + 2 \) nodes \( x_0, \ldots, x_{n/2}, x_{n/2}, \ldots, x_n \), with \( x_{n/2} \) repeated, as in the case of the midpoint rule and Simpson’s rule.

XIV.2.12.58. There are similar results for the open Newton-Cotes formulas \( NC_o^n \), which also gain an extra order of precision for \( n \) even (e.g. for the midpoint rule \( NC_0^0 \)). In this case the constants are positive.

XIV.2.12.59. These error formulas are for simple Newton-Cotes procedures. Similar error formulas for compound Newton-Cotes procedures can be obtained in exactly the same manner as for the trapezoid, midpoint, and Simpson’s rule cases.

**Error Analysis for Gaussian Quadrature**

XIV.2.12.60. The error for Gaussian quadrature \( G_n \) on \([a, b]\) may be calculated in a similar manner: if \( f \) is \( C^{2n} \) on \([a, b]\), then

\[
E_n^G(f) = \int_a^b f(x) \, dx - G_n(f) = \frac{2}{(2n + 1)!} \left[ \frac{2^n(n!)^2}{(2n)!} \right]^2 (b - a)^{2n+1} f^{(2n)}(\xi)
\]

for some \( \xi \in (a, b) \). Using Stirling’s formula (\() to approximate the factorials, we get, for \( n \) large,

\[
E_n^G(f) \approx \frac{\pi n(b - a)^{2n+1}}{2^{2n-1}(2n + 1)!} f^{(2n)}(\xi)
\]

for some \( \xi \in (a, b) \). Thus if the derivatives of \( f \) do not grow too rapidly (e.g. if \( f \) is complex-analytic on a large enough region containing \([a, b]\)), the Gaussian quadrature approximations converge rapidly as \( n \to \infty \). See e.g. [IK94] for details.

XIV.2.12.61. In practice, knowing when a procedure gives a sufficiently accurate estimate is not easy. There are procedures which carefully combine results of a standard procedure done twice for different partitions to greatly improve accuracy and make it easier to know when to stop. A theoretically and computationally appealing such improvement of the trapezoid rule is Romberg integration (Exercise XIV.2.13.7.). A widely-used similar variation of Gaussian quadrature is Gauss-Kronrod integration.

There are also adaptive procedures for numerical integration, where the interval lengths and procedures are not fixed in advance but the details vary according to properties of the function being integrated. These are generally the best numerical procedures when feasible. Most software packages for numerical integration use some combination or variation of these procedures; further discussion is beyond our scope, but can be found in numerical analysis texts.
XIV.2.13. Exercises

XIV.2.13.1. Here are some additional relations among standard integration procedures on a fixed interval \([a, b]\).
(a) Show that \(T_{2n} = \frac{1}{2} (T_n + M_n)\) for any \(n\).
(b) Show that \(S_{2n} = \frac{1}{3} (4T_n - T_n)\) for any \(n\).

XIV.2.13.2. (a) Consider 
\[
\int_{-m}^{m} \frac{1}{x^2 + 1} \, dx.
\]
Compute the exact value, and the trapezoid and midpoint estimates using one subinterval. Show that the absolute trapezoid error is less than the absolute midpoint error if \(m > 1.44\), and the trapezoid estimate is much better than the midpoint estimate for \(m\) large.
(b) Consider 
\[
\int_{0}^{1} x^m \, dx.
\]
Compute the exact value, and the trapezoid and midpoint estimates using one subinterval. Show that the midpoint estimate is much better than the trapezoid estimate for \(m\) large.

Actually, none of the estimates are very good in these cases, as may be expected when only one interval is used. In (b), at least the midpoint errors approach 0 as \(m \to +\infty\), while the absolute trapezoid error increases as \(m\) increases. In (a), both the absolute trapezoid and midpoint errors increase as \(m\) increases, but the trapezoid errors are bounded and the midpoint errors unbounded as \(m \to +\infty\).

XIV.2.13.3. Consider the integral 
\[
\int_{-1}^{1} |x| \, dx.
\]
Show that either the trapezoid rule or the midpoint rule for \(n\) subintervals gives the exact answer if \(n\) is even (even \(n = 2\)), and not if \(n\) is odd. Thus the approximations do not necessarily become monotonically better as \(n\) increases (although they do converge to the exact integral as \(n \to \infty\)).

This function is not differentiable everywhere. But it can be uniformly approximated arbitrarily closely by a polynomial () for which the same statements are approximately true; in particular, approximations using a relatively small even number of intervals, even 2, are better than approximations of the same kind using a larger odd number of subintervals.

It can be shown that if \(f\) is a polynomial, then the absolute error \(E_T^n(f)\) monotonically decreases for sufficiently large \(n\), but this is not always true if \(f\) is merely smooth. See http://mathoverflow.net/questions/180542/monotonicity-of-trapezoid-approximations.

XIV.2.13.4. Simpson’s Three-Eighths Rule. Fix an interval \([a, b]\).
(a) Show that if \(f\) is a function on \([a, b]\), then
\[
NC_3(f) = \frac{3h}{8} [f(x_0) + 3f(x_1) + 3f(x_2) + f(x_3)]
\]
where \(h = \frac{b-a}{3}\).
(b) Show that if \( f \) is \( C^4 \) on \([a, b]\), then

\[
E^{NC}_3(f) = -\frac{3}{80} h^5 f^{(4)}(\xi)
\]

for some \( \xi \in (a, b) \).

(c) Compare \( E^{NC}_3(f) \) with \( E^{NC}_2(f) = E^{S}_2(f) \) (XIV.2.12.46). [Caution: the \( h \)'s are different in the two cases, and the \( \xi \)'s are also normally different.]

(d) If \( n = 3m \) is divisible by 3, let \( R_n \) be the composite quadrature procedure obtained by dividing \([a, b]\) into \( m \) equal subintervals and applying \( NC_3 \) on each (so \([a, b]\) is divided into \( n \) equal subintervals of length \( h = \frac{b-a}{n} \)). Show that if \( f \) is \( C^4 \) on \([a, b]\), then

\[
E_R^n(f) = \int_a^b f(x) \, dx - R_n(f) = -\frac{3}{80} \frac{(b-a)^5}{n^5} [f^{(4)}(\xi_1) + \cdots + f^{(4)}(\xi_m)] = -\frac{1}{80} \frac{(b-a)^5}{n^4} f^{(4)}(\xi)
\]

for some \( \xi_k \in (x_{3k-3}, x_{3k}) \) and some \( \xi \in (a, b) \).

(e) Suppose \( f \) is \( C^4 \) on \([a, b]\), and \( n \) is divisible by 6 and large enough that \( f^{(4)} \) is almost constant on each subinterval. Show that \( |E^{S}_n(f)| \) is “typically” smaller than \( |E^n_R(f)| \).

XIV.2.13.5. Let \( w \) be a nonnegative Riemann-integrable function on \([a, b]\) with \( \int_a^b w(x) \, dx > 0 \). Define a real inner product on the set of polynomials (with real coefficients) by

\[
\langle p, q \rangle = \int_a^b p(x)q(x)w(x) \, dx .
\]

(a) Show that for each \( n \in \mathbb{N} \) there is a unique (up to scalar multiple) nonzero polynomial \( p \) of degree \( n \) which is orthogonal to all polynomials of degree \( \leq n - 1 \) under this inner product.

(b) Suppose \( p \) changes sign exactly \( m \) times in \([a, b]\), at \( x_1, \ldots, x_m \) in \((a, b)\), i.e. \( x_1, \ldots, x_m \) are the distinct roots of \( p \) of odd order in \((a, b)\). Show that \( p \) cannot be orthogonal to

\[
q(x) = (x - x_1)(x - x_2)\cdots(x - x_m)
\]

(\( q(x) = 1 \) if \( m = 0 \)) since \( pq \) does not change sign on \([a, b]\). Thus \( m = \deg(q) \geq n \).

(c) Conclude that all the roots of \( p \) are real and distinct and lie in \((a, b)\).

XIV.2.13.6. [Ham86, 17.7] Consider the following quadrature procedure for twice-differentiable functions on \([-1, 1] \):

\[
Q(f) = \frac{1}{21} [5f(-1) + 32f(0) + 5f(1)] - \frac{1}{315} [f''(-1) + 32f''(0) + f''(1)] .
\]

(a) Show that \( Q \) has order of precision 6.

(b) Show that \( Q \) is not an osculating procedure.
XIV.2.13.7. Romberg Integration. Fix an interval $[a, b]$. Let $T^n_0$ be the trapezoid rule $T_n$ for any $n$. Recursively define

$$T^n_k = \frac{1}{4^k - 1} (4^k T^{k-1}_n - T^{k-1}_n)$$

for all $n$ and $k$.

(a) Show that $T^n_1 = S_{2n}$ for any $n$.

(b) Show that $T^n_4$ is $NC_{4, n}$, the process of dividing $[a, b]$ into $n$ subintervals of equal length and applying $NC_4$ on each subinterval.

(c) The simple relation of (a) and (b) with the Newton-Cotes formulas does not persist. Show that

$$T^n_3 = \frac{4h}{2835} (217f(x_0) + 1024f(x_1) + 352f(x_2) + 1024f(x_3) + 436f(x_4) + 1024f(x_5) + 352f(x_6) + 1024f(x_7) + 217f(x_8))$$

($h = \frac{b-a}{8}$) which is not the same as $NC_8$ (however, the coefficients of $T^n_3$ are all positive, which is desirable computationally, and the sizes of the coefficients do not vary greatly).

The simple relation of (a) and (b) with the Newton-Cotes formulas does not persist. Show that

$$T^n_3 = \frac{4h}{2835} (217f(x_0) + 1024f(x_1) + 352f(x_2) + 1024f(x_3) + 436f(x_4) + 1024f(x_5) + 352f(x_6) + 1024f(x_7) + 217f(x_8))$$

($h = \frac{b-a}{8}$) which is not the same as $NC_8$ (however, the coefficients of $T^n_3$ are all positive, which is desirable computationally, and the sizes of the coefficients do not vary greatly).

The Romberg integration procedure is as follows. Fix an $n$ (in practice $n = 1$ is often used). Successively calculate $T^n_k$ for $k \leq 2^m$. The results can be conveniently collected in a triangular array

$$\begin{array}{cccc}
T^0_0 & T^1_0 & T^2_0 & T^3_0 \\
T^n_0 & T^n_1 & T^n_2 & T^n_3 \\
\vdots & \vdots & \vdots & \vdots \\
\end{array}$$

where each entry is computed from the one to the left and the one diagonally above to the left (the entries in the first column are computed from the trapezoid rule using additional function evaluations; note that $T^n_{2m+1}$ can be calculated from $T^n_{2m}$ by only $2^m n$ additional function evaluations). In practice the entries are rounded to the desired accuracy and the process stops when two identical numbers to the desired accuracy are obtained. The process is computationally efficient and frequently produces the desired accuracy with fewer function evaluations than Simpson’s Rule. The convergence rate is comparable to the rate using correction terms (XIV.2.12.39.), and is more computationally efficient and avoids making a careful estimate of the starting $n$ needed. See books on Numerical Analysis for details and error analyses.
XIV.3. Jordan Content and Riemann Integration in $\mathbb{R}^n$

Generalization of Riemann integration to $\mathbb{R}^n$ is in many ways straightforward, but there are some significant technicalities to overcome. One is to nail down what kinds of sets functions can be reasonably integrated over, and the answer is considerably more complicated than in the one-dimensional case where intervals are the obvious answer. There is a natural collection of subsets called Jordan regions which work nicely for Riemann integration and which are general enough to cover most cases of practical interest. As a special case of integration, we also have a natural notion of “volume,” called Jordan content, for Jordan regions.

XIV.3.1. Integration over Rectangles

It is most straightforward to integrate over rectangles in $\mathbb{R}^n$ whose edges are parallel to the axes. The following definition will be used throughout this section (a more general definition is used in (1)).

**XIV.3.1. Definition.** A rectangle in $\mathbb{R}^n$ is a set $R$ of the form $I_1 \times \cdots \times I_n$, where each $I_k$ is a closed bounded interval $[a_k, b_k]$ or degenerate interval (if $a_k = b_k$) in $\mathbb{R}$, i.e.

$$ R = \{ (x_1, \ldots, x_n) : a_k \leq x_k \leq b_k \text{ for all } k \} . $$

The rectangle is degenerate if $I_k$ is degenerate for at least one $k$. The content (n-dimensional content), or volume (n-dimensional volume) of $R$ is

$$ V(R) = \prod_{k=1}^{n} \ell(I_k) = \prod_{k=1}^{n} (b_k - a_k) . $$

Such rectangles should more properly be called closed coordinate rectangles or closed aligned rectangles, since there are more general sets which can be called rectangles. However, rectangles as defined in XIV.3.1. are exclusively used in developing Riemann integration and it is pedantic to have to constantly qualify them.

XIV.3.1.2. We use the term “rectangle” in any number of dimensions even though it is only geometrically accurate if $n = 2$; in $\mathbb{R}^3$ a rectangle by our definition is what is usually called a rectangular solid, and for $n > 3$ there is not a standard geometric name. Note that the case $n = 1$ is not excluded; a rectangle in $\mathbb{R}$ is just a closed bounded interval or single point. Similarly, “volume” is only strictly appropriate if $n = 3$, which is why we prefer the term “content”: if $n = 2$ content is usually called “area” (and for $n = 1$ it is “length”). We will, however, use the notation $V(R)$ which suggests the term “volume” no matter what $n$ is. To emphasize the dimension, we can (but rarely will) write $V_n$ in place of $V$.

Note that the $n$-dimensional content of a degenerate rectangle is always 0. A degenerate rectangle is geometrically $m$-dimensional for some $m < n$ (the number of nondegenerate coordinate intervals) and so has an $m$-dimensional “content”; thus we must exercise some care in fixing $n$ and interpreting “content” to be $n$-dimensional content for this $n$.

It is a matter of taste whether to regard $\emptyset$ as a rectangle; whether we do or not necessarily leads to some notational complications, which are greater if we do. We will not.

The next observation is obvious from the fact that the intersection of two intervals in $\mathbb{R}$ is an interval or degenerate interval.
XIV.3.1.3. **Proposition.** If $R$ and $S$ are rectangles in $\mathbb{R}^n$, and $R \cap S \neq \emptyset$, then $R \cap S$ is also a rectangle.

**Proof:** If $R = I_1 \times \cdots \times I_n$ and $S = J_1 \times \cdots \times J_n$, then $R \cap S = (I_1 \cap J_1) \times \cdots \times (I_n \cap J_n)$.

XIV.3.1.4. **Definition.** Let $R$ and $S$ be rectangles in $\mathbb{R}^n$. Then $R$ and $S$ are nonoverlapping if either $R \cap S = \emptyset$ or $R \cap S$ is a degenerate rectangle.

### Partitions and Grids

XIV.3.1.5. **Definition.** Let $R$ be a rectangle in $\mathbb{R}^n$. A partition of $R$ is a set $\mathcal{P} = \{R_1, \ldots, R_m\}$ of pairwise nonoverlapping rectangles in $\mathbb{R}^n$ with $R = \bigcup_{k=1}^m R_k$.

A partition $\mathcal{Q}$ is a refinement of $\mathcal{P}$ if every rectangle in $\mathcal{Q}$ is contained in a rectangle of $\mathcal{P}$.

A grid in $R$ is a partition of $R = I_1 \times \cdots \times I_n$ of the form $\mathcal{G} = \mathcal{P}_1 \times \cdots \times \mathcal{P}_n$, where $\mathcal{P}_k$ is a partition of $I_k$.

Note that a partition of a rectangle is not necessarily a grid. See Figure XIV.18. It is convenient to allow degenerate rectangles in partitions, as our definition does; thus a partition of an interval in $\mathbb{R}$ by this definition is slightly more general than the definition in (1), since repeated points are allowed. This will make no practical difference but simplifies some notation. We could develop the whole theory just using grids, but it is convenient to allow partitions which are not grids. Every partition has a refinement which is a grid (see the proof of XIV.3.1.6).

By XIV.3.1.3., any two partitions of a rectangle have a common refinement obtained by intersecting the subrectangles. If the partitions are grids, so is the common refinement constructed in this way.

Note that there is no natural ordering of the rectangles in a partition, even a grid, if $n > 1$. We have notationally fixed an ordering, but the ordering is not part of the definition of the partition.

Here is a technicality which may be considered geometrically “obvious” (but see the discussion in I.5.1.1.); however, it needs proof (if $n > 1$). This is one of the fundamental observations which gets Jordan content and Riemann integration theory in $\mathbb{R}^n$ off the ground.

XIV.3.1.6. **Proposition.** Let $R$ be a rectangle in $\mathbb{R}^n$. Suppose $R$ is a union of a finite number of pairwise nonoverlapping subrectangles $R = \bigcup_{k=1}^m R_k$. Then

$$V(R) = \sum_{k=1}^m V(R_k).$$

To prove XIV.3.1.6., we will first prove a special case where the subdivision is a grid:
XIV.3.1.7. Lemma. Let $R = [a_1, b_1] \times \cdots \times [a_n, b_n]$ be a rectangle in $\mathbb{R}^n$. For each $k$ let $\mathcal{P}_k$ be a partition of $[a_k, b_k]$, and let $\mathcal{G} = \mathcal{P}_1 \times \cdots \times \mathcal{P}_n$ be the corresponding grid. Let $\{R_1, \ldots, R_p\}$ be the subrectangles in the grid. Then

$$V(R) = \sum_{k=1}^p V(R_k).$$

Proof: We write the proof for $n = 2$; the proof for general $n > 1$ is nearly identical but notationally offensive. So we have $R = [a_1, b_1] \times [a_2, b_2]$, $\mathcal{P}_1 = \{c_0, \ldots, c_r\}$, $\mathcal{P}_2 = \{d_0, \ldots, d_s\}$. Set

$$R_{jk} = [c_{j-1}, c_j] \times [d_{k-1}, d_k]$$

so

$$V(R_{jk}) = (c_j - c_{j-1})(d_k - d_{k-1}).$$

We then have

$$\sum_{j,k} V(R_{jk}) = \sum_{j=1}^r \left[ \sum_{k=1}^s (c_j - c_{j-1})(d_k - d_{k-1}) \right]$$

$$= \sum_{j=1}^r \left[ (c_j - c_{j-1}) \sum_{k=1}^s (d_k - d_{k-1}) \right] = \sum_{j=1}^r (c_j - c_{j-1})(b_2 - a_2)$$
\[
(b_2 - a_2) \sum_{j=1}^{r} (c_j - c_{j-1}) = (b_2 - a_2)(b_1 - a_1) = V(R) .
\]

We now give the proof of XIV.3.1.6.

**Proof:** Let \( R = [a_1, b_1] \times \cdots \times [a_n, b_n] \) and \( R_k = [a_{k,1}, b_{k,1}] \times \cdots \times [a_{k,n}, b_{k,n}] \). For each \( j \), let \( \mathcal{P}_j \) be the partition of \([a_j, b_j]\) consisting of all the \( a_{k,j} \) and \( b_{k,j} \). Let \( \mathcal{G} \) be the corresponding grid, and let \( \{R_{j_1, \ldots, j_n}\} \) be the rectangles in the grid. Then, by XIV.3.1.7.,

\[
V(R) = \sum_{j_1, \ldots, j_n} V(R_{j_1, \ldots, j_n}) .
\]

For each \( k \), set

\[
I_k = \{ (j_1, \ldots, j_n) : R_{j_1, \ldots, j_n} \subseteq R_k \} .
\]

Every \((j_1, \ldots, j_n)\) for which \( R_{j_1, \ldots, j_n} \) is nondegenerate is in exactly one \( I_k \). For each \( k \), the \( R_{j_1, \ldots, j_n} \) for \((j_1, \ldots, j_n) \in I_k\) form a grid subdivision of \( R_k \), so again by XIV.3.1.7. we have

\[
V(R_k) = \sum_{(j_1, \ldots, j_n) \in I_k} V(R_{j_1, \ldots, j_n})
\]

for each \( k \), and thus we have

\[
V(R) = \sum_{j_1, \ldots, j_n} V(R_{j_1, \ldots, j_n}) = m \left[ \sum_{k=1}^{m} \sum_{(j_1, \ldots, j_n) \in I_k} V(R_{j_1, \ldots, j_n}) \right] = m \sum_{k=1}^{m} V(R_k) .
\]

See Figure XIV.19.

**Upper and Lower Integrals over a Rectangle**

We now proceed just as we did to define the integral of a bounded function over an interval in \( \mathbb{R} \):

**XIV.3.1.8.** **Definition.** Let \( R \) be a rectangle in \( \mathbb{R}^n \), and \( f : R \to \mathbb{R} \) a bounded function. If \( \mathcal{P} = \{R_1, \ldots, R_m\} \) is a partition of \( R \), for each \( k \) set \( M_k = \sup \{ f(x) : x \in R_k \} \) and \( m_k = \inf \{ f(x) : x \in R_k \} \). Then the **upper and lower sums for \( f \) with respect to \( \mathcal{P} \)** are

\[
\mathcal{S}(f, \mathcal{P}) = \sum_{k=1}^{m} M_k \cdot V(R_k)
\]

\[
\mathcal{L}(f, \mathcal{P}) = \sum_{k=1}^{m} m_k \cdot V(R_k) .
\]

This definition agrees with the one in () if \( n = 1 \). Note that it does not make sense unless \( f \) is bounded.
XIV.3.1.9. It is clear that if $Q$ is a refinement of $P$, then

$$\mathcal{S}(f, P) \leq \mathcal{S}(f, Q) \leq \mathcal{S}(f, Q) \leq \mathcal{S}(f, P)$$

for any bounded function $f$. Thus the following definition is reasonable:

XIV.3.1.10. **Definition.** Let $R$ be a rectangle in $\mathbb{R}^n$, and $f : R \to \mathbb{R}$ a bounded function. The *upper and lower integrals* of $f$ over $R$ are

$$\int_R f \, dV = \inf_P \mathcal{S}(f, P)$$

$$\int_R f \, dV = \sup_P \mathcal{S}(f, P) .$$

The function $f$ is *(Riemann)* integrable over $R$ if $\int_R f \, dV = \int_R f \, dV$; in this case, the common value is the integral of $f$ over $R$, denoted $\int_R f \, dV$.

XIV.3.1.11. If $n = 1$, this definition is consistent with (): If $R = [a, b]$ and $f : R \to \mathbb{R}$ is bounded, then $f$ is integrable over $R$ if and only if it is Riemann integrable in the sense of (), and we have

$$\int_R f \, dV = \int_{[a, b]} f \, dV = \int_a^b f(x) \, dx .$$
XIV.3.1.12. Of course we have \( \int_R f \, dV \leq \overline{\int}_R f \, dV \) for any \( R \) and \( f \). As in (\() we have:

XIV.3.1.13. Proposition. Let \( R \) be a rectangle in \( \mathbb{R}^n \), and \( f : R \rightarrow \mathbb{R} \) a bounded function. Then \( f \) is integrable on \( R \) if and only if, for every \( \epsilon > 0 \), there is a partition \( \mathcal{P} \) of \( R \) such that
\[
\overline{\mathcal{S}}(f, \mathcal{P}) - \underline{\mathcal{S}}(f, \mathcal{P}) < \epsilon .
\]
Reasonable functions turn out to be Riemann integrable. Most importantly, we have the following higher-dimensional version of (\(), which is proved almost identically. We omit the proof since we will obtain a more general result in XIV.3.2.21. with almost the same proof.

XIV.3.1.14. Theorem. Let \( R \) be a rectangle in \( \mathbb{R}^n \), and \( f : R \rightarrow \mathbb{R} \) a continuous function. Then \( f \) is integrable over \( R \).

However, functions which are too discontinuous are not integrable:

XIV.3.1.15. Example. Let \( A \) be a subset of \( \mathbb{R}^n \) which is dense and has dense complement, e.g. the set of points with rational coordinates. If \( R \) is any rectangle in \( \mathbb{R}^n \) and \( \mathcal{P} \) is any partition of \( R \), then \( \overline{\mathcal{S}}(\chi_A, \mathcal{P}) = V(R) \) and \( \underline{\mathcal{S}}(\chi_A, \mathcal{P}) = 0 \). Thus \( \int_R \chi_A \, dV = V(R) \) and \( \int_R \chi_A \, dV = 0 \), so \( \chi_A \) is not integrable on \( R \) unless \( R \) is degenerate.

Additivity of Upper and Lower Integrals

XIV.3.1.16. Proposition. Let \( R \) be a rectangle in \( \mathbb{R}^n \), and \( f : R \rightarrow \mathbb{R} \) a bounded function. If \( \mathcal{P} = \{R_1, \ldots, R_m\} \) is a partition of \( R \), then we have
\[
\int_R f \, dV = \sum_{k=1}^{m} \int_{R_k} f \, dV \quad \text{and} \quad \int_R f \, dV = \sum_{k=1}^{m} \int_{R_k} f \, dV .
\]

Proof: In calculating \( \int_R f \, dV \), only partitions of \( R \) refining \( \mathcal{P} \) need be considered. Each such partition \( \mathcal{Q} \) splits into partitions \( \mathcal{Q}_k \) of \( R_k \) for each \( k \), so we obtain
\[
\overline{\mathcal{S}}(f, \mathcal{Q}) = \sum_{k=1}^{m} \overline{\mathcal{S}}(f, \mathcal{Q}_k) .
\]
Conversely, if \( \mathcal{Q}_k \) is a partition of \( R_k \) for each \( k \), the union of the \( \mathcal{Q}_k \) is a partition of \( R \) refining \( \mathcal{P} \). So the infimum over partitions can be taken separately in each term. The argument for \( \underline{\mathcal{S}}(f, \mathcal{Q}) \) is essentially identical.
XIV.3.1.17. Also note that if \( R \) is a degenerate rectangle and \( f \) is any bounded function on \( R \), then \( f \) is integrable on \( R \) and \( \int_R f \, dV = 0 \).

**Linearity of the Integral**

**XIV.3.1.18. Proposition.** Let \( R \) be a rectangle in \( \mathbb{R}^n \), \( f : R \to \mathbb{R} \) a bounded function, and \( \alpha \in \mathbb{R} \). Then

\[
\int_R \alpha f \, dV = \begin{cases} 
\alpha \int_R f \, dV & \text{if } \alpha \geq 0 \\
\alpha \int_R f \, dV & \text{if } \alpha < 0 
\end{cases}
\]

\[
\int_R \alpha f \, dV = \begin{cases} 
\alpha \int_R f \, dV & \text{if } \alpha \geq 0 \\
\alpha \int_R f \, dV & \text{if } \alpha < 0 
\end{cases}
\]

In particular, if \( f \) is integrable over \( R \), then so is \( \alpha f \), and

\[
\int_R \alpha f \, dV = \alpha \int_R f \, dV .
\]

**Proof:** This is obvious from the fact that if \( P = \{R_1, \ldots, R_m\} \) is any partition of \( R \), then, for \( 1 \leq k \leq m \),

\[
M_k(\alpha f) = \alpha M_k(f) \text{ if } \alpha \geq 0 \quad \text{and} \quad M_k(\alpha f) = \alpha m_k(f) \text{ if } \alpha < 0,
\]

so that \( \mathcal{S}(\alpha f, P) = \alpha \mathcal{S}(f, P) \) if \( \alpha \geq 0 \) and \( \mathcal{S}(\alpha f, P) = \alpha \mathcal{S}(f, P) \) if \( \alpha < 0 \), and similarly for the other.

**XIV.3.1.19. Proposition.** Let \( R \) be a rectangle in \( \mathbb{R}^n \), and \( f \) and \( g \) bounded functions on \( R \). Then

\[
\int_R (f + g) \, dV \leq \int_R f \, dV + \int_R g \, dV
\]

\[
\int_R (f + g) \, dV \geq \int_R f \, dV + \int_R g \, dV
\]

In particular, if \( f \) and \( g \) are integrable over \( R \), then so is \( f + g \), and

\[
\int_R (f + g) \, dV = \int_R f \, dV + \int_R g \, dV .
\]

**Proof:** This is similar to the previous proposition, noting that if \( P = \{R_1, \ldots, R_m\} \) is any partition of \( R \), then, for \( 1 \leq k \leq m \),

\[
M_k(f + g) \leq M_k(f) + M_k(g) \quad \text{and} \quad m_k(f + g) \geq m_k(f) + m_k(g)
\]

\( \)
Thus the integral over a fixed rectangle is linear: if \( f \) and \( g \) are integrable over a rectangle \( R \), and \( \alpha, \beta \in \mathbb{R} \), then \( \alpha f + \beta g \) is integrable over \( R \) and
\[
\int_R (\alpha f + \beta g) \, dV = \alpha \int_R f \, dV + \beta \int_R g \, dV.
\]
However, the upper and lower integrals are not linear for functions which are not integrable. For example, if \( A \) is a dense set with dense complement, then for any nondegenerate \( R \) we have
\[
V(R) = \int_R 1 \, dV = \int_R (\chi_A + \chi_{A^c}) \, dV < \int_R \chi_A \, dV + \int_R \chi_{A^c} \, dV = 2V(R)
\]
and similarly for the lower integral for \( -\chi_A - \chi_{A^c} \).

**Order Properties of the Integral**
The order properties of the integral are obvious (consider partitions):

**Proposition.** Let \( R \) be a rectangle in \( \mathbb{R}^n \), and \( f \) and \( g \) bounded functions on \( R \). If \( f \leq g \) on \( R \), then \( \int_R f \, dV \leq \int_R g \, dV \) and \( \int_R f \, dV \leq \int_R g \, dV \).

**Corollary.** Let \( R \) be a rectangle in \( \mathbb{R}^n \), and \( f \) a bounded function on \( R \). If \( m \leq f(x) \leq M \) for all \( x \in R \), then
\[
m \cdot V(R) \leq \int_R f \, dV \leq \int_R f \, dV \leq M \cdot V(R) .
\]
In particular, if \( f \geq 0 \) on \( R \), then \( \int_R f \, dV \geq 0 \).

**Integrability of Products**

Although the result is a special case of the general characterization of integrable functions in (), we can give a simple proof that a product of integrable functions is integrable.

**Lemma.** Let \( R \) be a rectangle in \( \mathbb{R}^n \), and \( f \) a bounded function on \( R \). If \( |f(x)| \leq B \) for all \( x \in R \), then, for any partition \( \mathcal{P} = \{R_1, \ldots, R_m\} \) of \( R \),
\[
\mathbb{S}(f,\mathcal{P}) - \mathbb{S}(f^2,\mathcal{P}) \leq 2B[\mathbb{S}(f,\mathcal{P}) - \mathbb{S}(f,\mathcal{P})] .
\]

**Proof:** For \( 1 \leq k \leq m \), we have, for any \( x, y \in R_k \),
\[
f(x)^2 - f(y)^2 = (f(x) + f(y))(f(x) - f(y))
\]
\[
|f(x)^2 - f(y)^2| = |(f(x) + f(y))(f(x) - f(y))| \leq 2B|f(x) - f(y)|
\]
and therefore \( M_k(f^2) - m_k(f^2) \leq 2B(M_k(f) - m_k(f)) \), and the result follows by summing over \( k \).
XIV.3.1.24. **Corollary.** Let \( R \) be a rectangle in \( \mathbb{R}^n \), and \( f \) a bounded function on \( R \). If \( |f(x)| \leq B \) for all \( x \in R \), then
\[
\int_R f^2 \, dV - \int_R f^2 \, dV \leq 2B \left[ \int_R f \, dV - \int_R f \, dV \right].
\]
In particular, if \( f \) is integrable over \( \mathbb{R} \), then so is \( f^2 \).

XIV.3.1.25. **Proposition.** Let \( R \) be a rectangle in \( \mathbb{R}^n \), and \( f \) and \( g \) bounded functions on \( R \). If \( f \) and \( g \) are integrable over \( R \), then so is \( fg \).

**Proof:** We have \( f + g \) integrable over \( R \) by XIV.3.1.19., and thus \( f^2, g^2, \) and \( (f + g)^2 \) are integrable over \( R \) by XIV.3.1.24.. Since
\[
fg = \frac{1}{2} [(f + g)^2 - f^2 - g^2]
\]
we have that \( fg \) is integrable over \( R \) by XIV.3.1.20..

**Expanding the Rectangle**

We now obtain a technical result which will be important when extending the notion of Riemann integral from rectangles to more general regions. If \( R \) is a rectangle, \( S \) is a subrectangle, and \( f \) is integrable on \( S \), extend \( f \) to \( \mathbb{R}^n \) by setting \( f(x) = 0 \) for \( x \in \mathbb{R}^n \setminus S \). Then the integral of the extended function over \( R \) should be the same as the integral of \( f \) over \( S \). It is:

XIV.3.1.26. **Theorem.** Let \( R \) be a rectangle in \( \mathbb{R}^n \), and \( S \) a subrectangle of \( R \). Let \( f : S \rightarrow \mathbb{R} \) be a bounded function. Define \( g : R \rightarrow \mathbb{R} \) by
\[
g(x) = \begin{cases} f(x) & \text{if } x \in S \\ 0 & \text{if } x \in R \setminus S \end{cases}.
\]
Then
\[
\int_R g \, dV = \int_S f \, dV \text{ and } \int_R g \, dV = \int_S f \, dV.
\]
In particular, \( g \) is integrable over \( R \) if and only if \( f \) is integrable over \( S \), and in this case
\[
\int_R g \, dV = \int_S f \, dV.
\]

There would seem to be a simple proof: consider partitions of \( R \) consisting of a partition of \( S \) and some additional rectangles on which \( f \) is zero. But the problem is that the rectangles in a partition are only nonoverlapping, not disjoint, so some of the additional rectangles will contain points of \( \partial S \) at which \( f \) may well be nonzero. Thus we must work harder to prove the theorem, taking partitions for which all the rectangles covering \( \partial S \) but not in \( S \) have a small total content.
The following construction will be used in the proof. Let \( S = [a_1, b_1] \times \cdots \times [a_n, b_n] \) be a rectangle in \( \mathbb{R}^n \). If \( \delta > 0 \), set
\[
S_\delta = [a_1 - \delta, b_1 + \delta] \times \cdots \times [a_n - \delta, b_n + \delta].
\]
Then \( S_\delta \) is a rectangle in \( \mathbb{R}^n \) containing \( S \) in its interior. \( V(S_\delta) \) is a polynomial in \( \delta \), so by continuity, for any \( \epsilon > 0 \) there is a \( \delta > 0 \) such that \( V(S) < V(S_\delta) < V(S) + \epsilon \).

We now give the proof of XIV.3.1.26.

**Proof:** We may assume \( R \) contains \( S \) in its interior, since if not two applications of the theorem for a larger rectangle containing both \( R \) and \( S \) in its interior give the result. Then \( S_\delta \subseteq R \) for all sufficiently small \( \delta > 0 \). Note that if \( S_\delta \subseteq R \), any partition of \( S \) can be extended to a partition of \( R \) in which \( S_\delta \) as well as \( S \) is a union of rectangles in the partition.

Fix \( \epsilon > 0 \). Let \( B \) be a bound for \( |f| \) on \( S \). Choose \( \delta > 0 \) so that \( S_\delta \subseteq R \) and \( V(S_\delta) < V(S) + \frac{\epsilon}{3B} \). If \( \mathcal{P} \) is any partition of \( S \), extend \( \mathcal{P} \) to a partition \( \mathcal{Q} \) of \( R \) for which \( S_\delta \) is a union of rectangles in \( \mathcal{Q} \). Let \( \mathcal{Q}_1 \) be the set of rectangles in \( \mathcal{Q} \) contained in \( S_\delta \) but not in \( S \), and \( \mathcal{Q}_2 \) the set of rectangles in \( \mathcal{Q} \) not contained in \( S_\delta \). Then
\[
\mathcal{S}(g, \mathcal{Q}) = \sum_{k=1}^m M_k \cdot V(R_k) = \sum_{R_k \in \mathcal{P}} M_k \cdot V(R_k) + \sum_{R_k \in \mathcal{Q}_1} M_k \cdot V(R_k) + \sum_{R_k \in \mathcal{Q}_2} M_k \cdot V(R_k).
\]
The first sum is exactly \( \mathcal{S}(f, \mathcal{P}) \), and the last sum is 0 since \( g \) is identically 0 on the rectangles in \( \mathcal{Q}_2 \). If \( R_k \in \mathcal{Q}_2, |M_k| \leq B \), so the second sum in absolute value is dominated by
\[
\sum_{R_k \in \mathcal{Q}_2} B \cdot V(R_k) = B(V(S_\delta) - V(S)) < \frac{\epsilon}{3}
\]
and therefore
\[
|\mathcal{S}(f, \mathcal{P}) - \mathcal{S}(g, \mathcal{Q})| < \frac{\epsilon}{3}
\]
i.e. for every partition \( \mathcal{P} \) of \( S \) there is a partition \( \mathcal{Q} \) of \( R \) for which this holds. On the other hand, if \( \mathcal{Q} \) is any refinement of \( \mathcal{Q} \), then \( \mathcal{Q} \) is of this form for some refinement \( \mathcal{P} \) of \( \mathcal{P} \). We can thus choose \( \mathcal{P} \) and \( \mathcal{Q} \) so that
\[
\mathcal{S}(f, \mathcal{P}) - \int_S f \, dV < \frac{\epsilon}{3}
\]
and
\[
\mathcal{S}(g, \mathcal{Q}) - \int_R g \, dV < \frac{\epsilon}{3}
\]
from which it follows that
\[
\left| \int_S f \, dV - \int_S g \, dV \right| < \epsilon.
\]
Since \( \epsilon > 0 \) is arbitrary, the upper integrals are equal. The argument for the lower integrals is almost identical.

See XIV.3.11.8. for an alternate version of the proof.
XIV.3.2. Content and Jordan Regions

Using the integral over rectangles, we can say what the “volume” is of more general subsets of Euclidean space.

XIV.3.2.1. Definition. Let $E$ be a bounded subset of $\mathbb{R}^n$. The upper $n$-dimensional (Jordan) content of $E$ is

$$V_n(E) = \int_R \chi_E \, dV$$

where $R$ is a rectangle in $\mathbb{R}^n$ containing $E$.

The lower $n$-dimensional (Jordan) content of $E$ is

$$\underline{V}_n(E) = \int_R \chi_E \, dV$$

where $R$ is a rectangle in $\mathbb{R}^n$ containing $E$.

$E$ is a Jordan region if $V_n(E) = \underline{V}_n(E)$; the (Jordan) content $V_n(E)$ is the common value.

XIV.3.2.2. Note that the upper and lower content are well defined and independent of the containing rectangle $R$ by XIV.3.1.26. We usually suppress the words “$n$-dimensional” and the subscript $n$, but the dimension must be carefully kept in mind. Some authors use the term “volume” instead of (Jordan) content. See XIV.3.1.2.

XIV.3.2.3. A bounded subset $E$ of $\mathbb{R}^n$ is a Jordan region if and only if $\chi_E$ is integrable over some (hence every by XIV.3.1.26.) rectangle $R$ containing $E$, and $V(E) = \int_R \chi_E \, dV$.

XIV.3.2.4. Proposition. If $R$ is a rectangle in $\mathbb{R}^n$, then $R$ is a Jordan region and its Jordan content is $V(R)$, as defined in XIV.3.1.1.

Proof: We can take the containing rectangle to be $R$ itself. Then $\chi_R$ is the constant function 1 on $R$. By XIV.3.1.22. (or by simple direct calculation), $\chi_R$ is integrable on $R$ and $\int_R \chi_R \, dV = \int_R 1 \, dV = V(R)$. \(\Box\)

Thus our notation and terminology is consistent.

XIV.3.2.5. A subset of $\mathbb{R}^n$ is a Jordan region if and only if it boundary has zero content (XIV.3.2.24.). “Geometrically reasonable” subsets of $\mathbb{R}^n$ are thus Jordan regions. But a set like the intersection of the set $A$ of XIV.3.1.15. with a rectangle is not a Jordan region. Note that Jordan regions are by definition bounded.

XIV.3.2.6. If $A$ and $B$ are bounded subsets of $\mathbb{R}^n$ with $A \subseteq B$, then $\overline{V}(A) \leq \overline{V}(B)$ and $\underline{V}(A) \leq \underline{V}(B)$ (cf. XIV.3.1.22.).

The next observation will be considerably improved in XIV.3.2.25., but this form is needed to logically develop the theory and characterization of Jordan regions:
**XIV.3.2.7. Lemma.** Let $A$ and $B$ be Jordan regions in $\mathbb{R}^n$. Then $A \cup B$ is a Jordan region if and only if $A \cap B$ is a Jordan region. In this case, we have

$$V(A \cup B) = V(A) + V(B) - V(A \cap B).$$

**Proof:** We have $\chi_{A \cup B} = \chi(A) + \chi(B) - \chi(A \cap B)$. Let $R$ be a rectangle containing both $A$ and $B$. By assumption, $\chi(A)$ and $\chi(B)$ are integrable over $R$, so it follows from XIV.3.1.20. that $\chi_{A \cup B}$ is integrable over $R$ if and only if $\chi_{A \cap B}$ is. The volume formula also follows from XIV.3.1.20.

**XIV.3.2.8. Corollary.** If \{R_1, \ldots, R_m\} is a finite set of rectangles in $\mathbb{R}^n$, not necessarily nonoverlapping, then $\bigcup_{k=1}^m R_k$ is a Jordan region and

$$V\left(\bigcup_{k=1}^m R_k\right) \leq \sum_{k=1}^m V(R_k)$$

with equality if and only if the $R_k$ are nonoverlapping.

**Proof:** For $m = 2$ the result follows immediately from XIV.3.2.4. and XIV.3.2.7. since the intersection of two rectangles is a rectangle. The result for general $m$ follows by induction.

Along the same lines, the next observation is needed for the logical development although it will be improved in XIV.3.2.25.:

**XIV.3.2.9. Proposition.** Let $E$ be a Jordan region, and $R$ a rectangle containing $E$. Then $R \setminus E$ is also a Jordan region, and $V(R \setminus E) = V(R) - V(E)$.

**Proof:** We have that $\chi_{R \setminus E} = \chi_R - \chi_E$: $\chi_E$ is integrable over $R$ by assumption, and $\chi_R$ is integrable over $R$ by XIV.3.2.4., so $\chi_{R \setminus E}$ is integrable over $R$ and the content formula holds by XIV.3.1.20.

**An Alternate Description of Content**

We can give an illuminating direct description of content by explicitly describing upper and lower sums for the integral of an indicator function.

**XIV.3.2.10.** Let $E$ be a bounded subset of $\mathbb{R}^n$. If $R$ is a rectangle in $\mathbb{R}^n$ containing $E$ and $\mathcal{P} = \{R_1, \ldots, R_m\}$ is a partition of $R$, we have

$$\mathcal{S}(\chi_E, \mathcal{P}) = \sum_{R_k \cap E \neq \emptyset} V(R_k)$$

and

$$\mathcal{S}(\chi_E, \mathcal{P}) = \sum_{R_k \subseteq E} V(R_k)$$

1563
i.e. $\overline{V}(E)$ is estimated as the content of the union of the rectangles in $P$ containing points of $E$, and $\overline{V}(E)$ is estimated as the content of the union of the rectangles in $P$ entirely contained in $E$; in fact, they are the infimum and supremum of such contents over all partitions of $R$.

Combining with XIV.3.2.8, we obtain:

**XIV.3.2.11. Proposition.** If $E$ is a bounded subset of $\mathbb{R}^n$, then

$$\overline{V}(E) = \sup \left( \sum_{k=1}^{m} V(R_k) \right)$$

where the supremum is over all finite sets $\{R_1, \ldots, R_m\}$ of pairwise nonoverlapping rectangles contained in $E$.

For upper sums, since any finite set of rectangles has a subdivision into nonoverlapping rectangles, we can relax the requirement that the rectangles be nonoverlapping:

**XIV.3.2.12. Proposition.** If $E$ is a bounded subset of $\mathbb{R}^n$, then

$$\underline{V}(E) = \inf \left( \sum_{k=1}^{m} V(R_k) \right)$$

where the infimum is over all finite sets $\{R_1, \ldots, R_m\}$ of rectangles covering $E$.

Sets of Zero Content

**XIV.3.2.13. Definition.** A subset $E$ of $\mathbb{R}^n$ has *zero content* if $\overline{V}(E) = 0$.

Two subsets $A$ and $B$ of $\mathbb{R}^n$ are *nonoverlapping* if $A \cap B$ has zero content.

**XIV.3.2.14.** If $E$ has zero content, it is a Jordan region since $0 \leq \overline{V}(E) \leq \overline{V}(E) = 0$. Any subset of a set of zero content also has zero content. A rectangle has zero content if and only if it is degenerate. Thus two rectangles are nonoverlapping in the sense of XIV.3.2.13, if and only if they are nonoverlapping in the sense of XIV.3.1.4.

The next result is then an immediate consequence of XIV.3.2.7:

**XIV.3.2.15. Proposition.** Let $E_1, \ldots, E_m$ be pairwise nonoverlapping Jordan regions. Then $\bigcup_{k=1}^{m} E_k$ is a Jordan region and

$$\overline{V} \left( \bigcup_{k=1}^{m} E_k \right) = \sum_{k=1}^{m} V(E_k) .$$
XIV.3.2.16. **COROLLARY.** A finite union of sets of zero content has zero content.

The next result gives a large supply of sets of zero content:

XIV.3.2.17. **PROPOSITION.** Let $E$ be a compact Jordan region in $\mathbb{R}^{n-1}$, $\phi : E \to \mathbb{R}$ a continuous function, and $G$ the graph of $\phi$, i.e.,

$$G = \{(x_1, \ldots, x_n) : (x_1, \ldots, x_{n-1}) \in E, x_n = \phi(x_1, \ldots, x_{n-1})\} \subseteq \mathbb{R}^n.$$  

Then $G$ is a set of zero content in $\mathbb{R}^n$.

**Proof:** Let $R$ be a rectangle in $\mathbb{R}^n$ containing $E$. Let $\epsilon > 0$. Since $E$ is compact, $\phi$ is uniformly continuous on $E$, so there is a $\delta > 0$ such that $|\phi(x) - \phi(y)| < \frac{\epsilon}{\sqrt{V(R)}}$ whenever $x, y \in E$ and $|x - y| < \delta$. There is a partition $P = \{R_1, \ldots, R_m\}$ of $R$ such that the diameter of each $R_k$ is less than $\delta$; thus if $M_k$ and $m_k$ are the supremum and infimum of $\phi$ over $R_k \cap E$ for each $R_k$ containing points of $E$, we have $M_k - m_k \leq \frac{\epsilon}{\sqrt{V(R)}}$ for all such $k$. Then if $\tilde{R}_k = R_k \times [m_k, M_k]$ for each such $k$, then the $\tilde{R}_k$ are nonoverlapping rectangles covering $G$, and

$$\sum_k V(\tilde{R}_k) \leq \sum_k V(R_k) \cdot \frac{\epsilon}{\sqrt{V(R)}} \leq \epsilon$$

(the sum is over all $k$ for which $R_k \cap E \neq \emptyset$). Thus $\overline{V_n}(G) \leq \epsilon$. Since $\epsilon > 0$ is arbitrary, $\overline{V_n}(G) = 0$.  

XIV.3.2.18. If $E$ is a compact set in $\mathbb{R}^n$ and every point of $E$ has a neighborhood in $E$ which is a set of zero content in $\mathbb{R}^n$, then a simple compactness argument and XIV.3.2.16. shows that $E$ is a set of zero content. In particular, if $E$ is compact and locally the graph of a continuous function of some $n - 1$ of the coordinates, then $E$ is a set of zero content. Many sets can be shown to be of this form by the Implicit Function Theorem.

XIV.3.2.19. It is crucial to specify the $n$ when saying that a set has zero content in $\mathbb{R}^n$. If we regard $\mathbb{R}^n$ as a subset of $\mathbb{R}^{n+1}$ by identifying it with an affine subspace, every bounded subset of $\mathbb{R}^n$ has zero content in $\mathbb{R}^{n+1}$. In fact, the notion of Jordan region in $\mathbb{R}^n$ depends on $n$: any bounded subset of $\mathbb{R}^n$ is thus a Jordan region in $\mathbb{R}^{n+1}$. So the property of $E$ being a Jordan region is not intrinsic to $E$, but depends on the choice of Euclidean space containing $E$ (and also how $E$ is embedded in that space).

XIV.3.2.20. **PROPOSITION.** Let $A$ and $B$ be bounded regions in $\mathbb{R}^p$ and $\mathbb{R}^q$ respectively. If $A$ has zero content in $\mathbb{R}^p$, then $A \times B$ has zero content in $\mathbb{R}^{p+q}$.

**Proof:** Let $S$ be a bounded rectangle in $\mathbb{R}^q$ containing $B$. Let $\epsilon > 0$. There is a finite set $\{R_1, \ldots, R_n\}$ in $\mathbb{R}^p$ covering $A$ with

$$\sum_{k=1}^n V(R_k) < \frac{\epsilon}{V(S) + 1}.$$  

1565
Then \( \{R_1 \times S, \ldots, R_n \times S\} \) is a finite set of rectangles covering \( A \times B \), and \( V(R_k \times S) = V(R_k)V(S) \), so

\[
V(A \times B) \leq \sum_{k=1}^{n} V(R_k \times S) = V(S) \sum_{k=1}^{n} V(R_k) < \epsilon .
\]

The next theorem is a key result about integrability, generalizing XIV.3.14. This is, however, not the ultimate characterization of integrability, which will be given in ( ).

**Theorem.** Let \( R \) be a rectangle in \( \mathbb{R}^n \), and \( f : R \to \mathbb{R} \) a bounded function. If \( f \) is continuous except on a set of zero content, then \( f \) is integrable over \( R \).

**Proof:** Suppose \( f \) is continuous except on a set \( A \) with \( V(A) = 0 \). We will use the following notation. If \( \mathcal{P} = \{R_1, \ldots, R_m\} \) is a partition of \( R \), set \( J = \{j : R_j \cap A \neq \emptyset\} \) and \( K = \{k : R_k \cap A = \emptyset\} \).

Let \( M \) be a bound for \( |f| \) on \( R \). Let \( \epsilon > 0 \). Then, since \( A \) has volume 0, there is a partition \( \mathcal{P} \) of \( R \) such that

\[
\sum_{j \in J} V(R_j) < \epsilon .
\]

Let \( B = \bigcup_{k \in K} R_k \). Then \( B \) is compact and \( f \) is continuous on \( B \), hence uniformly continuous, so there is a \( \delta > 0 \) such that \( |f(x) - f(y)| < \epsilon \frac{1}{2V(R)} \) whenever \( x, y \in B \) and \( |x - y| < \delta \). By subdividing the \( R_k \) for \( k \in K \) if necessary, we may assume that the diameter of each \( R_k \) is less than \( \delta \). Thus if \( M_k \) and \( m_k \) are the supremum and infimum of \( f \) over \( R_k \), we have

\[
M_k - m_k \leq \frac{\epsilon}{2V(R)} .
\]

Furthermore, for each \( j \in J \) we have \( M_j - m_j \leq 2M \). Thus

\[
\mathcal{S}(f, \mathcal{P}) - \mathcal{S}(f, \mathcal{P}) = \sum_{j \in J} (M_j - m_j)V(R_j) + \sum_{k \in K} (M_k - m_k)V(R_k)
\]

\[
\leq 2M \sum_{j \in J} V(R_j) + \frac{\epsilon}{2V(R)} \sum_{k \in K} V(R_k) \leq 2M \frac{\epsilon}{4M} + \frac{\epsilon}{2V(R)} V(R) = \epsilon .
\]

Since \( \epsilon > 0 \) is arbitrary, \( f \) is integrable over \( R \).

**Characterization of Jordan Regions**

The first result is a corollary of XIV.3.2.21.

**Corollary.** Let \( E \) be a bounded set in \( \mathbb{R}^n \). If \( \partial E \) has zero content, then \( E \) is a Jordan region.

**Proof:** The indicator function \( \chi_E \) is discontinuous exactly on \( \partial E \).
XIV.3.2.23. Proposition. If $E$ is a Jordan region in $\mathbb{R}^n$, then $\bar{E}$ and $E^o$ are also Jordan regions, and

$$V(\bar{E}) = V(E^o) = V(E).$$

Proof: Let $R$ be a rectangle containing $E$. Let $\epsilon > 0$, and let $P = \{R_1, \ldots, R_m\}$ be a partition of $R$ such that

$$\sum_{j \in J} V(R_j) < V(E) + \epsilon$$

where $J$ is the set of $j$ for which $R_j \cap E \neq \emptyset$. Let $B = \bigcup_{j \in J} R_j$. Then $B$ is a closed set and $E \subseteq B$, so $\bar{E} \subseteq B$, and $B$ is a Jordan region by XIV.3.2.24. We have

$$V(E) = V(\bar{E}) \leq V(E) \leq V(B) = \sum_{j \in J} V(R_j) < V(E) + \epsilon.$$

Since $\epsilon > 0$ is arbitrary, we have

$$V(E) = V(\bar{E}) = V(E) = V(E)$$

so $\bar{E}$ is a Jordan region and $V(\bar{E}) = V(E)$.

By XIV.3.2.9, $R \setminus E$ is a Jordan region, so $\overline{R \setminus E} = R \setminus E^o$ is a Jordan region, and hence $E^o$ is a Jordan region; and we have

$$V(R) - V(E^o) = V(R \setminus E^o) = V(R \setminus E) = V(R \setminus E) = V(R) - V(E)$$

and it follows that $V(E^o) = V(E)$.

We now come to the main theorem characterizing Jordan regions.

XIV.3.2.24. Theorem. Let $E$ be a bounded subset of $\mathbb{R}^n$. Then $E$ is a Jordan region in $\mathbb{R}^n$ if and only if $\partial E$ has zero content.

Proof: If $\partial E$ has zero content, then $E$ is a Jordan region by XIV.3.2.22. Conversely, suppose $E$ is a Jordan region. Then $\bar{E}$ and $E^o$ are also Jordan regions, and $V(\bar{E}) = V(E^o) = V(E)$ by XIV.3.2.23. Let $R$ be a rectangle containing $E$. If $P = \{R_1, \ldots, R_m\}$ is a partition of $R$, we can partition $\{1, \ldots, m\}$ into three sets $I, J, K$, where $I$ is the set of $i$ such that $R_i \subseteq E^o$, $J$ is the set of $j$ such that $R_j \subseteq R \setminus E$ (i.e. such that $R_j \cap \bar{E} = \emptyset$), and $K$ is the set of $k$ such that $R_k \cap \partial E \neq \emptyset$.

Let $\epsilon > 0$. If $P$ is sufficiently fine, then by XIV.3.2.11. and XIV.3.2.9, we have

$$\sum_{i \in I} V(R_i) > V(E^o) - \frac{\epsilon}{2} = V(E) - \frac{\epsilon}{2}$$

$$\sum_{j \in J} V(R_j) > V(R \setminus \bar{E}) - \frac{\epsilon}{2} = V(R) - V(E) - \frac{\epsilon}{2}.$$

$$\sum_{i \in I} V(R_i) + \sum_{j \in J} V(R_j) > \left[ V(E) - \frac{\epsilon}{2} \right] + \left[ V(R) - V(E) - \frac{\epsilon}{2} \right] = V(R) - \epsilon.$$
By XIV.3.1.6., we have
\[ V(R) = \sum_{i \in I} V(R_i) + \sum_{j \in J} V(R_j) + \sum_{k \in K} V(R_k) \]
so we conclude
\[ \sum_{k \in K} V(R_k) < \epsilon . \]

If we let \( B = \bigcup_{k \in K} R_k \), then \( \partial E \subseteq B \), so by XIV.3.2.8.
\[ \overline{V}(\partial E) \leq V(B) = \sum_{k \in K} V(R_k) < \epsilon \]
and since \( \epsilon > 0 \) is arbitrary, \( \overline{V}(\partial E) = 0. \)

**XIV.3.2.25. Corollary.** Let \( A \) and \( B \) be Jordan regions in \( \mathbb{R}^n \). Then \( A \cup B, A \cap B, \) and \( A \setminus B \) are Jordan regions, and
\[ V(A \cup B) = V(A) + V(B) - V(A \cap B) \]
\[ V(A \setminus B) = V(A) - V(A \cap B) . \]

**Proof:** By XIV.3.2.24., \( \partial A \) and \( \partial B \) have zero content. We have \( \partial(A \cup B) \subseteq \partial A \cup \partial B \), and \( \partial A \cup \partial B \) has zero content by XIV.3.2.16.; thus \( \partial(A \cup B) \) has zero content and \( A \cup B \) is a Jordan region by XIV.3.2.24.. It then follows from XIV.3.2.7. that \( A \cap B \) is a Jordan region and the first content formula holds. If \( R \) is a rectangle containing \( A \) and \( B \), then \( R \setminus B \) is a Jordan region by XIV.3.2.9., so \( A \setminus B = A \cap (R \setminus B) \) is a Jordan region. We have
\[ V(A) = V(A \cap B) + V(A \setminus B) \]
since \( A \cap B \) and \( A \setminus B \) are disjoint.

**XIV.3.2.26. Corollary.** Let \( A \) and \( B \) be Jordan regions in \( \mathbb{R}^p \) and \( \mathbb{R}^q \) respectively. Then \( A \times B \) is a Jordan region in \( \mathbb{R}^{p+q} \).

**Proof:** We have \( \partial(A \times B) = (\partial A \times B) \cup (A \times \partial B) \), which is a set of zero content by XIV.3.2.20..

**XIV.3.3. Integration over Jordan Regions**

It is now a simple matter to extend the integral to general Jordan regions.

**XIV.3.3.1. Definition.** Let \( E \) be a Jordan region in \( \mathbb{R}^n \), and \( f : E \to \mathbb{R} \). Denote by \( f \chi_E \) the function from \( \mathbb{R}^n \) to \( \mathbb{R} \) defined by
\[ f \chi_E(x) = \begin{cases} f(x) & \text{if } x \in E \\ 0 & \text{if } x \notin E \end{cases} . \]

This definition is a slight abuse of notation since \( f \) is only defined on \( E \), so \( f \chi_E \) is technically not a product; but this ambiguity will cause no trouble.
XIV.3.3.2. Definition. Let $E$ be a Jordan region in $\mathbb{R}^n$, and $f : E \to \mathbb{R}$ a function. Then $f$ is (Riemann) integrable over $E$ if $f \chi_E$ is integrable over some (hence every) rectangle containing $E$. If $f$ is integrable over $E$, define

$$\int_E f \, dV = \int_R f \chi_E \, dV$$

where $R$ is any rectangle containing $E$ (cf. XIV.3.1.26.).

Note that an integrable function is necessarily bounded.

XIV.3.3.3. Comparing definitions, the constant function 1 is integrable over $E$, and $\int_E 1 \, dV = V(E)$. (This example indicates that it is not reasonable to try to similarly define the integral of a function over a set which is not a Jordan region, since even constant functions will not then be integrable).

XIV.3.3.4. Proposition. Let $A$ and $B$ be Jordan regions in $\mathbb{R}^n$, with $A \subseteq B$. If $f : A \to \mathbb{R}$ is integrable on $A$, then $f|_B$ is integrable on $B$.

Proof: We have $f \chi_B = (f \chi_A) \chi_B$ (this is an honest product). If $R$ is a rectangle containing $A$, then $f \chi_A$ and $\chi_B$ are integrable over $R$ by assumption, so $(f \chi_A) \chi_B$ is integrable over $R$ by XIV.3.1.25..)

The next extension of XIV.3.2.21. gives a large supply of integrable functions including almost all functions of interest in applications:

XIV.3.3.5. Theorem. Let $E$ be a Jordan region in $\mathbb{R}^n$, and $f : E \to \mathbb{R}$ a bounded function. If $f$ is continuous except on a set of zero content, then $f$ is integrable over $E$.

Proof: Suppose $f$ is continuous on $E$ except on a subset $A$ of zero content. If $R$ is a rectangle containing $E$, then $f \chi_E$ is continuous on $R$ except (possibly) on $A \cup \partial E$, which is a set of zero content (XIV.3.2.16.). Thus $f \chi_E$ is integrable over $R$ by XIV.3.2.21..)

Note that even if $f$ is continuous on $E$, XIV.3.2.21. is needed to show that $f$ is integrable on $E$; XIV.3.1.14. is not enough.

Properties of the Integral

The standard properties of the integral over Jordan regions then follow immediately from the properties of integrals over rectangles (note e.g. that $(f + g) \chi_E = f \chi_E + g \chi_E$, etc.)

XIV.3.3.6. Proposition. The integral over a fixed Jordan region is linear: if $f$ and $g$ are integrable over a Jordan region $E$, and $\alpha, \beta \in \mathbb{R}$, then $\alpha f + \beta g$ is integrable over $E$ and

$$\int_E (\alpha f + \beta g) \, dV = \alpha \int_E f \, dV + \beta \int_E g \, dV$$.
XIV.3.3.7. Proposition. Let $E$ be a Jordan region in $\mathbb{R}^n$, and $f$ and $g$ bounded functions on $E$. If $f \leq g$ on $E$, then

$$\int_E f\,dV \leq \int_E g\,dV.$$ 

XIV.3.3.8. Corollary. Let $E$ be a Jordan region in $\mathbb{R}^n$, and $f$ a bounded function on $E$. If $m \leq f(x) \leq M$ for all $x \in E$, then

$$m \cdot V(E) \leq \int_E f\,dV \leq M \cdot V(E).$$

In particular, if $f \geq 0$ on $E$, then $\int_E f\,dV \geq 0$.

XIV.3.3.9. Proposition. Let $E$ be a set of zero content, and $f : E \to \mathbb{R}$ a bounded function. Then $f$ is integrable over $E$, and $\int_E f\,dV = 0$.

Proof: Suppose $m \leq f(x) \leq M$ for all $x \in E$. If $R$ is a rectangle containing $E$, then $m\chi_E \leq f\chi_E \leq M\chi_E$ on $R$, so

$$0 = mV(E) = \int_R m\chi_E\,dV \leq \int_R f\chi_E\,dV \leq \int_R M\chi_E\,dV = 0.$$

XIV.3.3.10. Proposition. Let $A$ and $B$ be Jordan regions in $\mathbb{R}^n$, and $f : A \cup B \to \mathbb{R}$ an integrable function. Then $f$ is integrable over $A$, $B$, and $A \cap B$, and

$$\int_{A \cup B} f\,dV = \int_A f\,dV + \int_B f\,dV - \int_{A \cap B} f\,dV.$$

Proof: We have $f$ integrable over $A$, $B$, $A \cap B$ by XIV.3.3.4., and the formula then follows by linearity.

XIV.3.3.11. Corollary. Let $E_1, \ldots, E_m$ be pairwise nonoverlapping Jordan regions in $\mathbb{R}^n$, and $E = E_1 \cup \cdots \cup E_n$. If $f : E \to \mathbb{R}$ is a function, then $f$ is integrable over $E$ if and only if $f|_{E_k}$ is integrable over $E_k$ for each $k$. If this is the case, then

$$\int_E f\,dV = \sum_{k=1}^m \int_{E_k} f\,dV.$$
XIV.3.4. Fubini’s Theorem

XIV.3.4.1. The definition of the integral works more or less the same for \( \mathbb{R}^n \), \( n > 1 \), as it does for \( \mathbb{R} \). But there is one dramatic difference: so far we have no effective way of calculating integrals in the multivariable case, i.e. there is no Fundamental Theorem of Calculus in the vector case (actually there is, Stokes’ Theorem \(), but this is usually not useful for computing the integral).

XIV.3.4.2. Many authors use different notation for multivariable integrals, e.g. writing

\[
\int_R f \, dA \quad (n = 2)
\]

\[
\int_R \int_R f \, dV \quad (n = 3)
\]

\[
\cdots \int_R f \, dV \quad (n \text{ integral signs})
\]

in general for \( \int_R f \, dV \). I prefer the single integral sign notation, since the integral is a single integral over a multidimensional set; to emphasize the dimension, we can write \( \int_R f \, dV_n \). But the multiple integral notation is suggestive of a possible way to compute the integral: as an \( n \)-fold repeated one-dimensional integral, each of which can (potentially) be calculated using the Fundamental Theorem of Calculus. Fubini’s Theorem (the Riemann integral form) says that this can be done under reasonable hypotheses.

Iterated Integrals

XIV.3.4.3. If \( A \subseteq \mathbb{R}^p \) and \( B \subseteq \mathbb{R}^q \), we can regard \( A \times B \) as a subset of \( \mathbb{R}^{p+q} \cong \mathbb{R}^p \times \mathbb{R}^q \). If \( f \) is a bounded real-valued function on \( A \times B \), for each \( x \in A \) we have a function \( f[x] : B \to \mathbb{R} \) defined by \( f[x](y) = f(x, y) \). If \( A \) and \( B \) are Jordan regions and we set

\[
g(x) = \int_B f[x] \, dV
\]

then \( g \) is a bounded function from \( A \) to \( \mathbb{R} \); we symbolically write

\[
\int_A g \, dV = \int_A \left[ \int_B f(x, y) \, dV(y) \right] \, dV(x) = \int_A \int_B f(x, y) \, dV(y) \, dV(x)
\]

(the brackets are typically omitted), and similarly

\[
h(x) = \int_B f[x] \, dV
\]

\[
\int_A h \, dV = \int_A \int_B f(x, y) \, dV(y) \, dV(x)
\]

In the same way, for each \( y \in B \) we have a function \( f[y] : A \to \mathbb{R} \) defined by \( f[y](x) = f(x, y) \), and if

\[
g(y) = \int_A f[y] \, dV
\]
we write
\[ \int_B g \, dV = \int_B \int_A f(x, y) \, dV(x) \, dV(y) \]
and if
\[ h(y) = \int_A f(y) \, dV \]
\[ \int_B h \, dV = \int_B \int_A f(x, y) \, dV(x) \, dV(y) . \]
These are called \textit{iterated upper and lower integrals} (we could in principle also define \( \int_A \int_B f(x, y) \, dV(y) \, dV(x) \), etc., but these are rarely if ever used). If all the functions involved are integrable, we can write
\[ \int_A \int_B f(x, y) \, dV(y) \, dV(x) \text{ or } \int_B \int_A f(x, y) \, dV(x) \, dV(y) . \]
These are \textit{iterated integrals}.

\textbf{Fubini’s Theorem for Rectangles}

\textbf{XIV.3.4.4. Theorem. [Fubini’s Theorem, Upper and Lower Form]} Let \( R \) be a rectangle in \( \mathbb{R}^p \) and \( S \) a rectangle in \( \mathbb{R}^q \), so that \( R \times S \) is a rectangle in \( \mathbb{R}^{p+q} \). Let \( f : R \times S \to \mathbb{R} \) be a bounded function. Then
\[ \int_{R \times S} f \, dV \leq \int_R \int_S f(x, y) \, dV(y) \, dV(x) \leq \int_{R \times S} f \, dV . \]

To emphasize the dimensions of the integrals, we can write
\[ \int_{R \times S} f \, dV_{p+q} \leq \int_R \int_S f(x, y) \, dV_p(y) \, dV_q(x) \leq \int_{R \times S} f \, dV_{p+q} . \]

\textbf{XIV.3.4.5. Note that the order of \( R \) and \( S \) is arbitrary: we equally obtain}
\[ \int_{R \times S} f \, dV \leq \int_S \int_R f(x, y) \, dV(x) \, dV(y) \leq \int_{R \times S} f \, dV . \]

\textbf{Proof:} We prove the third inequality; the proof of the first is almost identical, and the second inequality is trivial. So, for \( x \in R \), set
\[ g(x) = \int_S f(x, y) \, dV = \int_S f(x, y) \, dV(y) . \]
We must prove
\[ \int_R g \, dV \leq \int_{R \times S} f \, dV . \]
Since every grid partition of $R \times S$ is of the form $\mathcal{P} \times \mathcal{Q}$ for some partitions $\mathcal{P}$ of $R$ and $\mathcal{Q}$ of $S$, it suffices to show that
\[ \mathcal{S}(g, \mathcal{P}) \leq \mathcal{S}(f, \mathcal{P} \times \mathcal{Q}) \]
for any such $\mathcal{P}$ and $\mathcal{Q}$, since then the desired inequality is obtained by taking the infimum over all $\mathcal{P}$ and $\mathcal{Q}$.

So let $\mathcal{P} = \{R_1, \ldots, R_m\}$ and $\mathcal{Q} = \{S_1, \ldots, S_n\}$ be partitions of $R$ and $S$. For $1 \leq j \leq m$ and $1 \leq k \leq n$, let $M_{jk}(f)$ be the supremum of $f$ over $R_j \times S_k$, and let $M_j(g)$ be the supremum of $g$ over $R_j$. We then have
\[ \mathcal{S}(f, \mathcal{P} \times \mathcal{Q}) = \sum_{j=1}^{m} \sum_{k=1}^{n} M_{jk}(f) V(R_j) V(S_k) \]
\[ \mathcal{S}(g, \mathcal{P}) = \sum_{j=1}^{m} M_j(g) V(R_j) \]
so it suffices to show that for each $j$,
\[ M_j(g) \leq \sum_{k=1}^{n} M_{jk}(f) V(S_k) . \]

Fix $j$. For $x \in R_j$,
\[ g(x) = \int_{S} f_{[x]} \, dV \leq \mathcal{S}(f_{[x]}, \mathcal{Q}) = \sum_{k=1}^{n} M_k(f_{[x]}) V(S_k) \]
where
\[ M_k(f_{[x]}) = \sup_{y \in S_k} f(x, y) \leq M_{jk}(f) \]
since $x \in R_j$. Thus
\[ g(x) \leq \sum_{k=1}^{n} M_{jk}(f) V(S_k) \]
and, taking the supremum $M_j(g)$ over $x \in R_j$, the desired inequality follows.

The next result, an immediate corollary of XIV.3.4.4., is the case of most interest:

**XIV.3.4.6.** Corollary. [Fubini’s Theorem, Riemann Integral Version] Let $R$ be a rectangle in $\mathbb{R}^p$ and $S$ a rectangle in $\mathbb{R}^q$, so that $R \times S$ is a rectangle in $\mathbb{R}^{p+q}$. Let $f : R \times S \to \mathbb{R}$ be a bounded function.

(i) Suppose $f$ is integrable over $R \times S$ and, for each $x \in R$, $f_{[x]}$ is integrable over $S$. If
\[ g(x) = \int_{S} f_{[x]} \, dV \]
for $x \in R$, then $g$ is integrable over $R$, and
\[ \int_{R \times S} f \, dV = \int_{R} g \, dV = \int_{R} \int_{S} f(x, y) \, dV(y) \, dV(x) . \]
(ii) Suppose \( f \) is integrable over \( R \times S \) and, for each \( y \in S \), \( f[y] \) is integrable over \( R \). If
\[
h(y) = \int_{R} f[y] \, dV
\]
for \( y \in S \), then \( h \) is integrable over \( S \), and
\[
\int_{R \times S} f \, dV = \int_{S} h \, dV = \int_{S} \int_{R} f(x, y) \, dV(x) \, dV(y) .
\]

(iii) If both (i) and (ii) hold (i.e. if \( f \) and each \( f[x] \) and \( f[y] \) are integrable), then
\[
\int_{R} \int_{S} f(x, y) \, dV(y) \, dV(x) = \int_{S} \int_{R} f(x, y) \, dV(x) \, dV(y) \quad \left( = \int_{R \times S} f \, dV \right) .
\]

**Proof:** (i): From the Theorem, we have
\[
\int_{R \times S} f \, dV \leq \int_{R} \int_{S} f(x, y) \, dV(y) \, dV(x) \leq \int_{R} \int_{S} f(x, y) \, dV(y) \, dV(x) \leq \int_{R \times S} f \, dV
\]
so the inequalities are equalities, and the middle equality exactly says that \( g \) is integrable over \( R \). The proof of (ii) is almost identical, and (iii) is just a combination of (i) and (ii).

A clean and especially important special case (cf. XIV.3.14., XV.8.3.5.(c)) is:

**XIV.3.4.7.** Corollary. [Fubini’s Theorem, Continuous Version] Let \( R \) be a rectangle in \( \mathbb{R}^p \) and \( S \) a rectangle in \( \mathbb{R}^q \), so that \( R \times S \) is a rectangle in \( \mathbb{R}^{p+q} \). Let \( f : R \times S \to \mathbb{R} \) be a continuous function. Then
\[
\int_{R \times S} f \, dV = \int_{R} \int_{S} f(x, y) \, dV(y) \, dV(x) = \int_{S} \int_{R} f(x, y) \, dV(x) \, dV(y) .
\]
In particular, the two iterated integrals are equal.

**XIV.3.4.8.** This result (XIV.3.4.6.) can be interpreted, and used, in two different ways. On the one hand, it says that (under certain conditions) the integral over \( R \times S \) can be computed by an iterated integral. On the other hand, (iii) says that (under certain conditions) the order of integration can be reversed in an iterated integral. Both interpretations are important in different contexts; for example, it is sometimes possible to evaluate an iterated integral in one order but not the other using the FTC (cf. XIV.3.11.11.).

**XIV.3.4.9.** Actually these versions of “Fubini’s Theorem” may have been “known” before Fubini, who proved a general version for Lebesgue integration (). All theorems involving changing the order of iterated summation or integration are now generically called “Fubini’s Theorem” since they are special cases of (). See XIV.3.4.34. for further comments.

If \( p = q = 1 \), XIV.3.4.7. can be rephrased, changing notation slightly:
XIV.3.4.10. **Theorem.** [Fubini’s Theorem in \( \mathbb{R}^2 \), Rectangle Continuous Version] Let \( R = [a, b] \times [c, d] \) be a rectangle in \( \mathbb{R}^2 \), and \( f : R \to \mathbb{R} \) a continuous function. Then

\[
\int_R f \, dV = \int_a^b \int_c^d f(x, y) \, dy \, dx = \int_c^d \int_a^b f(x, y) \, dx \, dy.
\]

In particular, the two iterated integrals are equal.

XIV.3.4.11. In calculating the inner integral (e.g. by the FTC), the outer variable is treated as a constant. Thus the inner integral can be regarded as a “partial antiderivative.”

XIV.3.4.12. If \( p \) or \( q \) is greater than 1, the iterated integrals can be further broken into iterated integrals of smaller dimension by repeatedly applying the various versions of Fubini’s Theorem. It is cumbersome to explicitly state the appropriate hypotheses for the higher iterated version of XIV.3.4.6., but XIV.3.4.7. can be cleanly stated. We only state the ultimate reduced version as in XIV.3.4.10.:

XIV.3.4.13. **Theorem.** [Fubini’s Theorem in \( \mathbb{R}^n \), Rectangle Continuous Version] Let \( R = [a_1, b_1] \times \cdots \times [a_n, b_n] \) be a rectangle in \( \mathbb{R}^n \), and \( f : R \to \mathbb{R} \) a continuous function. Then

\[
\int_R f \, dV = \int_{a_1}^{b_1} \cdots \int_{a_n}^{b_n} f(x_1, \ldots, x_n) \, dx_n \cdots dx_2 dx_1.
\]

The iterated integrals can be done in any order.

**Iterated Integrals over Other Regions**

In applications we frequently want to integrate over regions more general than rectangles. In good cases such integrals can also be calculated as iterated integrals. Note that even to do this when integrating a continuous function requires the version of Fubini’s Theorem in XIV.3.4.6., i.e. XIV.3.4.7. is not enough.

We will not try to do this in the utmost generality, which requires cumbersome notation and hypotheses; instead, we will restrict to clean forms which are adequate for almost all applications. The first version is straightforward:

XIV.3.4.14. **Theorem.** Let \( A \) and \( B \) be Jordan regions in \( \mathbb{R}^p \) and \( \mathbb{R}^q \) respectively (so \( A \times B \) is a Jordan region in \( \mathbb{R}^{p+q} \)). If \( f : A \times B \to \mathbb{R} \) is bounded and continuous, then

\[
\int_{A \times B} f \, dV = \int_A \int_B f(x, y) \, dV(y) \, dV(x) = \int_B \int_A f(x, y) \, dV(x) \, dV(y)
\]

(in particular, the iterated integrals exist and are equal).

**Proof:** \( A \times B \) is a Jordan region (XIV.3.2.26.). Let \( R \) and \( S \) be rectangles containing \( A \) and \( B \) respectively, and apply XIV.3.4.6. to \( f \chi_{A \times B} \) on \( R \times S \) (it is easily checked that the hypotheses apply).  

\[\Box\]
XIV.3.4.15. Corollary. Let $A$ and $B$ be Jordan regions in $\mathbb{R}^p$ and $\mathbb{R}^q$ respectively (so $A \times B$ is a Jordan region in $\mathbb{R}^{p+q}$). Then $V(A \times B) = V(A)V(B)$.

To handle regions more general than products, we begin with subsets of $\mathbb{R}^2$:

XIV.3.4.16. Definition. A subset $E$ of $\mathbb{R}^2$ is projectable (with respect to the order $x, y$) if there are intervals $[a, b]$ and continuous functions $\phi, \psi : [a, b] \to \mathbb{R}$ with $\phi \leq \psi$ and

$$E = \{(x, y) : a \leq x \leq b, \ \phi(x) \leq y \leq \psi(x)\}.$$  

XIV.3.4.17. See Figure XIV.20 (adapted from http://tutorial.math.lamar.edu/Classes/CalcIII/DIGeneralRegion.aspx). We can also define projectability in the order $y, x$: $E$ is projectable in the order $y, x$ if there is an interval $[c, d]$ and functions $\phi, \psi : [c, d] \to \mathbb{R}$ such that

$$E = \{(x, y) : c \leq y \leq d, \ \phi(y) \leq x \leq \psi(y)\}.$$  

A set $E$ is projectable if it is projectable in at least one order; some simple regions are projectable in either order, and others projectable in one order but not the other. Most regions in $\mathbb{R}^2$ one would want to integrate over are projectable, or at least a finite union of nonoverlapping projectable regions. Note that a projectable region is compact.

![Projectable Regions](http://tutorial.math.lamar.edu/Classes/CalcIII/DIGeneralRegion.aspx)

Figure XIV.20: Projectable Regions.

XIV.3.4.18. The boundary of a projectable region

$$E = \{(x, y) : a \leq x \leq b, \ \phi(x) \leq y \leq \psi(x)\}$$

consists of the graphs of $\phi$ and $\psi$, and the vertical line segments

$$\{(a, y) : \phi(a) \leq y \leq \psi(a)\} \text{ and } \{(b, y) : \phi(b) \leq y \leq \psi(b)\}$$

(one or both vertical segments can be degenerate), all of which have volume 0 in $\mathbb{R}^2$ by XIV.3.2.17. Thus $E$ is a Jordan region in $\mathbb{R}^2$. 

1576
If \( E \) is the projectable region above, fix \( c \) and \( d \) with \( c \leq \phi(x) \leq \psi(x) \leq d \) for all \( x \in [a, b] \).

If \( f : E \to \mathbb{R} \) is a function, then \( f \) can be considered a function on \( R = [a, b] \times [c, d] \) in the usual way by setting it 0 on \( R \setminus E \). If \( f \) is continuous on \( E \), then for each \( x \in [a, b] \) we have that \( f(x) \) is piecewise-continuous on \([c, d]\), supported on \([\phi(x), \psi(x)]\), hence integrable on \([c, d]\). Fubini’s Theorem (XIV.3.4.6. (i) form) applies to give

\[
\int_E f \, dV = \int_R f \, dV = \int_a^b \int_c^d f(x, y) \, dy \, dx = \int_a^b \int_{\phi(x)}^{\psi(x)} f(x, y) \, dy \, dx .
\]

Thus we obtain:

**Theorem.** [Fubini’s Theorem for Projectable Sets in \( \mathbb{R}^2 \)] Let

\( E = \{(x, y) : a \leq x \leq b, \ \phi(x) \leq y \leq \psi(x)\} \)

be a projectable region (with respect to the order \( x, y \)) in \( \mathbb{R}^2 \), and \( f : E \to \mathbb{R} \) a continuous function. Then

\[
\int_E f \, dV = \int_a^b \int_{\phi(x)}^{\psi(x)} f(x, y) \, dy \, dx
\]

(in particular, the iterated integral exists).

Of course, the same result holds with \( x \) and \( y \) interchanged: if

\( E = \{(x, y) : c \leq y \leq d, \ \phi(y) \leq x \leq \psi(y)\} \)

and \( f \) is continuous on \( E \), then

\[
\int_E f \, dV = \int_c^d \int_{\phi(y)}^{\psi(y)} f(x, y) \, dx \, dy .
\]

If \( E \) is projectable in either order, we thus get a result about interchanging order of integration:

**Corollary.** [Fubini’s Theorem for Iterated Integrals on Projectable Regions] Let

\( E = \{(x, y) : a \leq x \leq b, \ \phi_1(x) \leq y \leq \psi_1(x)\} = \{(x, y) : c \leq y \leq d, \ \phi_2(y) \leq x \leq \psi_2(y)\} \)

be a region in \( \mathbb{R}^2 \) which is projectable in either order. If \( f : E \to \mathbb{R} \) is continuous, then

\[
\int_a^b \int_{\phi_1(x)}^{\psi_1(x)} f(x, y) \, dy \, dx = \int_c^d \int_{\phi_2(y)}^{\psi_2(y)} f(x, y) \, dx \, dy
\]

(in particular, the iterated integrals exist).
XIV.3.4.23. However, note that in general $[c, d] \neq [a, b]$, $\phi_2 \neq \phi_1$, $\psi_2 \neq \psi_1$, so the limits of integration must be carefully modified. It is frequently easy to do an iterated integral in one order and difficult or even impossible in the other order; cf. XIV.3.11.11.

XIV.3.4.24. We can do the same thing in higher dimensions, although the notation becomes cumbersome. Fix an ordering $x_1, \ldots, x_n$ of the coordinates of $\mathbb{R}^n$. To streamline notation, we will write things out with $j_k = k$ for all $k$; the masochist reader can easily adapt to the general situation. Inductively define $E_k \subseteq \mathbb{R}^k$ as follows. Let $E_1 = [a, b]$ be an interval in $\mathbb{R}$, and $\phi_1, \psi_1 : E_1 \to \mathbb{R}$ continuous functions with $\phi_1 \leq \psi_1$ on $E_1$. Suppose $E_1, \ldots, E_k$ have been defined, and $\phi_k, \psi_k : E_k \to \mathbb{R}$ continuous functions with $\phi_k \leq \psi_k$ on $E_k$. Set

$$E_{k+1} = \{(x_1, \ldots, x_{k+1}) \in \mathbb{R}^{k+1} : (x_1, \ldots, x_k) \in E_k, \phi_k(x_1, \ldots, x_k) \leq x_{k+1} \leq \psi_k(x_1, \ldots, x_k)\}.$$ 

By inductively applying XIV.3.2.17. as in XIV.3.4.18., we obtain that $E_k$ is a Jordan region in $\mathbb{R}^k$ for each $k$.

XIV.3.4.25. Definition. A set $E \subseteq \mathbb{R}^n$ is called a projectable region with respect to the order $x_1, \ldots, x_n$ if $E = E_n$ for some set of continuous functions as in XIV.3.4.24..

Let $E$ be a projectable region (for the order $x_1, \ldots, x_n$), and $f : E \to \mathbb{R}$ a continuous function. Use the notation of XIV.3.4.24. By successively applying the argument of XIV.3.4.19., we obtain (note that all the integrals exist as Riemann integrals):

XIV.3.4.26. Theorem. [Fubini’s Theorem for Projectable Sets in $\mathbb{R}^n$] Let $E$ be a projectable region (for the order $x_1, \ldots, x_n$), and $f : E \to \mathbb{R}$ a continuous function. Then

$$\int_E f \, dV = \int_a^b \int_{\phi_1(x_1)}^{\psi_1(x_1)} \cdots \int_{\phi_{n-1}(x_1, \ldots, x_{n-1})}^{\psi_{n-1}(x_1, \ldots, x_{n-1})} f(x_1, \ldots, x_n) \, dx_n \cdots dx_2 \, dx_1.$$ 

XIV.3.4.27. If $E$ is also projectable in another ordering of the coordinates, the integral $\int_E f \, dV$ can be computed by an iterated integral in that order, although the $\phi_k$ and $\psi_k$ will change in general when the ordering of the coordinates is changed. Thus we obtain as a corollary that the iterated integrals in the two orders are equal. The precise statement along the lines of XIV.3.4.22. is left to the reader.

The case $n = 3$ is important enough for applications that it is worth stating explicitly:

XIV.3.4.28. Theorem. [Fubini’s Theorem for Projectable Sets in $\mathbb{R}^3$] Let $[a, b]$ be an interval in $\mathbb{R}$, $\phi_1, \psi_1$ continuous functions from $[a, b]$ to $\mathbb{R}$ with $\phi_1 \leq \psi_1$ on $[a, b]$, $E_2 = \{(x, y) : a \leq x \leq b, \phi_1(x) \leq y \leq \psi_1(x)\}$, $\phi_2, \psi_2$ continuous functions from $E_2$ to $\mathbb{R}$ with $\phi_2 \leq \psi_2$, and $E = \{(x, y, z) : a \leq x \leq b, \phi_1(x) \leq y \leq \psi_1(x), \phi_2(x, y) \leq z \leq \psi_2(x, y)\}$.
Let \( f : E \to \mathbb{R} \) be a continuous function. Then
\[
\int_E f \, dV = \int_a^b \int_{\phi_1(x)}^{\phi_2(x,y)} f(x, y, z) \, dz \, dy \, dx .
\]

If \( E \) can be similarly written with respect to a different ordering of \( x, y, z \), \( \int_E f \, dV \) can be also calculated as an iterated integral in that order, and in particular the iterated integrals in the two orders are equal.

Most calculus texts have extensive examples of computing areas, volumes, and multiple integrals.

**Counterexamples**

We now give some examples showing that the hypotheses of Fubini’s Theorem are necessary.

**XIV.3.4.29. Examples.** Existence and equality of the iterated integrals does not imply integrability of \( f \):

(i) Let \( R = [0, 1]^2 \subseteq \mathbb{R}^2 \). Define \( f : R \to \mathbb{R} \) by
\[
f(x, y) = \begin{cases} 
2^n & \text{if } 2^{-n} < x, y \leq 2^{-n+1} \\
0 & \text{otherwise}
\end{cases} .
\]

Then \( f\{x\} \) and \( f\{y\} \) are integrable for all \( x \) and \( y \), and all have integral 1, so the iterated integrals exist and
\[
\int_0^1 \int_0^1 f(x, y) \, dy \, dx = \int_0^1 \int_0^1 f(x, y) \, dx \, dy = 1.
\]

But \( f \) is not integrable over \( R \) since it is unbounded.

(ii) A bounded example is more complicated. Let \( R = [0, 1]^2 \subseteq \mathbb{R}^2 \). Define \( f : R \to \mathbb{R} \) by setting \( f(x, y) = 1 \) if \( x \) and \( y \) are rational numbers with the same denominator when written in lowest terms, and \( f(x, y) = 0 \) otherwise. Then for fixed \( x \), \( f(x, y) = 1 \) for only finitely many \( y \), hence \( f\{y\} \) is integrable and has integral 0. Similarly, any \( f\{x\} \) is integrable and has integral 0. Thus the iterated integrals both exist and are 0. However, if \( \mathcal{P} \) is any partition of \( R \), it is easily seen that \( S(f, \mathcal{P}) = 1 \) and \( S(f, \mathcal{P}) = 0 \), so \( f \) is not integrable over \( R \). In fact, \( f \) is discontinuous everywhere on \( R \).

**XIV.3.4.30. Example.** Existence of the iterated integrals does not imply they are equal if \( f \) is not integrable: let \( R = [0, 1]^2 \subseteq \mathbb{R}^2 \). Define \( f : R \to \mathbb{R} \) by
\[
f(x, y) = \begin{cases} 
2^{2n} & \text{if } 2^{-n} < x, y \leq 2^{-n+1} \\
-2^{2n+1} & \text{if } 2^{-n} < x \leq 2^{-n+1}, 2^{-n-1} < y \leq 2^{-n} \\
0 & \text{otherwise}
\end{cases} .
\]

Then \( f\{x\} \) is integrable on \([0, 1]\) and \( \int_0^1 f\{x\}(y) \, dy = 0 \) for all \( x \); thus
\[
\int_0^1 \int_0^1 f(x, y) \, dy \, dx \text{ exists and equals 0 .}
\]
Also, \( f[y] \) is integrable on \([0, 1]\) for all \( y \): \( \int_0^1 f[y](x) \, dx = 0 \) if \( y \leq \frac{1}{2} \) but \( \int_0^1 f[y](x) \, dx = 2 \) if \( y > \frac{1}{2} \); thus
\[
\int_0^1 \int_0^1 f(x, y) \, dy \, dx \text{ exists and equals 1}.
\]

So the iterated integrals are not equal. Note that \( f \) is unbounded and hence not integrable on \( \mathbb{R} \).

This example is an adaptation of the double sum example IV.2.10.6.

XIV.3.4.31. \textbf{Example.} Integrability of \( f \) does not imply integrability of \( f[x] \) or \( f[y] \) for all \( x, y \): let
\( R = [0, 1]^2 \subset \mathbb{R}^2 \), \( B \) any finite subset of \([0, 1]\), and set

\[
f(x, y) = \begin{cases} 1 & \text{if } x \in B, \ y \in \mathbb{Q} \\ 0 & \text{otherwise} \end{cases}.
\]

Then \( f \) is bounded, and continuous except on \( B \times [0, 1] \), a set of content 0, so \( f \) is integrable on \( R \). However, for \( x \in B \), \( f[x] \) is not integrable on \([0, 1]\). The example can be easily modified to also make \( f[y] \) nonintegrable for finitely many \( y \). Replacing \( B \) with the Cantor set \( () \) gives examples where \( f[x] \) and/or \( f[y] \) are nonintegrable for infinitely many \( x, y \).

XIV.3.4.32. The full measure-theoretic form of Fubini’s Theorem implies that if \( f \) is Riemann integrable on \( R \times S \), hence continuous except on a set \( E \) of measure 0, then the vertical cross sections \( E_x \) have measure 0 for almost all \( x \), and similarly \( f[y] \) is Riemann integrable on \( R \) for almost all \( y \). Thus XIV.3.4.31. is nearly as bad as the situation can get. But \( f[x] \) and/or \( f[y] \) can fail to be Riemann integrable for a dense set of \( x \) and/or \( y \) (Exercise XIV.3.11.10.).

XIV.3.4.33. The example XIV.3.4.30. of an \( f \) where the iterated integrals exist but are unequal has an unbounded \( f \). In fact, a bounded example is impossible. For the full Fubini Theorem () implies that if \( f : R \times S \to \mathbb{R} \) is bounded and Lebesgue measurable, a very mild restriction satisfied by any function which can be explicitly described, the iterated integrals (which automatically exist as Lebesgue integrals) are equal. Whether or not \( f \) is Lebesgue measurable (but bounded), if \( f[x] \) and \( f[y] \) are Riemann integrable for all \( x \) and \( y \), the iterated integrals automatically exist as Riemann integrals and are equal ([?], [?]; cf. [Bog07, 3.10.57]). Tonelli’s Theorem () also rules out an example with an unbounded nonnegative (measurable) \( f \), hence an example with (measurable) \( f \) bounded either above or below.

XIV.3.4.34. Some authors have objected to the use of the name “Fubini’s Theorem” for results like XIV.3.4.10. or even XIV.3.4.6., on the grounds that they were “known” to people like Euler, long before Fubini. But the multidimensional Riemann integral was not even defined until the 1870s (by Jordan), so XIV.3.4.10. as stated could not have been known to Euler. The part of this result about interchanging order of integration in an iterated integral (the “Weak Fubini Theorem” XIV.3.5.2.), or its equivalent XIV.3.5.1., might have been a folklore result in Euler’s time, but it is highly doubtful it had been proved (for one thing, at some point in the proof compactness or uniform continuity is needed, conceptions not understood until the nineteenth century). Even justifying interchanging order of summation in a double infinite sum (IV.2.10.8.) requires careful analysis not nailed down until the nineteenth century. Some results which can be viewed as
special cases of Fubini’s Theorem, or more accurately of Cavalieri’s Principle, such as computing the volume of a solid of revolution, had been proved (by the standards of the time), but such results only occasionally involved iterated integrals. I have yet to see clear evidence that anyone proved XIV.3.4.10. or any other true version of Fubini’s Theorem before FUBINI. Thus I see no reason not to continue to use the term “Fubini’s Theorem” generically for these results.

**XIV.3.5. Interchanging Differentiation and Integration**

From Fubini’s Theorem we can obtain an important result on interchanging the order of differentiation and integration: for a function of two or more variables, differentiation with respect to one variable commutes with integration with respect to another variable. We will obtain a more general version in XIV.5.1.1., but from XIV.3.4.10. we can easily get the continuous version, which is adequate for many (perhaps most) applications.

**XIV.3.5.1. Theorem.** Let $I$ be an open interval in $\mathbb{R}$, $[c, d]$ a closed bounded interval in $\mathbb{R}$, and $R = I \times [c, d]$ the corresponding rectangle in $\mathbb{R}^2$. Let $f : R \to \mathbb{R}$ be a function such that $f$ and $\frac{\partial f}{\partial x}$ are continuous on $R$. For $x \in I$ define

$$g(x) = \int_c^d f(x, y) \, dy .$$

Then $g$ is $C^1$ on $I$ and, for $x \in I$,

$$g'(x) = \int_c^d \frac{\partial f}{\partial x}(x, y) \, dy .$$

Slightly informally,

$$\frac{d}{dx} \left( \int_c^d f(x, y) \, dy \right) = \int_c^d \frac{\partial f}{\partial x}(x, y) \, dy$$

(often called “differentiation under the integral sign.”)

In fact, for the proof we only need the part of Fubini’s Theorem asserting that iterated integrals are equal:

**XIV.3.5.2. Theorem.** [Weak Fubini Theorem] Let $R = [a, b] \times [c, d]$ be a rectangle in $\mathbb{R}^2$, and $f : R \to \mathbb{R}$ a continuous function. Then

$$\int_a^b \int_c^d f(x, y) \, dy \, dx = \int_c^d \int_a^b f(x, y) \, dx \, dy .$$

In particular, the two iterated integrals exist as Riemann integrals.

**XIV.3.5.3.** Actually, Theorem XIV.3.5.1. is equivalent to the Weak Fubini Theorem in the sense that each is an easy corollary of the other.

For the proofs, we need the following uniform continuity result, which is a special case of ():
XIV.3.5.4. **Proposition.** Let $I$ be an interval and $[c, d]$ a closed bounded interval in $\mathbb{R}$, and let $f : I \times [c, d] \to \mathbb{R}$ be a continuous function. Then for every $x_0 \in I$ and $\epsilon > 0$, there is a $\delta > 0$ such that $|f(x, y) - f(x_0, y)| < \epsilon$ for any $x \in I$, $|x - x_0| < \delta$, and every $y \in [c, d]$.

XIV.3.5.5. **Corollary.** Let $I$ be an interval and $[c, d]$ a closed bounded interval in $\mathbb{R}$, and let $f : I \times [c, d] \to \mathbb{R}$ be a continuous function. For $x \in I$, define $$\phi(x) = \int_c^d f(x, y) \, dy.$$ Then $\phi$ is a continuous function from $I$ to $\mathbb{R}$.

**Proof:** Let $x_0 \in I$. If $\epsilon > 0$, choose $\delta > 0$ such that $|f(x, y) - f(x_0, y)| < \frac{\epsilon}{d-c}$ for any $x \in I$, $|x - x_0| < \delta$, and every $y \in [c, d]$. Then, for $x \in I$, $|x - x_0| < \delta$,

$$|\phi(x) - \phi(x_0)| = \left| \int_c^d [f(x, y) - f(x_0, y)] \, dy \right| \leq \int_c^d |f(x, y) - f(x_0, y)| \, dy < \frac{\epsilon}{d-c}(d-c) = \epsilon .$$

XIV.3.5.6. We now give the proof of XIV.3.5.1. from XIV.3.5.2.:

**Proof:** For $x \in I$, define $$\phi(x) = \int_c^d \frac{\partial f}{\partial x}(x, y) \, dy .$$ Then $\phi$ is a continuous function from $I$ to $\mathbb{R}$ (XIV.3.5.5). Fix $x_0 \in I$, and fix $a \in I$, $a < x_0$. For $x \in I$, $x > a$, define $$h(x) = \int_a^x \phi(t) \, dt = \int_a^x \int_c^d \frac{\partial f}{\partial x}(t, y) \, dy \, dt .$$ Then, by the Fundamental Theorem of Calculus (FTC1), $h$ is differentiable and $h'(x) = \phi(x)$ for $x \in I$, $x > a$, and in particular $h'(x_0) = \phi(x_0)$. On the other hand, by XIV.3.5.2. and the FTC2, for $x \in I$, $x > a$ we have

$$h(x) = \int_c^d \int_a^x \frac{\partial f}{\partial x}(t, y) \, dt \, dy = \int_c^d [f(x, y) - f(a, y)] \, dy$$

$$= \int_c^d f(x, y) \, dy - \int_c^d f(a, y) \, dy = g(x) - g(a)$$

so $g$ is differentiable and $g'(x) = h'(x) = \phi(x)$ for $x \in I$, $x > a$, and in particular $g$ is differentiable at $x_0$ and $g'(x_0) = \phi(x_0)$.

\[\Box\]
XIV.3.5.7. Conversely, we can easily deduce XIV.3.5.2. from XIV.3.5.1.:

**Proof:** Let $B > b$ and extend $f$ to a continuous function from $[a, B] \times [c, d]$ to $\mathbb{R}$ by setting $f(x, y) = f(b, y)$ for $x \in [b, B]$, $y \in [c, d]$. For $x \in [a, B]$, define

$$g(x) = \int_{c}^{d} \int_{a}^{x} f(t, y) \, dt \, dy.$$ 

Then $g(a) = 0$, and by XIV.3.5.1. and the FTC1 $g$ is differentiable on $(a, B)$ and

$$g'(x) = \int_{c}^{d} \frac{\partial}{\partial x} \left[ \int_{a}^{x} f(t, y) \, dt \right] \, dy = \int_{c}^{d} f(x, y) \, dy$$

for $x \in (a, B)$. Since $g'$ is continuous, by the FTC2 we have, for $x \in (a, B)$,

$$g(x) = g(a) + \int_{a}^{x} g'(t) \, dt = \int_{c}^{d} f(t, y) \, dy \, dt.$$ 

Then XIV.3.5.2. follows by setting $x = b$.

XIV.3.5.8. We can give a direct proof of Theorem XIV.3.5.1., which by XIV.3.5.7. gives an alternate proof of XIV.3.5.2.:

**Proof:** Fix $x_{0} \in I$. Then, for $h$ small enough that $x_{0} + h \in I$, we have

$$\frac{g(x_{0} + h) - g(x_{0})}{h} - \int_{c}^{d} \frac{\partial f}{\partial x}(x_{0}, y) \, dy = \int_{c}^{d} \left[ f(x_{0} + h, y) - \frac{f(x_{0}, y)}{h} \right] \, dy.$$ 

By the Mean Value Theorem, if the interval between $x_{0}$ and $x_{0} + h$ is contained in $I$, then for each $y \in [c, d]$ there is a $u_{y}$ between $x_{0}$ and $x_{0} + h$ (depending on $y$ and $h$) with

$$\frac{f(x_{0} + h, y) - f(x_{0}, y)}{h} = \frac{\partial f}{\partial x}(u_{y}, y).$$

Let $\epsilon > 0$. Since $\frac{\partial f}{\partial x}$ is continuous, by XIV.3.5.4. there is a $\delta > 0$ such that

$$\left| \frac{\partial f}{\partial x}(x, y) - \frac{\partial f}{\partial x}(x_{0}, y) \right| < \frac{\epsilon}{d - c}$$

whenever $x \in I$, $|x - x_{0}| < \delta$, and $y \in [c, d]$. Thus, if $h$ is sufficiently small,

$$\left| \frac{g(x_{0} + h) - g(x_{0})}{h} - \int_{c}^{d} \frac{\partial f}{\partial x}(x_{0}, y) \, dy \right| = \left| \int_{c}^{d} \left[ \frac{\partial f}{\partial x}(u_{y}, y) - \frac{\partial f}{\partial x}(x_{0}, y) \right] \, dy \right|$$

$$\leq \int_{c}^{d} \left| \frac{\partial f}{\partial x}(u_{y}, y) - \frac{\partial f}{\partial x}(x_{0}, y) \right| \, dy < \frac{\epsilon}{d - c}(d - c) = \epsilon.$$ 

Note, however, that this does not give a proof of the full Fubini Theorem, even XIV.3.4.10., without additional argument.

Using the Chain Rule, we can extend XIV.3.5.1. to integration over more general regions:
XIV.3.5.9. Theorem. Let $U$ be an open set in $\mathbb{R}^2$ containing the closed set
\[ S = \{(x, y) : a \leq x \leq b, u(x) \leq y \leq v(x)\} \]
where $u$ and $v$ are differentiable functions from $I = [a, b]$ to $\mathbb{R}$ with $u \leq v$. Let $f : U \rightarrow \mathbb{R}$ be a function such that $f$ and $\frac{\partial f}{\partial x}$ are continuous on $U$. For $x \in I$ define
\[ g(x) = \int_{u(x)}^{v(x)} f(x, y) dy. \]
Then $g$ is differentiable on $I$ and, for $x \in I$,
\[ g'(x) = \int_{u(x)}^{v(x)} \frac{\partial f}{\partial x}(x, y) dy + f(x, v(x))v'(x) - f(x, u(x))u'(x). \]
If $u$ and $v$ are $C^1$, so is $g$.

Proof: Set $\phi(x, u, v) = \int_u^v f(x, y) dy$. Then $\phi$ is defined on a suitable neighborhood $W$ of
\[ \{(x, u, v) : a \leq x \leq b, u(x) \leq u \leq v \leq v(x)\} \]
in $\mathbb{R}^3$, and $g(x) = \phi(x, u(x), v(x))$. By XIV.3.5.1,
\[ \frac{\partial \phi}{\partial x}(x, u, v) = \int_u^v \frac{\partial f}{\partial x}(x, y) dy. \]
In particular, $\frac{\partial \phi}{\partial x}$ exists and is continuous on $W$. By the FTC, $\frac{\partial \phi}{\partial u}(x, u, v) = f(x, v)$ and $\frac{\partial \phi}{\partial v}(x, u, v) = -f(x, u)$ and are thus continuous on $W$. Therefore $\phi$ is differentiable ($C^1$) on $W$. By the Chain Rule, $g$ is differentiable on $I$ and, for $x \in I$,
\[
\begin{align*}
g'(x) &= \frac{\partial \phi}{\partial x}(x, u(x), v(x)) \cdot 1 + \frac{\partial \phi}{\partial u}(x, u(x), v(x))u'(x) + \frac{\partial \phi}{\partial v}(x, u(x), v(x))v'(x) \\
&= \int_{u(x)}^{v(x)} \frac{\partial f}{\partial x}(x, y) dy - f(x, u(x))u'(x) + f(x, v(x))v'(x).
\end{align*}
\]

Multidimensional versions can be obtained similarly, such as (cf. Exercise XIV.3.11.13):
XIV.3.6. Change of Variable

XIV.3.7. Improper Integrals
XIV.3.8. Step Functions

Riemann integration can be alternately described via step functions. There are some subtleties which must be addressed in this approach concerning values on boundaries of rectangles; these subtleties are “wasted” in the sense that they have no ultimate effect, but they are necessary for a logically complete development, and they can be handled cleanly if done right.

XIV.3.8.1. Definition. A step function on $\mathbb{R}^p$ is a finite linear combination of indicator functions of rectangles (degenerate rectangles are allowed).

XIV.3.8.2. Any (finite) linear combination of step functions is a step function.

XIV.3.8.3. If $\phi = \sum_{k=1}^{n} \alpha_k \phi_{R_k}$ is a step function, there is a rectangle $R$ such that $R_k \subseteq R$ for all $k$. A partition $\mathcal{P}$ of $R$ is $\phi$-fine if each $R_k$ is a union of rectangles in $\mathcal{P}$. By (), every step function $\phi$ has a $\phi$-fine partition of any sufficiently large rectangle. Any refinement of a $\phi$-fine partition is $\phi$-fine.

XIV.3.8.4. In the step function approach to Riemann integration, it is very convenient to allow partitions which include degenerate rectangles. In fact, it is most convenient to work with full partitions $\mathcal{P}$, in which any nonempty intersection of rectangles in $\mathcal{P}$ is also in $\mathcal{P}$ (all such intersections are, of course, degenerate since the rectangles in $\mathcal{P}$ are nonoverlapping). A grid in which every one-dimensional factor has all transition points included as degenerate intervals is a full partition, so any partition has a full refinement.

If $\phi$ is a step function and $\mathcal{P}$ is a full $\phi$-fine partition, then $\phi$ can be written as a linear combination of indicator functions of rectangles in $\mathcal{P}$. This is an immediate consequence of the following fact, which has a straightforward but notationally complex proof by induction on $n$ left to the reader:

XIV.3.8.5. Proposition. Let $X$ be a set, and $A_1, \ldots, A_n$ subsets of $X$. Then

$$\chi_{A_1 \cup \cdots \cup A_n} = \sum_{k=1}^{n} \chi_{A_k} - \sum_{j<k} \chi_{A_j \cap A_k} + \sum_{i<j<k} \chi_{A_i \cap A_j \cap A_k} - \cdots + (-1)^{n+1} \chi_{A_1 \cap \cdots \cap A_n}$$

where each sum is over all strictly increasing sets of distinct indices.

XIV.3.8.6. Each rectangle $R$ has an “interior” $R^o$ consisting of all points of $R$ not contained in a boundary rectangle of smaller dimension. If $R$ is a singleton, set $R^o = R$. Note that $R^o$ is not the topological interior of $R$ in $\mathbb{R}^p$ if $R$ is degenerate, but is rather the topological interior relative to the affine subspace of $\mathbb{R}^p$ generated by $R$. $R^o$ is a relatively open subset of $R$. If $\mathcal{P}$ is a full partition of a rectangle $R$, for each $R_k \in \mathcal{P}$ we have that $R^o_k$ is the set of points of $R_k$ not contained in any $R_j \in \mathcal{P}$ properly contained in $R_k$. Then $R$ is the disjoint union of the $R^o_k$. Any linear combination $\phi$ of the indicator functions of the $R^o_k$ is a step function (use XIV.3.8.5.) for which $\mathcal{P}$ is $\phi$-fine, and any step function $\psi$ for which $\mathcal{P}$ is $\psi$-fine can be written uniquely as a linear combination of these indicator functions.

XIV.3.8.7. It follows immediately that any finite maximum or minimum of step functions is a step function. [Consider a full partition which is fine for all the step functions.]
Integrals of Step Functions

XIV.3.8.8. If $\phi = \sum_{k=1}^{m} \alpha_k \chi_{R_k}$ is a step function, then $\phi$ is Riemann integrable over any rectangle $R$ containing all the $R_k$ and

$$\int_R \phi \, dV = \sum_{k=1}^{m} \alpha_k V(R_k).$$

It is fairly easily verified using XIV.3.8.5. that the sum on the right depends only on $\phi$ and not on how it is written as a linear combination of indicator functions; thus it can be taken as the definition of the integral of $\phi$ over $R$. The integral of step functions so defined is easily verified to be linear, additive, and monotone. It also has a continuity property (XIV.3.8.10.).

We first note a way of showing certain sets have measure 0 using step functions. This will be generalized to a characterization of measure 0 (XIV.3.8.14.).

XIV.3.8.9. Lemma. Let $R$ be a rectangle in $\mathbb{R}^p$, and $A \subseteq R$. If, for every $\epsilon > 0$, there is a nonnegative step function $\phi$ such that $\phi(x) \geq 1$ for all $x \in A$ and $\int_R \phi \, dV < \epsilon$, then $A$ has measure 0.

Proof: Let $\epsilon > 0$ and $\phi$ the corresponding step function. Let $\phi = \sum \alpha_k \chi_{R_k}$ be the canonical representation of $\phi$ (XIV.3.8.6.), and let $k_1, \ldots, k_n$ be the $k$ for which $\alpha_k \geq 1$. Then $A \subseteq \bigcup_{j=1}^{n} R_{k_j}$ and

$$\sum_{j=1}^{n} V(R_{k_j}) \leq \sum_{j=1}^{n} \alpha_{k_j} V(R_{k_j}) \leq \int_R \phi \, dV < \epsilon.$$

Since $\epsilon > 0$ is arbitrary, $A$ has measure 0.

XIV.3.8.10. Proposition. Let $(\psi_n)$ be a nonincreasing sequence of nonnegative step functions supported on a fixed rectangle $R$. If

$$\lim_{n \to \infty} \int_R \psi_n \, dV = \inf_n \int_R \psi_n \, dV = 0$$

Then $\psi_n \to 0$ pointwise a.e.

Proof: It suffices to show that $A_m = \{x \in R : \inf_n \psi_n(x) \geq \frac{1}{m}\}$ has measure 0 for all $m \in \mathbb{N}$, since $\psi_n \to 0$ pointwise on the complement of $\bigcup_m A_m$. Fix $m$. For any $\epsilon > 0$, there is an $n$ such that $\int_R \psi_n \, dV < \frac{\epsilon}{m}$. Then $\phi = m \psi_n$ is a step function with $\phi(x) \geq 1$ for all $x \in A_m$ and $\int_R \phi \, dV < \epsilon$. Thus $A_m$ has measure 0 by XIV.3.8.9..

We will prove an important converse in ().

XIV.3.8.11. The Riemann integral can be alternately defined and constructed using this integral for step functions, without using the upper and lower sum definitions previously used ().
Maximum and Minimum Step Functions

XIV.3.8.12. Let $R$ be a rectangle and $f$ a bounded function on $R$. If $\mathcal{P}$ is a full partition of $R$, then there is a unique largest step function $\phi$ for which $\mathcal{P}$ is $\phi$-fine and $\phi \leq f$. If $\mathcal{P} = \{R_1, \ldots, R_m\}$, then $\phi$ is the function whose value on $R_k$ is the infimum of $f$ on $R_k$. Similarly, there is a smallest step function $\psi$ for which $\mathcal{P}$ is $\psi$-fine and $\psi \leq f$. We have

$$S(f, \mathcal{P}) \leq \int_R \phi \, dV \leq \int_R f \, dV \leq \int_R \psi \, dV \leq S(f, \mathcal{P}).$$

Write $\phi(f, \mathcal{P})$ and $\psi(f, \mathcal{P})$ for $\phi$ and $\psi$. If $Q$ is a refinement of $\mathcal{P}$, then $\phi(f, \mathcal{P}) \leq \phi(f, Q)$ and $\psi(f, Q) \leq \psi(f, \mathcal{P})$.

XIV.3.8.13. Proposition. Let $R$ be a rectangle in $\mathbb{R}^p$, and $f : \mathbb{R} \to \mathbb{R}$ a bounded function. The following are equivalent:

(i) $f$ is Riemann integrable on $R$.

(ii) There are sequences $(\phi_n)$ and $(\psi_n)$ of step functions supported on $R$ with

$$\phi_n \leq \phi_{n+1} \leq f \leq \psi_{n+1} \leq \psi_n$$

on $R$ for all $n$ and

$$\lim_{n \to \infty} \int_R \phi_n \, dV = \sup_n \int_R \phi_n \, dV = \inf_n \int_R \psi_n \, dV = \lim_{n \to \infty} \int_R \psi_n \, dV.$$

Proof: (ii) $\Rightarrow$ (i) since

$$\int_R \phi_n \, dV \leq \int_R f \, dV \leq \int_R \psi_n \, dV$$

for each $n$ by monotonicity.

For (i) $\Rightarrow$ (ii), choose a sequence $\mathcal{P}_n$ of full partitions of $R$ such that $\mathcal{P}_{n+1}$ refines $\mathcal{P}_n$ for all $n$ and

$$\lim_{n \to \infty} |S(f, \mathcal{P}_n) - S(f, \mathcal{P}_n)| = 0.$$ Set $\phi_n = \phi(f, \mathcal{P}_n)$, $\psi_n = \psi(f, \mathcal{P}_n)$ and apply XIV.3.8.12.

Two more equivalent conditions will be added in XIV.3.10.6.

Characterization of Sets of Measure Zero

Sets of measure 0 can be characterized using integrals of step functions:

XIV.3.8.14. Theorem. Let $R$ be a rectangle in $\mathbb{R}^p$, and $A \subseteq R$. Then $A$ has measure 0 if and only if, for every $\epsilon > 0$, there is a nondecreasing sequence $(\phi_n)$ of step functions such that $\sup_n \phi_n(x) \geq 1$ for all $x \in A$ and $\int_R \phi_n \, dV < \epsilon$ for all $n$.  

1588
XIV.3.9. The Monotone Convergence Theorem

The Monotone Convergence Theorem is an important continuity property of integrals:

XIV.3.9.1. Theorem. [Monotone Convergence Theorem for Riemann Integration] Let \( R \) be a rectangle in \( \mathbb{R}^p \), and \( (f_n) \) a nondecreasing sequence of nonnegative Riemann integrable functions on \( R \) converging pointwise a.e. on \( R \) to a Riemann integrable function \( f \). Then

\[
\int_R f \, dV = \lim_{n \to \infty} \int_R f_n \, dV = \sup_n \int_R f_n \, dV.
\]

Note that it is the sequence which is nondecreasing, i.e. \( f_n(x) \leq f_{n+1}(x) \) for all \( n \) and all \( x \in R \).

XIV.3.9.2. There are two difficulties with this statement. First, the hypothesis that the limit function \( f \) is Riemann integrable on \( R \) is not automatic, even if the \( f_n \) are uniformly bounded. For example, let \( (r_n) \) be an enumeration of the rational numbers in \( [0, 1] \), and define \( f_n(x) \) to be 1 if \( x = r_k \) for some \( k, 1 \leq k \leq n \), and \( f_n(x) = 0 \) otherwise. Then \( f_n \) is 0 except at finitely many points, hence is Riemann integrable on \( [0, 1] \), but \( f_n \to \chi_{[0,1]} \) pointwise on \( [0,1] \), and \( \chi_{[0,1]} \) is not Riemann integrable on \( [0,1] \). Thus the Riemann integrability of \( f \) must be included as a hypothesis. To avoid this difficulty, replacing \( f_n \) by \( f - f_n \) and using linearity of the Riemann integral the theorem may be more cleanly stated:

XIV.3.9.3. Theorem. Let \( R \) be a rectangle in \( \mathbb{R}^p \), and \( (f_n) \) a nonincreasing sequence of nonnegative Riemann integrable functions on \( R \) converging pointwise a.e. on \( R \) to 0. Then

\[
\lim_{n \to \infty} \int_R f_n \, dV = \inf_n \int_R f_n \, dV = 0.
\]

XIV.3.9.4. There is a second difficulty: proving this theorem. Although a direct proof can be given, it is quite complicated to do so. The simplest approach is to work via the Lebesgue integral and prove a more general theorem applicable to arbitrary Lebesgue measurable functions (XIV.4.4.1). In fact, overcoming both the difficulties with the Riemann integration statement of the theorem was one of the principal motivations for developing Lebesgue integration theory.

XIV.3.9.5. We will content ourselves here with proving only the following special case, which will be crucial in developing the Daniell integral ()

XIV.3.9.6. Theorem. [Monotone Convergence Theorem for Step Functions] Let \( R \) be a rectangle in \( \mathbb{R}^p \), and \( (\psi_n) \) a nonincreasing sequence of nonnegative step functions on \( R \) converging pointwise a.e. on \( R \) to 0. Then

\[
\lim_{n \to \infty} \int_R \psi_n \, dV = \inf_n \int_R \psi_n \, dV = 0.
\]
Proof: Let $A$ be the set of $x \in R$ for which $(\psi_n(x))$ fails to converge to 0, and $B$ the set of $x$ at which at least one $\psi_n$ is discontinuous, and $C = A \cup B$. Then $C$ has measure 0. Let $M$ be a bound for $\phi_1$ on $R$.

Let $\epsilon > 0$. There is a sequence $(R^0_k)$ of open rectangles covering $C$ for which

$$\sum_{k=1}^{\infty} V(R^0_k) < \frac{\epsilon}{2M}.$$ 

If $E = R \setminus \cup_k R^0_k$, then for each $x \in E$ there is an $n_x$ and an open rectangle $R^*_x$ containing $x$ such that $\psi_{n_x}$ takes a constant value less than $\frac{\epsilon}{2M}$ on $R^*_x$. The $R^0_k$ and $R^*_x$ cover $R$, so by compactness finitely many $R^0_k$ and $R^*_x$ cover $E$, say $R^0_{k_1}, \ldots, R^0_{k_r}, R^*_x, \ldots, R^*_m$. Let $R_{x_k}$ be the closure of $R^*_x$. By subdividing and eliminating overlaps we may assume the $R_{x_k}$ are nonoverlapping, so $\sum_{k=1}^{m} V(R_{x_k}) \leq V(R)$.

Set $N = \max \{ n_{x_1}, \ldots, n_{x_m} \}$. Then if $n \geq N$, we have

$$\int_R \psi_n dV \leq \sum_{j=1}^{r} \int_{R^0_{k_j}} \psi_n dV + \sum_{k=1}^{m} \int_{R_{x_k}} \psi_n dV < \frac{\epsilon}{2M} \sum_{k=1}^{\infty} M V(R^0_k) + \sum_{k=1}^{m} \frac{\epsilon}{2V(R)} V(R_{x_k}) \leq \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon.$$ 

\[ \square \]

XIV.3.9.7. What this argument really shows is a special case of Egorov’s Theorem (XIII.1.8.1.): under the hypotheses, $\psi_n$ for $n$ sufficiently large is actually uniformly close to 0 on the complement of a set of small measure. This is also reminiscent of Dini’s Theorem ( ).
XIV.3.10. Characterization of Riemann Integrable Functions

Using the Monotone Convergence Theorem (XIV.3.9.6.), we can add a third equivalent condition to the characterization of Riemann integrability:

Theorem. Let $R$ be a rectangle in $\mathbb{R}^p$, and $f : R \to \mathbb{R}$ a bounded function. The following are equivalent:

(i) $f$ is Riemann integrable on $R$.

(ii) There are sequences $(\phi_n)$ and $(\psi_n)$ of step functions supported on $R$ with

$$\phi_n \leq \phi_{n+1} \leq f \leq \psi_{n+1} \leq \psi_n$$

on $R$ for all $n$ and

$$\lim_{n \to \infty} \int_R \phi_n dV = \sup_n \int_R \phi_n dV = \inf_n \int_R \psi_n dV = \lim_{n \to \infty} \int_R \psi_n dV.$$

(iii) There are sequences $(\phi_n)$ and $(\psi_n)$ of step functions supported on $R$ with

$$\phi_n \leq \phi_{n+1} \leq f \leq \psi_{n+1} \leq \psi_n$$

on $R$ for all $n$ and $\phi_n \to f$ a.e. and $\psi_n \to f$ a.e. on $R$.

Proof: (i) $\iff$ (ii) by XIV.3.8.13.. For (ii) $\Rightarrow$ (iii), let $\phi_n, \psi_n$ be as in (ii). Then $(\psi_n - \phi_n)$ is a nonincreasing sequence of nonnegative step functions with

$$\lim_{n \to \infty} \int_R (\psi_n - \phi_n) dV = 0$$

and hence $\psi_n - \phi_n \to 0$ pointwise a.e., i.e. $\liminf_n \psi_n(x) = \sup_n \phi_n(x)$ for almost all $x \in R$. Since $\sup_n \phi_n(x) \leq f(x) \leq \inf_n \psi_n(x)$ for all $x \in R$, it follows that $\phi_n \to f$ a.e. and $\psi_n \to f$ a.e. (XIV.3.8.10.).

Conversely, suppose $\phi_n$ and $\psi_n$ are as in (iii). Then $(\psi_n - \phi_n)$ is a nonincreasing sequence of nonnegative step functions on $R$ and $\psi_n - \phi_n \to 0$ pointwise a.e. Then by the Monotone Convergence Theorem we have

$$\lim_{n \to \infty} \int_R (\psi_n - \phi_n) dV = 0$$

so (ii) is satisfied.

Upper and Lower Envelopes

There is an alternate way of describing condition (iii) of XIV.3.10.1. which leads to Lebesgue’s characterization of Riemann integrability. Let $f$ be a bounded function on a rectangle $R$. For each $a \in R$, define

$$f'(a) = \min \left( f(a), \liminf_{x \to a} f(x) \right)$$
XIV.3.10.3. Let $\mathcal{P}$ be a partition of $R$, and let $\phi(f, \mathcal{P})$ and $\psi(f, \mathcal{P})$ be the step functions defined in XIV.3.8.12. Then $\phi_n(f, \mathcal{P}) \leq f$ on the interior of any nondegenerate rectangle in $\mathcal{P}$, hence $\phi_n(f, \mathcal{P}) \leq f$ a.e. on $R$. Thus, if $\phi$ is any step function with $\phi \leq f$ a.e. on $R$, then $\phi \leq f$ a.e. on $R$. Similarly, if $\psi$ is any step function with $f \leq \psi$ a.e. on $R$, then $\overline{f} \leq \psi$ a.e. on $R$.

PROOF: The union of the degenerate rectangles in $\mathcal{P}_n$ has measure 0 (zero content) for each $n$. Hence if $A$ is the set of points of $R$ which are interior points of nondegenerate rectangles of $\mathcal{P}_n$ for every $n$, then $R \setminus A$ has measure 0. Fix $a \in A$, and let $\epsilon > 0$. There is a $\delta > 0$ such that $f(x) > f(a) - \epsilon$ for all $x \in R \cap B_\delta(a)$. Then there is a $N$ with $\|\mathcal{P}_n\| < \delta$ for $n \geq N$; for such an $n$ the nondegenerate rectangle in $\mathcal{P}_n$ containing $a$ is contained in $B_\delta(a)$ and thus $f(a) - \epsilon \leq \phi(f, \mathcal{P}_n)(a) \leq f(a)$. Therefore $\phi(f, \mathcal{P}_n)(a) \to f(a)$. So $\phi(f, \mathcal{P}_n) \to f$ pointwise on $A$. Similarly, $\psi(f, \mathcal{P}_n) \to \overline{f}$ pointwise on $A$.

XIV.3.10.5. In fact, it is easily verified () that $\underline{f}$ is precisely the supremum of all step functions $\phi$ satisfying $\phi \leq f$, and $\overline{f}$ the infimum of all step functions $\psi$ satisfying $f \leq \psi$.

We can then add another equivalent condition for Riemann integrability:

XIV.3.10.6. Theorem. Let $R$ be a rectangle in $\mathbb{R}^p$, and $f : \mathbb{R} \to \mathbb{R}$ a bounded function. The following are equivalent:

(i) $f$ is Riemann integrable on $R$.

(ii) There are sequences $(\phi_n)$ and $(\psi_n)$ of step functions supported on $R$ with

\[ \phi_n \leq \phi_{n+1} \leq f \leq \psi_{n+1} \leq \psi_n \]

on $R$ for all $n$ and

\[ \lim_{n \to \infty} \int_R \phi_n \, dV = \sup_n \int_R \phi_n \, dV = \inf_n \int_R \psi_n \, dV = \lim_{n \to \infty} \int_R \psi_n \, dV. \]

(iii) There are sequences $(\phi_n)$ and $(\psi_n)$ of step functions supported on $R$ with

\[ \phi_n \leq \phi_{n+1} \leq f \leq \psi_{n+1} \leq \psi_n \]

on $R$ for all $n$ and $\phi_n \to f$ a.e. and $\psi_n \to f$ a.e. on $R$. 

1592
(iv) We have \( \underline{f} = \overline{f} \) a.e. on \( R \) (and in particular \( \underline{f} = f \) a.e. and \( \overline{f} = f \) a.e. on \( R \)).

**Proof:** (i)–(iii) are equivalent by XIV.3.10.1. If \( \phi_n, \psi_n \) are as in (iii), we have
\[
\phi_n \leq f \leq \psi_n \quad \text{a.e.}
\]
for each \( n \); since \( \phi_n \to f \) a.e. and \( \psi_n \to f \) a.e. we have \( f = \underline{f} = \overline{f} \) a.e.

Conversely, if (iv) is satisfied, let \( (P_n) \) be a sequence of full partitions of \( R \) such that \( \|P_n\| \to 0 \) as \( n \to \infty \), such that \( P_{n+1} \) refines \( P_n \) for all \( n \). Then by XIV.3.10.4. \( \phi(f, P_n) \not\to f \) a.e. and \( \psi(f, P_n) \not\to f \) a.e. on \( R \), so (iii) is satisfied.

Noting that \( \underline{f} = f = \overline{f} \) precisely at the points of continuity of \( f \), we obtain Lebesgue’s characterization:

**XIV.3.10.7. Corollary.** Let \( R \) be a rectangle in \( \mathbb{R}^p \), and \( f : R \to \mathbb{R} \). Then \( f \) is Riemann integrable on \( R \) if and only if \( f \) is continuous almost everywhere and bounded on \( R \).
XIV.3.11. Exercises

XIV.3.11.1. (a) Show that a function which is continuous almost everywhere and zero on a dense set is zero almost everywhere. [Show it is zero wherever it is continuous.]

(b) If \( f \) and \( g \) are functions which are each continuous almost everywhere, and \( f \) and \( g \) agree on a dense set, then \( f = g \) a.e.

XIV.3.11.2. Show that a finite union of sets of zero content has zero content. [You can mimic the proof of XIV.2.7.6., but there is an easier argument.]

XIV.3.11.3. Prove Proposition XIV.2.7.11.

XIV.3.11.4. This problem is a continuation of V.8.6.7.

(a) Show that every regulated function on an interval \( I \) is Riemann-integrable on any closed bounded subinterval of \( I \). Then deduce V.8.6.7.(c) from XIV.2.9.3.

(b) Let \( g(x) = \sin(1/x) \) for \( x \neq 0 \), and \( g(0) = 0 \). Let \( (r_n) \) be an enumeration of \( \mathbb{Q} \), and set

\[
 f(x) = \sum_{n=1}^{\infty} 2^{-n} g(x - r_n) .
\]
Show that $f$ is discontinuous at every point of $\mathbb{Q}$ and continuous at every point of $\mathbb{J}$.

(c) Show that $f$ is Riemann-integrable over every closed bounded subinterval of $\mathbb{R}$ (give two proofs, one using XIV.2.8.5. and one using ()), but $f$ is not regulated on any interval.

(d) Show using XIV.2.9.8.(iii) and V.8.5.5. that $f$ has an antiderivative on $\mathbb{R}$.

XIV.3.11.5. Let $f$ be a bounded function on an interval $[a, b]$, and $\overline{f}$ its upper envelope (XIV.2.8.1.).

(a) Show that

$$\overline{f} = \inf \{ \psi : \psi \geq f, \psi \text{ an upper semicontinuous step function} \} .$$

[Use the argument of the proof of XIV.2.8.2.]

(b) Show that, for every $x_0 \in [a, b],$

$$\overline{f}(x_0) = \max \left( f(x_0), \limsup_{x \to x_0} f(x) \right).$$

(c) Give similar characterizations of $f$.

XIV.3.11.6. Let $E$ be a subset of $[a, b], and consider the indicator function $\chi_E$.

(a) Show that the upper envelope (XIV.2.8.1.) $\overline{\chi_E}$ is $\chi_E$, and the lower envelope $\underline{\chi_E}$ is $\chi_E^\circ$.

(b) Show that $\chi_E$ is Riemann-integrable on $[a, b]$ if and only if $\partial E$ has zero content (), i.e. $E$ is a Jordan region () in $\mathbb{R}$.

XIV.3.11.7. Use the continuous version of Fubini’s Theorem (XIV.3.4.7.; XIV.3.5.2. suffices) to prove the following version of the equality of mixed partials VIII.2.2.4. (compare with VIII.2.2.8.):

**Theorem.** Let $U$ be an open set in $\mathbb{R}^2$, and $f : U \to \mathbb{R}$ a function such that $\frac{\partial^2 f}{\partial x \partial y}$ and $\frac{\partial^2 f}{\partial y \partial x}$ exist and are continuous on $U$. Then $\frac{\partial^2 f}{\partial x \partial y} = \frac{\partial^2 f}{\partial y \partial x}$ on $U$.

(a) Show using the Fundamental Theorem of Calculus that if $R = [a, b] \times [c, d] \subseteq U$, then

$$\int_c^b \int_c^d \frac{\partial^2 f}{\partial y \partial x}(x, y) \, dy \, dx = \int_c^d \int_a^b \frac{\partial^2 f}{\partial x \partial y}(x, y) \, dx \, dy.$$

(b) If there is an $(x_0, y_0) \in U$ with $\frac{\partial^2 f}{\partial y \partial x}(x_0, y_0) > \frac{\partial^2 f}{\partial x \partial y}(x_0, y_0)$, then there is a rectangle $R$ around $(x_0, y_0)$ contained in $U$ such that $\frac{\partial^2 f}{\partial y \partial x} - \frac{\partial^2 f}{\partial x \partial y} > 0$ on $R$, and hence

$$\int_R \left[ \frac{\partial^2 f}{\partial y \partial x} - \frac{\partial^2 f}{\partial x \partial y} \right] \, dV > 0.$$

Draw a similar conclusion if there is an $(x_0, y_0) \in U$ with $\frac{\partial^2 f}{\partial y \partial x}(x_0, y_0) < \frac{\partial^2 f}{\partial x \partial y}(x_0, y_0)$.

(c) Use Fubini’s Theorem to obtain a contradiction from (a) and (b).

(d) Extend to functions of several variables and higher-order mixed partials.
XIV.3.11.8. Explain why Theorem XIV.3.1.26. is not an immediate corollary of Proposition XIV.3.1.16. Identify what else in addition to XIV.3.1.16. is needed, and prove it.

XIV.3.11.9. Let $A$ be a Jordan region in $\mathbb{R}^n$, and $f : A \to \mathbb{R}$ a nonnegative continuous function. Let

$$B = \{(x, y) : x \in A, 0 \leq y \leq f(x)\} \subseteq \mathbb{R}^{n+1}.$$ 

Show that $B$ is a Jordan region in $\mathbb{R}^{n+1}$, and that

$$V_{n+1}(B) = \int_A f \, dV_n.$$

XIV.3.11.10. Let $E$ be the subset of $R = [0, 1]^2 \subseteq \mathbb{R}^2$ consisting of the points on the $x$-axis and, for each rational $x = \frac{p}{q}$ in lowest terms, the points in a Cantor set of positive measure () on the vertical segment

$$\left\{ (x, y) : 0 \leq y \leq \frac{1}{q}\right\}.$$

(i) Show that $E$ is a closed set of measure 0, hence of content 0.
(ii) Show that $f = \chi_E$ is Riemann integrable over $R$, but that $f[x]$ is not Riemann integrable on $[0, 1]$ if $x$ is rational.
(iii) Modify this example to one for which $f[y]$ is also not Riemann integrable for $y$ rational.

XIV.3.11.11. Evaluate

$$\int_0^1 \int_x^1 e^{-y^2} \, dy \, dx$$

by applying Fubini’s Theorem to interchange the order of integration.

XIV.3.11.13. (a) Prove XIV.3.5.10.
(b) Generalize to the case where $S$ is replaced by an arbitrary Jordan region in $\mathbb{R}^q$ (cf. XIV.3.4.14.).
XIV.4. The Lebesgue Integral

This section treats the heart of modern integration theory, the general integral first defined by Lebesgue and subsequently refined by other authors. The term “Lebesgue integral” is commonly used to mean two different things:

(i) Lebesgue’s generalization of the Riemann integral for functions from \( \mathbb{R} \) to \( \mathbb{R} \).

(ii) The general integral for real-valued functions on a measure space, often called the abstract Lebesgue integral.

As the integral is normally done today, the Lebesgue integral on \( \mathbb{R} \) is just the special case of the general abstract Lebesgue integral for the measure space \((\mathbb{R}, \mathcal{M}, \lambda)\), and it is no easier and even no different to develop this special case than the general integral. Thus we will work generally and point out the few important special properties of the Lebesgue integral on \( \mathbb{R} \) as we go. We will usually suppress the name “Lebesgue” from the general abstract integral, except when this integral must be distinguished from integrals defined in other ways, and mostly reserve it for the special case of Lebesgue measure on \( \mathbb{R} \) (or \( \mathbb{R}^n \)).

If \((X, \mathcal{A}, \mu)\) is a measure space, we want to assign an extended real number to any extended real-valued measurable function \( f \), and \( E \in \mathcal{A} \), called the integral of \( f \) over \( E \) and denoted \( \int_E f \, d\mu \), in such a way that the integral has standard nice properties we would like and expect. It turns out not to be possible to do this for every extended real-valued measurable function in general (because of the obstacle of defining \( \infty - \infty \)), but only for nonnegative functions and general functions whose positive and negative parts are not “too large” (“integrable” functions). We will build up the integral in three steps (the process is called bootstrapping):

(i) Simple functions.

(ii) Nonnegative extended real-valued measurable functions.

(iii) Integrable functions.

XIV.4.1. Properties of the Integral

We can give a list of properties we want the integral to have. This list might be regarded as a “wish list” at the moment, but we will be able to get almost everything on the list.

XIV.4.1.1. Let \((X, \mathcal{A}, \mu)\) be a measure space. We would like the assignment \((f, E) \mapsto \int_E f \, d\mu\) to have the following properties:

(i) [MONOTONICITY] If \( f \leq g \), then \( \int_E f \, d\mu \leq \int_E g \, d\mu \) for any \( E \).

(ii) [LINEARITY] \( \int_E (f + g) \, d\mu = \int_E f \, d\mu + \int_E g \, d\mu \) for any \( f, g, E \).

(iii) [HOMOGENEITY] \( \int_E \alpha f \, d\mu = \alpha \int_E f \, d\mu \) for any \( f, E, \alpha \in \mathbb{R} \) (where we always interpret \( 0 \cdot \infty = 0 \)).

(iv) [ADDITIVITY] If \((E_k)\) are pairwise disjoint in \( \mathcal{A} \) and \( E = \bigcup_k E_k \), then \( \int_E f \, d\mu = \sum_{k=1}^{\infty} \int_{E_k} f \, d\mu \).

(v) If \( f = g \text{ a.e. (} \mu\text{-a.e.)} \), then \( \int_E f \, d\mu = \int_E g \, d\mu \) for any \( E \).
(vi) If $\mu(E) = 0$, then $\int_E f \, d\mu = 0$ for any $f$.

(vii) [Continuity] If $f_n \to f$ pointwise, then $\int_E f_n \, d\mu \to \int_E f \, d\mu$ for any $E$.

(viii) [Normalization] $\int_E 1 \, d\mu = \mu(E)$ for any $E$.

**XIV.4.1.2.** Actually, (ii) and (iii) together are usually called “linearity,” and can be replaced by the single condition

$$(ii') \, \int_E (\alpha f + g) \, d\mu = \alpha \int_E f \, d\mu + \int_E g \, d\mu$$

for any $f, g, E$, and $\alpha \in \mathbb{R}$.

We have used “linearity” for (ii) instead of “additivity” to distinguish it from (iii), although the way we will proceed it will turn out that (iii), at least for finitely many sets, is a consequence of (ii).

**XIV.4.1.3.** We will be able to get everything on this list except Continuity, although in several others we will have to make modest restrictions to avoid the $\infty - \infty$ problem. Continuity in the general form of (vii) is simply not possible in general (XIV.4.7.1.); however, the major convergence theorems of integration theory (MCT, DCT) will show that continuity holds under some reasonable additional assumptions.

**XIV.4.2.** Integral of Simple Functions

Recall the definition of a simple function $\phi$. To avoid verbosity, we will restrict the definition to only include functions which are nonnegative and measurable:

**XIV.4.2.1.** Definition. Let $(X, \mathcal{A})$ be a measurable space. A simple function on $(X, \mathcal{A})$ is a nonnegative real-valued measurable function which takes only finitely many values.

If $\phi$ is a simple function on $(X, \mathcal{A})$ taking exactly the values $\alpha_1, \ldots, \alpha_n$, for each $k$ set

$$A_k = \{ x \in X : \phi(x) = \alpha_k \} .$$

Then $\{A_1, \ldots, A_n\}$ is a partition of $X$ into nonempty measurable subsets, and

$$\phi = \sum_{k=1}^{n} \alpha_k \chi_{A_k}$$

is the canonical representation of $\phi$.

In some references, a term with $\alpha_k = 0$ is deleted from the canonical representation, but we prefer to keep such a term to force $\{A_1, \ldots, A_n\}$ to be a partition of $X$. This will have no practical effect.

**XIV.4.2.2.** Any nonnegative (finite) linear combination of indicator functions of measurable sets is a simple function. A sum

$$\phi = \sum_{j=1}^{m} \beta_j \chi_{B_j}$$

may not be a canonical representation of $\phi$ for four reasons:

1. The $B_j$ may not be disjoint.
The $\beta_j$ may not all be distinct.

We may not have $\cup_j B_j = X$.

Some of the $B_j$ may be empty.

(3) and (4) are easy to remedy: for (3), set $B_{m+1} = X \setminus \cup_{j=1}^m B_j$ and $\beta_{m+1} = 0$, and for (4), just delete any terms with $B_j = \emptyset$. The others can also be systematically fixed: for (1), let $A_1, \ldots, A_n$ consist of all nonempty finite intersections of the $B_j$ and their complements (i.e. the nonempty sets in the partition of $\cup_{j=1}^m B_j$ generated by the $B_j$), and if $A_k = B_{j_1} \cap \cdots \cap B_{j_r} \cap B_{j_{r+1}} \cap \cdots B_{j_c}^c$, set $\alpha_k = \beta_{j_1} + \cdots + \beta_{j_c}$. Then for (2) just combine together terms with equal $\beta_j$, using that $\chi_{A\cup B} = \chi_A + \chi_B$ if $A$ and $B$ are disjoint. If these corrections are done in the order (1), (3), (4), (2), each only needs to be done once and the representation is converted into canonical form.

A representation in which all the $B_j$ are disjoint, but (2), (3), (4) are allowed, is said to be in semicanonical form.

XIV.4.2.3. Note that if $\phi$ is simple and $E \in \mathcal{A}$, then $\phi \chi_E$ is also simple: if $\phi = \sum_{j=1}^m \beta_j \chi_{B_j}$, then $\phi \chi_E = \sum_{j=1}^m \beta_j \chi_{B_j \cap E}$. If the representation of $\phi$ is in semicanonical form, so is this representation of $\phi \chi_E$; but the representation of $\phi \chi_E$ is not necessarily in canonical form even if the representation of $\phi$ is.

The Integral of a Simple Function

We can define the integral of a simple function in the only way possible if we hope to have linearity and normalization:

XIV.4.2.4. Definition. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $\phi$ a simple function on $(X, \mathcal{A})$. Write $\phi = \sum_{k=1}^n \alpha_k \chi_{A_k}$ in canonical form. Then

$$\int_X \phi \, d\mu = \sum_{k=1}^n \alpha_k \mu(A_k)$$

where $0 \cdot \infty$ is always interpreted to be 0, and $r \cdot \infty = \infty$ if $r > 0$. If $E \in \mathcal{A}$, set

$$\int_E \phi \, d\mu = \int_X \phi \chi_E \, d\mu .$$

A few simple properties are immediate from the definition:

XIV.4.2.5. Proposition. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $E \in \mathcal{A}$.

(i) If $\phi$ is a simple function on $(X, \mathcal{A})$, and $r \geq 0$, then

$$\int_E r \phi \, d\mu = r \int_E \phi \, d\mu .$$
(ii) If $\phi$ and $\psi$ are simple functions and $\phi = \psi$ a.e. on $E$ (i.e. $\phi \chi_E = \psi \chi_E$ a.e.), then

$$\int_E \phi \, d\mu = \int_E \psi \, d\mu .$$

(iii) If $\mu(E) = 0$, then $\int_E \phi \, d\mu = 0$ for any simple function $\phi$.

**Proof:** (i): If $r > 0$ and $\phi \chi_E = \sum_{k=1}^n \alpha_k \chi_{A_k}$ is the canonical representation, then the canonical representation of $r \phi \chi_E$ is $\sum_{k=1}^n \alpha_k \chi_{A_k}$. And if $r = 0$, both sides are 0 (recall the convention that $0 \cdot \infty = 0$).

(ii): If $\phi \chi_E = \sum_{k=1}^n \alpha_k \chi_{A_k}$ and $\psi \chi_E = \sum_{j=1}^m \beta_j \chi_{B_j}$ are the canonical representations, then each $\alpha_k$ corresponds to a unique $\beta_j$ unless $\mu(A_k) = 0$ in which case the term $\alpha_k \mu(A_k)$ can be deleted from the sum, and conversely: thus once zero terms are deleted the terms in the sums are in one-one correspondence. For each $k$ the sets $A_k$ and $B_{j_k}$ differ by a null set, so $\mu(A_k) = \mu(B_{j_k})$. Thus the remaining terms are numerically identical.

(iii): If $\mu(E) = 0$, then in the canonical representation $\phi \chi_E = \sum_{k=1}^n \alpha_k \chi_{A_k}$, in any term with $\alpha_k > 0$ we have $A_k \subseteq E$, so $\mu(A_k) = 0$. Thus all the terms in $\sum_{k=1}^n \alpha_k \mu(A_k)$ are zero. \(\diamondsuit\)

The key technical fact giving reasonable properties of the integral defined this way is that the formula in the definition holds for any representation of $\phi$, not just the canonical one:

**XIV.4.2.6. Proposition.** Let $(X, A, \mu)$ be a measure space, and $\phi$ a simple function on $(X, A)$. If $\phi = \sum_{j=1}^m \beta_j \chi_{B_j}$ is any representation of $\phi$, then

$$\int_X \phi \, d\mu = \sum_{j=1}^m \beta_j \mu(B_j) .$$

**Proof:** We must observe that the sum does not change as the four corrections of XIV.4.2.2. are made to convert the given representation of $\phi$ to the canonical one. Corrections (3) and (4) obviously do not affect the sum (using the convention $0 \cdot \infty = 0$ for (3)), and correction (2) is easily seen to also leave the sum unchanged if the $B_j$ are disjoint (using finite additivity of $\mu$).

Correction (1) requires a little more work. We disjointize $B_1$ and $B_2$ into $B_1 \cap B_2$, $B_1 \setminus B_2$, and $B_2 \setminus B_1$. Observe that

$$\beta_1 \chi_{B_1} + \beta_2 \chi_{B_2} = \beta_1 \chi_{B_1 \setminus B_2} + \beta_2 \chi_{B_2 \setminus B_1} + (\beta_1 + \beta_2) \chi_{B_1 \cap B_2}$$

and that

$$\beta_1 \mu(B_1 \setminus B_2) + \beta_2 \mu(B_2 \setminus B_1) + (\beta_1 + \beta_2) \mu(B_1 \cap B_2)$$

$$= \beta_1 [\mu(B_1 \setminus B_2) + \mu(B_1 \cap B_2)] + \beta_2 [\mu(B_2 \setminus B_1) + \mu(B_1 \cap B_2)] = \beta_1 \mu(B_1) + \beta_2 \mu(B_2)$$

by finite additivity of $\mu$; thus the sum for the beginning representation equals the sum obtained by disjointing $B_1$ and $B_2$. We can then successively disjointize any two non-disjoint remaining sets in the new representation in the same way without affecting the sum or the previous disjointizations. After a finite number of steps the representation is converted to semicanonical form and the sum is unchanged. \(\diamondsuit\)

Most of the important properties of the integral for simple functions follow easily. First is a formula for the integral of a simple function over a subset:
XIV.4.2.7. Corollary. Let \((X, \mathcal{A}, \mu)\) be a measure space, and \(\phi = \sum_{k=1}^{n} \alpha_k \chi_{A_k}\) a simple function on \((X, \mathcal{A})\) (not necessarily in canonical form). If \(E \in \mathcal{A}\), then

\[
\int_E \phi \, d\mu = \int_X \phi \chi_E \, d\mu = \sum_{k=1}^{n} \alpha_k \mu(A_k \cap E).
\]

Linearity and (finite) additivity also follow easily:

XIV.4.2.8. Corollary. Let \((X, \mathcal{A}, \mu)\) be a measure space, and \(\phi\) and \(\psi\) simple functions on \((X, \mathcal{A})\). If \(E \in \mathcal{A}\), then

\[
\int_E (\phi + \psi) \, d\mu = \int_E \phi \, d\mu + \int_E \psi \, d\mu.
\]

Proof: If \(\phi \chi_E = \sum_{k=1}^{n} \alpha_k \chi_{A_k}\) and \(\psi \chi_E = \sum_{j=1}^{m} \beta_j \chi_{B_j}\) are representations (not necessarily canonical), then

\[
(\phi + \psi) \chi_E = \sum_{k=1}^{n} \alpha_k \chi_{A_k} + \sum_{j=1}^{m} \beta_j \chi_{B_j}
\]

is a representation.

Note that the representation of \((\phi + \psi) \chi_E\) in the proof is almost necessarily non-canonical, so the proposition is necessary to establish linearity of the integral for simple functions.

XIV.4.2.9. Corollary. Let \((X, \mathcal{A}, \mu)\) be a measure space, and \(\phi\) a simple function on \((X, \mathcal{A})\). If \(D_1, \ldots, D_n \in \mathcal{A}\) are pairwise disjoint and \(E = D_1 \cup \cdots \cup D_n\), then

\[
\int_E \phi \, d\mu = \sum_{k=1}^{n} \left[ \int_{D_k} \phi \, d\mu \right].
\]

Proof: We have \(\phi \chi_E = \phi \chi_{D_1} + \cdots + \phi \chi_{D_n}\).

Finite additivity can be extended to countable additivity (XIV.4.2.12.).

We can also obtain monotonicity:
XIV.4.2.10. COROLLARY. Let \((X, \mathcal{A}, \mu)\) be a measure space, and \(\phi\) and \(\psi\) simple functions on \((X, \mathcal{A})\). If \(E \in \mathcal{A}\) and \(\phi \leq \psi\) a.e. on \(E\), then
\[
\int_E \phi \, d\mu \leq \int_E \psi \, d\mu .
\]

PROOF: By modifying \(\phi\) on a null set (cf. XIV.4.2.5 (ii)), we may assume \(\phi \chi_E \leq \psi \chi_E\) everywhere. Let \(\phi \chi_E = \sum_{k=1}^{m} \alpha_k \chi_{A_k} \) and \(\psi \chi_E = \sum_{j=1}^{n} \beta_j \chi_{B_j} \) be canonical representations. Then
\[
\phi \chi_E = \sum_{j=1}^{m} \sum_{k=1}^{n} \alpha_k \chi_{A_k \cap B_j} \\
\psi \chi_E = \sum_{j=1}^{m} \sum_{k=1}^{n} \beta_j \chi_{A_k \cap B_j}
\]
are semicanonical representations; and whenever \(A_k \cap B_j \neq \emptyset\), we have \(\alpha_k \leq \beta_j\) since \(\phi \chi_E \leq \psi \chi_E\). Thus
\[
\int_E \phi \, d\mu = \sum_{j=1}^{m} \sum_{k=1}^{n} \alpha_k \mu(A_k \cap B_j) \leq \sum_{j=1}^{m} \sum_{k=1}^{n} \beta_j \mu(A_k \cap B_j) = \int_E \psi \, d\mu .
\]

We also have the following slight extension of the Baby Monotone Convergence Theorem (), which will be used to establish the full Monotone Convergence Theorem and other continuity properties of the integral:

XIV.4.2.11. PROPOSITION. [JUNIOR MONOTONE CONVERGENCE THEOREM] Let \((X, \mathcal{A}, \mu)\) be a measure space, and \(\phi\) a simple function on \((X, \mathcal{A})\). If \(E_1, E_2, \ldots\) is an increasing sequence of sets in \(\mathcal{A}\), and \(E = \bigcup_{n=1}^{\infty} E_n\), then
\[
\int_E \phi \, d\mu = \lim_{n \to \infty} \left[ \int_{E_n} \phi \, d\mu \right] = \sup_n \left[ \int_{E_n} \phi \, d\mu \right] .
\]

PROOF: Let \(\phi = \sum_{k=1}^{m} \alpha_k \chi(A_k)\) be a representation (not necessarily canonical). Fix \(k\). Then we have \(A_k \cap E_1 \subseteq A_k \cap E_2 \subseteq \cdots\) and \(A_k \cap E = \bigcup_{n=1}^{\infty} [A_k \cap E_n]\), so by the Baby MCT we have
\[
\alpha_k \mu(A_k \cap E) = \lim_{n \to \infty} \alpha_k \mu(A_k \cap E_n) = \sup_n \alpha_k \mu(A_k \cap E_n) .
\]

This is true for all \(k\), and since the sum is finite, we have
\[
\sum_{k=1}^{m} \alpha_k \mu(A_k \cap E) = \lim_{n \to \infty} \left[ \sum_{k=1}^{m} \alpha_k \mu(A_k \cap E_n) \right] = \sup_n \left[ \sum_{k=1}^{m} \alpha_k \mu(A_k \cap E_n) \right] .
\]
XIV.4.2.12. Corollary. Let \((X, \mathcal{A}, \mu)\) be a measure space, and \(\phi\) a simple function on \((X, \mathcal{A})\). If \(D_1, \ldots, D_n, \ldots \in \mathcal{A}\) are pairwise disjoint and \(E = \bigcup_{k=1}^{\infty} D_k\), then

\[
\int_E \phi \, d\mu = \sum_{k=1}^{\infty} \left[ \int_{D_k} \phi \, d\mu \right].
\]

Proof: For each \(n\) set \(E_n = D_1 \cup \cdots \cup D_n\). Then the \(E_n\) are increasing and \(E = \bigcup_{n} E_n\), so by XIV.4.2.11. and XIV.4.2.9. we have

\[
\int_E \phi \, d\mu = \lim_{n \to \infty} \left( \int_{E_n} \phi \, d\mu \right) = \lim_{n \to \infty} \left( \sum_{k=1}^{n} \left[ \int_{D_k} \phi \, d\mu \right] \right) = \sum_{k=1}^{\infty} \left[ \int_{D_k} \phi \, d\mu \right].
\]

XIV.4.3. The Integral of a Nonnegative Measurable Function

We can now define the integral of a general nonnegative measurable function:

XIV.4.3.1. Definition. Let \((X, \mathcal{A}, \mu)\) be a measure space, and \(f\) a nonnegative extended real-valued measurable function on \((X, \mathcal{A})\). Define

\[
\int_X f \, d\mu = \sup \left\{ \int_X \phi \, d\mu : \phi \text{ simple, } \phi \leq f \right\}.
\]

If \(E \in \mathcal{A}\), define

\[
\int_E f \, d\mu = \int_X f \chi_E \, d\mu.
\]

Note that if \(f\) itself is a simple function, then this definition of \(\int_E f \, d\mu\) agrees with the previous definition (cf. XIV.4.2.10.); thus the definitions are consistent and unambiguous.

XIV.4.3.2. The following properties of the integral are immediate:

(i) \(0 \leq \int_E f \, d\mu \leq \infty\) for any \(f\) and \(E\).

(ii) If \(f \leq g\) on \(E\), then \(\int_E f \, d\mu \leq \int_E g \, d\mu\).

(iii) If \(\alpha \geq 0\), then \(\int_E \alpha f \, d\mu = \alpha \int_E f \, d\mu\) (using \(0 \cdot \infty = 0\) and \(\alpha \cdot \infty = \infty\) if \(\alpha > 0\)). In particular, \(\int_E 0 \, d\mu = 0\) for any \(E\).

(iv) If \(\mu(E) = 0\), then \(\int_E f \, d\mu = 0\) for any \(f\) (cf. XIV.4.2.5.).
XIV.4.3.3. **Proposition.** Let \((X,\mathcal{A},\mu)\) be a measure space, and \(f\) and \(g\) nonnegative extended real-valued measurable functions on \((X,\mathcal{A})\). If \(f = g\) a.e. (\(\mu\)-a.e.) on \(E\), then
\[
\int_E f \, d\mu = \int_E g \, d\mu .
\]

**Proof:** If \(f\chi_E = g\chi_E\) on \(X \setminus C\), where \(C \in \mathcal{A}\) and \(\mu(C) = 0\), and \(\phi\) is a simple function with \(\phi \leq f\), then \(\psi = \phi\chi_{X \setminus C}\) is a simple function with \(\psi \leq g\chi_E\), and \(\psi = \phi\) a.e., so \(\int_X \psi \, d\mu = \int_X \phi \, d\mu\) by XIV.4.2.5.. Thus \(\int_E f \, d\mu \leq \int_E g \, d\mu\). Symmetrically, \(\int_E g \, d\mu \leq \int_E f \, d\mu\).

Combining this with XIV.4.3.2 (ii), we obtain:

XIV.4.3.4. **Proposition.** Let \((X,\mathcal{A},\mu)\) be a measure space, and \(f\) and \(g\) nonnegative extended real-valued measurable functions on \((X,\mathcal{A})\). If \(f \leq g\) a.e. (\(\mu\)-a.e.) on \(E\), then
\[
\int_E f \, d\mu \leq \int_E g \, d\mu .
\]

XIV.4.3.5. We have thus established all the desired properties of the integral (for nonnegative functions) from XIV.4.1.1. except for the crucial properties of linearity, additivity, and continuity. These are trickier to show; we will first prove one of the important continuity properties, the Monotone Convergence Theorem, and use it to obtain linearity and additivity (and much more).

**Integrable Functions**

The integral of a nonnegative extended real-valued measurable function can be \(\infty\) (even the integral of a simple function can be infinite). But functions with finite integral are the most interesting ones:

XIV.4.3.6. **Definition.** Let \((X,\mathcal{A},\mu)\) be a measure space, and \(f\) a nonnegative extended real-valued measurable function on \((X,\mathcal{A})\). Then \(f\) is \(\mu\)-integrable if
\[
\int_X f \, d\mu < \infty .
\]

If \(E \in \mathcal{A}\), then \(f\) is \(\mu\)-integrable on \(E\) if \(\int_E f \, d\mu < \infty\).

XIV.4.3.7. Note that a \(\mu\)-integrable function is by definition measurable. We often write “integrable” in place of “\(\mu\)-integrable” when the \(\mu\) is understood. But note that, although measurability of a function \(f\) depends only on \(\mathcal{A}\) and not on \(\mu\), integrability of \(f\) depends on \(\mu\).

When \(\mu\) is Lebesgue measure \(\lambda\) on \(\mathbb{R}\) (or a subset), we will say \(f\) is Lebesgue integrable if it is \(\lambda\)-integrable. We usually, but not always, write “Lebesgue integrable” in this context to distinguish the notion from Riemann integrability (or other types of integrability on \(\mathbb{R}\) such as H-K integrability).
XIV.4.3.8. A nonnegative measurable function dominated by an integrable function is integrable. A nonnegative measurable function equal almost everywhere to an integrable function is integrable (XIV.4.3.3).

If \( \mu \) is finite, any bounded nonnegative measurable function on \((X, \mathcal{A})\) is integrable; but if \( \mu \) is infinite, even a (nonzero) constant function is not integrable.

An integrable function can be unbounded. It can even take the value \(1\) on a null set, e.g. \(f = \infty \cdot \chi_A\), where \(\mu(A) = 0\). But an integrable function must be finite a.e., hence equal a.e. to a real-valued measurable function:

XIV.4.3.9. **Proposition.** Let \((X, \mathcal{A}, \mu)\) be a measure space, and \(f\) a nonnegative extended real-valued measurable function on \((X, \mathcal{A})\). Set \(A = \{x \in X : f(x) = \infty\}\). If \(f\) is integrable, then \(\mu(A) = 0\).

**Proof:** If \(\phi_n = n \chi_A\), then \(\phi_n\) is a simple function and \(\phi_n \leq f\). Thus
\[
n\mu(A) = \int_X \phi_n \, d\mu \leq \int_X f \, d\mu
\]
for all \(n\), which implies \(\mu(A) = 0\). \(\Box\)

Similarly, if \(f\) is integrable, the support \((\cdot)\) of \(f\) has “almost finite measure” (it need not actually have finite measure; cf. ()):  

XIV.4.3.10. **Proposition.** Let \((X, \mathcal{A}, \mu)\) be a measure space, and \(f\) a nonnegative extended real-valued measurable function on \((X, \mathcal{A})\). Fix \(\epsilon > 0\), and set \(A_\epsilon = \{x \in X : f(x) \geq \epsilon\}\). Then
\[
\mu(A_\epsilon) \leq \frac{1}{\epsilon} \int_X f \, d\mu.
\]
In particular, if \(f\) is integrable, then \(\mu(A_\epsilon) < \infty\) for all \(\epsilon > 0\).

**Proof:** Set \(\phi_\epsilon = \epsilon \chi_{A_\epsilon}\). Then \(\phi_\epsilon\) is a simple function and \(\phi_\epsilon \leq f\). Thus
\[
\epsilon \mu(A_\epsilon) = \int_X \phi_\epsilon \, d\mu \leq \int_X f \, d\mu.
\]
\(\Box\)

XIV.4.3.11. **Corollary.** Let \((X, \mathcal{A}, \mu)\) be a measure space, and \(f\) a nonnegative extended real-valued measurable function on \((X, \mathcal{A})\). If \(E \in \mathcal{A}\) and \(\int_E f \, d\mu = 0\), then \(f = 0\) a.e. on \(E\).

**Proof:** If \(A = \{x \in E : f(x) > 0\}\), then \(A = \cup_{n=1}^\infty A_n\), where \(A_n = \{x \in E : f(x) \geq \frac{1}{n}\}\), and
\[
\mu(A_n) \leq n \int_E f \, d\mu = 0.
\]
\(\Box\)
XIV.4.3.12. Proposition XIV.4.3.10. is not only interesting for $\epsilon$ small; it is of interest for arbitrary positive $\epsilon$. In fact, as $\epsilon \to \infty$ we obtain XIV.4.3.9. The proposition says that an integrable function is small except on a set of reasonable finite measure, and not too large except on a set of small measure.

XIV.4.3.13. Corollary. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $f$ a nonnegative integrable function on $(X, \mathcal{A})$. Then the support of $f$ is a set of $\sigma$-finite measure.

Proof: If $E = \{x \in X : f(x) > 0\}$ is the support of $f$, then $E = \cup_{n=1}^{\infty} A_{1/n}$.

XIV.4.3.14. Thus, although integration is defined on arbitrary measure spaces, it is only a nontrivial theory if there are sufficiently many sets of finite measure (e.g. if the measure is semifinite). If there are no sets of nonzero finite measure, then the only nonnegative integrable functions are ones equal to 0 almost everywhere.

Integration for Counting Measure

By far the most important example of the integral we have constructed is the Lebesgue integral on $\mathbb{R}$, discussed in Section XIV.4.6. But another illuminating example is counting measure on $\mathbb{N}$.

XIV.4.3.15. Consider the measure space $(\mathbb{N}, \mathcal{P}(\mathbb{N}), \mu)$, where $\mu$ is counting measure on $(\mathbb{N}, \mathcal{P}(\mathbb{N}))$. A real-valued function on $\mathbb{N}$ is just a sequence, and every such function is measurable since the $\sigma$-algebra is $\mathcal{P}(\mathbb{N})$. An extended real-valued function is one where some terms of the sequence are allowed to be $\infty$. A simple function is a sequence of nonnegative real numbers where only finitely many distinct numbers occur; such a function is integrable if and only if only finitely many terms are nonzero, and the integral is just the sum of the terms.

Thus if $x = (x_1, x_2, \ldots)$ is a nonnegative sequence, then $\int_{\mathbb{N}} x \, d\mu$ is just the unordered sum

$$\sum_{n \in \mathbb{N}} x_n$$

which converges if and only if all terms are finite and the infinite series

$$\sum_{n=1}^{\infty} x_n$$

converges ($\cdot$).

We will see ($\cdot$) that a general function (sequence) $(x_n)$ is integrable with respect to $\mu$ if and only if the infinite series

$$\sum_{n=1}^{\infty} x_n$$

converges absolutely. Thus the theory of absolutely convergent infinite series is the special case of the integral for counting measure. In fact, it is worthwhile to view integration in general as some sort of “continuous” version of absolute summation.
XIV.4.4. The Monotone Convergence Theorem

The Monotone Convergence Theorem (MCT) is one of the three main convergence or continuity theorems of integration theory, the others being Fatou’s Lemma and the Dominated Convergence Theorem.

XIV.4.4.1. Theorem. [Monotone Convergence Theorem] Let \((X, \mathcal{A}, \mu)\) be a measure space, and \((f_n)\) a nondecreasing sequence of nonnegative extended real-valued measurable functions converging pointwise a.e. to a (nonnegative) extended real-valued measurable function \(f\). If \(E \in \mathcal{A}\), then

\[
\int_E f \, d\mu = \lim_{n \to \infty} \int_E f_n \, d\mu = \sup_n \int_E f_n \, d\mu .
\]

Note that it is the \(\text{sequence} (f_n)\) which is nondecreasing, i.e. \(f_1 \leq f_2 \leq \cdots\), not the individual functions which are nondecreasing. In fact, since the \(f_n\) are real-valued functions on a general set \(X\), it does not even make sense to ask whether such a function is nondecreasing. Note also that the hypothesis that \(f\) is measurable is almost, but not quite, automatic (if the measure space is not complete, \(f\) might have to be modified on a subset of a null set to make it measurable).

Proof: By modifying \(f\) on a null set, we may assume that \(f_n \to f\) pointwise everywhere. Since \(f_n \leq f\) for all \(n\), we have \(\int_E f_n \, d\mu \leq \int_E f \, d\mu\) for all \(n\). Thus if

\[
L := \lim_{n \to \infty} \int_E f_n \, d\mu = \sup_n \int_E f_n \, d\mu
\]

(the limit exists since the sequence of integrals is nondecreasing), we have \(L \leq \int_E f \, d\mu\).

So we need to show \(\int_E f \, d\mu \leq L\). If \(L = \infty\) there is nothing to show, so we may assume \(L < \infty\).

Fix \(r\), \(0 < r < 1\). Let \(\phi\) be a simple function with \(\phi \leq f\chi_E\), and set

\[
E_n = \{x \in E : r\phi(x) \leq f_n(x)\} .
\]

Then \(E_n\) is measurable \([E_n = E \cap \{x \in X : f_n(x) - r\phi(x) \geq 0\}\) and \(f_n - r\phi\) is a measurable function], and \(E_n \subseteq E_{n+1}\) for all \(n\) since \(f_n \leq f_{n+1}\). If \(x \in E\) and \(f(x) > 0\), then \(f_n(x) \to f(x) > r\phi(x)\), so there is an \(n\) such that \(f_k(x) > r\phi(x)\) for all \(k \geq n\); thus \(x \in E_n\). And if \(f(x) = 0\), then \(\phi(x) = f_n(x) = 0\) for all \(n\), so \(x \in E_n\) for all \(n\). Thus \(\bigcup_n E_n = E\). And, for each \(n\), \(r\phi \chi_{E_n} \leq f_n \chi_{E_n}\), so \(\int_{E_n} r\phi \, d\mu \leq \int_{E_n} f_n \, d\mu \leq \int_E f_n \, d\mu \leq L\) by monotonicity.

By the Junior Monotone Convergence Theorem (XIV.4.2.11.),

\[
\int_E r\phi \, d\mu = \sup_n \int_{E_n} r\phi \, d\mu \leq \sup_n \int_{E_n} f_n \, d\mu \leq L
\]

Thus

\[
\int_E \phi \, d\mu \leq \frac{1}{r} L .
\]

This is true for all simple \(\phi \leq f\chi_E\), so we have

\[
\int_E f \, d\mu = \sup_{\phi \leq f\chi_E} \int_E \phi \, d\mu \leq \frac{1}{r} L
\]

Since this is true for all \(r < 1\), we conclude \(\int_E f \, d\mu \leq L\).
XIV.4.4.2. In some references, the MCT or its series version XIV.4.5.5. is called the Beppo Levi Theorem. While there is some historical justification for this, and we do like Beppo’s name (perhaps the main reason mathematicians use this terminology?), we prefer the more descriptive MCT term.

XIV.4.5. Consequences of the Monotone Convergence Theorem

The Monotone Convergence Theorem is the key to several more important properties of the integral.

Linearity

XIV.4.5.1. Theorem. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $f$ and $g$ nonnegative extended real-valued measurable functions on $(X, \mathcal{A})$. If $E \in \mathcal{A}$, then

$$\int_E (f + g) \, d\mu = \int_E f \, d\mu + \int_E g \, d\mu.$$  

Proof: Let $(\phi_n)$ and $(\psi_n)$ be nondecreasing sequences of simple functions converging pointwise to $f \chi_E$ and $g \chi_E$ respectively. Then $(\phi_n + \psi_n)$ is an increasing sequence of simple functions converging pointwise to $(f + g) \chi_E$, and by XIV.4.2.8. we have

$$\int_E (\phi_n + \psi_n) \, d\mu = \int_E \phi_n \, d\mu + \int_E \psi_n \, d\mu$$

for all $n$. Thus by three applications of the MCT, along with (),

$$\int_E (f + g) \, d\mu = \lim_{n \to \infty} \int_E (\phi_n + \psi_n) \, d\mu = \lim_{n \to \infty} \left[ \int_E \phi_n \, d\mu + \int_E \psi_n \, d\mu \right]$$

$$= \left[ \lim_{n \to \infty} \int_E \phi_n \, d\mu \right] + \left[ \lim_{n \to \infty} \int_E \psi_n \, d\mu \right] = \int_E f \, d\mu + \int_E g \, d\mu.$$  

Additivity

We next establish finite additivity:

XIV.4.5.2. Corollary. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $f$ a nonnegative extended real-valued measurable function on $(X, \mathcal{A})$. If $D_1, \ldots, D_n \in \mathcal{A}$ are pairwise disjoint and $E = D_1 \cup \cdots \cup D_n$, then

$$\int_E f \, d\mu = \sum_{k=1}^n \int_{D_k} f \, d\mu.$$  

Proof: We have $f \chi_E = f \chi_{D_1} + \cdots + f \chi_{D_n}$.

Before extending to countable additivity, we note the following special case of the MCT which extends the Junior MCT:
XIV.4.5.3. Corollary. Let \((X, \mathcal{A}, \mu)\) be a measure space, and \(f\) a nonnegative extended real-valued measurable function on \((X, \mathcal{A})\). If \(E_1, E_2, \ldots\) is an increasing sequence of sets in \(\mathcal{A}\), and \(E = \bigcup_{n=1}^{\infty} E_n\), then

\[
\int_E f \, d\mu = \lim_{n \to \infty} \left[ \int_{E_n} f \, d\mu \right] = \sup_n \left[ \int_{E_n} f \, d\mu \right].
\]

Proof: The sequence \((f_{\chi_{E_n}})\) is nondecreasing and converges pointwise to \(f_{\chi_E}\).

We then obtain countable additivity:

XIV.4.5.4. Corollary. Let \((X, \mathcal{A}, \mu)\) be a measure space, and \(f\) a nonnegative extended real-valued measurable function on \((X, \mathcal{A})\). If \(D_1, \ldots, D_n, \ldots \in \mathcal{A}\) are pairwise disjoint and \(E = \bigcup_{k=1}^{\infty} D_k\), then

\[
\int_E f \, d\mu = \sum_{k=1}^{\infty} \left[ \int_{D_k} f \, d\mu \right].
\]

Proof: For each \(n\) set \(E_n = D_1 \cup \cdots \cup D_n\). Then the \(E_n\) are increasing and \(E = \bigcup_{n} E_n\), so by XIV.4.5.3. and XIV.4.5.2. we have

\[
\int_E f \, d\mu = \lim_{n \to \infty} \left( \int_{E_n} f \, d\mu \right) = \lim_{n \to \infty} \left( \sum_{k=1}^{n} \left[ \int_{D_k} f \, d\mu \right] \right) = \sum_{k=1}^{\infty} \left[ \int_{D_k} f \, d\mu \right].
\]

The Monotone Convergence Theorem for Series

More generally, we have the following series version of the MCT:

XIV.4.5.5. Theorem. [MONOTONE CONVERGENCE THEOREM FOR SERIES] Let \((X, \mathcal{A}, \mu)\) be a measure space, and \((g_k)\) a sequence of nonnegative extended real-valued measurable functions on \((X, \mathcal{A})\). Set

\[
f = \sum_{k=1}^{\infty} g_k
\]

(the series converges pointwise to an extended real-valued function since the terms are nonnegative). If \(E \in \mathcal{A}\), then

\[
\int_E f \, d\mu = \sum_{k=1}^{\infty} \left[ \int_E g_k \, d\mu \right].
\]

Proof: For each \(n\) set

\[
f_n = \sum_{k=1}^{n} g_k.
\]
Then \( (f_n) \) is a nondecreasing sequence of nonnegative extended real-valued measurable functions converging pointwise to \( f \). By the MCT and XIV.4.5.1,

\[
\int_E f \, d\mu = \lim_{n \to \infty} \int_E f_n \, d\mu = \lim_{n \to \infty} \left[ \sum_{k=1}^{n} \int_E g_k \, d\mu \right] = \sum_{k=1}^{\infty} \left[ \int_E g_k \, d\mu \right].
\]

The Downward MCT

If \( (f_n) \) is a nonincreasing sequence of nonnegative real-valued measurable functions on a measure space \((X, \mathcal{A}, \mu)\), it is not necessarily true that \( \int_X f_n \, d\mu \to \int_X f \, d\mu \), even if the \( f_n \) are indicator functions of measurable sets (XIV.4.7.1). However, if the \( f_n \) are integrable, downward continuity holds:

**XIV.4.5.6. Theorem. [Downward Monotone Convergence Theorem]** Let \((X, \mathcal{A}, \mu)\) be a measure space, and \( (f_n) \) a nonincreasing sequence of nonnegative extended real-valued measurable functions converging pointwise a.e. to a (nonnegative) extended real-valued measurable function \( f \). If \( E \in \mathcal{A} \), and \( \int_E f_1 \, d\mu < \infty \), then

\[
\int_E f \, d\mu = \lim_{n \to \infty} \int_E f_n \, d\mu = \inf_n \int_E f_n \, d\mu.
\]

**Proof:** If \( A = \{ x \in X : f_1(x) = \infty \} \), then \( \mu(A \cap E) = 0 \) by XIV.4.3.9. Thus we may replace \( f_n \) by \( f_n \chi_{A^c} \) for each \( n \) without affecting the integrals over \( E \), i.e. we may assume the \( f_n \) are real-valued.

For each \( n \), set \( g_n = f_1 - f_n \) (this is well defined since the functions are real-valued). Then \( (g_n) \) is a nondecreasing sequence of nonnegative real-valued measurable functions converging pointwise a.e. to \( f_1 - f \); thus by the MCT

\[
\int_E (f_1 - f) \, d\mu = \lim_{n \to \infty} \int_E g_n \, d\mu = \lim_{n \to \infty} \int_E (f_1 - f_n) \, d\mu.
\]

For each \( n \) we have

\[
\int_E f_1 \, d\mu = \int_E f_n \, d\mu + \int_E (f_1 - f_n) \, d\mu
\]

and, since the integrals are finite,

\[
\int_E (f_1 - f_n) \, d\mu = \int_E f_1 \, d\mu - \int_E f_n \, d\mu.
\]

Similarly,

\[
\int_E (f_1 - f) \, d\mu = \int_E f_1 \, d\mu - \int_E f \, d\mu.
\]

Thus we have

\[
\int_E f_1 \, d\mu - \int_E f \, d\mu = \lim_{n \to \infty} \left[ \int_E f_1 \, d\mu - \int_E f_n \, d\mu \right] = \int_E f_1 \, d\mu - \lim_{n \to \infty} \int_E f_n \, d\mu
\]

and the result follows.
XIV.4.5.7. The requirement that \( \int_E f_1 \, d\mu < \infty \) may be relaxed to \( \int_E f_n \, d\mu < \infty \) for some \( n \) by passing to a subsequence. The Downward MCT is also an immediate corollary of the Dominated Convergence Theorem.

Approximation From Above

We now discuss when the integral of a nonnegative real-valued function can be approximated from above by integrals of simple functions. Fix a measure space \((X, \mathcal{A}, \mu)\).

XIV.4.5.8. An unbounded nonnegative real-valued function cannot be dominated by a simple function, since simple functions are bounded. And if \( \mu \) is infinite, an integrable \( f \) whose support has infinite measure cannot be dominated by an integrable simple function, since the support of an integrable simple function has finite measure. Thus the only functions for which there is a hope of approximating the integral from above by integrals of simple functions are bounded (nonnegative) functions whose support has finite measure.

XIV.4.5.9. Theorem. Let \((X, \mathcal{A}, \mu)\) be a measure space, and \( f \) a nonnegative extended real-valued measurable function on \((X, \mathcal{A})\). Let \( S \) be the support of \( f \). If \( E \in \mathcal{A} \) and \( \mu(E \cap S) < \infty \), and \( f \) is bounded on \( E \), then

\[
\int_E f \, d\mu = \inf \left\{ \int_E \psi \, d\mu : \psi \text{ simple}, f \chi_E \leq \psi \right\}.
\]

Proof: Suppose \( f \leq M \) on \( E \). Then \( f \chi_E \leq \theta := M \chi_{E \cap S} \), \( \theta \) is a simple function, and \( \int_E \theta \, d\mu < \infty \). We have

\[
\int_E (\theta - f) \, d\mu = \sup \left\{ \int_E \phi \, d\mu : \phi \text{ simple}, \phi \leq \theta - f \chi_E \right\}.
\]

If \( \phi \) is a simple function with \( \phi \leq \theta - f \chi_E \), then \( \psi = \theta - \phi \) is a simple function with \( f \chi_E \leq \psi \leq \theta \), and conversely if \( f \chi_E \leq \psi \leq \theta \); thus

\[
\int_E (\theta - f) \, d\mu = \sup \left\{ \int_E (\theta - \psi) \, d\mu : \phi \chi_E \leq \psi \right\}.
\]

If \( \psi \leq \theta \), we have

\[
\int_E f \, d\mu = \int_E \psi \, d\mu + \int_E (\theta - \psi) \, d\mu,
\]

and, since the integrals are finite, we have

\[
\int_E (\theta - \psi) \, d\mu = \int_E \theta \, d\mu - \int_E \psi \, d\mu.
\]

Similarly, we have

\[
\int_E f \, d\mu = \int_E \theta \, d\mu - \int_E (\theta - f) \, d\mu,
\]

\[
= \int_E \theta \, d\mu - \sup \left\{ \left[ \int_E \theta \, d\mu - \int_E \psi \, d\mu \right] : \phi \text{ simple}, f \chi_E \leq \psi \leq \theta \right\}.
\]
Here is a simpler version of XIV.4.5.9. which captures its essence:

**XIV.4.5.10.** Corollary. Let \((X, \mathcal{A}, \mu)\) be a finite measure space, and \(f\) a bounded nonnegative real-valued measurable function on \((X, \mathcal{A})\). Then

\[
\int_X f \, d\mu = \inf \left\{ \int_X \psi \, d\mu : \psi \text{ simple}, f \leq \psi \right\}.
\]

In particular,

\[
\sup \left\{ \int_X \phi \, d\mu : \phi \text{ simple}, \phi \leq f \right\} = \inf \left\{ \int_X \psi \, d\mu : \psi \text{ simple}, f \leq \psi \right\}.
\]

**XIV.4.5.11.** With more work, this theorem can be proved directly without use of the MCT or linearity of the integral. It then easily implies linearity of the integral for bounded functions with finite support (\(\ast\)). From this one can obtain general additivity with some additional work (\(\ast\)). One can then readily deduce Fatou’s Lemma (\(\ast\)), and obtain the MCT as a corollary of Fatou’s Lemma (\(\ast\)). This is the approach taken in [Roy88], for example. The approach we have taken, which is used e.g. in [MW99], seems a little better pedagogically.

**The Role of Measurability**

One can only reasonably define the integral directly for an indicator function or simple function if it is measurable. But the definition

\[
\int_X f \, d\mu = \sup \left\{ \int_X \phi \, d\mu : \phi \text{ simple}, \phi \leq f \right\}
\]

makes sense for any nonnegative extended real-valued function, measurable or not. Why not integrate arbitrary nonnegative functions this way? Since measurability is used in the MCT, and hence for linearity, it might be suspected that something goes wrong; in fact, the following converse of XIV.4.5.10. shows that additivity must fail if we do not restrict to “almost measurable” functions.
XIV.4.5.12. PROPOSITION. Let \((X, \mathcal{A}, \mu)\) be a finite measure space, and \(f\) a bounded nonnegative real-valued function on \((X, \mathcal{A})\). If
\[
\sup \left\{ \int_X \phi \, d\mu : \phi \text{ simple, } \phi \leq f \right\} = \inf \left\{ \int_X \psi \, d\mu : \psi \text{ simple, } f \leq \psi \right\}
\]
then \(f\) is equal a.e. to an \(\mathcal{A}\)-measurable function.

PROOF: The supremum/infimum \(I\) is finite. Choose a sequence \((\phi_n)\) of (measurable) simple functions with \(\phi_n \leq f\) for all \(n\) and \(\int_X \phi_n \, d\mu \to I\). Replacing \(\phi_n\) by \(\max_{1 \leq k \leq n} \phi_k\), we may assume \((\phi_n)\) is nondecreasing. Similarly, let \((\psi_n)\) be a nonincreasing sequence of simple functions with \(f \leq \psi_n\) for all \(n\) and \(\int_X \psi_n \, d\mu \to I\). Then \((\phi_n)\) and \((\psi_n)\) converge pointwise to measurable functions \(g\) and \(h\) respectively, and \(g \leq f \leq h\). By monotonicity,
\[
\int_X g \, d\mu = \int_X h \, d\mu = I
\]
so \(\int_X (h - g) \, d\mu = 0\), and hence \(h - g = 0\) a.e. (XIV.4.3.11.). Thus \(f = g\) a.e. 

XIV.4.5.13. This result does not quite imply that \(f\) is measurable in general if the measure space is not complete (), only that \(f\) is equal a.e. to a measurable function. But if \((X, \mathcal{A}, \mu)\) is complete, e.g. if it is Lebesgue measure on \((X, \mathcal{L})\), then \(f\) must be measurable.

Restricting and Extending Measures

In this connection, we obtain a (hardly unexpected) relation between integrals with respect to restrictions of a measure, and in particular between a measure and its completion:

XIV.4.5.14. PROPOSITION. Let \((X, \mathcal{A}, \mu)\) be a measure space, \(\mathcal{B}\) a sub-\(\sigma\)-algebra of \(\mathcal{A}\), and \(\nu = \mu|_\mathcal{B}\). If \(f\) is a nonnegative extended real-valued \(\mathcal{B}\)-measurable function, and \(E \in \mathcal{B}\), then
\[
\int_E f \, d\nu = \int_E f \, d\mu .
\]

PROOF: This is a good example of bootstrapping. First suppose \(f\) is \(\chi_E\) for some \(E \in \mathcal{B}\). Then \(B\) and \(B \cap E\) are in \(\mathcal{A}\), so we have
\[
\int_E \chi_B \, d\nu = \nu(B \cap E) = \mu(B \cap E) = \int_E \chi_B \, d\mu .
\]

By linearity, if \(\phi\) is a \(\mathcal{B}\)-measurable simple function, then \(\int_E \phi \, d\nu = \int_E \phi \, d\mu\). Now, if \(f\) is a general nonnegative extended real-valued \(\mathcal{B}\)-measurable function, there is an increasing sequence \((\phi_n)\) of \(\mathcal{B}\)-measurable simple functions converging pointwise to \(f\). Then by two applications of the MCT,
\[
\int_E f \, d\nu = \sup_n \int_E \phi_n \, d\nu = \sup_n \int_E \phi_n \, d\mu = \int_E f \, d\mu .
\]

\(\Box\)
XIV.4.5.15. Corollary. Let $(X, \mathcal{A}, \mu)$ be a measure space, with completion $(X, \tilde{\mathcal{A}}, \tilde{\mu})$. If $f$ is a nonnegative extended real-valued $\mathcal{A}$-measurable function, and $E \in \mathcal{A}$, then

$$\int_E f \, d\mu = \int_E f \, d\tilde{\mu}.$$ 

XIV.4.5.16. Thus when a measure is extended to a larger $\sigma$-algebra, more functions become measurable and hence potentially integrable, but the integrals of functions which were already measurable do not change.
XIV.4.6. The Lebesgue Integral and Riemann Integral

We now examine the Lebesgue integral, which is by definition the integral on the measure space \((\mathbb{R}, \mathcal{L}, \lambda)\), and its relation with the Riemann integral. We only consider nonnegative functions for now; this is not a serious restriction for bounded functions on finite intervals since a constant function can be added to make them nonnegative. The Lebesgue integral for general functions is discussed in (). In this section, “measurable” will always mean “Lebesgue measurable.”

XIV.4.6.1. If \(E\) is a measurable subset of \(\mathbb{R}\) and \(f\) a nonnegative extended real-valued measurable function on \(\mathbb{R}\), the Lebesgue integral of \(f\) over \(E\) is
\[
\int_E f \, d\lambda = \sup \left\{ \int_E \phi \, d\lambda : \phi \text{ simple, } \phi \leq f \right\}
\]
where the integral of a simple function \(\phi = \sum_{k=1}^n \alpha_k \chi_{A_k}\) is
\[
\int_E \phi \, d\lambda = \sum_{k=1}^n \alpha_k \lambda(A_k \cap E)
\]
as in XIV.4.2.4.. If \(E = [a, b]\) and \(f\) is Riemann integrable on \(E\), write the Riemann integral of \(f\) over \(E\) as
\[
\int_a^b f(x) \, dx
\]
to distinguish it notationally from the Lebesgue integral.

XIV.4.6.2. If an extended real-valued measurable function is defined only on a measurable subset \(E\) of \(\mathbb{R}\), we will always canonically extend it to a function on \(\mathbb{R}\) by setting \(f(x) = 0\) for \(x \notin E\). The extended function is also measurable, and (if nonnegative) has the same integral over any (measurable) subset of \(E\). Note the following fact which is used constantly:

XIV.4.6.3. Proposition. Let \(I\) be an interval in \(\mathbb{R}\), and \(f\) a nonnegative extended real-valued real-valued measurable function on \(\mathbb{R}\) (or on a measurable subset of \(\mathbb{R}\), extended canonically to \(\mathbb{R}\)). Then
\[
\int_I f \, d\lambda = \int_I f \, d\lambda .
\]

Proof: We have \(f \chi_I = f \chi_I\) a.e. \(\Diamond\)

XIV.4.6.4. More generally, if \(A\) and \(B\) are measurable subsets of \(\mathbb{R}\) differing by a null set (i.e. \(\lambda(A \Delta B) = 0\)), then \(f \chi_A = f \chi_B\) a.e., so \(\int_A f \, d\lambda = \int_B f \, d\lambda\).

The following result shows that the Lebesgue integral agrees with the Riemann integral for Riemann integrable functions, and thus the Lebesgue integral extends and generalizes the Riemann integral:
**Theorem.** Let \([a, b]\) be a closed bounded interval in \(\mathbb{R}\), and \(f : [a, b] \to \mathbb{R}\) a function. Extend \(f\) to \(\mathbb{R}\) by setting \(f(x) = 0\) for \(x \notin [a, b]\). If \(f\) is Riemann integrable on \([a, b]\), then \(f\) is Lebesgue integrable on \(\mathbb{R}\) and on \([a, b]\), and

\[
\int_{\mathbb{R}} f \, d\lambda = \int_{[a, b]} f \, d\lambda = \int_{a}^{b} f(x) \, dx .
\]

**Proof:** It is almost transparent that the Riemann integral equals the Lebesgue interval for nonnegative step functions (cf. ()), which are nothing but piecewise-continuous simple functions. A general (necessarily bounded) nonnegative function \(f\) is Riemann integrable on \([a, b]\) if and only if there are an increasing sequence of (nonnegative) step functions \((\phi_n)\) (corresponding to lower Darboux sums) and a decreasing sequence of step functions \((\psi_n)\) such that \(\phi_n \leq f \leq \psi_n\) for all \(n\) and

\[
\sup_n \left[ \int_{a}^{b} \phi_n(x) \, dx \right] = \sup_n \left[ \int_{[a, b]} \phi_n \, d\lambda \right] = \inf_n \left[ \int_{[a, b]} \psi_n \, d\lambda \right] = \inf_n \left[ \int_{a}^{b} \phi_n(x) \, dx \right] .
\]

Thus by (), \(f\) is equal a.e. to a Lebesgue measurable function and, since Lebesgue measure is complete, \(f\) is Lebesgue measurable. By monotonicity, we have that

\[
\int_{[a, b]} \phi_n \, d\lambda \leq \int_{[a, b]} f \, d\lambda \leq \int_{[a, b]} \psi_n \, d\lambda
\]

\[
\int_{a}^{b} \phi_n(x) \, dx \leq \int_{a}^{b} f(x) \, dx \leq \int_{a}^{b} \psi_n(x) \, dx
\]

and since the suprema of the integrals on the left and the infima of the integrals on the right are all the same, it follows that

\[
\int_{[a, b]} f \, d\lambda = \int_{a}^{b} f(x) \, dx .
\]

**XIV.4.6.6.** It follows easily from the Characterization Theorem () that a Riemann integrable function is Lebesgue measurable. However, we did not need to use this theorem to obtain the result.

**Lebesgue Integrable Functions Which Are Not Riemann Integrable**

There are many additional functions on \(\mathbb{R}\) which are Lebesgue Integrable, as the following examples show.

**Examples.** (i) The indicator function \(\chi_{\mathbb{Q}}\) is not Riemann Integrable over any interval () because it is “too discontinuous.” But it is Lebesgue integrable over \(\mathbb{R}\), or any measurable subset \(E\) of \(\mathbb{R}\) (in particular, over any interval), and

\[
\int_{E} \chi_{\mathbb{Q}} \, d\lambda = 0
\]

1616
for any \( E \in \mathcal{L} \).

(ii) Set

\[
f(x) = \begin{cases} 
\frac{1}{\sqrt{x}} & \text{if } x > 0 \\
0 & \text{if } x \leq 0 
\end{cases}
\]

Then \( f \) is not Riemann integrable on \([0,1]\) even though it is piecewise-continuous, since it is unbounded. But \( f \) is measurable, and Riemann integrable on \([\frac{1}{n}, 1]\) for any \( n \), so

\[
\int_{[0,1]} f \, d\lambda = \int_{[0,1]} f \, d\lambda = \sup_n \int_{[\frac{1}{n}, 1]} f \, d\lambda 
\]

\[
= \sup_n \int_{\frac{1}{n}}^1 \frac{1}{\sqrt{x}} \, dx = \sup_n \left[ 2\sqrt{x} \right]_{\frac{1}{n}}^1 = \sup_n \left[ 2 - \frac{2}{\sqrt{n}} \right] = 2
\]

by XIV.4.5.3., so \( f \) is Lebesgue integrable on \([0,1]\). In fact, \( f \) is Lebesgue integrable on any bounded interval (more generally, on any bounded measurable set) by a similar argument. Note that \( f \) is improperly Riemann integrable on \([0,1]\) (XIV.4.6.8.).

(iii) Set

\[
f(x) = \begin{cases} 
\frac{x}{r} & \text{if } x > 0 \\
0 & \text{if } x \leq 0 
\end{cases}
\]

Then \( f \) is measurable, and Riemann integrable on \([\frac{1}{n}, 1]\) for any \( n \), so

\[
\int_{[0,1]} f \, d\lambda = \int_{[0,1]} f \, d\lambda = \sup_n \int_{[\frac{1}{n}, 1]} f \, d\lambda 
\]

\[
= \sup_n \int_{\frac{1}{n}}^1 \frac{1}{x} \, dx = \sup_n \left[ \log x \right]_{\frac{1}{n}}^1 = \sup_n \left[ -\log \frac{1}{n} \right] = \infty
\]

so \( f \) is not Lebesgue integrable over \([0,1]\). In fact, if

\[
f(x) = \begin{cases} 
x^{-r} & \text{if } x > 0 \\
0 & \text{if } x \leq 0 
\end{cases}
\]

then \( f \) is Lebesgue integrable on \([0,1]\) if and only if \( r < 1 \). Note that these are exactly the power functions which are improperly Riemann integrable on \([0,1]\).

(iii) Set

\[
f(x) = \begin{cases} 
\frac{1}{x} & \text{if } x > 0 \\
0 & \text{if } x \leq 0 
\end{cases}
\]

Then \( f \) is measurable, but not Lebesgue integrable on \([0,1]\). It is Riemann integrable on \([1,b]\) for any \( b > 1 \), so

\[
\int_{[1,\infty)} f \, d\lambda = \sup_n \int_{[1,n]} f \, d\lambda 
\]

\[
= \sup_n \int_1^n \frac{1}{x^2} \, dx = \sup_n \left[ -\frac{1}{x} \right]_1^n = \sup_n \left[ 1 - \frac{1}{n} \right] = 1
\]

1617
so \( f \) is Lebesgue integrable over \([1, \infty)\). In fact, if
\[
f(x) = \begin{cases} 
  x^{-r} & \text{if } x > 0 \\
  0 & \text{if } x \leq 0
\end{cases}
\]
then \( f \) is Lebesgue integrable on \([1, \infty)\) if and only if \( r > 1 \). Note that these are exactly the power functions which are improperly Riemann integrable on \([1, \infty)\).

**The Lebesgue Integral and the Improper Riemann Integral**

The fact that unbounded functions cannot be Riemann integrable is partially compensated by the various forms of improper Riemann integration.

**XIV.4.6.8.** If \( f \) is a nonnegative function defined on \((a, b]\), and Riemann integrable on \([a + \epsilon, b]\) for every \( \epsilon > 0 \), recall (XIV.2.11.1.) that \( f \) is *improperly Riemann integrable* from \( a \) to \( b \) if
\[
\lim_{\epsilon \to 0^+} \left[ \int_{a+\epsilon}^{b} f(x) \, dx \right] = \sup_{\epsilon > 0} \left[ \int_{a+\epsilon}^{b} f(x) \, dx \right] < \infty
\]
and in this case, we define
\[
\int_{a}^{b} f(x) \, dx = \lim_{\epsilon \to 0^+} \left[ \int_{a+\epsilon}^{b} f(x) \, dx \right].
\]

**XIV.4.6.9.** PROPOSITION. If \( f \) is a nonnegative function defined on \((a, b]\), and Riemann integrable on \([a + \epsilon, b]\) for every \( \epsilon > 0 \), then \( f \) is improperly Riemann integrable from \( a \) to \( b \) if and only if \( f \) is Lebesgue integrable on \([a, b]\), and
\[
\int_{a}^{b} f(x) \, dx = \int_{[a, b]} f \, d\lambda.
\]

PROOF: We have that \( f \chi_{[a + \frac{1}{n}, b]} \) is measurable for all \( n \) and \( f \chi_{[a + \frac{1}{n}, b]} \to f \chi_{(a, b]} \), so \( f \chi_{(a, b]} \) is measurable. Thus
\[
\int_{[a, b]} f \, d\lambda = \int_{(a, b)} f \, d\lambda = \sup_{n} \left[ \int_{[a + \frac{1}{n}, b]} f \, d\lambda \right] = \sup_{n} \left[ \int_{a + \frac{1}{n}}^{b} f(x) \, dx \right] = \int_{a}^{b} f(x) \, dx
\]
by XIV.4.5.3., and in particular the suprema are either both finite or both infinite.

**XIV.4.6.10.** There are unbounded nonnegative functions which are continuous a.e. and Lebesgue integrable, but not improperly Riemann integrable in any reasonable sense. Let \((r_{k})\) be an enumeration of the left endpoints of the intervals removed in the construction of the Cantor set (), and
\[
g(x) = \sum_{k=1}^{\infty} 2^{-k} f(x - r_{k})
\]
where \( f \) is the function in XIV.4.6.7.(ii). Then \( g \) is Lebesgue integrable on \([0, 1]\) by XIV.4.5.5., and continuous at all points not in the Cantor set, but not improperly Riemann integrable on \([0, 1]\) in any of the usual senses.
XIV.4.7. Continuity and Fatou’s Lemma

To put the Monotone Convergence Theorem in perspective, we now note in more detail the failure of Continuity for integration (XIV.4.1.1.) in general.

XIV.4.7.1. Examples. (i) Let \( \mu \) be counting measure on \((\mathbb{N}, \mathcal{P}(\mathbb{N}))\). Let \( E_n = \{ k : k \geq n \} \). Then \( \cap_n E_n = \emptyset \), so \( \chi_{E_n} \to 0 \) pointwise. But \[
\infty = \int_{\mathbb{N}} \chi_{E_n} \, d\mu \not\to \int_{\mathbb{N}} 0 \, d\mu = 0 .
\]

Maybe the problem is just that the \( \chi_{E_n} \) are not integrable. But:

(ii) Consider \((\mathbb{N}, \mathcal{P}(\mathbb{N}), \mu)\) again. Let \( f_n = \frac{1}{n} \chi_{\{1, \ldots, n\}} \). Then \( f_n \to 0 \), even uniformly; however,

\[
1 = \int_{\mathbb{N}} f_n \, d\mu \not\to \int_{\mathbb{N}} 0 \, d\mu = 0 .
\]

(iii) Consider Lebesgue measure on \([0, 1]\). Let \( f_n \) be the continuous function with the following graph:

Figure XIV.22: A continuous function
If \( x \in (0, 1] \), then for sufficiently large \( N \) we have \( \frac{2}{N} \leq x \), so \( f_n(x) = 0 \) for all \( n \geq N \). And \( f_n(0) = 0 \) for all \( n \). So \( f_n \to 0 \) pointwise. However,

\[
1 = \int_{[0,1]} f_n \, d\lambda \rightarrow \int_{[0,1]} 0 \, d\lambda = 0.
\]

Maybe the problem is that the functions are not uniformly bounded. But it is not quite so simple (cf. also (ii)):

(iv) Suppose we take \( f_n \) as in (iii), but the height of the triangle is \( n^r \) for fixed \( r \). Then \( f_n \to 0 \) pointwise as before. If \( r > 0 \), the \( f_n \) are not uniformly bounded. But

\[
\int_{[0,1]} f_n \, d\lambda = n^{r-1}
\]

so \( \int_{[0,1]} f_n \, d\lambda \to \int_{[0,1]} 0 \, d\lambda \) if and only if \( r < 1 \).

**XIV.4.7.2.** One might note that in (iv), the difference between the case \( r < 1 \) and the case \( r \geq 1 \) is that in the case \( r < 1 \), there is an integrable function \( g \) such that \( f_n \leq g \) for all \( n \), namely \( g(x) = x^{-r} \) (with \( g(0) = 0 \)). (It may not be obvious that there is no such \( g \) if \( r \geq 1 \).) This is also the root of the difficulty in (ii). In fact, the Dominated Convergence Theorem (cf. XIV.4.7.10.) states that existence of such a \( g \) is sufficient for convergence of the integrals.

**Fatou’s Lemma**

**XIV.4.7.3.** Another observation which might be made in these examples is that the integral of the limit is always less than or equal to the limit of the integrals. Actually this is a no-brainer in these examples since the functions are nonnegative and the integral of the limit function is zero; but experiments with less trivial similar examples suggest this is a general principle.

**XIV.4.7.4.** Another motivation for why this should be so is that if \( (a_n) \) and \( (b_n) \) are (nonnegative) sequences of real numbers, then

\[
\lim \inf_{n \to \infty} a_n + \lim \inf_{n \to \infty} b_n \leq \lim \inf_{n \to \infty} (a_n + b_n)
\]

\( (\cdot) \), and equality does not hold in general, i.e. “the lim inf of a sum is greater than or equal to the sum of the lim inf’s.” Since integration is a continuous version of summation, we should have that “the integral of a lim inf is less than or equal to the lim inf of the integrals.”

The second of the three main convergence theorems of measure theory asserts this:

**XIV.4.7.5.** **Theorem. [Fatou’s Lemma]** Let \( (X, \mathcal{A}, \mu) \) be a measure space, and \( (f_n) \) a sequence of nonnegative extended real-valued measurable functions on \( (X, \mathcal{A}) \). Set

\[
f(x) = \lim \inf_{n \to \infty} f_n(x) = \lim_{n \to \infty} \left[ \inf_{k \geq n} f_k(x) \right] = \sup_n \left[ \inf_{k \geq n} f_k(x) \right]
\]
(note that \( f \) is a well defined nonnegative extended real-valued measurable function). If \( E \in \mathcal{A} \), then
\[
\int_E f \, d\mu \leq \liminf_{n \to \infty} \int_E f_n \, d\mu .
\]

The following special case is the one most commonly used:

**XIV.4.7.6. Corollary.** Let \((X, \mathcal{A}, \mu)\) be a measure space, and \((f_n)\) a sequence of nonnegative extended real-valued measurable functions on \((X, \mathcal{A})\), converging pointwise a.e. to a measurable function \( f \). If \( E \in \mathcal{A} \), then
\[
\int_E f \, d\mu \leq \liminf_{n \to \infty} \int_E f_n \, d\mu .
\]

**XIV.4.7.7.** Fatou’s Lemma has the most general hypotheses of the three major convergence theorems, but also not surprisingly the weakest conclusion.

The proof of Fatou’s Lemma is easy given the Monotone Convergence Theorem:

**Proof:** For each \( n \) set
\[
g_n = \inf_{k \geq n} f_k .
\]

Then \((g_n)\) is a nondecreasing sequence of nonnegative extended real-valued measurable functions, and \(g_n \to f\) pointwise. We also have \(g_n \leq f_k\) for all \( k \geq n \), and thus
\[
\int_E g_n \, d\mu \leq \int_E f_k \, d\mu
\]
for \( k \geq n \) by monotonicity. Thus by the MCT we have
\[
\int_E f \, d\mu = \sup_n \left[ \int_E g_n \, d\mu \right] \leq \sup_n \left[ \inf_{k \geq n} \int_E f_k \, d\mu \right] = \liminf_{n \to \infty} \int_E f_n \, d\mu .
\]

**XIV.4.7.8.** Note that the MCT also follows almost immediately from Fatou’s Lemma: if the sequence \((f_n)\) is nondecreasing, we get \( \int_E f \, d\mu \geq \sup_n \int_E f_n \, d\mu \) by monotonicity and \( \int_E f \, d\mu \leq \liminf_n \int_E f_n \, d\mu \) by Fatou, so \( \int_E f \, d\mu = \lim_n \int_E f_n \, d\mu \).

Of course, we used the MCT to prove Fatou’s Lemma; but there are approaches where Fatou’s Lemma is proved first and the MCT obtained as a consequence (cf. ()).

**XIV.4.7.9.** The examples of XIV.4.7.1. show that the inequality in Fatou’s Lemma cannot be replaced by an equality in general.
The Dominated Convergence Theorem for Nonnegative Functions

We can then obtain almost immediately the nonnegative version of the Dominated Convergence Theorem:

**Theorem.** [Dominated Convergence Theorem, Nonnegative Version] Let \((X, \mathcal{A}, \mu)\) be a measure space, and \((f_n)\) a sequence of nonnegative extended real-valued measurable functions on \((X, \mathcal{A})\), converging pointwise a.e. to a measurable function \(f\). Suppose there is a nonnegative integrable function \(g\) with \(f_n \leq g\) a.e. for all \(n\). If \(E \in \mathcal{A}\), then \(f\) is integrable on \(E\) and

\[
\int_E f \, d\mu = \lim_{n \to \infty} \int_E f_n \, d\mu
\]

(in particular, the limit exists).

**Proof:** Note that \(f\) is automatically integrable since \(f \leq g\) a.e. We have that \(g f_n\) is nonnegative a.e. for all \(n\) and \(g f_n \to g f\) a.e. By two applications of Fatou’s Lemma, we have

\[
\int_E f \, d\mu \leq \liminf_{n \to \infty} \int_E f_n \, d\mu
\]

\[
\int_E g \, d\mu - \int_E f \, d\mu = \int_E (g - f) \, d\mu \leq \liminf_{n \to \infty} \int_E (g - f_n) \, d\mu
\]

\[
= \liminf_{n \to \infty} \left[ \int_E g \, d\mu - \int_E f_n \, d\mu \right] = \int_E g \, d\mu - \limsup_{n \to \infty} \int_E f_n \, d\mu
\]

(the integrals are finite so subtraction is valid). Rearranging the last inequality, we obtain

\[
\int_E f \, d\mu \geq \limsup_{n \to \infty} \int_E f_n \, d\mu
\]

\(\blacksquare\)

**Corollary.** [Bounded Convergence Theorem, Nonnegative Version] Let \((X, \mathcal{A}, \mu)\) be a measure space, and \((f_n)\) a uniformly bounded sequence of nonnegative real-valued measurable functions on \((X, \mathcal{A})\), converging pointwise a.e. to a measurable function \(f\). If \(E \in \mathcal{A}\) with \(\mu(E) < \infty\), then \(f\) is integrable on \(E\) and

\[
\int_E f \, d\mu = \lim_{n \to \infty} \int_E f_n \, d\mu
\]

(in particular, the limit exists).

**Proof:** If \(f_n(x) \leq M\) for all \(n\) and all \(x \in E\), then \(M \chi_E\) is a dominating function for \((f_n \chi_E)\).

\(\blacksquare\)

**The restriction that \(\mu(E) < \infty\) is necessary in general, even if the \(f_n\) and \(f\) are assumed to be integrable on \(E\) and the convergence is uniform (XIV.4.7.1(ii)).**
XIV.4.8. The Integral For General Functions

We can extend the integral to many measurable functions which take both positive and negative values, as long as we carefully avoid the $\infty - \infty$ problem. The simplest and most satisfactory way to proceed is:

XIV.4.8.1. Definition. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $f$ a real-valued function on $X$. Then $f$ is $\mu$-integrable if $f = g - h$ for nonnegative real-valued integrable functions $g$ and $h$. Define the integral of $f$ to be

$$\int_X f \, d\mu = \int_X g \, d\mu - \int_X h \, d\mu.$$ 

If $E \in \mathcal{A}$, then $f \chi_E = g \chi_E - h \chi_E$ is also $\mu$-integrable; define

$$\int_E f \, d\mu = \int_X f \chi_E \, d\mu = \int_E g \, d\mu - \int_E h \, d\mu.$$ 

XIV.4.8.2. Note that we are here only considering real-valued functions, since if $g$ and $h$ are nonnegative extended real-valued functions, $g - h$ might not be well defined. We consider extended real-valued functions in $()$.

A $\mu$-integrable function is a difference of two measurable functions, hence automatically measurable. We often write “integrable” for “$\mu$-integrable” if the $\mu$ is understood.

We have defined the integral of an integrable function in the only possible way to obtain a linear integral; however, it is not entirely obvious that the integral is independent of the choice of $g$ and $h$. But it is:

XIV.4.8.3. Proposition. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $f$ a real-valued integrable function on $X$. Then the integral of $f$ is well defined.

Proof: Suppose $f = g_1 - h_1 = g_2 - h_2$ with $g_i, h_i$ nonnegative real-valued integrable functions. Then $g_1 + h_2 = g_2 + h_1$, so, for any $E \in \mathcal{A}$,

$$\int_E g_1 \, d\mu + \int_E h_2 \, d\mu = \int_E (g_1 + h_2) \, d\mu = \int_E (g_2 + h_1) \, d\mu = \int_E g_2 \, d\mu + \int_E h_1 \, d\mu$$

and since the integrals are finite we may rearrange the equation by subtraction to obtain

$$\int_E g_1 \, d\mu - \int_E h_1 \, d\mu = \int_E g_2 \, d\mu - \int_E h_2 \, d\mu.$$ 

XIV.4.8.4. Although the definition in XIV.4.8.1. is logically satisfactory in light of XIV.4.8.3., it is perhaps uncomfortably indefinite because the $g$ and $h$ are (usually) not unique. It is more satisfying to have a canonical way to write a general integrable function as a difference of two nonnegative integrable functions. This is possible:
**XIV.4.8.5. Definition.** Let $X$ be a set, and $f : X \to \mathbb{R}$ a function. The positive part of $f$ is $f_+ = \max(f, 0)$ and the negative part of $f$ is $f_- = -\min(f, 0) = |\min(f, 0)|$.

We have

$$f_+(x) = \begin{cases} f(x) & \text{if } f(x) \geq 0 \\ 0 & \text{if } f(x) < 0 \end{cases}$$

$$f_-(x) = \begin{cases} |f(x)| & \text{if } f(x) \leq 0 \\ 0 & \text{if } f(x) > 0 \end{cases}$$

so $f_+$ and $f_-$ are nonnegative functions with the properties $f_+ - f_- = f$, $f_+ + f_- = |f|$, $f_+ f_- = 0$.

Conversely, if $g$ and $h$ are nonnegative functions with $f = g - h$ and $gh = 0$, then necessarily $g = f_+$ and $h = f_-$.

If $(X, \mathcal{A})$ is a measurable space and $f$ is measurable, then $f_+$ and $f_-$ are also measurable. (And if $(X, \mathcal{T})$ is a topological space and $f$ is continuous, then $f_+$ and $f_-$ are also continuous.)

**XIV.4.8.6. Proposition.** Let $(X, \mathcal{A}, \mu)$ be a measure space, and $f$ a real-valued measurable function on $X$. Then $f$ is integrable if and only if $f_+$ and $f_-$ are integrable. If $f$ is integrable, then

$$\int_E f \, d\mu = \int_E f_+ \, d\mu - \int_E f_- \, d\mu$$

for any $E \in \mathcal{A}$.

**Proof:** If $f_+$ and $f_-$ are integrable, then $f$ is integrable and by definition

$$\int_E f \, d\mu = \int_E f_+ \, d\mu - \int_E f_- \, d\mu$$

for any $E \in \mathcal{A}$. Conversely, if $f$ is integrable, write $f = g - h$ for nonnegative integrable functions $g$ and $h$. If $x \in X$ and $f(x) \geq 0$, then $f_+(x) = f(x) = g(x) - h(x) \leq g(x)$; if $f(x) < 0$, then $0 = f_+(x) \leq g(x)$. Thus $f_+ \leq g$. Similarly, $f_- \leq h$. Thus $f_+$ and $f_-$ are integrable.

**XIV.4.8.7. Corollary.** Let $(X, \mathcal{A}, \mu)$ be a measure space, and $f$ a real-valued function on $X$. If $f$ is integrable, then $|f|$ is integrable. If $f$ is measurable and $|f|$ is integrable, then $f$ is integrable.

**Proof:** If $f$ is integrable, then $f_+$ and $f_-$ are integrable, so $|f| = f_+ + f_-$ is integrable. Conversely, if $f$ is measurable and $|f|$ is integrable, then $f_+, f_- \leq |f|$ so $f_+$ and $f_-$ are integrable.

**XIV.4.8.8.** Note that it is not quite correct to say that $f$ is integrable if and only if $|f|$ is integrable: if $|f|$ is integrable, $f$ might not be measurable. For example, if $A$ is a subset of $[0, 1]$ which is not Lebesgue measurable, set

$$f(x) = \begin{cases} 1 & \text{if } x \in A \\ -1 & \text{if } x \in [0, 1] \setminus A \\ 0 & \text{if } x \notin [0, 1] \end{cases}$$

Then $|f| = \chi_{[0,1]}$ is Lebesgue integrable, but $f$ is not Lebesgue measurable.

It is correct to say that if $f$ is measurable, then $f$ is integrable if and only if $|f|$ is integrable. (Note that if $f$ is measurable, then $|f|$ is also measurable.)
XIV.4.8.9. Thus, except for the measurability problem, a function is integrable if and only if its absolute value is integrable. So the theory of abstract Lebesgue integration is an “absolute” integration theory, analogous to the theory of absolutely convergent infinite series. In fact:

XIV.4.8.10. Corollary. Let $\mu$ be counting measure on $(\mathbb{N}, \mathcal{P}(\mathbb{N}))$. If $x = (x_1, x_2, \ldots)$ is a sequence in $\mathbb{R}$ (a real-valued function on $\mathbb{N}$), then $x$ is $\mu$-integrable if and only if the infinite series

$$\sum_{k=1}^{\infty} x_k$$

converges absolutely. We then have

$$\int_{\mathbb{N}} x \, d\mu = \sum_{k=1}^{\infty} x_k .$$

A Vanishing Criterion

There is a convenient and useful criterion for an integrable function to vanish almost everywhere:

XIV.4.8.11. Proposition. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $f$ an integrable extended real-valued function on $X$. If $\int_A f \, d\mu = 0$ for all $A \in \mathcal{A}$, then $f = 0$ a.e.

Proof: Let $A = \{x \in X : f(x) \geq 0\}$ and $B = \{x \in X : f(x) \leq 0\}$. Since $\int_A f \, d\mu = \int_B f \, d\mu = 0$, we have that $f|_A$ and $f|_B$ are zero a.e. by XIV.4.3.11.

Actually we only need to assume that $\int_A f \, d\mu$ for a set of $A$’s which generate $\mathcal{A}$ as a $\sigma$-algebra, since it then follows that $\int_X f \, d\mu = 0$, and under this assumption it is easily checked that $\{B \in \mathcal{A} : \int_B f \, d\mu = 0\}$ is a $\sigma$-algebra. The set of such $A$ even only needs to generate $\mathcal{A}$ up to null sets. The following special case is especially useful:

XIV.4.8.12. Corollary. Let $[a, b]$ be an interval in $\mathbb{R}$, and $f$ a Lebesgue integrable function on $[a, b]$. If

$$\int_a^x f \, d\lambda = 0$$

for all $x \in [a, b]$, then $f = 0$ a.e. on $[a, b]$. 

1625
XIV.5. The Dominated Convergence Theorem

Except for the Fundamental Theorem of Calculus (1) which is the basis for the actual calculation of elementary integrals, the Dominated Convergence Theorem is probably the most important theorem in integration theory in the sense that it is the result used most often in applications, although the Fubini-Tonelli Theorem is a close second.

XIV.5.1. Applications of the DCT

Here is a general result about interchanging the order of differentiation and integration. It is phrased in terms of Lebesgue measure, but can be adapted to general measure spaces with the same proof (Exercise (1)).

XIV.5.1.1. Theorem. Let $I$ and $J$ be intervals in $\mathbb{R}$, and let $F : I \times J \to \mathbb{R}$. Assume that

(a) For each $y \in J$, the function $f[y] : I \to \mathbb{R}$ defined by $f[y](x) = F(x, y)$ is Lebesgue measurable.

(b) There is a $y_0 \in J$ such that $f[y_0]$ is Lebesgue integrable on $I$.

(c) For almost all $x \in I$, $\frac{\partial F}{\partial y}(x, y)$ exists for all $y \in J$.

(d) There is a nonnegative Lebesgue integrable function $g$ on $I$ such that, for almost all $x \in I$,

$$\left| \frac{\partial F}{\partial y}(x, y) \right| \leq g(x)$$

for all $y \in J$.

Then we have

(i) $f[y]$ is Lebesgue integrable on $I$ for all $y \in J$.

(ii) For every $y \in J$, the function $\phi^y$ defined by $\phi^y(x) = \frac{\partial F}{\partial y}(x, y)$ (defined a.e.) is integrable on $I$.

(iii) For every $y_1 \in J$,

$$\frac{d}{dy} \left[ \int_I F(x, y) \, d\lambda(x) \right] (y_1) = \frac{d}{dy} \left[ \int_I f[y](x) \, d\lambda(x) \right] (y_1) \text{ exists and equals } \int_I \frac{\partial F}{\partial y}(x, y_1) \, d\lambda(x) .$$

Proof: Let $A$ be a subset of $I$ such that (c) and (d) hold for all $x \in A$ and $\lambda(I \setminus A) = 0$.

(i): Fix $y \in J$, and set $\psi(x) = F(x, y) - F(x, y_0).$ Thus $f[y] = f[y_0] + \psi,$ so to show that $f[y]$ is Lebesgue integrable it suffices to show that $\psi$ is Lebesgue integrable. Note that it is Lebesgue measurable by (a). For any $x \in A$, there is a $c$ (depending on $x$) such that

$$\psi(x) = \frac{\partial F}{\partial y}(x, c)(y - y_0)$$

by the Mean Value Theorem (1), and hence we have

$$|\psi(x)| \leq g(x)|y - y_0|$$

1626
for almost all \( x \in I \) by (d). Since \( y - y_0 \) is a constant, \( \psi \) is Lebesgue integrable.

(ii): Fix \( y_1 \in J \). If \((h_n)\) is any sequence converging to 0 such that \( y_1 + h_n \in J \) for all \( n \), set

\[ \phi_n(x) = \frac{F(x, y_1 + h_n) - F(x, y_1)}{h_n} \]

for each \( n \) and note that each \( \phi_n \) is Lebesgue measurable by (a). We have \( \phi_n \to \phi^{y_1} \) pointwise a.e., so \( \phi^{y_1} \) is Lebesgue measurable. Since \( |\phi^{y_1}(x)| \leq g(x) \) for almost all \( x \) by (d), \( \phi^{y_1} \) is Lebesgue integrable.

(iii): We use the sequential criterion. Fix \( y_1 \in J \), and let

\[ L = \int_I \frac{\partial F}{\partial y}(x, y_1) \, d\lambda(x) = \int_I \phi^{y_1}(x) \, d\lambda(x) \]

(note that this integral is defined by (ii)). To prove (iii), it suffices to show that whenever \((h_n)\) is a sequence of nonzero numbers such that \( y_1 + h_n \in J \) for all \( n \), we have

\[ \lim_{n \to \infty} \int_I \frac{F(x, y_1 + h_n) - F(x, y_1)}{h_n} \, d\lambda(x) = L \]

We have

\[ \int_I \frac{F(x, y_1 + h_n) - F(x, y_1)}{h_n} \, d\lambda(x) = \int_I \phi_n(x) \, d\lambda(x) \]

where \( \phi_n \) is as in the proof of (ii). For each \( n \) and \( x \in A \), by the MVT there is a \( c_n \) (depending on \( x \) as well as \( n \)) between \( y_1 \) and \( y_1 + h_n \) such that

\[ \phi_n(x) = \frac{F(x, y_1 + h_n) - F(x, y_1)}{h_n} = \frac{\partial F}{\partial y}(x, c_n) \]

and thus \( |\phi_n(x)| \leq g(x) \) for all \( n \) and almost all \( x \) by (d). Thus by the DCT,

\[ \lim_{n \to \infty} \int_I \phi_n(x) \, d\lambda(x) = \int_I \phi^{y_1}(x) \, d\lambda(x) = L \]

since \( \phi_n \to \phi^{y_1} \) pointwise a.e., and the result follows.

XIV.5.1.2. Hypothesis (a) is not automatic, as the following example shows. For (a) to hold, it suffices that \( F \) be a Borel measurable function from \( I \times J \) to \( \mathbb{R} \). It does not quite suffice for \( F \) to be Lebesgue measurable (), but in the presence of (c) Lebesgue measurability might be sufficient. Hypotheses (a) and (b) are obviously necessary to even make sense of the left side of the equation in (iii), and hypothesis (c) is necessary to make sense of the right side (technically what we need to define the right side is that for each \( y \), \( \frac{\partial F}{\partial y}(x, y) \) is defined for almost all \( x \)).

XIV.5.1.3. Example. Let \( I = J = [-1, 1] \). Let \( A \) be a nonmeasurable subset of \( I \), and set

\[ F(x, y) = \begin{cases} y & \text{if } x \in A \\ 0 & \text{if } x \notin A \end{cases} \]

Then \( F \) satisfies (b), (c), and (d), but not (a).
XIV.6. Integration on Product Spaces

XIV.6.1. The Fubini-Tonelli Theorems

XIV.6.1.1. The Fubini-Tonelli Theorems concern calculation of integrals over a product space by iterated integrals, and/or interchange of order of integration in iterated integrals. There are two distinct but closely related results, one concerning integration of nonnegative measurable functions and the other concerning integration of integrable functions which are not necessarily nonnegative (in line with the development of Lebesgue integration itself, first done for nonnegative functions and then for general integrable functions).

It is conventional to call the nonnegative version “Tonelli’s Theorem” and the integrable version “Fubini’s Theorem.” But the actual history is more complicated, and these names are not quite accurate historically: both FUBINI and TONELLI (who worked roughly simultaneously but independently) were partially responsible for both results. We will nonetheless follow convention and use the names “Tonelli’s Theorem” and “Fubini’s Theorem” since it is convenient to have distinct names for the two results, with just the warning that the names are not well justified historically.

Fubini’s Theorem is one of the two most important theorems of integration theory, along with the Dominated Convergence Theorem, in the sense that these two theorems are by far the results used most often in applications.

XIV.6.1.2. Some versions of Fubini’s Theorem were previously “known” (if not proved); cf. XIV.3.4.34. But it is conventional to call all versions “Fubini’s Theorem” and we will follow the convention.

Preliminaries

XIV.6.1.3. Proposition. Let \((X, A, \mu)\) and \((Y, B, \nu)\) be measure spaces, \(C \subseteq A \otimes B\). Then \(C\) is of \(\sigma\)-finite measure if and only if there are \(A \in A, B \in B\) of \(\sigma\)-finite measure, and \(M \in A, N \in B\) of measure 0, such that \(C \subseteq (A \times B) \cup (M \times Y) \cup (X \times N)\).

Proof: It is obvious that if there are such \(A, B, M,\) and \(N\), then \(C\) is \(\sigma\)-finite (see Exercise ()). Conversely, let \(C = \bigcup_{n=1}^{\infty} C_n\), with \((\mu \times \nu)(C_n) < \infty\). For each \(n\) there is a sequence \(R_{n,k} = A_{n,k} \times B_{n,k}\) of rectangles with \(A_{n,k} \in A, B_{n,k} \in B, C_n \subseteq \bigcup_k R_{n,k}\), and \(\sum_k \mu(A_{n,k})\nu(B_{n,k}) < (\mu \times \nu)(C_n) + 1 < \infty\). For each \(k\), \(\mu(A_{n,k}) = \infty\) implies \(\nu(B_{n,k}) = 0\) and \(\nu(B_{n,k}) = \infty\) implies \(\mu(A_{n,k}) = 0\). Let \(M_n\) be the union of the \(A_{n,k}\) with \(\mu(A_{n,k}) = 0\), and \(N_n\) the union of the \(B_{n,k}\) with \(\nu(B_{n,k}) = 0\); renumbering, we may assume \(\nu(A_{n,k}) < \infty\) for all \(k\) and \(C_n \subseteq (M_n \times Y) \cup (X \times N_n) \cup \bigcup_k R_{n,k}\). Set \(A = \bigcup_{n,k} A_{n,k}, B = \bigcup_{n,k} B_{n,k}, M = \bigcup_n M_n, N = \bigcup_n N_n\). Then \(\mu(M) = \nu(N) = 0\), \(A\) and \(B\) have \(\sigma\)-finite measure, and \(C \subseteq (A \times B) \cup (M \times Y) \cup (X \times N)\).

XIV.6.1.4. Note: it is not true that a set of \(\sigma\)-finite measure in \(A \otimes B\) is contained in a product of sets of \(\sigma\)-finite measure in general. For example, if \(\nu\) is not \(\sigma\)-finite, and \(x \in X\) is not an atom, then \(\{x\} \times Y\) has \(\mu \times \nu\)-measure zero, hence is \(\sigma\)-finite, but is not contained in a rectangle \(A \times B\) with \(B\) of \(\sigma\)-finite measure.

We will use the following notation, which was partially introduced in ():
XIV.6.1.5. Definition. Let $X$ and $Y$ be sets.

(i) If $C \subseteq X \times Y$, for each $x \in X$ the vertical cross section of $C$ at $x$ is

$$C_x = \{y \in Y : (x, y) \in C\}$$

and, for each $y \in Y$, the horizontal cross section of $C$ at $y$ is

$$C^y = \{x \in X : (x, y) \in C\}.$$  

(ii) If $f : X \times Y \to \mathbb{R}$ (or to $\mathbb{C}$) is a function, for each $x \in X$ define $f_{[x]} : Y \to \mathbb{R}$ by

$$f_{[x]}(y) = f(x, y)$$

and for each $y \in Y$, define $f^{[y]} : X \to \mathbb{R}$ by

$$f^{[y]}(x) = f(x, y).$$

The functions $f_{[x]}$ and $f^{[y]}$ are called the marginal functions of $f$.

Cross sections and marginal functions are well-behaved under set-theoretic and algebraic operations:

XIV.6.1.6. Proposition. Let $X$ and $Y$ be sets.

(i) If $C \subseteq X \times Y$, then $[(X \times Y) \setminus C]_x = Y \setminus C_x$ for all $x \in X$ and $[(X \times Y) \setminus C]^y = X \setminus C^y$ for all $y \in Y$ (informally, $(C^c)_x = (C_x)^c$ and $(C^c)^y = (C^y)^c$ for all $x$ and $y$).

(ii) If $\{C_i : i \in I\}$ is a collection of subsets of $X \times Y$, then $(\bigcup_{i \in I} C_i)_x = \bigcup_{i \in I} (C_i)_x$ for all $x \in X$ and $(\bigcup_{i \in I} C_i)^y = \bigcup_{i \in I} (C_i)^y$ for all $y \in Y$.

(iii) If $f$ and $g$ are functions from $X \times Y$ to $\mathbb{R}$, and $\alpha \in \mathbb{R}$, then $(f + g)_{[x]} = f_{[x]} + g_{[x]}$ and $(\alpha f)_{[x]} = \alpha f_{[x]}$ for all $x \in X$ and $(f + g)^{[y]} = f^{[y]} + g^{[y]}$ and $(\alpha f)^{[y]} = \alpha f^{[y]}$ for all $y \in Y$.

(iv) If $C \subseteq X \times Y$, then $(\chi_C)_x = \chi_{C_x}$ and $(\chi_C)^y = \chi_{C^y}$ for all $x \in X$, $y \in Y$.

The straightforward proof is left to the reader.

XIV.6.1.7. Now let $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ be measure spaces. Form the product $\sigma$-algebra $\mathcal{A} \otimes \mathcal{B}$ and the product measure $\mu \times \nu$ on $\mathcal{A} \otimes \mathcal{B}$. We need several technical results guaranteeing that various sets and functions arising in iterated integrals are measurable. These results might be expected, but it turns out that some $\sigma$-finite hypotheses are necessary.

The first results are that cross sections of measurable sets are measurable, and margins of measurable functions are measurable. No measures are needed for these results, and in particular no $\sigma$-finite hypotheses are needed (or even make sense!)
XIV.6.1.8. Lemma. Let \((X, \mathcal{A})\) and \((Y, \mathcal{B})\) be measurable spaces, and \(C \in \mathcal{A} \otimes \mathcal{B}\). Then \(C_x \in \mathcal{B}\) for all \(x \in X\) and \(C^y \in \mathcal{A}\) for all \(y \in Y\).

Proof: Let \(\mathcal{C}\) be the collection of all \(C \in \mathcal{A} \otimes \mathcal{B}\) for which the conclusion holds. If \(C = A \times B \in \mathcal{A} \times \mathcal{B}\), then
\[
C_x = \begin{cases} B & \text{if } x \in A \\ \emptyset & \text{if } x \notin A \end{cases}
\]
and thus \(C_x \in \mathcal{B}\) for any \(x\), and similarly \(C^y \in \mathcal{A}\) for any \(y\). Thus \(C \in \mathcal{C}\), i.e. \(\mathcal{A} \times \mathcal{B} \subseteq \mathcal{C}\). In particular, \(\emptyset\) and \(X \times Y\) are in \(\mathcal{C}\). If \(C \in \mathcal{C}\), then \((C^n)_x = (C_x)^c \in \mathcal{B}\) for any \(x \in X\) since \(\mathcal{B}\) is closed under complements, and similarly \((C^n)^y \in \mathcal{A}\) for all \(y\), so \(C^n \in \mathcal{C}\), i.e. \(\mathcal{C}\) is closed under complements.

If \((C_n)\) is a sequence in \(\mathcal{C}\), then \((\cup_n C_n)_x = \cup_n C_x \in \mathcal{B}\) for all \(x\) since \(\mathcal{B}\) is closed under countable unions, and similarly \((\cup_n C_n)^y \in \mathcal{A}\) for all \(y\), so \(\cup_n C_n \in \mathcal{C}\) and \(\mathcal{C}\) is a \(\sigma\)-algebra containing \(\mathcal{A} \times \mathcal{B}\), and thus \(\mathcal{C}\) contains (and therefore equals) \(\mathcal{A} \otimes \mathcal{B}\). \(\Box\)

XIV.6.1.9. Lemma. Let \((X, \mathcal{A})\) and \((Y, \mathcal{B})\) be measurable spaces, and \(f : X \times Y \to \mathbb{R}\). If \(f\) is \((\mathcal{A} \otimes \mathcal{B})\)-measurable, then \(f[x]\) is \(\mathcal{B}\)-measurable for all \(x \in X\) and \(f[y]\) is \(\mathcal{A}\)-measurable for all \(y \in Y\).

Proof: We bootstrap. If \(f = \chi_C\) for \(C \in \mathcal{A} \otimes \mathcal{B}\), then \(f\) is measurable by XIV.6.1.6.(iv) and XIV.6.1.8.. If \(f\) is a simple function, then \(f\) is measurable by XIV.6.1.6.(iii). And if \(f\) is a general measurable function, there is a sequence \((s_n)\) of simple functions converging pointwise to \(f\) \((\ast)\). For each \(x\) the sequence \(((s_n)[x])\) converges pointwise to \(f[x]\), and thus \(f[x]\) is measurable. Similarly, \(f[y]\) is measurable. \(\Box\)

We now need measures and a \(\sigma\)-finite hypothesis. The next result is the most delicate part of the proof of the Fubini-Tonelli Theorems.

XIV.6.1.10. Lemma. Let \((X, \mathcal{A}, \mu)\) and \((Y, \mathcal{B}, \nu)\) be \(\sigma\)-finite measure spaces, and \(C \in \mathcal{A} \otimes \mathcal{B}\). For \(x \in X\) set \(g(x) = \nu(C_x)\) and for \(y \in Y\) set \(h(y) = \mu(C^y)\). Then \(g\) is \(\mathcal{A}\)-measurable and \(h\) is \(\mathcal{B}\)-measurable.

Proof: Let \(\mathcal{D}\) be the set of all \(C\) in \(\mathcal{A} \otimes \mathcal{B}\) for which the functions \(g\) and \(h\) are measurable. We will show that \(\mathcal{D}\) equals \(\mathcal{A} \otimes \mathcal{B}\) by the Monotone Class Theorem \((\ast)\).

First note that if \(C = A \times B \in \mathcal{A} \times \mathcal{B}\), then \(g = \nu(B)\chi_A\) and \(h = \mu(A)\chi_B\), so \(g\) and \(h\) are measurable and \(C \in \mathcal{D}\), i.e. \(\mathcal{A} \times \mathcal{B} \subseteq \mathcal{D}\). Now note that \(\mathcal{E}\) is the set of finite disjoint unions of sets in \(\mathcal{A} \times \mathcal{B}\). If \(C\) is the disjoint union of \(A_k \times B_k\), \(1 \leq k \leq n\), then
\[
g = \sum_{k=1}^{n} \nu(B_k)\chi_{A_k}, \quad h = \sum_{k=1}^{n} \mu(A_k)\chi_{B_k}
\]
so \(g\) and \(h\) are again measurable and \(C \in \mathcal{D}\), i.e. \(\mathcal{E} \subseteq \mathcal{D}\).

Now suppose \((C_n)\) is an increasing sequence in \(\mathcal{D}\) with union \(C\). Let \(g_n, h_n\) be the functions corresponding to \(C_n\), and \(g\) and \(h\) the functions corresponding to \(C\). For each \(x \in X\), we have that \(((C_n)_x)\) is an increasing sequence in \(\mathcal{B}\) with union \(C_x\), and thus \(g_n(x) = \nu((C_n)_x)\) increases to \(g(x) = \nu(C_x)\) by the Baby Monotone Convergence Theorem \((\ast)\), i.e. \(g_n \to g\) pointwise. Since \(C_n \in \mathcal{D}\) for all \(n\), the \(g_n\) are measurable, hence \(g\) is
also measurable. By an almost identical argument, \( h \) is also measurable, so \( C \in \mathcal{D} \), i.e. \( \mathcal{D} \) is closed under increasing sequential unions.

Next we handle decreasing intersections. This is the trickiest part, and we must use the hypothesis that \( \mu \) and \( \nu \) are \( \sigma \)-finite. Let \( R_m = A_m \times B_m \) be an increasing sequence of rectangles with \( A_m \in \mathcal{A} \), \( \bigcup_{m=1}^{\infty} A_m = X \), \( B_m \in \mathcal{B} \), \( \bigcup_{m=1}^{\infty} B_m = Y \), \( \mu(A_m) < \infty \), \( \nu(B_m) < \infty \) for all \( m \).

Set

\[
\mathcal{F} = \{ C \in \mathcal{A} \otimes \mathcal{B} : C \cap (A_m \times B_m) \in \mathcal{D} \text{ for all } m \}.
\]

By arguments identical to the ones above (or by just applying them to the product space obtained by replacing \( X \) and \( Y \) by \( A_m \) and \( B_m \)), we have that \( \mathcal{E} \subseteq \mathcal{F} \) and \( \mathcal{F} \) is closed under increasing sequential unions. To show that \( \mathcal{F} \) is closed under decreasing intersections, let \( (F_n) \) be a decreasing sequence in \( \mathcal{F} \) with intersection \( F \). Fix \( m \), and let \( g_n \) and \( h_n \) be the functions corresponding to \( Z_n := F_n \cap (A_m \times B_m) \), and \( g \) and \( h \) the functions corresponding to \( Z := F \cap (A_m \times B_m) \). Then \( (Z_n) \) is a decreasing sequence in \( \mathcal{D} \) with intersection \( Z \). If \( x \in X \), then \( ((Z_n)_x) \) is a decreasing sequence in \( Y \) with intersection \( Z_x \), and since each \( (Z_n)_x \) is contained in \( B_m \) and thus has finite \( \nu \)-measure, we have \( g_n(x) = \nu((Z_n)_x) \rightarrow \nu(Z_x) = g(x) \) by downward continuity \( (\cdot) \), i.e. \( g_n \rightarrow g \) pointwise. Since each \( Z_n \) is in \( \mathcal{D} \), \( g_n \) is measurable, so \( g \) is measurable. Similarly, \( h \) is measurable. So \( Z \in \mathcal{D} \). This is true for every \( m \), so \( F \in \mathcal{F} \). Thus \( \mathcal{F} \) is a monotone class containing \( \mathcal{E} \), so it contains (and equals) \( \sigma(\mathcal{E}) = \mathcal{A} \otimes \mathcal{B} \) by the Monotone Class Theorem.

Finally, let \( C \in \mathcal{A} \otimes \mathcal{B} \). Set \( C_m := C \cap (A_m \times B_m) \). Then \( (C_m) \) is an increasing sequence with union \( C \). We have that \( C_m \in \mathcal{D} \) for all \( m \) since \( C \in \mathcal{F} \). Since \( \mathcal{D} \) is closed under increasing sequential unions, \( C \in \mathcal{D} \). Thus \( \mathcal{D} = \mathcal{A} \otimes \mathcal{B} \).

**XIV.6.1.11. ****L**e**m**a**. Let \((X, \mathcal{A}, \mu)\) and \((Y, \mathcal{B}, \nu)\) be \( \sigma \)-finite measure spaces, and \( f : X \times Y \rightarrow \mathbb{R} \) a nonnegative extended real-valued \((\mathcal{A} \otimes \mathcal{B})\)-measurable function. Set

\[
g(x) = \int_Y f_{[x]} \, d\nu = \int_Y f(x, y) \, d\nu(y) \]

\[
h(y) = \int_X f^{[y]} \, d\mu = \int_X f(x, y) \, d\mu(x) .
\]

Then \( g \) is \( \mathcal{A} \)-measurable and \( h \) is \( \mathcal{B} \)-measurable.

**Proof:** Bootstrap. If \( f = \chi_C \) for \( C \in \mathcal{A} \otimes \mathcal{B} \), then \( f_{[x]} = \chi_{C_x} \) and \( f^{[y]} = \chi_{C^y} \) for \( x \in X \), \( y \in Y \), so

\[
g(x) = \int_Y f_{[x]} \, d\nu = \int_Y \chi_{C_x} \, d\nu = \nu(C_x)
\]

\[
h(y) = \int_X f^{[y]} \, d\mu = \int_X \chi_{C^y} \, d\mu = \mu(C^y)
\]

so \( g \) and \( h \) are measurable by Lemma XIV.6.1.10. Note also that if \( f_1, \ldots, f_n \) are nonnegative extended real-valued measurable functions with corresponding \( g_1, \ldots, g_n \) and \( h_1, \ldots, h_n \), then \( f = f_1 + \cdots + f_n \) has corresponding functions \( g = g_1 + \cdots + g_n \) and \( h = h_1 + \cdots + h_n \), so if all \( g_k \) and \( h_k \) are measurable, so are \( g \) and \( h \). Similarly, if \( f \) has measurable \( g \) and \( h \), and \( \alpha > 0 \), then \( \alpha f \) has measurable \( \alpha g \) and \( \alpha h \). In particular, if \( f \) is a simple function, then the corresponding \( g \) and \( h \) are measurable.

1631
For a general $f$ with corresponding functions $g$ and $h$, let $(s_n)$ be an increasing sequence of simple functions converging pointwise to $f$, with corresponding functions $g_n$ and $h_n$. Then, for each $x \in X$, $((s_n)_x)$ is an increasing sequence of $\mathcal{B}$-measurable functions converging pointwise to $f_x$, so

$$g_n(x) = \int_Y (s_n)_x \; d\nu \to \int_Y f_x \; d\nu = g(x)$$

by the Monotone Convergence Theorem, i.e. $g_n \to g$ pointwise. Each $g_n$ is measurable, so $g$ is measurable. Similarly, $h$ is measurable.

The Junior Tonelli Theorem

The next result is called the Junior Tonelli Theorem since it is Tonelli's theorem for characteristic or indicator functions. It is a measure-theoretic version of Cavalieri's Principle: to find the volume of a solid, integrate the cross-sectional area over the length of the solid (cf. []).

**XIV.6.1.12. Theorem.** [Junior Tonelli Theorem] Let $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ be $\sigma$-finite measure spaces, and $C \in \mathcal{A} \otimes \mathcal{B}$. Then $C_x \in \mathcal{B}$ for each $x \in X$, $C^y \in \mathcal{A}$ for all $y \in A$, $g(x) = \nu(C_x)$ is $\mu$-measurable, $h(y) = \mu(C^y)$ is $\nu$-measurable, and

$$(\mu \times \nu)(C) = \int_X \nu(C_x) \; d\mu(x) = \int_Y \mu(C^y) \; d\nu(y).$$

**Proof:** If $C \in \mathcal{A} \otimes \mathcal{B}$, the first four assertions hold by Lemmas XIV.6.1.8. and XIV.6.1.10., so the integrals make sense. For $C \in \mathcal{A} \otimes \mathcal{B}$, define

$$\theta(C) = \int_X \nu(C_x) \; d\mu = \int_X g \; d\mu.$$

We show $\theta$ is a measure. Obviously $\theta(\emptyset) = 0$. If $(C_n)$ is a sequence of pairwise disjoint sets in $\mathcal{A} \otimes \mathcal{B}$ with union $C$, then for each $x \in X$, $((C_n)_x)$ is a sequence of pairwise disjoint sets in $\mathcal{B}$, so we have

$$\theta(C) = \theta \left( \bigcup_{n=1}^{\infty} C_n \right) = \int_X \nu \left( \left[ \bigcup_{n=1}^{\infty} C_n \right]_x \right) \; d\mu = \int_X \nu \left( \bigcup_{n=1}^{\infty} (C_n)_x \right) \; d\mu = \int_X \left[ \sum_{n=1}^{\infty} \nu((C_n)_x) \right] \; d\mu$$

$$= \sum_{n=1}^{\infty} \int_X \nu((C_n)_x) \; d\mu = \sum_{n=1}^{\infty} \theta(C_n)$$

where the interchange of integral and sum is justified by the Monotone Convergence Theorem. So $\theta$ is a measure. If $A \times B \in \mathcal{A} \times \mathcal{B}$, then

$$\theta(A \times B) = \int_X \nu((A \times B)_x) \; d\mu = \int_X \nu(B)_A \; d\mu = \mu(A) \nu(B) = (\mu \times \nu)(A \times B).$$

Thus by the uniqueness part of the Extension Theorem in the $\sigma$-finite case, $\theta = \mu \times \nu$ on $\mathcal{A} \otimes \mathcal{B}$, and the first equality is proved. The proof that $(\mu \times \nu)(C) = \int_Y \mu(C^y) \; d\nu(y)$ for $C \in \mathcal{A} \otimes \mathcal{B}$ is analogous. □
Tonelli’s Theorem

Tonelli’s Theorem concerns calculating the integral of a nonnegative measurable function over a product space by iterated integrals, and/or interchanging the order of integration in iterated integrals of nonnegative measurable functions.

XIV.6.1.13. Theorem. [Tonelli’s Theorem] Let \((X, \mathcal{A}, \mu)\) and \((Y, \mathcal{B}, \nu)\) be \(\sigma\)-finite measure spaces, and \(f\) a nonnegative extended real-valued \((\mathcal{A} \otimes \mathcal{B})\)-measurable function on \(X \times Y\), with marginal functions \(f_x\) and \(f_y\). Then

(i) \(f_x\) is \(\mathcal{B}\)-measurable for all \(x \in X\).

(i') \(f_y\) is \(\mathcal{A}\)-measurable for all \(y \in Y\).

(ii) \(g\) defined by \(g(x) = \int_Y f_x \, d\nu\) is \(\mathcal{A}\)-measurable.

(ii') \(h\) defined by \(h(y) = \int_X f_y \, d\mu\) is \(\mathcal{B}\)-measurable.

(iii) We have

\[
\int_{X \times Y} f \, d(\mu \times \nu) = \int_X g \, d\mu = \int_X \left[ \int_Y f_x \, d\nu \right] \, d\mu = \int_X \left[ \int_Y f(x, y) \, d\nu(y) \right] \, d\mu(x)
\]

\[
= \int_Y h \, d\nu = \int_Y \left[ \int_X f_y \, d\mu \right] \, d\nu = \int_Y \left[ \int_X f(x, y) \, d\mu(x) \right] \, d\nu(y).
\]

In particular, the iterated integrals

\[
\int_X \left[ \int_Y f(x, y) \, d\nu(y) \right] \, d\mu(x) = \int_Y \left[ \int_X f(x, y) \, d\mu(x) \right] \, d\nu(y)
\]

exist and are equal.

Proof: We have (i) and (i') by Lemma XIV.6.1.9., and (ii) and (ii') by Lemma XIV.6.1.11.. For (iii), we bootstrap. If \(f = \chi_C, C \in \mathcal{A} \otimes \mathcal{B}\), the equalities hold by the Junior Tonelli Theorem XIV.6.1.12.. It is also clear from the (nonnegative) linearity of integrals that if the equalities hold for \(f_1, \ldots, f_n\), and if \(\alpha_1, \ldots, \alpha_n \geq 0\), then the equalities hold for \(\alpha_1 f_1 + \cdots + \alpha_n f_n\). In particular, they hold if \(f\) is a simple function.

Now let \(f\) be a general nonnegative \((\mathcal{A} \otimes \mathcal{B})\)-measurable function. Let \((s_n)\) be a sequence of simple functions increasing pointwise to \(f\). Then \((s_n)[x]\) increases pointwise to \(f[x]\) for all \(x \in X\), so by the Monotone Convergence Theorem we have

\[
g_n(x) := \int_Y (s_n)[x] \, d\nu \to \int_Y f[x] \, d\nu = g(x)
\]

for all \(x \in X\), i.e. \(g_n\) increases pointwise to \(g\). Thus, by two more applications of the MCT,

\[
\int_{X \times Y} f \, d(\mu \times \nu) = \lim_{n \to \infty} \int_{X \times Y} s_n \, d(\mu \times \nu) = \lim_{n \to \infty} \int_Y g_n \, d\mu = \int_Y g \, d\mu
\]

and the first equality is proved for \(f\). The proof of the second equality is analogous. \(\Box\)
Fubini’s Theorem

Fubini’s Theorem is analogous to Tonelli’s Theorem, but instead of nonnegative measurable functions it deals with integrable functions which are not necessarily nonnegative.

XIV.6.1.14. Theorem. [Fubini’s Theorem] Let \((X, A, \mu)\) and \((Y, B, \nu)\) be \(\sigma\)-finite measure spaces, and \(f\) a complex-valued \((A \otimes B)\)-measurable function with marginal functions \(f_{[x]}\) and \(f^{[y]}\) for \(x \in X, y \in Y\). Assume at least one of the following integrals exists and is finite:

\[
\int_{X \times Y} |f| \, d(\mu \times \nu), \quad \int_Y \left[ \int_X |f(x, y)| \, d\mu(x) \right] \, d\nu(y), \quad \int_X \left[ \int_Y |f(x, y)| \, d\nu(y) \right] \, d\mu(x).
\]

Then all three integrals exist and are finite and equal, hence \(f\) is \((\mu \times \nu)\)-integrable, and

(i) \(f_{[x]}\) is \(\nu\)-integrable for \(\mu\)-almost all \(x \in X\).

(ii) \(f^{[y]}\) is \(\mu\)-integrable for \(\nu\)-almost all \(y \in Y\).

(iii) \(g\) defined by \(g(x) = \int_Y f_{[x]} \, d\nu\) (which is defined \(\mu\)-a.e.) is equal \(\mu\)-a.e. to a \(\mu\)-integrable function.

(ii) \(h\) defined by \(h(y) = \int_X f^{[y]} \, d\mu\) (which is defined \(\nu\)-a.e.) is equal \(\nu\)-a.e. to a \(\nu\)-integrable function.

(iii) We have

\[
\int_{X \times Y} f \, d(\mu \times \nu) = \int_X g \, d\mu = \int_X \left[ \int_Y f_{[x]} \, d\nu \right] \, d\mu = \int_X \left[ \int_Y f(x, y) \, d\nu(y) \right] \, d\mu(x)
\]

= \int_Y h \, d\nu = \int_Y \left[ \int_X f^{[y]} \, d\mu \right] \, d\nu = \int_Y \left[ \int_X f(x, y) \, d\mu(x) \right] \, d\nu(y).

In particular, the iterated integrals

\[
\int_X \left[ \int_Y f(x, y) \, d\nu(y) \right] \, d\mu(x) = \int_Y \left[ \int_X f(x, y) \, d\mu(x) \right] \, d\nu(y)
\]

exist and are equal.

Proof: We prove the theorem for \(f\) real-valued; the complex-valued case follows by taking real and imaginary parts.

The first integral in the hypotheses automatically exists, and by Tonelli’s Theorem the other two also exist and equal the first one; thus if one is finite, they all are, and are equal. For each \(x \in X\), we have that \(f_{[x]}\) is \(B\)-measurable by Lemma XIV.6.1.9., and \(|f_{[x]}| = |f|_{[x]}\); and since

\[
\int_{X \times Y} |f| \, d(\mu \times \nu) = \int_Y \left[ \int_X |f_{[x]}| \, d\nu \right] \, d\mu = \int_X \left[ \int_Y |f_{[x]}| \, d\nu \right] \, d\mu < \infty
\]

it follows that

\[
\int_X |f_{[x]}| \, d\nu < \infty
\]
for almost all \( x \), i.e. \( f_{[x]} \) is \( \nu \)-integrable for almost all \( x \in X \). Similarly, \( f^{[y]} \) is \( \mu \)-integrable for almost all \( y \in Y \).

Let \( f_+ \) and \( f_- \) be the positive and negative parts of \( f \); then \( f_+, f_- \leq |f| \), so are \((\mu \times \nu)\)-integrable. We have \((f_+)_x = (f_{[x]})_+ \) and \((f_-)_x = (f_{[x]})_- \) for all \( x \in X \), and if

\[
   g_+(x) = \int_Y (f_+)_x \, d\nu = \int_Y (f_{[x]})_+ \, d\nu
\]

\[
   g_-(x) = \int_Y (f_-)_x \, d\nu = \int_Y (f_{[x]})_- \, d\nu
\]

we have that

\[
   g_+(x) \leq \bar{g}(x) := \int_Y |f_{[x]}| \, d\nu = \int_Y |f|_{[x]} \, d\nu
\]

and since

\[
   \int_X \bar{g} \, d\mu = \int_{X \times Y} |f| \, d(\mu \times \nu) < \infty
\]

by Tonelli’s Theorem, \( g_+ \) is \( \mu \)-integrable. Similarly, \( g_- \) is \( \mu \)-integrable. In particular, \( g_+ \) and \( g_- \) are finite \( \mu \)-a.e., and if they are both finite at \( x \), then \( f_{[x]} = (f_{[x]})_+ - (f_{[x]})_- \) and

\[
   g(x) = \int_Y f_{[x]} \, d\mu = \int_Y [(f_{[x]})_+ - (f_{[x]})_-] \, d\mu = \int_Y (f_{[x]})_+ \, d\mu - \int_Y (f_{[x]})_- \, d\mu = g_+(x) - g_-(x) .
\]

Thus \( g \) is defined \( \mu \)-a.e. and is equal \( \mu \)-a.e. to a \( \mu \)-integrable function (note though that \( g_+ \) and \( g_- \) are not necessarily the positive and negative parts of \( g \)). We also have

\[
   \int_X g \, d\mu = \int_X g_+ \, d\mu - \int_X g_- \, d\mu = \int_X \left[ \int_Y (f_+)_x \, d\nu \right] \, d\mu - \int_X \left[ \int_Y (f_-)_x \, d\nu \right] \, d\mu
\]

\[
   = \int_{X \times Y} f_+ \, d(\mu \times \nu) - \int_{X \times Y} f_- \, d(\mu \times \nu) = \int_{X \times Y} f \, d(\mu \times \nu)
\]

by Tonelli’s Theorem applied to \( f_+ \) and \( f_- \). The proof of the second equality is analogous.

Examples where \( \sigma \)-finite hypothesis is necessary

The Complete Case

Extension to Sets of \( \sigma \)-Finite Measure

Fubini-Tonelli

We have the following corollary of the Fubini-Tonelli Theorem, which can be used to justify the usual iterated integrals encountered in vector calculus problems:
XIV.6.1.15. Corollary. Let \((X, \mathcal{A}, \mu)\) and \((Y, \mathcal{B}, \nu)\) be measure spaces, \(C \in \mathcal{A} \otimes \mathcal{B}\) of \(\sigma\)-finite measure, and \(f : C \to \mathbb{R}\) a function which is either nonnegative and \((\mu \times \nu)\)-measurable, or integrable over \(C\) (i.e. \(f\chi_C\) is integrable over \(X \times Y\)). Then

(i) The function \(g(x) = \int_{C_x} f(x, y) \, d\nu(y)\) is \(\mathcal{A}\)-measurable, and is \(\mu\)-integrable for almost all \(x\) if \(f\) is \((\mu \times \nu)\)-integrable over \(C\). ***FIX

(ii) The function \(h(y) = \int_{C_y} f(x, y) \, d\mu(x)\) is \(\mathcal{B}\)-measurable, and is \(\nu\)-integrable for almost all \(x\) if \(f\) is \((\mu \times \nu)\)-integrable over \(C\). ***FIX

(iii) We have that

\[
\int_C f \, d(\mu \times \nu) = \int_X \left[ \int_{C_x} f(x, y) \, d\nu(y) \right] d\mu(x) = \int_Y \left[ \int_{C_y} f(x, y) \, d\mu(x) \right] d\nu(y).
\]

Proof: Let \(A, M \in \mathcal{A}\), \(B, N \in \mathcal{B}\) be as in the proposition. Then

\[
\int_C f \, d(\mu \times \nu) = \int_{X \times Y} f \chi_C \, d(\mu \times \nu) = \int_{A \times B} f \chi_C \, d(\mu \times \nu)
\]

(since \(f\chi_C = f\chi_C \chi_{A \times B}\) a.e.) Then, by the Fubini-Tonelli Theorem applied to \(f\chi_C\) on \(A \times B\), \(g_0(x) = \int_B f(x, y) \chi_C(x, y) \, d\nu(y) = \int_{B \cap C_x} f(x, y) \, d\nu(y)\) is \(\mathcal{A}\)-measurable, and integrable for almost all \(x\) if \(f\) is integrable. Since \(C_x \setminus B \subseteq N\), we have \(g_0(x) = \int_{C_x} f(x, y) \, d\nu(y)\), i.e. \(g(x) = g_0(x)\) for \(x \in A\). Also, \(g(x) = 0\) for \(x \notin A \cup M\) since \(C_x \subseteq N\), so \(g(x) = 0\) a.e. on \(X \setminus A\). Then, by Fubini-Tonelli on \(A \times B\),

\[
\int_{A \times B} f \chi_C \, d(\mu \times \nu) = \int_A \left[ \int_B f(x, y) \chi_C(x, y) \, d\nu(y) \right] d\mu(x)
\]

\[
= \int_A \left[ \int_{C_x} f(x, y) \chi_{C_x}(x, y) \, d\nu(y) \right] d\mu(x) = \int_A \left[ \int_{C_x} f(x, y) \, d\nu(y) \right] d\mu(x)
\]

\[
= \int_A \left[ \int_{C_x} f(x, y) \, d\nu(y) \right] d\mu(x) + \int_M \left[ \int_{C_x} f(x, y) \, d\nu(y) \right] d\mu(x) +
\]

\[
+ \int_{X \setminus (A \cup M)} \left[ \int_{C_x} f(x, y) \, d\nu(y) \right] d\mu(x) = \int_X \left[ \int_{C_x} f(x, y) \, d\nu(y) \right] d\mu(x)
\]

since \(\mu(M) = 0\) and \(\nu(C_x) = 0\) for \(x \notin A \cup M\). The proof for the iterated integral in the opposite order is nearly identical.

\(\diamondsuit\)

XIV.6.1.16. As a sample application, suppose \(C\) is a region in \(\mathbb{R}^2\) of the form

\[
\{(x, y) : g(x) \leq y \leq h(x), a \leq x \leq b\}
\]

where \(g, h\) are continuous functions with \(g(x) \leq h(x)\) for \(a \leq x \leq b\), and suppose \(f\) is a Lebesgue measurable function from \(C\) to \(\mathbb{R}\) which is either nonnegative or integrable over \(C\) (e.g. a continuous function.) Then \(C_x = [g(x), h(x)]\) for each \(x \in [a, b]\), and so

\[
\int_C f \, d\lambda^2 = \int_{[a,b]} \left[ \int_{[g(x), h(x)]} f(x, y) \, d\lambda(y) \right] \, d\lambda(x) = \int_a^b \left[ \int_{g(x)}^{h(x)} f(x, y) \, dy \right] \, dx.
\]

1636
XIV.6.2. Lebesgue Integration on $\mathbb{R}^n$

XIV.6.3. Exercises

XIV.6.3.1. Another Nonmeasurable Set. [?] Assume the Continuum Hypothesis, and let $\preceq$ be a well-ordering on $[0, 1]$ according to the first uncountable ordinal, i.e. such that the set of predecessors of any element is countable. Set

$$E = \{(x, y) \in [0, 1]^2 : x \preceq y\}.$$ 

(a) For fixed $y \in [0, 1]$, the set $E^y = \{x \in [0, 1] : x \preceq y\}$ is countable, hence Lebesgue measurable, and $\lambda(E^y) = 0$. Thus, if $E$ is Lebesgue measurable, by the Junior Tonelli Theorem (XIV.6.1.12.)

$$\lambda^2(E) = \int_0^1 \lambda(E^y) \, d\lambda(y) = 0.$$ 

(b) For fixed $x \in [0, 1]$, the set $E_x = \{y \in [0, 1] : x \preceq y\}$ is cocountable, hence Lebesgue measurable, and $\lambda(E_x) = 1$. Thus, if $E$ is Lebesgue measurable, by the Junior Tonelli Theorem

$$\lambda^2(E) = \int_0^1 \lambda(E_x) \, d\lambda(x) = 1.$$ 

(c) Conclude that $E$ is not a Lebesgue measurable subset of $[0, 1]^2$.

This suggests why the CH cannot be proved in ZF: there can be no “measurable” bijection from $\mathbb{R}$ to $\omega_1$.

XIV.6.3.2. [?] Let $X$ be the set of ordinals less than the first uncountable ordinal, $\mathcal{A}$ the $\sigma$-algebra of countable-cocountable subsets of $X$, and $\mu$ the measure on $(X, \mathcal{A})$ with $\mu(A) = 0$ if $A$ is countable and $\mu(A) = 1$ if $A$ is cocountable. Let $E = \{(\alpha, \beta) : \alpha \leq \beta\} \subseteq X \times X$.

(a) Show that the iterated integrals

$$\int_X \int_X \chi_E(\alpha, \beta) \, d\mu(\alpha) \, d\mu(\beta) \text{ and } \int_X \int_X \chi_E(\alpha, \beta) \, d\mu(\beta) \, d\mu(\alpha)$$

both exist but are not equal.

(b) Conclude that $E$ is not $(\mathcal{A} \otimes \mathcal{A})$-measurable, i.e. $\chi_E$ is not $(\mu \times \mu)$-integrable. (It is not hard to see directly that $E \notin \mathcal{A} \otimes \mathcal{A}$.)

This is a variation of XIV.6.3.1. which does not use the Continuum Hypothesis or the AC.
XIV.7. The Henstock-Kurzweil Integral

The Henstock-Kurzweil (HK) integral on \( \mathbb{R} \) is a beautiful and rather simple extension of the Riemann integral. The only modification which needs to be made is to consider a more general and flexible notion of “fineness” of a partition than its mesh. Once some preliminary technicalities are handled, the theory proceeds essentially identically to the Riemann integral case. One ends up with an integral which not only extends the Riemann integral, but even (slightly) the Lebesgue integral, with nice properties such as an unrestricted Fundamental Theorem of Calculus.

XIV.7.1. Definition and Basic Properties

Recall the definition of gauges and fine partitions ().

XIV.7.1.1. Definition. Let \([a, b]\) be a closed bounded interval and \(f : [a, b] \to \mathbb{R}\) a function. Then \(f\) is \(HK\)-integrable on \([a, b]\), with integral \(I\), if for every \(\epsilon > 0\) there is a gauge \(\delta\) on \([a, b]\) such that \(|\mathcal{R}(f, \mathcal{P}) - I| < \epsilon\) for every \(\delta\)-fine partition \(\mathcal{P}\) of \([a, b]\).

It is obvious that the integral \(I\) is unique if it exists.

We first observe that the HK-integral extends the Riemann integral:

XIV.7.1.2. Proposition. Let \(f : [a, b] \to \mathbb{R}\) be Riemann integrable on \([a, b]\). Then \(f\) is HK-integrable on \([a, b]\), with integral \(I = \int_a^b f(t) \, dt\).

Proof: Let \(\epsilon > 0\), and choose \(\delta > 0\) such that whenever \(\mathcal{P}\) is a tagged partition with \(\|\mathcal{P}\| < \delta\), we have \(|\mathcal{R}(f, \mathcal{P}) - I| < \epsilon\). Then the constant gauge \(\delta\) works in the definition of HK-integration. \(\Box\)

XIV.7.1.3. Thus we may justifiably use the notation \(\int_a^b f(t) \, dt\) for the HK-integral of an HK-integrable function.

Conversely, if we can always choose a constant gauge for any \(\epsilon\), then \(f\) is Riemann integrable. Since there are many nonconstant gauges with varying properties which can be used in the definition of HK-integration, it is much easier to satisfy the HK definition for a given \(f\) and one might expect that many more functions are HK-integrable. The next result illustrates this dramatically:

XIV.7.1.4. Theorem. Let \([a, b]\) be a closed bounded interval, and \(A\) a Lebesgue measurable subset of \([a, b]\). Then \(\chi_A\) is HK-integrable over \([a, b]\) with integral \(\lambda(A)\).

Proof: Set \(B = [a, b] \setminus A\). Let \(\epsilon > 0\). There is a sequence \((I_n)\) of open intervals such that \(A \subseteq \bigcup_n I_n\) and \(\sum_n \ell(I_n) < \lambda(A) + \epsilon\), and a sequence \((J_n)\) of open intervals such that \(B \subseteq \bigcup_n J_n\) and \(\sum_n \ell(J_n) < \lambda(B) + \epsilon\). If \(t \in A\), choose an \(n\) (say, the smallest \(n\)) for which \(t \in I_n\), and set \(\delta(t)\) equal to the distance from \(t\) to \(I_n^c\), and similarly if \(t \in B\) choose an \(n\) for which \(t \in J_n\) and set \(\delta(t)\) equal to the distance from \(t\) to \(J_n^c\). Then \(\delta\) is a gauge on \([a, b]\).

1638
Let \( \mathcal{P} = \{a = x_0, \ldots, x_m = b; t_1, \ldots, t_m\} \) be a \( \delta \)-fine partition of \([a, b]\). Then each \( t_k \) is either in \( A \) or \( B \). Let \( N_1 \) be the set of \( k \) for which \( t_k \in A \), and \( N_2 \) the set of \( k \) for which \( t_k \in B \). For each \( k \in N_1 \), the interval \((x_{k-1}, x_k)\) is contained in \( I_n \) for some \( n \); thus we have
\[
\sum_{k \in N_1} \ell([x_{k-1}, x_k]) \leq \sum_n \ell(I_n) < \lambda(A) + \epsilon .
\]
Similarly, we have
\[
\sum_{k \in N_2} \ell([x_{k-1}, x_k]) \leq \sum_n \ell(I_n) < \lambda(B) + \epsilon = (b - a) - [\lambda(A) - \epsilon] .
\]
Since
\[
\sum_{k \in N_1} \ell([x_{k-1}, x_k]) + \sum_{k \in N_2} \ell([x_{k-1}, x_k]) = \sum_{k=1}^m \ell([x_{k-1}, x_k]) = b - a
\]
we have
\[
\lambda(A) - \epsilon < \mathcal{R}(\chi_A, \mathcal{P}) = \sum_{k \in N_1} \ell([x_{k-1}, x_k]) < \lambda(A) + \epsilon .
\]

**XIV.7.1.5.** Unbounded functions cannot be Riemann integrable, but they can be HK-integrable because gauges can be made to force certain points to be tags. See **XIV.7.2.4.** for examples.

**XIV.7.2.** The Fundamental Theorem of Calculus

The following version of the Fundamental Theorem of Calculus is one of the most attractive features of HK-integration. It fails for Riemann integration \((\quad)\) and even for Lebesgue integration \((\quad)\). The proof is quite simple but uses a clever choice of gauge.

**XIV.7.2.1.** **Theorem.** [Fundamental Theorem of Calculus, HK Version] Let \([a, b]\) be a closed bounded interval, and \( f \) a differentiable function on \([a, b]\). Then \( f' \) is HK-integrable on \([a, b]\) and
\[
\int_a^b f'(t) \, dt = f(b) - f(a) .
\]

**Proof:** Let \( \epsilon > 0 \). For each \( t \in [a, b] \) there is a \( \delta(t) > 0 \) such that
\[
\left| \frac{f(x) - f(t)}{x - t} - f'(t) \right| < \frac{\epsilon}{b - a}
\]
whenever \( x \in [a, b], \; 0 < |x - t| < \delta(t) \). Then \( \delta \) is a gauge on \([a, b]\).

Let \( \mathcal{P} = \{a = x_0, \ldots, x_n = b; t_1, \ldots, t_n\} \) be a \( \delta \)-fine partition of \([a, b]\). For each \( k \), since \( x_{k-1} \leq t_k \leq x_k \) we have
\[
|f(x_k) - f(x_{k-1}) - f'(t_k)(x_k - x_{k-1})| = |f(x_k) - f(t_k) - f'(t_k)(x_k - t_k) + f(t_k) - f(x_{k-1}) - f'(t_k)(t_k - x_{k-1})|.
\]

1639
\[ \leq |f(x_k) - f(t_k) - f'(t_k)(x_k - t_k)| + |f(t_k) - f(x_{k-1}) - f'(t_k)(t_k - x_{k-1})| \]

\[ < \frac{\epsilon}{b-a}(x_k - t_k) + \frac{\epsilon}{b-a}(t_k - x_{k-1}) = \frac{\epsilon}{b-a}(x_k - x_{k-1}) \]

since \( x_k - t_k, t_k - x_{k-1} < \delta(t_k) \), and thus

\[ |f(b) - f(a) - \mathcal{R}(f', \hat{P})| = \left| \sum_{k=1}^{n} [f(x_k) - f(x_{k-1}) - f'(t_k)(x_k - x_{k-1})] \right| \]

\[ \leq \sum_{k=1}^{n} |f(x_k) - f(x_{k-1}) - f'(t_k)(x_k - x_{k-1})| \leq \sum_{k=1}^{n} \frac{\epsilon}{b-a}(x_k - x_{k-1}) = \frac{\epsilon}{b-a}(b-a) = \epsilon . \]

We can extend this result to the case where \( f \) is not quite differentiable everywhere:

**XIV.7.2.2. Theorem.** [Fundamental Theorem of Calculus, General HK Version] Let \([a, b]\) be a closed bounded interval, and \( f \) a continuous function on \([a, b]\) which is differentiable except at countably many points. If \( g \) is a function on \([a, b]\) which equals \( f' \) a.e. on \([a, b]\), then \( g \) is HK-integrable on \([a, b]\) and

\[ \int_{a}^{b} g(t) \, dt = f(b) - f(a) . \]

**XIV.7.2.3.** In XIV.7.2.2., we cannot relax the hypothesis that \( f \) be differentiable except at countably many points to simply require that \( f \) be differentiable almost everywhere. If \( g \) is a nonnegative measurable function on \([a, b]\) which is not Lebesgue integrable on \([a, b]\), hence not HK-integrable on \([a, b]\) (), there is a continuous and a.e. differentiable function \( f \) on \([a, b]\) with \( f' = g \) a.e. (XIV.7.2.10.).

**XIV.7.2.4. Examples.** (i) Let \( f(x) = x^2 \sin \frac{1}{x^2} \) (with \( f(0) = 0 \)). Then \( f \) is differentiable everywhere, and

\[ f'(x) = 2x \sin \frac{1}{x^2} - 2 \cos \frac{1}{x^2} \]

\( (f'(0) = 0) \). But \( f' \) is not Lebesgue integrable on any interval containing 0; however, it is HK-integrable on any (closed bounded) interval. This is an example of an unbounded function which is HK-integrable.

(ii) For a simpler example, \( f(x) = 2\sqrt{x} \) is continuous on \([0, 1]\) and differentiable except at 0. Then \( f'(x) = x^{-1/2} \) is HK-integrable on \([0, 1]\) even though it is unbounded. We have

\[ \int_{0}^{1} t^{-1/2} \, dt = 2\sqrt{1} - 2\sqrt{0} = 2 \]

i.e. the HK-integral equals the improper Riemann integral. This holds generally ().

1640
XIV.8. Convolution

The operation of convolution of functions is valuable in a great many contexts. It is a “multiplication” of functions quite different from ordinary pointwise product, which bears some resemblance to matrix multiplication.

An informal motivation for the operation of convolution comes from multiplying series. We give a completely heuristic version which ignores all questions of convergence. Suppose

\[ \sum_{k=-\infty}^{\infty} a_k x^k \quad \text{and} \quad \sum_{k=-\infty}^{\infty} b_k x^k \]

are two-way infinite summations. We want to “multiply” these to get a new two-way infinite summation

\[ \left[ \sum_{k=-\infty}^{\infty} a_k x^k \right] \left[ \sum_{k=-\infty}^{\infty} b_k x^k \right] = \sum_{k=-\infty}^{\infty} c_k x^k \]

and the “formula” for \( c_k \) is obtained by formally multiplying the two expressions and collecting together like powers of \( x \) to obtain

\[ c_k = \sum_{i+j=k} a_j b_i = \sum_{j=-\infty}^{\infty} a_j b_{k-j} . \]

Such a computation is meaningless as done informally here, but with suitable tweaking and interpretation becomes meaningful and useful.

We will not trace the full convoluted history of the development of this subject here.

XIV.8.1. Convolution of Functions on \( \mathbb{R} \), Continuous Case

In this subsection, we will discuss properties of convolution which do not require a knowledge of Lebesgue integration; all integrals in this subsection will be Riemann integrals or improper Riemann integrals. We will consider only continuous functions, and mostly only functions with compact support, i.e. functions which vanish (are identically zero) outside a bounded interval.

XIV.8.1.1. Definition. Let \( f \) and \( g \) be continuous functions from \( \mathbb{R} \) to \( \mathbb{R} \). Suppose for every \( x \in \mathbb{R} \) the integral

\[ \int_{-\infty}^{+\infty} f(y)g(x-y) \, dy = \int_{\mathbb{R}} f(y)g(x-y) \, dy \]

exists as an improper Riemann integral and is finite. The function \( f * g : \mathbb{R} \to \mathbb{R} \) defined by

\[ (f * g)(x) = \int_{-\infty}^{+\infty} f(y)g(x-y) \, dy \]

is called the convolution of \( f \) and \( g \).
XIV.8.1.2. Proposition. Let $f$ and $g$ be continuous functions on $\mathbb{R}$. If $f \ast g$ is defined, then $g \ast f$ is also defined and $g \ast f = f \ast g$.

Proof: Fix $x \in \mathbb{R}$. Then

$$(f \ast g)(x) = \int_{-\infty}^{+\infty} f(y)g(x-y) \, dy = \lim_{a \to -\infty, b \to +\infty} \int_a^b f(y)g(x-y) \, dy.$$ 

Make the change of variable $z = x - y$. Then, for $a, b \in \mathbb{R}$,

$$\int_a^b f(y)g(x-y) \, dy = \int_{x-a}^{x-b} f(x-z)g(z)(-1) \, dz = \int_{x-b}^{x-a} f(x-z)g(z) \, dz$$

and since $c = x - b \to -\infty$ and $d = x - a \to +\infty$ as $a \to -\infty$ and $b \to +\infty$, we have that

$$\int_{-\infty}^{+\infty} g(z)f(x-z) \, dz = \lim_{c \to -\infty, d \to +\infty} \int_c^d g(z)f(x-z) \, dz = \lim_{a \to -\infty, b \to +\infty} \int_a^b f(y)g(x-y) \, dy$$

eexists as an improper Riemann integral and equals $(f \ast g)(x)$. $\blacksquare$

XIV.8.1.3. One can be fooled into thinking that $g \ast f = -f \ast g$ since the substitution $z = x - y$ introduces a minus sign into the integrand. But the direction of integration is also reversed, canceling the negation. It is more straightforward to use the change-of-variables formula (\ref{civ1}); cf. (\ref{civ2}). To see that $g \ast f$ must be $+f \ast g$ and not $-f \ast g$, consider the case where $f$ and $g$ are nonnegative; then $f \ast g$ and $g \ast f$ are also nonnegative.

The Compact Support Case

XIV.8.1.4. Suppose $f$ and $g$ are continuous functions, and $f$ has compact support. Then $f \ast g$ is defined. For if $f$ vanishes outside $[a, b]$, then for each $x$ we have

$$(f \ast g)(x) = \int_{-\infty}^{+\infty} f(y)g(x-y) \, dy = \int_a^b f(y)g(x-y) \, dy$$

as an ordinary Riemann integral. The convolution $g \ast f$ is also defined by XIV.8.1.2. So for existence of the convolution it suffices that one of the functions have compact support.

Continuity of the Convolution

To discuss continuity of $f \ast g$, we need the following fact:

XIV.8.1.5. Proposition. Let $f$ be a continuous function on $\mathbb{R}$. For $x \in \mathbb{R}$, define $f_x(y) = f(x + y)$. If $x_n \to x$ in $\mathbb{R}$, then $f_{x_n} \to f_x$ u.c.

Proof: Let $\epsilon > 0$, and $[a, b]$ a bounded interval in $\mathbb{R}$. Since $f$ is uniformly continuous on bounded intervals (\ref{hiv1}), there is a $\delta > 0$ such that if $y, z \in [a + x - 1, b + x + 1]$ and $|y - z| < \delta$, then $|f(y) - f(z)| < \epsilon$. Fix $N$ such that $|x_n - x| < \min(\delta, 1)$ for all $n \geq N$. Then, if $y \in [a, b]$ and $n \geq N$, we have

$$|f_{x_n}(y) - f_x(y)| = |f(x_n + y) - f(x + y)| < \epsilon.$$ $\blacksquare$
XIV.8.1.6. PROPOSITION. Let \( f \) and \( g \) be continuous functions, with \( f \) of compact support. Then \( f \ast g \) is continuous.

PROOF: Let \( x_n \to x \) in \( \mathbb{R} \). Set \( h_n(y) = f(y)g(x_n - y) = f(y)g(x_n - y) \) and \( h(y) = f(y)g(x - y) = f(y)g(x - y) \).

Since \( g_{x_n} \to g_x \) u.c. by XIV.8.1.5., and \( f \) has compact support, \( h_n \to h \) uniformly on \( \mathbb{R} \); and the \( h_n \) and \( h \) all vanish outside a finite interval \([a, b]\) (the support of \( f \)). Thus

\[
(f \ast g)(x_n) = \int_{-\infty}^{+\infty} f(y)g(x_n - y) \, dy = \int_{a}^{b} h_n(y) \, dy \to \int_{a}^{b} h(y) \, dy = \int_{-\infty}^{+\infty} f(y)g(x - y) \, dy = (f \ast g)(x)
\]

so \( f \ast g \) is continuous by the Sequential Criterion.

XIV.8.1.7. PROPOSITION. Let \( f \) and \( g \) be continuous functions of compact support contained in \([a, b]\) and \([c, d]\) respectively. Then \( f \ast g \) has compact support contained in \([a + c, b + d]\).

PROOF: If \( x < a + c \), then for every \( y \) either \( y < a \) or \( x - y < c \), so \( f(y)g(x - y) = 0 \) for all \( y \), and similarly for \( x > b + d \).

Differentiability of the Convolution

The convolution of two functions \( f \) and \( g \) has the pleasant property of being least as smooth as the smoother of \( f \) and \( g \). We next show the continuous version of this principle.

XIV.8.1.8. THEOREM. Let \( f \) be a continuous function and \( g \) a \( C^r \) function on \( \mathbb{R} \) (\( 0 \leq r \leq \infty \)). Suppose either \( f \) or \( g \) has compact support. Then \( f \ast g \) is \( C^r \), and \( (f \ast g)^{(k)} = f \ast (g^{(k)}) \) for \( 1 \leq k \leq r \).

PROOF: The case \( r = 0 \) is XIV.8.1.6. Suppose \( g \) is \( C^1 \). Then the support of \( g' \) is contained in the support of \( g \), so \( f \ast (g') \) is defined.

Set \( H(x, y) = f(y)g(x - y) \). Then \( \frac{\partial H}{\partial x}(x, y) = f(y)g'(x - y) \), which is continuous by assumption.

If \( f \) has compact support contained in \([a, b]\), then by (1) we have

\[
(f \ast g)'(x) = \frac{d}{dx} \left( \int_{-\infty}^{+\infty} f(y)g(x - y) \, dy \right)(x) = \frac{d}{dx} \left( \int_{a}^{b} H(x, y) \, dy \right)(x)
\]

\[
= \int_{a}^{b} \frac{\partial H}{\partial x}(x, y) \, dy = \int_{-\infty}^{+\infty} f(y)g'(x - y) \, dy = (f \ast (g'))(x)
\]

The argument if \( g \) has compact support is similar, but slightly more complicated. Suppose the support of \( g \) is contained in \([a, b]\). Fix \( x_0 \), and fix an interval \([c, d]\) with \( x_0 \in (c, d) \). Then, restricting \( x \) to \([c, d]\),

\[
(f \ast g)'(x_0) = \frac{d}{dx} \left( \int_{-\infty}^{+\infty} f(y)g(x - y) \, dy \right)(x_0) = \frac{d}{dx} \left( \int_{c}^{d} H(x, y) \, dy \right)(x_0)
\]

\[
= \int_{c}^{d} \frac{\partial H}{\partial x}(x_0, y) \, dy = \int_{-\infty}^{+\infty} f(y)g'(x_0 - y) \, dy = (f \ast (g'))(x_0)
\]

This proves the result for \( r = 1 \). For larger \( r \) apply the \( r = 1 \) case inductively to \( f \) and \( g^{(k)} \).
XIV.8.1.9. Of course, by XIV.8.1.2., the result also holds if \( f \) is \( C^r \), \( g \) is continuous, and at least one has compact support; in this case \((f * g)(k) = (f^{(k)}) * g\). If \( f \) and \( g \) are both \( C^1 \), and at least one has compact support, then \((f') * g = f * (g')\). If \( f \) and \( g \) are \( C^2 \), then \((f'') * g = (f') * (g'') = f * (g'')\), etc.

In fact, we have:

XIV.8.1.10. Corollary. Let \( f \) be a \( C^r \) function and \( g \) a \( C^s \) function on \( \mathbb{R} \) \((0 \leq r, s < \infty)\). Suppose either \( f \) or \( g \) has compact support. Then \( f * g \) is \( C^{r+s} \), and \((f * g)^{(r+s)} = (f^{(r)}) * (g^{(s)})\).

Proof: The convolution \( f * g \) is \( C^r \) and \((f * g)^{(r)} = (f^{(r)}) * g\); and \((f^{(r)}) * g \) is \( C^s \) with \([f^{(r)}] * g^{(s)} = (f^{(r)}) * (g^{(s)})\).

Convolutions on Intervals

XIV.8.1.11. If \( f \) has compact support contained in \([a, b]\), and \( g \) is any continuous function on \( \mathbb{R} \), then for any interval \([c, d]\) the values of \( f * g \) on \([c, d]\) depend only on the values of \( g \) on the interval \([c - b, d - a]\).
This leads to two important observations:
(1) The function \( g \) can be modified arbitrarily outside the interval \([c - b, d - a]\) without affecting the values of \( f * g \) on \([c, d]\). In particular, there is a continuous function \( h \) of compact support such that \( f * h \) agrees with \( f * g \) on \([c, d]\). This observation is useful in studying local properties of \( f * g \); in particular, it can be used to give an alternate proof of the “harder” half of XIV.8.1.8.
(2) If \( g \) is any continuous function on \([c - b, d - a]\), then we can define the convolution of \( f \) and \( g \) as a function on the interval \([c, d]\).

Algebraic Properties of Convolution

Convolution satisfies all the algebraic properties of a reasonable “multiplication”. We have already established the commutative property \( f * g = g * f \) (XIV.8.1.2.). Another simple property whose proof is left to the reader (Exercise (i)) is the distributive or bilinear property:

XIV.8.1.12. Proposition. Let \( f_1, f_2, g \) be continuous functions on \( \mathbb{R} \), and \( \alpha \in \mathbb{R} \).

(i) If \( f_1 * g \) and \( f_2 * g \) are defined, then \((f_1 + f_2) * g \) is defined and \((f_1 + f_2) * g = f_1 * g + f_2 * g\).

(ii) If \( f_1 * g \) is defined, then \((\alpha f_1) * g \) is defined and \((\alpha f_1) * g = \alpha (f_1 * g)\).

In other words, for fixed \( g \), convolution \( f * g \) is linear in \( f \). Of course, by commutativity, \( f * g \) is also linear in \( g \) for fixed \( f \). Thus convolution is \emph{bilinear}.

The other important algebraic property, associativity, also holds; the proof requires Fubini’s Theorem for vector calculus (i).
XIV.8.1.13. Proposition. Let \( f, g, h \) be continuous functions on \( \mathbb{R} \). Suppose at least two of the functions have compact support. Then \( (f * g) * h = f * (g * h) \).

Proof: If \( x_0 \in \mathbb{R} \), then the function which does not have compact support can be replaced by a function of compact support without changing either \( (f * g) * h \) or \( f * (g * h) \) in an interval around \( x_0 \), by two applications of XIV.8.1.11.(1). Thus to prove the result we may assume all three functions have compact support. We have

\[
[f * g * h](x_0) = \int_{-\infty}^{+\infty} \left[ \int_{-\infty}^{+\infty} f(z)g(y-z) \, dz \right] h(x_0-y) \, dy
\]

\[
[f * (g * h)](x_0) = \int_{-\infty}^{+\infty} f(z) \left[ \int_{-\infty}^{+\infty} g(y)h(x_0-z-y) \, dy \right] \, dz
\]

where the integrals are actually over a sufficiently large bounded region (rectangle) in \( \mathbb{R}^2 \). By Fubini’s Theorem () the integrals are equal to the double integrals

\[
\int_{\mathbb{R}^2} f(z)g(y-z)h(x_0-y) \, dy \, dz
\]

\[
\int_{\mathbb{R}^2} f(z)g(y)h(x_0-z-y) \, dy \, dz
\]

respectively, where the integrals are again really over a sufficiently large bounded region.

Make the change of variables \( \phi(u,v) = (u+v, v) \). Writing \( y = u + v, z = v \), we have \( x_0 - y = x_0 - u - v \) and \( y - z = u \). We have \( \Delta_\phi(u,v) \equiv 1 \), so by the change-of-variables formula for double integrals () we have

\[
\int_{\mathbb{R}^2} f(z)g(y-z)h(x_0-y) \, dy \, dz = \int_{\mathbb{R}^2} f(v)g(u)h(x_0-u-v) \Delta_\phi(u,v) \, du \, dv = \int_{\mathbb{R}^2} f(v)g(u)h(x_0-u-v) \, du \, dv
\]

(where the integrals are over large bounded regions), so the double integrals are equal.

Integrable Functions

We can give various other conditions insuring the existence of the convolution. If neither function has compact support, then in general restrictions on both functions are necessary.

XIV.8.1.14. Definition. Let \( f : \mathbb{R} \to \mathbb{R} \) be a continuous function. Then \( f \) is integrable (over \( \mathbb{R} \)) if

\[
\|f\|_1 := \int_{-\infty}^{+\infty} |f(x)| \, dx < \infty
\]

(i.e. the improper integral converges).

XIV.8.1.15. The set \( CL^1(\mathbb{R}) \) of integrable continuous functions on \( \mathbb{R} \) is a real vector space, and \( \| \cdot \|_1 \) is a norm () on \( CL^1(\mathbb{R}) \). Every continuous function of compact support is in \( CL^1(\mathbb{R}) \), but \( CL^1(\mathbb{R}) \) is much larger than the set \( C_c(\mathbb{R}) \) of continuous functions of compact support: for example, an integrable continuous function need not even be bounded (Example XIV.8.1.19.). The set \( BCL^1(\mathbb{R}) \) of bounded continuous integrable functions on \( \mathbb{R} \) is a vector space properly between \( C_c(\mathbb{R}) \) and \( CL^1(\mathbb{R}) \).

1645
**XIV.8.1.16.** Proposition. Let \( f \) and \( g \) be continuous functions on \( \mathbb{R} \), with \( f \) integrable and \( g \) bounded. Then \( f \ast g \) is defined and bounded, and \( \| f \ast g \|_\infty \leq \| f \|_1 \| g \|_\infty \).

**Proof:** We have that, for each \( x \),
\[
\int_{-\infty}^{+\infty} |f(x-y)g(y)| \, dy \leq \int_{-\infty}^{+\infty} |f(x-y)| \| g \|_\infty \, dy = \| g \|_\infty \int_{-\infty}^{+\infty} |f(x-y)| \, dy = \| f \|_1 \| g \|_\infty
\]
so by (\( \) the improper integral
\[
\int_{-\infty}^{+\infty} f(x-y)g(y) \, dy
\]
converges and
\[
|(f \ast g)(x)| = \left| \int_{-\infty}^{+\infty} f(x-y)g(y) \, dy \right| \leq \int_{-\infty}^{+\infty} |f(x-y)g(y)| \, dy \leq \| f \|_1 \| g \|_\infty.
\]

**XIV.8.1.17.** Proposition. Let \( f \) and \( g \) be continuous functions on \( \mathbb{R} \), with \( f \) integrable and \( g \) bounded (or vice versa). Then \( f \ast g \) is continuous.

**Proof:** Let \( (f_n) \) be a sequence of continuous functions of compact support with \( \| f_n - f \|_1 \to 0 \) (\( \)). Then
\[
\| f_n \ast g - f \ast g \|_\infty = \| (f_n - f) \ast g \|_\infty \leq \| f_n - f \|_1 \| g \|_{\infty} \to 0
\]
so \( f_n \ast g \to f \ast g \) uniformly. By XIV.8.1.16., each \( f_n \ast g \) is continuous; hence \( f \ast g \) is continuous by (\( \)).

**XIV.8.1.18.** Proposition. Let \( f \) and \( g \) be integrable continuous functions on \( \mathbb{R} \), with at least one of \( f \) and \( g \) bounded. Then \( f \ast g \) is defined and in \( BCL^1(\mathbb{R}) \), and
\[
\| f \ast g \|_1 \leq \| f \|_1 \| g \|_1.
\]

**Proof:** By XIV.8.1.16. and XIV.8.1.17., \( f \ast g \) is defined, and is bounded and continuous. To show it is integrable, consider the integral
\[
\int \int_{\mathbb{R}^2} |f(y)||g(x-y)| \, dx \, dy.
\]
We can change variables in this integral using \( \phi : \mathbb{R}^2 \to \mathbb{R}^2 \) defined by \( \phi(z,y) = (z+y,y) \). Then \( x = z+y \), \( z = x-y \), and we have \( \Delta_\phi(z,y) \equiv 1 \), so
\[
\int \int_{\mathbb{R}^2} |f(y)||g(x-y)| \, dx \, dy = \int \int_{\mathbb{R}^2} |f(y)||g(z)||\Delta_\phi(z,y)| \, dz \, dy = \int \int_{\mathbb{R}^2} |f(y)||g(z)| \, dz \, dy.
\]
By the Fubini-Tonelli Theorem (\( \)) this integral can be computed as an iterated integral
\[
\int_{\mathbb{R}} \int_{\mathbb{R}} |f(y)||g(z)| \, dz \, dy = \int_{\mathbb{R}} |f(y)| \left[ \int_{\mathbb{R}} |g(z)| \, dz \right] \, dy = \left[ \int_{\mathbb{R}} |f(y)| \, dy \right] \left[ \int_{\mathbb{R}} |g(z)| \, dz \right] = \| f \|_1 \| g \|_1.
\]

\[1646\]
XIV.8.1.19. Example. Here is an example showing that the boundedness hypothesis in XIV.8.1.18. cannot be deleted. Define a nonnegative continuous function $f$ on $\mathbb{R}$ as follows:

$$f(x) = \begin{cases} 0 & \text{if } x \in [0, \frac{15}{8}] \\ n & \text{if } x \in [n - \frac{1}{2n^2}, n + \frac{1}{2n^2}], n \geq 2 \\ \text{linear} & \text{if } x \in [n - \frac{1}{n^3}, n - \frac{1}{2n^2}], n \geq 2 \\ \text{linear} & \text{if } x \in [n + \frac{1}{2n^2}, n + \frac{1}{n^3}], n \geq 2 \\ 0 & \text{if } x \in [n + \frac{1}{n^3}, n + 1 - \frac{1}{(n+1)^3}], n \geq 2 \\ f(-x) & \text{if } x < 0 \end{cases}$$

The graph of $f$ is identically 0 except for small “blunt spikes” around integers; see Figure (). We have

$$\int_{-\infty}^{+\infty} f(x) \, dx < \infty$$

$$\int_{-\infty}^{+\infty} [f(x)]^2 \, dx = \infty$$

i.e. $f$ is integrable but not square-integrable.

Consider $f * f$. We have

$$\int_{-\infty}^{+\infty} f(y)f(-y) \, dy = \int_{-\infty}^{+\infty} [f(y)]^2 \, dy = \infty$$

so $f * f(0)$ is not defined. In fact, $f * f(x)$ is defined if and only if $x$ is not an integer.

XIV.8.1.20. It turns out that using Lebesgue measure and integration we can still make a reasonable definition of the convolution $f * f$ of XIV.8.1.19. (or of any two integrable functions), but the convolution is not continuous and only defined “almost everywhere.” This is in fact one of the historical motivations for developing a more general theory of measure and integration. See section ().

XIV.8.1.21. Thus convolution gives a binary operation of $BCL^1(\mathbb{R})$. Convolution on $BCL^1(\mathbb{R})$ retains nice algebraic properties: associativity (), commutativity (XIV.8.1.2.), and bilinearity ()

XIV.8.1.22. Using Hölder’s inequality (), XIV.8.1.16. can be extended. If $1 \leq p < \infty$, a continuous function $f$ on $\mathbb{R}$ is $p$-integrable if

$$\|f\|_p^p := \int_{-\infty}^{+\infty} |f(x)|^p \, dx < \infty .$$
**XIV.8.1.23. Theorem.** Let $1 < p < \infty$, and $q = \frac{p}{p-1}$ the conjugate exponent () of $p$. Let $f$ and $g$ be continuous functions which are $p$-integrable and $q$-integrable respectively. Then $f \ast g$ is defined, continuous, and bounded, and $\|f \ast g\|_\infty \leq \|f\|_p \|g\|_q$.

See () for the proof, which actually gives a more general statement not requiring $f$ and $g$ to be continuous. Using this, another version of XIV.8.1.18. can be obtained with an identical proof:

**XIV.8.1.24. Corollary.** Let $f$ and $g$ be integrable continuous functions on $\mathbb{R}$. Suppose there is a $p$, $1 < p < \infty$, such that $f$ is $p$-integrable and $g$ is $q$-integrable, where $q = \frac{p}{p-1}$ is the conjugate exponent to $p$. Then $f \ast g$ is defined and in $BCL^1(\mathbb{R})$, and

$$\|f \ast g\|_1 \leq \|f\|_1 \|g\|_1.$$ 

In particular, if $f$ and $g$ are continuous, integrable, and 2-integrable (square-integrable), then $f \ast g$ is defined, continuous, and bounded.
XIV.9. The Radon-Nikodým Theorem

XIV.9.1. Exercises

1. Let $\nu$ be a complex measure on $(X, \mathcal{A})$.
   (a) Use the complex Radon-Nikodým Theorem to show that there is a $u \in L^1_{\mathbb{C}}(X, \mathcal{A}, \nu)$ such that
       $$\nu(A) = \int_A u \, d|\nu|$$
   for all $A \in \mathcal{A}$.
   (b) Use Exercise XIII.6.4.1.(b) to show that $|u| = 1$ a.e.
   (c) Let $f \in L^1_{\mathbb{C}}(X, \mathcal{A}, \nu)$, and define a complex measure $\sigma$ on $(X, \mathcal{A})$ by $\sigma(A) = \int_A f \, d\nu$. Show that
       $$|\sigma|(A) = \int_A |f| \, d|\nu|$$
   for $A \in \mathcal{A}$. 

XIV.10. Appendix B

XIV.10.1. Space-Filling Curves

In this section, we will show that there is a continuous function from \([0,1]\) onto the square \([0,1]^2\). This remarkable fact was first discovered by Peano in -_. There are actually many ways to construct such a “space-filling curve”; our approach will be somewhat unconventional, exploiting properties of the Cantor set. For other constructions of space-filling curves, see, for example, [1] or [2] (or many other references.) Essentially the same construction will yield a continuous function from \([0,1]\) onto \([0,1]^n\) for any \(n\), and even a continuous function from \([0,1]\) onto the Hilbert cube \([0,1]^\mathbb{N}\) (an “ultimate space-filling curve”).

Recall that the Cantor set \(K\) is the subset of \([0,1]\) consisting of all numbers which have a triadic expansion consisting only of 0’s and 2’s. Every element of \(K\) has a unique such expansion. \(K\) is an uncountable compact subset of \([0,1]\) which is totally disconnected but without isolated points, which is nowhere dense and has Lebesgue measure 0.

The proof of the next proposition is straightforward and is left to the reader.

**Proposition.** The map
\[
(a_1, a_2, \ldots) \mapsto .a_1a_2\ldots
\]
is a homeomorphism from \(\{0,2\}^\mathbb{N}\) onto \(K\).

Thus \(K\) is homeomorphic to a countably infinite product of 2-point spaces. The key fact about \(K\) we will need, which follows immediately from this (since \(n_0 = nN_0 = 8^2\)), is that \(K\) is homeomorphic to \(K^2 = K \times K\), and also to \(K^n\) for any \(n\) and even to \(K^\mathbb{N}\). An explicit homeomorphism from \(K\) to \(K^2\) is given by:
\[
\rho(a_1a_2a_3\cdots) = (.a_1a_3a_5\cdots, a_2a_4a_6\cdots)
\]
where the \(a_i\) are the triadic digits, either 0 or 2. A similar homeomorphism can be given from \(K\) to \(K^n\) for any \(n\). To get a homeomorphism from \(K\) to \(K^\mathbb{N}\), let \(\gamma\) be a bijection from \(\mathbb{N} \times \mathbb{N}\) to \(\mathbb{N}\), for example \(\gamma(m,n) = 2^m-1(2n-1)\), and set
\[
\sigma(a_1a_2a_3\cdots) = (\sigma_1(a_1a_2a_3\cdots), \sigma_2(a_1a_2a_3\cdots), \sigma_3(a_1a_2a_3\cdots), \cdots)
\]
where \(\sigma_m(a_1a_2a_3\cdots) = a_{\gamma(m,1)}a_{\gamma(m,2)}a_{\gamma(m,3)}\cdots\). So, for the above \(\gamma\),
\[
\sigma(a_1a_2a_3\cdots) = (a_1a_3a_5\cdots, a_2a_4a_6\cdots, a_4a_1a_2a_3\cdots, \cdots)
\]

There is a standard continuous function from \(K\) onto \([0,1]\), defined by
\[
\theta(a_1a_2a_3\cdots) = b_1b_2b_3\cdots
\]
where the \(a_n\) are triadic digits, either 0 or 2, \(b_n = a_n/2\) (i.e. \(b_n = 0\) if \(a_n = 0\) and \(b_n = 1\) if \(a_n = 2\)), and \(b_1b_2b_3\cdots\) is the binary expansion of the image number. This function \(\theta\) is just the restriction of the Cantor function () to \(K\).

Applying \(\theta\) coordinatewise, we obtain continuous functions \(\theta^n\) from \(K^n\) onto \([0,1]^n\), and \(\theta^\mathbb{N}\) from \(K^\mathbb{N}\) onto \([0,1]^\mathbb{N}\). Composing these with the homeomorphisms \(\rho\) and \(\sigma\) above, we obtain continuous surjective maps

\[
\phi = \theta^2 \circ \rho : K \to [0,1]^2, \quad \psi = \theta^\mathbb{N} \circ \sigma : K \to [0,1]^\mathbb{N}
\]
Let $\phi_n$ $(n = 1, 2)$ be the coordinate functions of $\phi$, and $\psi_n$ $(n \in \mathbb{N})$ the coordinate functions of $\psi$. By (\_), $\phi_n$ and $\psi_n$ extend to continuous functions on all of $[0, 1] \setminus K$; also call these extensions $\phi_n$ and $\psi_n$ respectively. Using these as coordinate functions, we obtain surjective continuous functions $\phi : [0, 1] \to [0, 1]^2$ and $\psi : [0, 1] \to [0, 1]^\mathbb{N}$, which is what we wanted. Thus:

**Theorem.** There are continuous functions $\phi$ from $[0, 1]$ onto $[0, 1]^2$, and $\psi$ from $[0, 1]$ onto $[0, 1]^\mathbb{N}$.

The functions we have defined have the following properties:

1. The coordinate functions are differentiable on $[0, 1] \setminus K$, hence differentiable a.e.
2. For any $(s_1, s_2) \in [0, 1]^2$, there is a $t \in [0, 1]$ with $\phi_1(t) = s_1$ and $\phi_2(t) = s_2$. Similarly, for any sequence $(s_1, s_2, \cdots)$ in $[0, 1]$, there is a $t \in [0, 1]$ with $\psi_n(t) = s_n$ for all $n$.

The functions $\phi$ and $\psi$ cannot be injective, since if they were they would be homeomorphisms by (\_); but cubes of different dimensions are not homeomorphic (\_). However, $\phi$ is not terribly far from being injective: no point of $[0, 1]^2$ is traversed more than 5 times (the point $(\frac{1}{2}, \frac{1}{2})$ is traversed exactly 5 times, as are countably many other points). Individual coordinate functions are very far from being injective, however. (In fact, see (\_).)

The coordinate functions $\phi_n$ and $\psi_n$, although differentiable a.e., are not of bounded variation. The graphs of $\phi_1$ and $\phi_2$ look as follows:

The graphs have a somewhat fractal character in that the same patterns are repeated in miniature. However, they are not truly fractal since the scaling factors are different on the horizontal and vertical axes ($\frac{1}{3}$ on the horizontal, $\frac{1}{2}$ on the vertical).

**XIV.11. The Borel Sets Are Not Countably Constructible**

In this section, we will show that none of the Baire classes $\mathcal{BC}_\alpha$ for countable $\alpha$ are equal to the class of all Borel measurable functions, and hence the set $\mathcal{BC}_\alpha$ of sets of Baire class $\alpha$ (for $\alpha$ countable) is not the entire class of Borel sets. Thus the classes $\mathcal{BC}_\alpha$ are strictly increasing in $\alpha$ for $\alpha$ countable, i.e. the entire class of Borel sets or Borel measurable functions cannot be constructed in finitely, or even countably, many steps.

This result was proved by Lebesgue in his 1905 paper [\?], and was the beginning of what today is called descriptive set theory (\_). The following slick refinement of Lebesgue’s original argument, due to W. Sierpiński, which uses an “ultimate space-filling curve,” is adapted from van Rooij and Schikhof, *A Second Course on Real Analysis* [vRS82]. For a rather different argument, see Billingsley, *Probability and Measure* [Bil95], p. 30-32.

**Definition.** Let $\mathcal{F}$ be a set of Borel measurable functions from $\mathbb{R}$ to $\mathbb{R}$. A *catalog* for $\mathcal{F}$ is a Borel measurable function $F : [0, 1] \times \mathbb{R} \to \mathbb{R}$ such that, for every $f \in \mathcal{F}$, there is an $s \in [0, 1]$ for which $f(t) = F(s, t)$ for all $t \in \mathbb{R}$.

If $\mathcal{F}$ has a catalog, then obviously so does any subset of $\mathcal{F}$.

We will prove:

**Theorem.** For each countable $\alpha$, $\mathcal{BC}_\alpha$ has a catalog. But $\mathcal{B}$ does not have a catalog. So $\mathcal{BC}_\alpha \neq \mathcal{B}$.

The proof will proceed in a number of steps.
PROPOSITION. For each \( n \), let \( \mathcal{F}_n \) be a set of Borel measurable functions, and let \( \mathcal{F} = \bigcup_n \mathcal{F}_n \). If each \( \mathcal{F}_n \) has a catalog, then \( \mathcal{F} \) has a catalog.

PROOF: Let \( F_n \) be a catalog for \( \mathcal{F}_n \). Let \( h_n \) be a linear (affine) function from \( [\frac{1}{2n}, \frac{1}{2n-1}] \) onto \( [0,1] \), and define \( G_n : [0,1] \times \mathbb{R} \to \mathbb{R} \) by setting \( G_n(s,t) = F_n(h_n(s),t) \) if \( s \in [\frac{1}{2n}, \frac{1}{2n-1}] \) and \( G_n(s,t) = 0 \) otherwise. Then \( G_n \) is Borel measurable by (1) and (2). The sequence of partial sums of \( \sum_n G_n \) converges pointwise on \( [0,1] \times \mathbb{R} \) to a function \( G \) which is thus Borel measurable; and \( G \) is a catalog for \( \mathcal{F} \) since, if \( f \in F_n \) and \( f(t) = F_n(s,t) \), then \( f(t) = G(h_n^{-1}(s),t) \).

COROLLARY. Any countable set of Borel measurable functions has a catalog.

PROOF: It is only necessary to observe that if \( f \) is a single Borel measurable function, then \( \mathcal{F} = \{f\} \) has a catalog. Set \( F(s,t) = f(t) \) for all \( s \).

If \( \mathcal{F} \) is a set of Borel measurable functions, write \( \mathcal{F}^* \) for the set of functions (also Borel measurable) which are pointwise limits of sequences of functions in \( \mathcal{F} \). For example, \( \mathcal{B}C^*_n = \mathcal{B}C_{n+1} \). In general, \( \mathcal{F} \subseteq \mathcal{F}^* \) (use constant sequences).

The most difficult part of the proof of the theorem is to show that if \( \mathcal{F} \) has a catalog, so does \( \mathcal{F}^* \). This will be done using the continuous function \( \psi \) of (1). We first need a useful variation of the notion of limit of a sequence:

DEFINITION. Let \( (a_n) \) be a sequence of numbers. Define \( \lim_{n \to \infty} a_n = \lim_{n \to \infty} a_n \) if the limit exists, and \( \lim_{n \to \infty} a_n = 0 \) if \( \lim_{n \to \infty} a_n \) does not exist.

Thus \( \lim_{n \to \infty} a_n \) exists for every sequence \( (a_n) \) of numbers. If \( (a_n) \subseteq [0,1] \), then \( \lim_{n \to \infty} a_n \in [0,1] \).

PROPOSITION. Let \( (X, \mathcal{A}) \) be a measurable space, and \( (f_n) \) a sequence of real-valued \( \mathcal{A} \)-measurable functions on \( X \). Let \( C = \{x \in X : (f_n(x)) \text{ converges}\} \). Then \( C \in \mathcal{A} \).

PROOF: If \( x \in X \), then \( x \in C \) if and only if \( (f_n(x)) \) is a Cauchy sequence. Thus

\[
C = \bigcap_{k \in \mathbb{N}} \bigcup_{r \in \mathbb{Q}} \bigcup_{n \in \mathbb{N}} \bigcap_{m \geq n} f_m^{-1} \left( \left[ r - \frac{1}{k}, r + \frac{1}{k} \right] \right).
\]

COROLLARY. Let \( (X, \mathcal{A}) \) be a measurable space, and \( (f_n) \) a sequence of real-valued \( \mathcal{A} \)-measurable functions on \( X \). For \( x \in X \), set \( f(x) = \lim_{n \to \infty} f_n(x) \). Then \( f \) is \( \mathcal{A} \)-measurable.

PROOF: If \( C \) is as above, then \( C \in \mathcal{A} \), and \( f_n \to f \) on \( C \), so \( f|_C \) is measurable. \( f \) is constant on \( X \setminus C \), hence measurable. Thus \( f \) is measurable by (1).

THEOREM. If \( \mathcal{F} \) is a set of Borel measurable functions from \( \mathbb{R} \) to \( \mathbb{R} \), and \( \mathcal{F} \) has a catalog, then \( \mathcal{F}^* \) also has a catalog.

1653
Proof: Let $F$ be a catalog for $\mathcal{F}$, and let $\psi : [0,1] \to [0,1]^\mathbb{N}$ be an ultimate space-filling curve as in ??, with coordinate functions $\psi_n \,(n \in \mathbb{N})$. For each $s \in [0,1]$, $t \in \mathbb{R}$, set $G_n(s,t) = F(\psi_n(s),t)$, and $G(s,t) = \lim_{n\to\infty} G_n(s,t)$. Since $h_n(s,t) = (\psi_n(s),t)$ is continuous and hence Borel measurable, so is $G_n = F \circ h_n$, and therefore $G$ is Borel measurable by XIV.11.

We claim $G$ is a catalog for $\mathcal{F}^*$. Suppose $(f_n)$ is a sequence in $\mathcal{F}$ with $f_n \to f$ pointwise. For each $n$ there is an $s_n \in [0,1]$ such that $f_n(t) = F(s_n,t)$ for all $t$. There is an $s \in [0,1]$ such that $s_n = \psi_n(s)$ for all $n \,$. Then $G(s,t) = f(t)$ for all $t \in \mathbb{R}$.

We next show that $\mathcal{B}C_\alpha$ has a catalog for $\alpha$ countable.

Definition. If $\mathcal{F}$ and $\mathcal{G}$ are sets of Borel measurable functions, we say $\mathcal{G}$ is locally uniformly dense in $\mathcal{F}$ if, for every $f \in \mathcal{F}$, $\epsilon > 0$, and $n \in \mathbb{N}$, there is a $g \in \mathcal{G}$ with $|f(t) - g(t)| < \epsilon$ for all $t \in [-n,n]$.

We usually apply this definition when $\mathcal{G} \subseteq \mathcal{F}$.

Example. Here is the most important example for us. Let $\mathcal{Q}$ be the set of polynomials with rational coefficients. Then by the Weierstrass Approximation Theorem $(),$ $\mathcal{Q}$ is locally uniformly dense in the set $\mathcal{C}$ of continuous functions from $\mathbb{R}$ to $\mathbb{R}$.

Proposition. If $\mathcal{G}$ is locally uniformly dense in $\mathcal{F}$, then $\mathcal{F}^* \subseteq \mathcal{G}^*$. (If $\mathcal{G} \subseteq \mathcal{F}$, it follows that $\mathcal{G}^* = \mathcal{F}^*$.)

Proof: Suppose $f_n \in \mathcal{F}$ and $f_n \to f$ pointwise. For each $n$, choose $g_n \in \mathcal{G}$ with $|f_n(t) - g_n(t)| < \frac{1}{n}$ for all $t \in [-n,n]$. Then it is easily checked that $g_n \to f$ pointwise.

In particular, we have $\mathcal{Q}^* = \mathcal{C}^* = \mathcal{B}C_1$.

Proposition. $\mathcal{B}C_\alpha$ has a catalog for every countable $\alpha$.

Proof: $\mathcal{Q}$ is countable, so it has a catalog by ??, Thus $\mathcal{Q}^* = \mathcal{B}C_1$ has a catalog by XIV.11.

Now proceed by transfinite induction. If $\mathcal{B}C_\alpha$ has a catalog, then $\mathcal{B}C_{\alpha+1}$ has a catalog by XIV.11. And if $\alpha$ is a countable limit ordinal, then $\mathcal{B}C_\alpha = \cup_{\beta < \alpha} \mathcal{B}C_\beta$, a countable union, so $\mathcal{B}C_\alpha$ has a catalog by ??.

The next result finishes the proof of ??, The proof is strongly reminiscent of Cantor’s diagonalization argument.

Proposition. $\mathcal{B}$ does not have a catalog.

Proof: Suppose $F$ is a catalog for $\mathcal{B}$. Define $f : \mathbb{R} \to \mathbb{R}$ by $f(t) = F(t,t) + 1$ if $t \in [0,1]$, and $f(t) = 0$ otherwise. Then $f|_{[0,1]}$ is a composition of two Borel measurable functions, hence Borel measurable; so $f$ is Borel measurable by $(,)$. Since $F$ is a catalog, there is an $s \in [0,1]$ such that $f(t) = F(s,t)$ for all $t$. But $f(s) = F(s,s) + 1 \neq F(s,s)$, a contradiction.

This completes the proof of ??, We have the following consequence:

Corollary. For any countable $\alpha$, $\mathcal{B}C_\alpha$ is a proper subset of $\mathcal{B}$. Thus the $\mathcal{B}C_\alpha$ are strictly increasing for $\alpha$ countable.

Proof: Suppose $\mathcal{B}C_\alpha = \mathcal{B}$ for some countable $\alpha$. Since $\mathcal{B}C_\alpha$ is an algebra of functions $()$, it follows that every simple Borel measurable function is in $\mathcal{B}C_\alpha$. Hence every Borel measurable function is in $\mathcal{B}C_{\alpha+1}$ by $(,)$, a contradiction.
If $\alpha < \beta < \omega_1$ and $\mathcal{B}_\alpha = \mathcal{B}_\beta$, any countable intersection of sets in $\mathcal{B}_\alpha$ is in $\mathcal{B}_\alpha+1 \subseteq \mathcal{B}_\beta = \mathcal{B}_\alpha$ by (1), and so it follows from (1) that $\mathcal{B}_\alpha$ is a $\sigma$-algebra and hence $\mathcal{B}_\alpha = \mathcal{B}$, a contradiction.  

We then have a fortiori that $\mathcal{B}_\alpha \neq \mathcal{B}_\beta$ for $\alpha < \beta < \omega_1$.

**XIV.12. Exercises**

1. Describe the “motion” of $\phi(t)$ through the unit square as $t$ goes from 0 to 1. [First describe $\phi(t)$ for $t \in \left[\frac{1}{3}, \frac{2}{3}\right]$, $t \in \left[\frac{1}{5}, \frac{2}{5}\right]$, $t \in \left[\frac{7}{9}, \frac{8}{9}\right]$, etc., and then find $\phi([0, \frac{1}{3}])$, $\phi([\frac{2}{3}, 1])$, $\phi([0, \frac{1}{9}])$, $\phi([\frac{2}{9}, \frac{1}{3}])$, etc.]

2. An occasional attempt is made to define a space-filling curve $\omega$ from $[0, 1]$ onto $[0, 1]^2$ by the formula

$$\omega(.b_1 b_2 b_3 \cdots) = (.b_1 b_3 b_5 \cdots , b_2 b_4 b_6 \cdots)$$

where the $b_n$ (0 or 1) are binary digits. Show why this approach does not work. Try to modify the formula to give a well-defined continuous surjection.

3. Each of the coordinate functions of $\phi$ or $\psi$ is a continuous function from $[0, 1]$ to $[0, 1]$ taking each value in $[0, 1]$ uncountably many times. [Fix $a \in [0, 1]$. For each $b \in [0, 1]$ there is a $t_b \in [0, 1]$ such that $\phi(t_b) = (a, b)$, so $\phi_1(t_b) = a$ for all $b$.]
XIV.12.1. A Plane Curve With Positive Area

It is easy to give examples of topologically one-dimensional, and even zero-dimensional, compact subsets of $\mathbb{R}^2$ which have positive planar (Lebesgue) measure (e.g. XIV.12.1.4.). In this section, we construct a simple closed curve in $\mathbb{R}^2$ (Jordan curve), i.e. a subset of $\mathbb{R}^2$ homeomorphic to $S^1$, which has positive planar measure.

Such a set, regarded as a curve, must be highly nondifferentiable: the image of a piecewise continuously differentiable curve (or, more generally, a Lipschitz function) has Hausdorff dimension 1, and hence plane measure 0 ().

The first example of a simple closed curve with positive planar measure was given by Osgood in 1902 ([Osg03], complete with color pictures!); another example was constructed by Besicovitch and Schoenberg in [BS61].

Cantor Sets

XIV.12.1.1. Recall one standard construction of Cantor sets in $\mathbb{R}$.

Let $\alpha$ be a real number $\geq 3$. The Cantor set $K_\alpha$ is constructed by beginning with the closed unit interval $[0,1]$ and at the $n$’th stage removing the open subintervals of length $\alpha^{-n}$ centered in each of the $2^{n-1}$ remaining intervals; $K_\alpha$ is the intersection. $K_\alpha$ is a compact totally disconnected set without isolated points, homeomorphic to a countable product of two-point spaces.

Since the total length of the removed subintervals is

$$\sum_{n=1}^{\infty} \frac{2^{n-1}}{\alpha^n} = \frac{1}{\alpha} \sum_{m=0}^{\infty} \left(\frac{2}{\alpha}\right)^m = \frac{1}{\alpha(1 - \frac{2}{\alpha})} = \frac{1}{\alpha - 2},$$

we obtain that the (one-dimensional) Lebesgue measure of $K_\alpha$ is

$$1 - \frac{1}{\alpha - 2} = \frac{\alpha - 3}{\alpha - 2}.$$  

XIV.12.1.2. The usual Cantor set is $K_3$, just denoted $K$. The measure of $K$ is zero. $K$ consists precisely of all elements of $[0,1]$ with a ternary (base 3) decimal expansion consisting only of 0’s and 2’s, and every element of $K$ has a unique such expansion.

XIV.12.1.3. Given any $\alpha$ and $\beta$, there is an evident homeomorphism of $\mathbb{R}$ (strictly increasing function) carrying $K_\alpha$ onto $K_\beta$. (Note that this shows the well-known fact () that a homeomorphism of $\mathbb{R}$ need not preserve sets of measure zero.)

XIV.12.1.4. If $K_\alpha^2 = K_\alpha \times K_\alpha$, then $K_\alpha^2$ is a compact subset of $[0,1]^2$ homeomorphic to $K$ (a specific homeomorphism will be described below.) The planar measure of $K_\alpha^2$ is

$$\left(\frac{\alpha - 3}{\alpha - 2}\right)^2.$$
A Wandering Curve

We will construct a homeomorphic image of $[0, 1]$ passing through every point of $K^2_\alpha$; thus if $\alpha > 3$ the image will have positive planar measure.

For notational simplicity, we will describe the construction for $\alpha = 3$. The construction for $\alpha > 3$ can be done directly in an analogous way, or by simply composing the curve for $\alpha = 3$ with a homeomorphism of $\mathbb{R}^2$ sending $K^2$ onto $K^2_\alpha$.

**XIV.12.1.5.** We first define an auxiliary function

$$
\psi : \{0\} \cup [1/9, 2/9] \cup [1/3, 2/3] \cup [7/9, 8/9] \cup \{1\} \to [0, 1]^2
$$

by setting $\psi(0) = (0, 0)$, $\psi(1/9) = (0, 1/3)$, $\psi(2/9) = (0, 2/3)$, $\psi(1/3) = (1/3, 2/3)$, $\psi(2/3) = (2/3, 2/3)$, $\psi(7/9) = (1, 2/3)$, $\psi(8/9) = (1, 1/3)$, $\psi(1) = (1, 1)$, and letting $\psi$ be linear (affine) on each of the subintervals. See Figure XIV.23.

![Figure XIV.23: The auxiliary function $\psi$](image)

**XIV.12.1.6.** Before defining the curve $\phi : [0, 1] \to [0, 1]^2$, let us make a definition. A square $S$ with sides parallel to the axes, of length $3^{-n}$ for some $n$, will be called *full* if the four corners of $S$ are in the closure of the intersection of $K^2$ with the interior of $S$. The whole unit square is full; and if a full square is divided into nine subsquares, it is the four corner subsquares which are also full.

**XIV.12.1.7.** We will now define $\phi$ in stages. It is convenient to do the first step of the definition somewhat differently from the others, in order to have $\phi(0) = (1/3, 0)$ and $\phi(1) = (2/3, 0)$; then the segment from $(2/3, 0)$ back to $(1/3, 0)$ can be added to give a simple closed curve. (This segment will be included in the pictures.) So in addition to these definitions of $\phi(0)$ and $\phi(1)$, in the first step we define $\phi$ on $[1/9, 2/9]$ to map linearly to the segment from $\phi(1/9) = (1/3, 1/3)$ to $\phi(2/9) = (1/3, 2/3)$; define $\phi$ on $[1/3, 2/3]$ to
map linearly to the segment from $\phi(1/3) = (1/3, 1)$ to $\phi(2/3) = (2/3, 1)$, and similarly $\phi$ maps $[7/9, 8/9]$ linearly to the segment from $\phi(7/9) = (2/3, 2/3)$ to $\phi(8/9) = (2/3, 1/3)$.

**XIV.12.1.8.** We now proceed inductively. After the $n$’th step $\phi$ is defined except on open intervals of the form $(k/9^n, k+1)/9^n$, where $k$ is 0, 2, 6, or 8 mod 9. For each such $k$, there is a unique full square $S$ with adjacent corners $\phi(k/9^n)$ and $\phi((k+1)/9^n)$, and a unique affine map $\theta$ from the unit square onto $S$ with $\theta(0, 0) = \phi(k/9^n)$ and $\theta(1, 0) = \phi((k+1)/9^n)$. Then for $t \in [1/9, 2/9] \cup [1/3, 2/3] \cup [7/9, 8/9]$ define

$$\phi\left(\frac{k + t}{9^n}\right) = \theta \circ \psi(t)$$

After the third step, the curve looks like Figure XIV.24.

![Figure XIV.24: Three steps of the definition of $\phi$](image)

**XIV.12.1.9.** After the inductive construction, $\phi$ is defined on a dense subset of $[0, 1]$. By construction, if $s, t \in [0, 1]$ and $|s - t| < 9^{-n}$, and $\phi(s)$ and $\phi(t)$ are defined, then $\|\phi(s) - \phi(t)\| < 3^{-n}\sqrt{2}$; thus $\phi$ is uniformly continuous and extends to a continuous map from all of $[0, 1]$ to $[0, 1]^2$.

**XIV.12.1.10.** Proposition. The image of $\phi$ contains $K^2$.

Proof: This is obvious, since after the $n$’th step in the construction every point of $K^2$ lies within $3^{-n}\sqrt{2}$ of a point on the curve.

1658
XIV.12.1.11. **Proposition.** The map $\phi$ is a homeomorphism onto its image.

**Proof:** By compactness, it is only necessary to show that $\phi$ is one-to-one. It clearly maps $[0,1]\setminus K$ one-one into $[0,1]^2\setminus K^2$, so we need only show that $\phi$ maps $K$ one-one into (actually onto) $K^2$. This is geometrically clear, but is rather complicated to write down explicitly. In fact, there is a precise (but complicated) formula giving the first $n$ places of the ternary decimal expansion of the two coordinates of $\phi(t)$ ($t \in K$) in terms of the first $2n$ places of the ternary decimal expansion of $t$. For example, if $t = a_1a_2 \cdots$, $\phi(t) = (b_1 \cdots, c_1 \cdots)$, where $b_1$ is always equal to $a_1$ and $c_1 = a_2$ if $a_1 = 0$, $c_1 = 2 - a_2$ if $a_1 = 2$. It can be checked that if $s, t \in K$ differ in the first $2n$ ternary decimal places, then $\phi(s)$ and $\phi(t)$ differ in the first $n$ ternary decimal places in at least one coordinate.  

XIV.12.1.12. The final curve is depicted in Figure XIV.25. The curve has a fractal character in that all of the full squares with sides of length $\leq 1/3$ are similar up to scaling and rotation.

![Figure XIV.25: The closed curve $\phi$](image)
Connection with Space-Filling Curves

XIV.12.13. This construction bears a close resemblance to one version of the Peano space-filling curve (see, for example, [Edg08, p. 64]). We obtain a space-filling curve by composing $\phi$ with $p \times p$, where $p$ is the usual map from $K$ onto $[0, 1]$ given by

$$p(a_1a_2a_3\cdots) = .b_1b_2b_3\cdots$$

where $a_1a_2\cdots$ is the ternary decimal expansion of $t \in K$, and $b_1b_2\cdots$ is the binary decimal expansion of $p(t)$, with $b_n = a_n/2$. The resulting map $(p \times p) \circ \phi$ maps $[0, 1]$ continuously onto $[0, 1]^2$. (It should be thought of as being constant on the intervals of $[0, 1]_K$.)

XIV.12.14. The map $p$ is not one-to-one since the binary decimal expansion of dyadic rational numbers is not unique, and any cross section $q : [0, 1] \rightarrow K$ for $p$ is necessarily discontinuous; however, the map $\sigma = (p \times p) \circ \phi \circ q$ is continuous and independent of $q$, and maps $[0, 1]$ onto $[0, 1]^2$. This map $\sigma$ is a more usual type of space-filling curve.

Summary and Variations

XIV.12.15. If $C_\alpha$ is the image of the curve $\phi$ done for the Cantor set $K_\alpha$, with the last segment filled in between the endpoints, then $C_\alpha$ is a simple closed curve, contained in $[0, 1]^2$, with planar measure at least the measure of $K_\alpha^2$. Actually, $C_\alpha$ is the union of $K_\alpha^2$ and a countable number of straight line segments, so the measure of $C_\alpha$ is exactly

$$\left(\frac{\alpha - 3}{\alpha - 2}\right)^2.$$

This can be any (nonnegative) number less than 1. If $\alpha$ is large enough ($\alpha > 4 + \sqrt{2}$ will do), the measure of this curve is greater than the measure of the region inside the curve!

There cannot be a simple closed curve in $[0, 1]^2$ of planar measure exactly one, since any nonempty open set in the plane has positive measure.

XIV.12.16. The curve $C_\alpha$ is a Jordan curve, but the region inside the curve is an open set in $\mathbb{R}^2$ (homeomorphic to an open disk) which is not a Jordan region () if $\alpha > 3$ since its boundary does not have measure zero.

XIV.12.17. The example in [BS61] has the additional property that for any $s, t, 0 \leq s < t \leq 1$, the arc from $\phi(s)$ to $\phi(t)$ has positive planar measure. Our example can be modified to have this property, by replacing each straight line segment by countably many small versions of the curve.

XIV.12.18. It would appear that a construction similar to the one of this section can be done in $[0, 1]^n$ for any $n$, giving a simple closed curve passing through every point of $K_\alpha^n$ and thus having positive $n$-dimensional Lebesgue measure. However, the details might be complicated to write carefully. Perhaps a similar construction can even be done in the Hilbert cube. See [PS92] for a version of OSGOOD’S example in $\mathbb{R}^n$. 

1660
XIV.13. Borel Measures on $\mathbb{R}$ and Cumulative Distribution Functions

A finite Borel measure on $\mathbb{R}$ is a finite measure defined on $(\mathbb{R}, B)$. We will also study finite Borel measures on intervals in $\mathbb{R}$, and defined in the same way, and $\sigma$-finite Borel measures on $\mathbb{R}$ which are finite on bounded sets (positive Radon measures). Such measures are important in many contexts, and especially in probability theory.

XIV.13.1. Cumulative Distribution Functions

We would like to have a way of describing the finite Borel measures on $\mathbb{R}$ (or an interval in $\mathbb{R}$). If $\mu$ is a finite Borel measure on $\mathbb{R}$, for each $x \in \mathbb{R}$ we can compute $\mu((1; x])$. It turns out that these numbers are sufficient to recover $\mu$ by the Carathéodory extension process (\()\). This data is conveniently described by a function $F$ from $\mathbb{R}$ to $\mathbb{R}$, setting $F(x) = \mu((1; x])$. Then if $a, b \in \mathbb{R}$, $a < b$, we have $\mu((a, b]) = F(b) - F(a)$.

**Definition.** $F$ is called the cumulative distribution function (or cdf) of $\mu$.

**Proposition.** The function $F$ has the following properties:

(i) $F$ is increasing (nondecreasing).

(ii) $F$ is continuous from the right.

(iii) $\lim_{x \to -\infty} F(x) = 0$.

(iv) $F$ is bounded, and $\sup_{x \in \mathbb{R}} F(x) = \lim_{x \to +\infty} F(x) = \mu(\mathbb{R})$.

**Proof:** (i) is obvious, and (iii) and (iv) follow immediately from (i) since $\bigcup_{n \in \mathbb{N}} (-\infty, n] = \mathbb{R}$ and $\bigcap_{n \in \mathbb{N}} (-\infty, -n] = \emptyset$. (ii) also follows from (i) since for any $x \in \mathbb{R}$, $(-\infty, x] = \bigcap_{n \in \mathbb{N}} (-\infty, x + \frac{1}{n}]$.

The choice to make cdf’s continuous from the right is simply an arbitrary convention. We could have equally well made them continuous from the left by defining $F'_\mu(x) = \mu((-\infty, x))$.

Conversely, a function satisfying (i)–(iv) is the cdf of a unique finite Borel measure:

**Theorem.** Let $F : \mathbb{R} \to \mathbb{R}$ be a function with the following properties:

(i) $F$ is increasing (nondecreasing).

(ii) $F$ is continuous from the right.

(iii) $\lim_{x \to -\infty} F(x) = 0$.

(iv) $F$ is bounded.

Then there is a unique finite Borel measure $\mu$ on $\mathbb{R}$ with $F = F_\mu$, and $\mu(\mathbb{R}) = \sup_{x \in \mathbb{R}} F(x) = \lim_{x \to +\infty} F(x)$.

This theorem will be proved in (\()). The finite Borel measure $\mu$ for which $F = F_\mu$ is called the Lebesgue-Stieltjes measure of (or corresponding to) $F$. If $g$ is a $\mu$-integrable function, $\int g \, d\mu$ is sometimes written $\int g \, dF$ and called the Lebesgue-Stieltjes integral of $g$ with respect to $F$. 

1661
If \( F \) is a nondecreasing function from \( \mathbb{R} \) to \( \mathbb{R} \) and \( E \) is a subset of \( \mathbb{R} \), write \( F^{-1}(E) \) for the “image” of \( E \), saturated by adding intervals for jump discontinuities of \( F \) as in (\).

**Theorem.** Let \( \mu \) be a finite Borel measure on \( \mathbb{R} \), with cdf \( F_\mu \). If \( E \) is any Borel subset of \( \mathbb{R} \), then \( F_\mu^{-1}(E) \) is a Borel set, and \( \mu(E) = \lambda(F_\mu^{-1}(E)) \).

Note that this result is false, even meaningless, if \( E \) is merely a Lebesgue measurable subset of \( \mathbb{R} \); \( F_\mu^{-1}(E) \) need not be Lebesgue measurable (\), and \( \mu(E) \) may not be defined.

**XIV.13.2. Density Functions and Absolute Continuity**

For some, but not all, finite Borel measures, there is a corresponding density function. If \( \mu \) is a finite Borel measure on \( \mathbb{R} \), and there is a Borel measurable function \( \phi \) from \( \mathbb{R} \) to \( \mathbb{R} \) (necessarily nonnegative and integrable) such that \( \mu(E) = \int_E \phi \, d\lambda \) for all Borel sets \( E \subseteq \mathbb{R} \), then \( \phi \) is called a density function for \( \mu \). Two density functions for \( \mu \) must agree almost everywhere (with respect to \( \lambda \)), so by slight abuse of terminology we may refer to the density function of \( \mu \). Any nonnegative integrable function \( \phi \) on \( \mathbb{R} \) is the density function of a unique measure \( \mu_\phi \), defined by \( \mu_\phi(E) = \int_E \phi \, d\lambda \) for \( E \subseteq \mathbb{R} \) Borel.

The function \( \phi \) can be thought of as the “derivative” of the function \( F_\mu \) in a certain sense. This is a precise relationship in nice cases:

**Example.** Let \( \phi \) be a nonnegative continuous function on \( \mathbb{R} \) with \( \int_{-\infty}^{\infty} \phi(t) \, dt \) finite. For a Borel set \( E \subseteq \mathbb{R} \), set \( \mu_\phi(E) = \int_E \phi \, d\lambda \) as above. Then, for \( a, b \in \mathbb{R}, a < b \), we have

\[
F_{\mu_\phi}(b) - F_{\mu_\phi}(a) = \mu_\phi((a, b]) = \int_a^b \phi(t) \, dt
\]

and thus by the Fundamental Theorem of Calculus (\), \( F_{\mu_\phi} \) is an antiderivative for \( \phi \), i.e. \( F_{\mu_\phi} \) is differentiable and \( F'_{\mu_\phi} = \phi \).

This example generalizes to arbitrary density functions \( \phi \):

**Theorem.** Let \( \phi \in L^1_+(\mathbb{R}) \), and \( F_{\mu_\phi} \) the cdf of the corresponding measure \( \mu_\phi \) with density function \( \phi \). Then \( F_{\mu_\phi} \) is continuous, differentiable \( \lambda \)-a.e., and \( F'_{\mu_\phi} = \phi \) \( \lambda \)-a.e.

This theorem will be proved in (\).

A finite Borel measure need not have a density function. Its cdf need not even be continuous:

**Example.** Let \( \delta_0 \) be the Dirac measure (unit point mass) at 0. Then

\[
F_{\delta_0}(x) = \begin{cases} 
1 & \text{if } x \geq 0 \\
0 & \text{if } x < 0
\end{cases}
\]

In fact, the cdf of a finite Borel measure \( \mu \) is a continuous function if and only if \( \mu \) is a continuous measure: in general, for \( x \in \mathbb{R} \),

\[
F_\mu(x+) - F_\mu(x-) = F_\mu(x) - F_\mu(x-) = \mu(\{x\})
\]

1662
where, as usual, \( F_\mu(x+) = \lim_{y \to x^+} F_\mu(y) \) and \( F_\mu(x-) = \lim_{y \to x^-} F_\mu(y) \). (This fact was crucial motivation for the choice of the term “continuous” for a measure with no atoms.)

But even a continuous \( \mu \) need not have a density function:

**Example.** Let \( F \) be the Cantor function on \([0,1]\), extended to be 0 on \((-\infty,0]\) and 1 on \([1,\infty)\). \( F \) satisfies the conditions of XIV.13.1, and thus it is \( F_\mu \) for a unique continuous finite Borel measure \( \mu \) on \( \mathbb{R} \) with \( \mu([0,1]) = 1 \). If \( \mu \) had a density function \( \phi \), then \( \phi \) would have to be equal to \( F' \) \( \lambda \)-a.e. But \( F' = 0 \) \( \lambda \)-a.e., so \( \phi \) would have to be 0 \( \lambda \)-a.e. and \( \mu \) would be 0. Thus \( \mu \) has no density function.

This \( \phi \) is not absolutely continuous with respect to \( \lambda \). For example, if \( K \) is the Cantor set, \( \lambda(K) = 0 \), but \( \mu(K) = 1 \): this follows from XIV.13.1, but can also easily be seen directly by noting that \( \mu(I) = 0 \) for any interval \( I \) in the complement of \( K \), since \( F \) is constant on \( I \). This \( \mu \) is actually the push-forward of the measure of \( \phi \) under the natural map from \( \{0,1\}^\mathbb{N} \) to \( K \subseteq \mathbb{R} \).

So which finite Borel measures have density functions? It follows immediately from (i) that for \( \mu \) to have a density function, it is necessary for \( \mu \) to be absolutely continuous with respect to \( \lambda \). This condition also turns out to be sufficient:

**Theorem.** A finite Borel measure has a density function if and only if it is absolutely continuous with respect to \( \lambda \).

The “if” part of this theorem is a special case of the Radon-Nikodým Theorem (i).

**Corollary.** A finite Borel measure \( \mu \) is absolutely continuous with respect to \( \lambda \) if and only if its cdf \( F_\mu \) is absolutely continuous in the sense of (i).

In fact, this result is the reason behind the choice of the term “absolutely continuous” for the functions of (i).

Even if \( \mu \) does not have a density function, it has a density in a generalized sense (i), which is the “derivative” of \( F_\mu \). Thus, for example, we informally think of the “Dirac \( \delta \)-function” as the “derivative” of the function \( \chi_{[0,\infty)} \). We can think of the actual measure \( \mu \) as being identified with \( F_\mu \), in which case the “density” of \( \mu \) is regarded as the “derivative” of \( \mu \), or we can regard \( \mu \) as being identified with its “density”, with \( F_\mu \) regarded as the “antiderivative” of \( \mu \). The second point of view is more common.

**XIV.13.3. Finite Borel Measures on Intervals**

If \( I \) is an interval in \( \mathbb{R} \), then finite Borel measures on \( I \) can be thought of as finite Borel measures on \( \mathbb{R} \) giving measure 0 to \( \mathbb{R} \setminus I \). The cdf of such a measure is constant on \( \mathbb{R} \setminus I \).

If \( I \) is bounded above, and \( b = \sup(I) \), then the cdf \( F_\mu \) of a finite Borel measure \( \mu \) on \( I \) must satisfy \( F_\mu(b) = \mu(I) \) (= \( \mu(\mathbb{R}) \)). If \( b \notin I \), then \( F_\mu \) is continuous at \( b \); but if \( b \in I \), then \( F_\mu \) can have a discontinuity at \( b \) if \( \mu(\{b\}) > 0 \). In any event, \( \mu(I) = \sup_{x \in I} F_\mu(x) \).

If \( I \) is bounded below with \( a = \inf(I) \), then \( F_\mu \) is identically 0 on \( (-\infty,a) \), but if \( a \in I \), then \( F_\mu(a) = \mu(\{a\}) \), so \( \inf_{x \in I} F_\mu(x) \) is not necessarily 0. But if \( a \notin I \), then we must have \( \inf_{x \in I} F_\mu(x) = 0 \).

**XIV.13.4. Unbounded Distribution Functions and Positive Radon Measures**

The requirement that \( \lim_{x \to -\infty} F(x) = 0 \) for a cdf \( F \) is a convenient normalization, but is not really necessary. If \( \mu \) is a finite Borel measure on \( \mathbb{R} \), \( c \) is any constant, and \( G(x) = F_\mu(x) + c \), then \( G \) can be used just as well.
as $F_\mu$ to recover $\mu$, since for any finite interval $(a, b]$, we have

$$\mu((a, b]] = F_\mu(b) - F_\mu(a) = G(b) - G(a).$$

If $F_\mu$ is regarded as an “antiderivative” of $\mu$, then the general “antiderivative” of $\mu$ is a constant translate of $F_\mu$, and one antiderivative is as good as another for most purposes.

Taking this observation one step farther, if $F$ is any nondecreasing, right-continuous function from $\mathbb{R}$ to $\mathbb{R}$, not necessarily bounded above or below, then $F$ has a Lebesgue-Stieltjes measure $\mu$ defined by the Carathéodory extension process using $\mu((a, b]) = F(b) - F(a)$ for $a, b \in \mathbb{R}$, $a < b$, and $F$ can be regarded as a cdf for $\mu$. This $\mu$ is a positive Radon measure (finite on bounded sets) which is always $\sigma$-finite, but not finite if $F$ is unbounded. Two nondecreasing right-continuous functions define the same Lebesgue-Stieltjes measure if and only if they differ by a constant. The function $F(x) = x$ is the cdf of Lebesgue measure itself.

If $F$ is such a cdf, and $a, b \in \mathbb{R}$, then $F$ can be truncated at $a$ and $b$ to a function $G$ by setting

$$G(x) = \begin{cases} F(a-) & \text{if } x < a \\ F(x) & \text{if } a \leq x \leq b \\ F(b) & \text{if } x > b \end{cases}.$$ 

Then $G$ is a cdf for the measure $\mu_{[a, b]}$, which is a finite Borel measure. Thus the study of positive Radon measures on $\mathbb{R}$ and their cdf’s can be effectively reduced to the theory of finite Borel measures.

The theory can be further extended by allowing $F$ to take extended real values. Then $\{x : F(x) \in \mathbb{R}\}$ is an interval $I$, and $F$ may be thought of as a positive Radon measure on $I$, i.e. finite on closed subintervals in the interior of $I$.

**Example.** Let $F(x) = \tan x$ for $-\pi/2 < x < \pi/2$. Set $F = -\infty$ on $(-\infty, -\pi/2]$ and $+\infty$ on $[\pi/2, \infty)$. Then $F$ is the cdf of a $\sigma$-finite Borel measure $\mu$ on $(-\pi/2, \pi/2]$ which is finite on any closed subinterval. This $\mu$ is absolutely continuous with respect to $\lambda|(-\pi/2, \pi/2)$, and has density function $g(x) = \sec^2 x$.

**XIV.13.5. Signed Measures and Nonincreasing Distribution Functions**

Using the theory of signed measures, many of the results of this section generalize to cdf’s which are not increasing. There are considerable complications in this case, but also important applications. Details are found in (1).
XIV.14. Monotone Functions

In this section, we describe the properties of monotone functions.

XIV.14.1. Definitions and Basics

XIV.14.1.1. Definition. Let $I$ be an interval. A function $f : I \to \mathbb{R}$ is nondecreasing on $I$ if $f(x) \leq f(y)$ whenever $x, y \in I$ and $x < y$, and nonincreasing on $I$ if $f(x) \geq f(y)$ whenever $x, y \in I$ and $x < y$. A function is monotone on $I$ if it is either nondecreasing or nonincreasing on $I$.

XIV.14.1.2. A nondecreasing function is sometimes called increasing, but this term is somewhat ambiguous. If $f(x) < f(y)$ whenever $x, y \in I$, $x < y$, we will say that $f$ is strictly increasing on $I$. A strictly increasing function is, of course, nondecreasing. Strictly decreasing functions are defined analogously. A function is strictly monotone on $I$ if it is strictly increasing or strictly decreasing on $I$. “Increasing” could potentially mean either “nondecreasing” or “strictly increasing,” and different authors use both meanings. We will avoid using the terms “increasing” and “decreasing” with regard to functions on intervals.

XIV.14.1.3. We will work with monotone functions on a closed bounded interval $[a, b]$ for simplicity. Analogous results hold for monotone functions on intervals which are not closed and/or not bounded, but there are some technical complications (e.g. such functions need not be bounded). We will also concentrate on the case of nondecreasing functions; the nonincreasing case is essentially identical with only a few notational changes needed.

The first result is almost obvious.

XIV.14.1.4. Proposition. Let $f$ be a monotone function on $[a, b]$. Then $f$ is bounded on $[a, b]$.

Proof: If $f$ is nondecreasing on $[a, b]$, then $f(a) \leq f(x) \leq f(b)$ for all $x \in [a, b]$. The argument for nonincreasing functions is almost identical. 

One of the most important facts about monotone functions is that they are “almost continuous”, and that the only possible discontinuities are of a very simple form.

XIV.14.1.5. Definition. Let $f$ be a function defined in a neighborhood of $c \in \mathbb{R}$, and $h > 0$. Then $f$ has a jump discontinuity of height $h$ at $c$ if $\lim_{x \to c^+} f(x)$ and $\lim_{x \to c^-} f(x)$ both exist and

$$ \left| \lim_{x \to c^+} f(x) - \lim_{x \to c^-} f(x) \right| = h $$

(One could also keep track of the sign of the jump by removing the absolute values and allowing $h < 0$.)

XIV.14.1.6. If $\lim_{x \to c^+} f(x)$ exists, we will denote it by $f(c^+)$. Similarly, if $\lim_{x \to c^-} f(x)$ exists, we will denote it by $f(c^-)$. We will extend this notation and the notion of a jump discontinuity at an endpoint of the domain of a function $f$: if $a$ is the left endpoint of the domain, set $f(a^-) = f(a)$, and at the right endpoint $b$ set $f(b^+) = f(b)$.
XIV.14.1.7. Proposition. Let \( f \) be a monotone function on an interval \( I \), and \( c \in I \). Then \( f(c+) \) and \( f(c-) \) both exist, and \( f(c) \) satisfies

\[
    f(c-) \leq f(c) \leq f(c+) \quad \text{if } f \text{ is nondecreasing on } I.
\]

\[
    f(c-) \geq f(c) \geq f(c+) \quad \text{if } f \text{ is nonincreasing on } I.
\]

If \( d \in I \) and \( c < d \), and \( f \) is nondecreasing [resp. nonincreasing], then \( f(c+) \leq f(d-) \) [resp. \( f(c+) \geq f(d-) \)].

Proof: We will suppose \( c \) is an interior point of \( I \); the case of an endpoint is similar but easier. Suppose \( f \) is nondecreasing on \( I \). Set \( u = \inf_{x>c} f(x) \). Since \( f(c) \leq f(x) \) for all \( x > c \), \( f(c) \) is a lower bound for \( \{ f(x) : x > c \} \), so \( u \) exists and \( f(c) \leq u \). We claim \( u = f(c+) \). Let \( \epsilon > 0 \). There is a \( y > c \) with \( f(y) < u + \epsilon \), by definition of \( u \). Set \( \delta = y - c \); then \( \delta > 0 \) and, if \( c < x < c + \delta \), then \( c < x < y \) and \( u \leq f(x) \leq f(y) < u + \epsilon \), so \( |f(x) - u| < \epsilon \). Similarly, if \( v = \sup_{x<c} f(x) \), then \( v = f(c-) \) and \( v \leq f(c) \). If \( d > c \), choose \( x \) with \( c < x < d \); then \( f(c+) \leq f(x) \leq f(d-) \). The proof for nonincreasing \( f \) is almost identical.

It follows that if \( f \) is monotone on \( I \) and \( c \in I \), then either \( f \) is continuous at \( c \) (if \( f(c-) = f(c+) \)), or \( f \) has a jump discontinuity at \( c \) (if \( f(c-) \neq f(c+) \)).

XIV.14.1.8. Proposition. Let \( f \) be monotone on a closed interval \( [a, b] \), with jump discontinuities at \( x_1, \ldots, x_n \in [a, b] \). Let \( h_j \) be the height of the jump discontinuity of \( f \) at \( x_j \). If \( M = |f(b) - f(a)| \), then \( \sum_{j=1}^{n} h_j \leq M \).

Proof: Suppose \( f \) is nondecreasing. We may assume

\[
    a \leq x_1 < x_2 < \cdots < x_n \leq b
\]

so we have

\[
    f(a) \leq f(x_1-) < f(x_1+) \leq f(x_2-) < f(x_2+) \leq \cdots \leq f(x_n-) < f(x_n+) \leq f(b)
\]

Thus,

\[
    h_1 + \cdots + h_n = [f(x_1+) - f(x_1-)] + \cdots + [f(x_n+) - f(x_n-)]
\]

\[
    \leq [f(x_1+) - f(a)] + [f(x_2+) - f(x_1+)] + \cdots + [f(b) - f(x_{n-1}+)] = M
\]

The case of nonincreasing \( f \) is the same with some inequalities reversed.

XIV.14.1.9. Corollary. Let \( f \) be monotone on \( [a, b] \), and \( \epsilon > 0 \). If \( M = |f(b) - f(a)| \), then \( f \) has no more than \( M/\epsilon \) jump discontinuities on \([a, b]\) of height \( \geq \epsilon \).

We summarize these results in a theorem.
XIV.14.1.10. THEOREM. Let \( f \) be monotone on an interval \( I \). Then \( f \) has only countably many discontinuities on \( I \), each of which is a jump discontinuity.

**Proof:** We have proved everything except the countability of the set of discontinuities. But if \([a, b] \subseteq I\), and \( M = |f(b) - f(a)|\), then for each \( n \in \mathbb{N} \), \( f \) has only finitely many jump discontinuities of height \( \geq \frac{1}{n} \) (no more than \( Mn \)) on \([a, b]\), and hence only countably many jump discontinuities in all. Since \( I \) is a countable union of closed bounded subintervals, \( f \) can only have countably many jump discontinuities on all of \( I \). \( \square \)

XIV.14.1.11. COROLLARY. Let \( f \) be a monotone function on an interval \( I \). Then there is a monotone function \( g \) on \( I \) which is right continuous on \( I \), and which agrees with \( f \) except at countably many points.

**Proof:** For \( x \in I \), set \( g(x) = f(x+) \). Wherever \( f \) is continuous, \( f(x) = f(x+) = g(x) \). \( \square \)

The same result holds if \( g \) is to be left continuous: set \( g(x) = f(x-) \) for all \( x \).

XIV.14.2. Differentiability of Monotone Functions

A much deeper and more remarkable result is true about monotone functions: they are not only continuous almost everywhere, but even differentiable almost everywhere. This result is due to Lebesgue.

XIV.14.2.12. THEOREM. Let \( f \) be monotone on an interval \( I \). Then \( f \) is differentiable almost everywhere (with respect to Lebesgue measure).

However, the set where a monotone function is nondifferentiable is not necessarily countable. For example, the Cantor function \( () \) is not differentiable at the points of \( K \), which is uncountable (but has measure 0).

XIV.14.2.13. THEOREM. Let \( f \) be a nondecreasing function on \([a, b]\). Then \( f' \) is integrable on \([a, b]\) and

\[
\int_a^b f' \, d\lambda \leq f(b) - f(a) .
\]

**Proof:** By XIV.14.2.12., \( f' \) is defined almost everywhere on \([a, b]\). Extend \( f \) to \([a, b + 1]\) by setting \( f(x) = f(b) \) for \( b \leq x \leq b + 1 \). Define

\[
g_n(x) = n \left[ f \left( x + \frac{1}{n} \right) - f(x) \right]
\]

for \( n \in \mathbb{N} \). Then \( g_n \to f' \) pointwise a.e., so \( f' \) is measurable. The \( g_n \) and \( f' \) are nonnegative, so by Fatou’s Lemma we have

\[
\int_a^b f' \, d\lambda \leq \liminf_n \int_a^b g_n \, d\lambda = \liminf_n \int_a^b \left[ f \left( x + \frac{1}{n} \right) - f(x) \right] \, d\lambda(x)
\]

\[
= \liminf_n \left[ n \int_{a + \frac{1}{n}}^{b + \frac{1}{n}} f \, d\lambda - n \int_a^b f \, d\lambda \right] = \liminf_n \left[ n \int_{b + \frac{1}{n}}^{b + \frac{1}{n}} f \, d\lambda - n \int_a^{a + \frac{1}{n}} f \, d\lambda \right] .
\]
Since $f$ is constant on $[b, b + \frac{1}{n}]$, the first integral in the last expression is $\frac{f(b)}{n}$; and $f(x) \geq f(a)$ for $a \leq x \leq a + \frac{1}{n}$, so the second integral is at least $\frac{f(a)}{n}$. Thus we have

$$\int_a^b f' d\lambda \leq f(b) - \limsup_n n \int_a^{a + \frac{1}{n}} f d\lambda \leq f(b) - f(a).$$

\[
\]

XIV.14.2.14. We do not have equality in XIV.14.2.13. in general. If $f$ is the Cantor function, then $f$ is nondecreasing on $[0, 1]$, but $f' = 0$ a.e., so we have

$$0 = \int_0^1 f' d\lambda < f(1) - f(0) = 1.$$

We do have equality for absolutely continuous functions (and only for absolutely continuous functions).

XIV.14.3. Fubini’s Series Theorem

We have the following interesting and useful result of Fubini. We call this “Fubini’s Series Theorem” (not a standard name) since the name “Fubini’s Theorem” is usually reserved for his better-known result on iterated integrals.

XIV.14.3.1. Theorem. [Fubini’s Series Theorem] Let $(f_k)$ be a sequence of nondecreasing functions on a closed bounded interval $[a, b]$. Suppose $\sum_{k=1}^{\infty} f_k$ converges pointwise on $[a, b]$ to a real-valued function $f$. Then

(i) The series $\sum_{k=1}^{\infty} f_k$ converges to $f$ uniformly on $[a, b]$.  

(ii) The series $\sum_{k=1}^{\infty} f'_k$ converges to $f'$ pointwise a.e. on $[a, b]$. In particular, $f'_k \to 0$ pointwise a.e. on $[a, b]$. (Note that by XIV.14.2.12., $f$ and each $f_k$ are differentiable a.e. on $[a, b]$.)

Of course, there is an analogous result for nonincreasing functions.

The statement of the theorem can be rephrased in terms of convergence of sequences of functions (i.e. the partial sums of the series), but it is a little awkward to do so since the hypothesis is that the successive differences of the functions in the sequence, not the functions themselves, must be nondecreasing.

For the proof of XIV.14.3.1., we need two lemmas:

XIV.14.3.2. Lemma. To prove the theorem, it suffices to assume that each $f_k$ is nonnegative and $f_k(a) = 0$.

Proof: Let $(f_k)$ be as in the statement of the theorem. For each $k$, set $g_k(x) = f_k(x) - f_k(a)$. Then $g_k(a) = 0$, and $g_k$ is nonnegative and nondecreasing since $f_k$ is nondecreasing. We have

$$\sum_{k=1}^{n} g_k(x) = \sum_{k=1}^{n} f_k(x) - \sum_{k=1}^{n} f_k(a)$$

1668
for each \( n \). Since the first sum converges to \( f(x) \) and the second sum to \( f(a) \) as \( n \to \infty \), \( \sum_{k=1}^{\infty} g_k(x) \) converges to \( g(x) := f(x) - f(a) \) for every \( x \in [a, b] \). If the conclusion of the theorem holds for the \( g_k \), then \( \sum_{k=1}^{\infty} g_k \) converges uniformly to \( g \), so for any \( \epsilon > 0 \) there is an \( N \) such that

\[
\left| g(x) - \sum_{k=1}^{n} g_k(x) \right| < \frac{\epsilon}{2}
\]

for all \( n \geq N \) and all \( x \in [a, b] \), and

\[
\left| f(a) - \sum_{k=1}^{n} f_k(a) \right| < \frac{\epsilon}{2}
\]

for all \( n \geq N \). Then, for all \( n \geq N \) and \( x \in [a, b] \),

\[
\left| f(x) - \sum_{k=1}^{n} f_k(x) \right| = \left| (g(x) + f(a)) - \sum_{k=1}^{n} (g_k(x) + f_k(a)) \right| \leq \left| f(x) - \sum_{k=1}^{n} f_k(x) \right| + \left| f(a) - \sum_{k=1}^{n} f_k(a) \right| < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon
\]

so \( \sum_{k=1}^{\infty} f_k \) converges uniformly to \( f \) on \([a, b]\). Part (ii) for \( f \) obviously follows from part (ii) for \( g \) since \( f' = g' \) for each \( k \) and \( f' = g' \).

**XIV.14.3.3. Lemma.** Under the hypotheses of XIV.14.3.1., we have that \( \sum_{k=1}^{\infty} f_k \) converges uniformly to \( f \) and that \( f'_k \to 0 \) pointwise a.e. on \([a, b]\).

**Proof:** By XIV.14.3.2., we may assume each \( f_k \) is nonnegative and \( f_k(a) = 0 \). For each \( n \), set

\[
s_n(x) = \sum_{k=1}^{n} f_k(x)
\]

If \( \epsilon > 0 \), choose \( N \) such that

\[
0 \leq f(b) - s_n(b) = f(b) - \sum_{k=1}^{n} f_k(b) < \epsilon
\]

for all \( n \geq N \). Then, for any \( n \geq N \) and \( x \in [a, b] \), we have

\[
0 \leq f(x) - s_n(x) \leq f(b) - s_n(b) < \epsilon
\]

since \( f - s_n \) is nonnegative and nondecreasing. Thus \( s_n \to f \) uniformly on \([a, b]\).

Set

\[
E = \{ x \in [a, b] : f \text{ and each } f_k \text{ are differentiable at } x \}
\]

By XIV.14.2.12., \([a, b] \setminus E\) is a countable union of null sets, so is a null set. Each \( s_n \) is differentiable on \( E \), and since \( s_{n+1} - s_n = f_{n+1} \) and \( f - s_n \) are nondecreasing, we have \((s_{n+1} - s_n)'(x) \geq 0\) and \((f - s_n)'(x) \geq 0\) for all \( x \in E \). So, for every \( x \in E \), we have

\[
s'_1(x) \leq s'_2(x) \leq \cdots \leq f'(x)
\]

and hence \((s'_n(x))\) converges for \( x \in E \), which implies that \( f'_n(x) \to 0 \) for all \( x \in E \).

\[\Box\]
XIV.14.3.4. To complete the proof of XIV.14.3.1., we need to show that \( s_n' \to f' \) pointwise a.e. on \([a, b]\). Let \( E \) be the set in the proof of XIV.14.3.3.. Since the sequence \( (s_n'(x)) \) is nondecreasing for each \( x \in E \), it suffices to find a subsequence that converges pointwise to \( f' \) a.e. on \( E \). For each \( j \), choose an \( n_j \) such that \( f(b) - s_{n_j}(b) < 2^{-j} \), and set \( t_j = f - s_{n_j} \). Then

\[
0 \leq t_j(x) = f(x) - s_{n_j}(x) \leq f(b) - s_{n_j}(b) < 2^{-j}
\]

for all \( x \in [a, b] \), and thus the series \( \sum_{j=1}^{\infty} t_j \) satisfies the hypotheses of XIV.14.3.1.. So by XIV.14.3.3. we have \( t_j' \to 0 \) pointwise on \( E' = \{ x \in [a, b] : t \text{ and each } t_j \text{ are differentiable at } x \} \)

(\( \text{where } t = \sum_{j=1}^{\infty} t_j \)), i.e. \( s_n' \to f' \) pointwise on \( E \cap E' \). Thus \( s_n' \to f' \) pointwise on \( E \cap E' \), whose complement is a null set.

XIV.14.3.5. Note that we do not necessarily have \( E \subset E' \) since there is no assurance that \( t \) is differentiable on \( E \), and thus \( \sum_{k=1}^{\infty} f_k' \) does not necessarily converge to \( f' \) on all of \( E \). See Exercise XIV.14.4.2..

Examples

Examples. (i) A nonconstant increasing function \( f \) can have \( f' = 0 \) a.e. The Cantor function () is an example. One can even have a strictly increasing function \( g \) with \( g' = 0 \) a.e.: take \( g = \sum_{n=1}^{\infty} 2^{-n} f_n \), where the \( f_n \) are copies of the Cantor function scaled to each of the subintervals where \( f \) and all the previous rescalings of \( f \) are constant. (Expand)***

(ii) There is a strictly increasing function \( f \) on \([0, 1]\) (or any other interval), which is continuously differentiable on all of \([0, 1]\), and whose derivative vanishes on a set of positive measure. Let \( K \) be a Cantor set of positive measure (), and \( g : [0, 1] \to [0, 1] \) a continuous function with \( g^{-1}([0]) = K \) (e.g. \( g(x) = \rho(x, K) \); cf. ()). Define

\[
f(x) = \int_0^x g(t) \, dt.
\]

Then \( f' = g \) exists and is continuous on all of \([0, 1]\) (), and, for any \( a, b \in [0, 1], a < b \),

\[
f(b) - f(a) = \int_a^b g(t) \, dt > 0
\]

since \( g \) is continuous, nonnegative, and not identically 0 on \([a, b]\) (); recall that \( K \) contains no nontrivial intervals). Thus \( f \) is strictly increasing. But \( f' = g = 0 \) on \( K \). \( K \) can be taken to have measure \( 1 - \epsilon \), for any \( \epsilon > 0 \).

Note that if \( f \) is differentiable everywhere on an interval \( I \) and \( f' = 0 \) a.e. on \( I \), then \( f \) is constant on \( I \) ().

(iii) [POMPEIU] [?] There is a strictly increasing everywhere differentiable function \( f \) on a closed bounded interval (actually any interval), with bounded derivative, for which \( f' = 0 \) on a dense set. Let \( (r_k) \) be an enumeration of the rationals in \([0, 1]\), and set \( g_k(x) = 2^{-k} \sqrt{x - r_k} \),

\[
g(x) = \sum_{k=1}^{\infty} g_k(x) = \sum_{k=1}^{\infty} 2^{-k} \sqrt{x - r_k}
\]

1670
for \( x \in [0, 1] \). The series converges uniformly on \([0, 1]\), and thus \( g \) is a strictly increasing continuous function on \([0, 1]\). Let \([a, b]\) be the range of \( g \), and \( f : [a, b] \rightarrow [0, 1] \) the inverse function.

We claim that \( f \) is differentiable everywhere on \([a, b]\). Each \( g_k \) is differentiable everywhere except at \( r_k \), where its extended derivative is \(+\infty\). Thus, by the Mean Value Theorem, we have, for all \( x, y \in [0, 1], x \neq y \), we have

\[
\frac{g(y) - g(x)}{y - x} \geq \frac{g_1(y) - g_1(x)}{y - x} > \frac{1}{6}
\]

and so all Dini derivatives of \( g \) are \( \geq \frac{1}{6} \) at every point. Thus to show that \( f \) is differentiable everywhere on \([a, b]\), by the Inverse Function Theorem \((x)\) it suffices to show that \( g \) has an extended derivative everywhere on \([0, 1]\). It will then also follow that \( 0 \leq f' (x) \leq 6 \) for all \( x \in [a, b] \).

In fact, we will show that at every \( x \in [0, 1] \), the extended derivative of \( g \) at \( x \) equals \( \sum_{k=1}^{\infty} g'_k (x) \). This is clear if \( x = r_k \in \mathbb{Q} \) \([g \text{ is the sum of } g_k \text{ and another nondecreasing continuous function, so } g' (x) = g'_k (x) = +\infty]\). Suppose \( x \notin \mathbb{Q} \) but \( \sum_{k=1}^{\infty} g'_k (x) = +\infty \). Set \( h_n = \sum_{k=1}^{n} g_k \). Then for each \( M \) there is an \( n \) such that

\[
h'_n (x) = \lim_{y \to x} \frac{h_n (y) - h_n (x)}{y - x} > M
\]

so there is a \( \delta > 0 \) such that for all \( y \in [x - \delta, x + \delta] \) we have

\[
\frac{g(y) - g(x)}{y - x} \geq \frac{h_n (y) - h_n (x)}{y - x} > M
\]

and thus \( g' (x) = +\infty = \sum_{k=1}^{\infty} g'_k (x) \).

Now suppose \( x \in [0, 1] \) and \( \sum_{k=1}^{\infty} g'_k (x) < \infty \). Then \( x \notin \mathbb{Q} \). We have

\[
|s^{1/3} - t^{1/3}| \leq \frac{4}{3} s^{-2/3} |s - t|
\]

for all \( s, t \in \mathbb{R}, s \neq 0 \) (Exercise XIV.14.4.1). Setting \( s = x - r_k \) (recall that \( x \notin \mathbb{Q} \)) and \( t = y - r_k \) we obtain

\[
\left| \frac{g_k (y) - g_k (x)}{y - x} \right| \leq 4 g'_k (x)
\]

for all \( k \) and all \( y \neq x \). Thus we have, for \( y \neq x \) and any \( n \),

\[
\left| \frac{g(y) - g(x)}{y - x} - \sum_{k=1}^{\infty} g'_k (x) \right| = \sum_{k=1}^{\infty} \left( \frac{g_k (y) - g_k (x)}{y - x} - g'_k (x) \right)
\]

\[
\leq \sum_{k=1}^{\infty} \left| \frac{g_k (y) - g_k (x)}{y - x} \right| - \left| g'_k (x) \right| = \sum_{k=1}^{n} \left| \frac{g_k (y) - g_k (x)}{y - x} - g'_k (x) \right| + \sum_{k=n+1}^{\infty} \left| \frac{g_k (y) - g_k (x)}{y - x} - g'_k (x) \right|
\]

for every \( y \neq x \) and every \( n \). Fix \( \varepsilon > 0 \) and choose \( n \) such that \( \sum_{k=1}^{\infty} 5 g'_k (x) < \frac{\varepsilon}{2} \). There is a \( \delta > 0 \) such that if \( 0 < |y - x| < \delta \), we have

\[
\left| \frac{g_k (y) - g_k (x)}{y - x} - g'_k (x) \right| < \frac{\varepsilon}{2n}
\]

for \( 1 \leq k \leq n \). For \( 0 < |y - x| < \delta \), we have

\[
\left| \frac{g(y) - g(x)}{y - x} - \sum_{k=1}^{\infty} g'_k (x) \right| \leq \sum_{k=1}^{n} \left| \frac{g_k (y) - g_k (x)}{y - x} - g'_k (x) \right| + \sum_{k=n+1}^{\infty} \left| \frac{g_k (y) - g_k (x)}{y - x} - g'_k (x) \right|
\]

1671
\[ \leq \sum_{k=1}^{n} \left| g_k(y) - g_k(x) \right| \frac{y-x}{x} + \sum_{k=n+1}^{\infty} n \frac{g_k'(x)}{x} < n \frac{\epsilon}{2n} + \frac{\epsilon}{2} = \epsilon . \]

Thus \( g'(x) \) exists and equals \( \sum_{k=1}^{n} g_k'(x) \).

Since the extended derivative of \( g \) is \( +\infty \) at every point of \( \mathbb{Q} \cap [0,1] \), we have \( f' = 0 \) at all points of \( g(\mathbb{Q} \cap [0,1]) \) (,), which is dense in \([a,b]\). We also have \( f'(x) = 0 \) for many \( x \) not in this countable set: the set

\[ A = \{ x \in [a,b] : f'(x) = 0 \} \]

is dense in \([a,b]\), hence \( A \) must contain the set

\[ B = \{ x \in [a,b] : f' \text{ is continuous at } x \} \]

which is a residual set by (,). (However, the meager set \([a,b] \setminus A \) must be dense in \([a,b]\) and have positive measure in every subinterval by (,).)

**XIV.4. Exercises**

**XIV.4.4.1.** Show that if \( s,t \in \mathbb{R}, s \neq 0 \), then

\[ |s^{1/3} - t^{1/3}| \leq \frac{4}{3} s^{-2/3}|s - t| . \]

[Convert the problem into showing that

\[ |y - z| \leq \frac{4}{3y^2}|y^3 - z^3| \]

for \( y \neq 0 \) and use the factorization

\[ y^3 - z^3 = (y - z)(y^2 + yz + z^2) . \]

**XIV.4.4.2.** \([\text{vRS82, 4.H]}\) For each \( k \), let

\[ f_k(x) = \frac{1}{k} \tan^{-1} kx - \frac{1}{k+1} \tan^{-1}(k+1)x . \]

(a) Show that \( f_k \) is strictly increasing and differentiable on \( \mathbb{R} \).

(b) Show that \( \sum_{k=1}^{\infty} f_k(x) \) converges pointwise (in fact, uniformly) to \( f(x) = \tan^{-1} x \).

(c) Show that \( \sum_{k=1}^{\infty} f_k'(0) \) does not converge to \( f'(0) \).

**XIV.4.4.3.** Let \( f \) be a monotone function on \([a,b]\).

(a) Show that \( f \) is Borel measurable. [Show that \( f^{-1}((c, +\infty)) \) is an interval for any \( c \in \mathbb{R} \).]

(b) Show that \( f \) is Baire class 1 (cf. XII.2.6.5.)
XIV.15. Convex Functions

In this section, we define and derive the most important properties of convex functions.

XIV.15.1. Definitions

XIV.15.1.1. Definition. Let \( f \) be a function from an interval \( I \) to \( \mathbb{R} \). Then \( f \) is convex on \( I \) if for all \( x, y \in I \) and \( 0 < t < 1 \), we have

\[
f(tx + (1-t)y) \leq tf(x) + (1-t)f(y).
\]

Geometrically, this means that the graph of \( f \) between \( x \) and \( y \) lies below the chord between \((x, f(x))\) and \((y, f(y))\), for any \( x, y \in I \) (Figure 1).

The terms concave upward and convex downward are sometimes used as synonyms for convex (although for us concave upward will mean “strictly convex,” cf. V.8.3.1.). The term convex is most common, and is motivated by the following observation:

XIV.15.1.2. Proposition. Let \( f \) be a real-valued function on an interval \( I \). Then \( f \) is a convex function if and only if its supergraph

\[
S_f = \{(x, y) : x \in I, y \geq f(x)\}
\]

is a convex subset () of \( \mathbb{R}^2 \).

XIV.15.1.3. Proposition. [Chordal Slope Criterion] Let \( I \) be an interval and \( f : I \to \mathbb{R} \). The following are equivalent:

(i) \( f \) is convex on \( I \).

(ii) For all \( x, y, z \in I \), \( x < y < z \), we have

\[
\frac{f(y) - f(x)}{y - x} \leq \frac{f(z) - f(x)}{z - x}.
\]

(iii) For all \( x, y, z \in I \), \( x < y < z \), we have

\[
\frac{f(z) - f(x)}{z - x} \leq \frac{f(z) - f(y)}{z - y}.
\]

(iv) For all \( x, y, z \in I \), \( x < y < z \), we have

\[
\frac{f(y) - f(x)}{y - x} \leq \frac{f(z) - f(y)}{z - y}.
\]
(See Figure 2.)

Proof: (i) \(\Rightarrow\) (ii): Suppose \(f\) is convex on \(I\) and \(x, y, z \in I, x < y < z\). Set \(t = \frac{z - y}{z - x}\). Then

\[
tx + (1 - t)z = \frac{z - y}{z - x} x + \frac{y - x}{z - x} z = \frac{xz - xy + yz - xz}{z - x} = \frac{yz - xy}{z - x} = y
\]

so

\[
f(y) \leq tf(x) + (1 - t)f(z) = \frac{z - y}{z - x} f(x) + \frac{y - x}{z - x} f(z)
\]

and therefore

\[
f(y) - f(x) \leq \left[\frac{z - y}{z - x} - 1\right] f(x) + \frac{y - x}{z - x} f(z)
\]

\[
= -\frac{y - x}{z - x} f(x) + \frac{y - x}{z - x} f(z) = \frac{y - x}{z - x} [f(z) - f(x)]
\]

So we have

\[
\frac{f(y) - f(x)}{y - x} \leq \frac{f(z) - f(x)}{z - x}.
\]

(ii) \(\Rightarrow\) (i): Let \(x, z \in I, x < z\), and \(0 < t < 1\), and set \(y = tx + (1 - t)z\). Then \(x < y < z\), and \(t = \frac{z - y}{z - x}\). The steps in (i) \(\Rightarrow\) (ii) can be reversed to show that

\[
f(y) \leq \frac{z - y}{z - x} f(x) + \frac{y - x}{z - x} f(z) = tf(x) + (1 - t)f(z)\,.
\]

(ii) \(\Rightarrow\) (iii): Let \(x, y, z \in I, x < y < z\). Suppose

\[
\frac{f(y) - f(x)}{y - x} \leq \frac{f(z) - f(x)}{z - x}.
\]

Since

\[
\frac{f(z) - f(x)}{z - x} (z - x) = f(z) - f(x) = \frac{f(y) - f(x)}{y - x} (y - x) + \frac{f(z) - f(y)}{z - y} (z - y)
\]

\[
\leq \frac{f(z) - f(x)}{z - x} (y - x) + \frac{f(z) - f(y)}{z - y} (z - y)
\]

we have

\[
\frac{f(z) - f(x)}{z - x} (z - x) - \frac{f(z) - f(x)}{z - x} (y - x) \leq \frac{f(z) - f(y)}{z - y} (z - y)
\]

\[
\frac{f(z) - f(x)}{z - x} [(z - x) - (y - x)] = \frac{f(z) - f(x)}{z - x} (z - y) \leq \frac{f(z) - f(y)}{z - y} (z - y)
\]

and the result follows from dividing by \(z - y\).

(iii) \(\Rightarrow\) (ii) is almost identical to (ii) \(\Rightarrow\) (iii), and is left to the reader.

(iii) \(\Rightarrow\) (iv): (iv) is an immediate combination of (ii) and (iii).

(iv) \(\Rightarrow\) (ii) and (iii): Let \(x, y, z \in I, x < y < z\). Then

\[
\frac{f(z) - f(x)}{z - x} = \frac{y - x}{z - x} f(y) - f(x) + \frac{z - y}{z - x} f(z) - f(y)
\]

so \(\frac{f(z) - f(x)}{z - x}\) is a weighted average of \(\frac{f(y) - f(x)}{y - x}\) and \(\frac{f(z) - f(y)}{z - y}\) and thus lies in between. \(\diamondsuit\)
XIV.15.1.4. This result can be rephrased (cf. [vRS82, §2]). For a function \( f \) defined on an interval \( I \), define, for \( x, y \in I \),

\[
\Phi_1 f(x, y) = \frac{f(y) - f(x)}{y - x}.
\]

For \( x, y, z \in I \), all distinct, define

\[
\Phi_2 f(x, y, z) = \frac{f(z) - f(y)}{z - y} - \frac{f(y) - f(x)}{y - x}.
\]

Note that the values of \( \Phi_1 f \) and \( \Phi_2 f \) are unchanged if the variables are permuted, i.e. \( \Phi_1 f(x, y) = \Phi_1 f(y, x) \), \( \Phi_2(x, y, z) = \Phi_2(x, z, y) \), etc.

XIV.15.1.5. Corollary. Let \( f \) be a real-valued function on an interval \( I \). The following are equivalent:

(i) \( f \) is convex on \( I \).

(ii) For each \( x \in I \), the function \( \Phi_1 f(x, \cdot) \) is increasing on \( I \setminus \{x\} \).

(iii) \( \Phi_2 f(x, y, z) \geq 0 \) for all distinct \( x, y, z \in I \).

Here are some other consequences of XIV.15.1.3.:

XIV.15.1.6. Corollary. Let \( f \) be convex on \( I \), and \( w, x, y, z \in I \), \( w < x < y < z \). Then

\[
\frac{f(x) - f(w)}{x - w} \leq \frac{f(z) - f(y)}{z - y}.
\]

Proof: Compare both to \( \frac{f(y) - f(x)}{y - x} \).

XIV.15.1.7. Corollary. If \( f \) is differentiable on \( I \), and \( f' \) is nondecreasing on \( I \), then \( f \) is convex on \( I \). In particular, if \( f'' \) exists and is nonnegative on \( I \), then \( f \) is convex on \( I \).

The converse is also true, and the assumption that \( f \) is differentiable is almost automatic (XIV.15.1.6.).

Proof: Suppose \( f' \) is nondecreasing on \( I \). Let \( x, y, z \in I \), \( x < y < z \). By the Mean Value Theorem (), there are \( c, d \in I \) with \( x < c < y < d < z \) such that

\[
f'(c) = \frac{f(y) - f(x)}{y - x} \quad \text{and} \quad f'(d) = \frac{f(z) - f(y)}{z - y}.
\]

Since \( f' \) is nondecreasing, \( f'(c) \leq f'(d) \). Apply XIV.15.1.3.(iv).
XIV.15.1.8. **Examples.** (i) Any linear (affine) function is convex on \((-\infty, \infty)\).
(ii) \(f(x) = x^r\) is convex on \([0, \infty)\) if \(r = 0\) or \(r \geq 1\), convex on \((0, \infty)\) if \(r < 0\), and not convex on any interval if \(0 < r < 1\). If \(n \in \mathbb{N}\) is even, \(f(x) = x^n\) is convex on \((-\infty, \infty)\) and \(g(x) = x^{-n}\) is convex on \((-\infty, 0)\).
(iii) \(f(x) = e^x\) is convex on \((-\infty, \infty)\).
(iv) A convex function need not be differentiable everywhere: \(f(x) = |x|\) is convex on \((-\infty, \infty)\).
(v) A convex function need not even be continuous. The following function is convex on \([0, 1]\):

\[
f(x) = \begin{cases} 
0 & \text{if } 0 \leq x < 1 \\
1 & \text{if } x = 1
\end{cases}
\]

XIV.15.1.9. **Proposition.** (i) If \(f\) and \(g\) are convex on \(I\), then \(f + g\) is convex on \(I\).
(ii) If \(f\) is convex on \(I\) and \(c \geq 0\), then \(cf\) is convex on \(I\).
(iii) If \(I\) and \(J\) are intervals, \(f\) is convex on \(I\), \(f(I) \subseteq J\), and \(g\) is nondecreasing and convex on \(J\), then \(g \circ f\) is convex on \(I\).

**Proof:** (i) and (ii) are straightforward, and are left to the reader. For (iii), if \(x, y \in I\) and \(0 < t < 1\), then

\[
g(f(tx + (1 - t)y)) \leq g(tf(x) + (1 - t)f(y)) \leq tg(f(x)) + (1 - t)g(f(y)).
\]

XIV.15.1.10. **Note,** however, that a product of convex functions is not convex in general, even if both are nonnegative and one is linear. For example \(f(x) = x^2\) and \(g(x) = 1 - x\) are convex and nonnegative on \([0, 1]\), but \(fg\) is not convex on \([0, 1]\). (A product of two nonnegative, nondecreasing, convex functions is convex (XIV.15.1.24.).) Also note that (iii) fails in general if \(g\) is not nondecreasing, e.g. if \(g(x) = -x\).

**Limits and Suprema of Convex Functions**

XIV.15.1.11. **Proposition.** Let \(I\) be an interval, and \((f_n)\) a sequence of convex functions on \(I\) converging pointwise on \(I\) to a function \(f\). Then \(f\) is convex on \(I\).

**Proof:** If \(x, y \in I\) and \(0 < t < 1\), then \(f_n(tx + (1 - t)y) \rightarrow f(tx + (1 - t)y)\) and \(tf_n(x) + (1 - t)f_n(y) \rightarrow tf(x) + (1 - t)f(y)\). It follows immediately that \(f\) is convex. 

In fact, such a convergent sequence of convex functions almost converges uniformly (XIV.15.3.1.).

XIV.15.1.12. **Proposition.** Let \(\{f_i\}\) be a set of convex functions on an interval \(I\). If \(f = \sup_i f_i\) is finite on \(I\), then \(f\) is convex on \(I\). In particular, if \(f_1, \ldots, f_n\) are convex on \(I\), then \(f_1 \lor \cdots \lor f_n = \max(f_1, \ldots, f_n)\) is convex on \(I\).

**Proof:** This follows immediately from XIV.15.1.2. and (.), since \(S_f = \cap_i S_{f_i}\). 

1676
Continuity of Convex Functions

The discontinuity in XIV.15.1.8.(v) can only happen at an endpoint. In fact, we have:

**XIV.15.1.13.** Proposition. Let \( f \) be convex on \( I \), and \([a,b]\) a closed bounded interval contained in the interior of \( I \). Then \( f \) is Lipschitz on \([a,b]\).

**Proof:** Let \( c,d \in I \), \( c < a < b < d \). If \( x,y \in [a,b] \), then by XIV.15.1.6. we have

\[
\frac{f(a) - f(c)}{a - c} \leq \frac{f(y) - f(x)}{y - x} \leq \frac{f(d) - f(b)}{d - b}
\]

and so \( |f(y) - f(x)| \leq M|y - x| \), where

\[
M = \max \left( \left| \frac{f(a) - f(c)}{a - c} \right|, \left| \frac{f(d) - f(b)}{d - b} \right| \right).
\]

**XIV.15.1.14.** Proposition. Let \( f \) be convex on \( I \). Then \( f \) is continuous on the interior of \( I \). If \( I \) has a left endpoint \( a \) [resp. right endpoint \( b \)], then \( \lim_{x \to a^+} f(x) \) exists [resp. \( \lim_{x \to b^-} f(x) \) exists], and \( \lim_{x \to a^+} f(x) \leq f(a) \) [resp. \( \lim_{x \to b^-} f(x) \leq f(b) \)]. In particular, \( f \) is lower semicontinuous at endpoints of \( I \).

**Proof:** Continuity of \( f \) on the interior of \( I \) follows immediately from XIV.15.1.13., since a Lipschitz function is (uniformly) continuous.

Suppose \( I \) has a left endpoint \( a \). Let \( c \in I \), \( c > a \). Then, if \( a < x < c \), we have by XIV.15.1.3.(iii),

\[
g(x) := \frac{f(c) - f(x)}{c - x} \geq \frac{f(c) - f(a)}{c - a}
\]

and \( g(x) \) decreases as \( x \) decreases; thus

\[
L := \lim_{x \to a^+} \frac{f(c) - f(x)}{c - x} = \inf_{a < x < c} \frac{f(c) - f(x)}{c - x}
\]

exists, and satisfies

\[
L \geq \frac{f(c) - f(a)}{c - a}.
\]

Since \( \lim_{x \to a^+} (c - x) = c - a \) exists and is nonzero, \( m := \lim_{x \to a^+} f(x) \) also exists and satisfies

\[
L = \frac{f(c) - m}{c - a} \geq \frac{f(c) - f(a)}{c - a}
\]

and so \( m = \lim_{x \to a^+} f(x) \leq f(a) \). The argument for a right endpoint \( b \) of \( I \) is virtually identical. ☑
Differentiability of Convex Functions

An almost identical argument shows that the left and right derivatives of a convex function exist at every point:

**XIV.15.1.15. Theorem.** Let $f$ be a convex function on an interval $I$. Then the left and right derivatives $D_Lf$ and $D_Rf$ of $f$ exist at every point of $I$ (except a left or right endpoint respectively), and are finite except possibly at endpoints of $I$. If $x, y \in I$, $x < y$, then

$$D_Lf(x) \leq D_Rf(x) \leq D_Lf(y) \leq D_Rf(y).$$

$D_Lf$ is continuous from the left wherever it is finite (i.e. except possibly at a right endpoint of $I$), and $D_Rf$ is continuous from the right wherever it is finite (i.e. except possibly at a left endpoint of $I$).

In fact, if $I$ has a right endpoint $b$, and $f$ is continuous at $b$, and $D_Lf(b) = +\infty$, then $\lim_{x \to b^-} D_Lf(x) = +\infty$ (cf. ?), i.e. $D_Lf$ is “continuous” at $b$. A similar statement holds for $D_Rf$ at a left endpoint of $I$.

**Proof:** Let $x \in I$, not a right endpoint. Then there is an $\epsilon > 0$ such that $x + \epsilon \in I$. Then

$$g(h) := \frac{f(x + h) - f(x)}{h}$$

exists for $0 < h < \epsilon$. By XIV.15.1.3.(ii), $g(h)$ decreases as $h$ decreases, so

$$D_Rf(x) = \lim_{h \to 0^+} \frac{f(x + h) - f(x)}{h} = \inf_{0 < h < \epsilon} \frac{f(x + h) - f(x)}{h}$$

exists as an extended real number and is not $+\infty$. If $x$ is not a left endpoint, let $a \in I$, $a < x$; then by XIV.15.1.3.(iv) we have

$$\frac{f(x + h) - f(x)}{h} \geq \frac{f(x) - f(a)}{x - a}$$

for $0 < h < \epsilon$, so $D_Rf(x)$ is finite (i.e. not $-\infty$). A similar argument shows that if $x$ is not a left endpoint, then $D_Lf(x)$ exists and is not $-\infty$; and if $x$ is not a right endpoint, $D_Lf(x)$ is finite (not $+\infty$). If $x, y \in I$, $x < y$, then

$$\frac{f(x + h) - f(x)}{h} \leq \frac{f(y) - f(y - h)}{h}$$

for $0 < h < (y - x)/2$ by XIV.15.1.6., and hence $D_Rf(x) \leq D_Lf(y)$.

To prove left-continuity of $D_Lf$, suppose $x$ is not a left endpoint of $I$ and $D_Lf(x)$ is finite. It follows that $f$ is continuous at $x$. Let $\epsilon > 0$. Then there is a $y \in I$, $y < x$, such that

$$D_Lf(x) - \epsilon < \frac{f(y) - f(x)}{y - x} \leq D_Lf(x).$$

If $(x_n)$ is a sequence in $(y, x)$ converging to $x$, we have $f(x_n) \to f(x)$, so for sufficiently large $n$ we have

$$D_Lf(x) - \epsilon < \frac{f(y) - f(x_n)}{y - x_n} \leq D_Lf(x_n) \leq D_Lf(x).$$

Right-continuity of $D_Rf$ is almost identical. ☞

1678
XIV.15.1.16. **Corollary.** Let \( f \) be convex on \( I \). Then \( f \) is differentiable on \( I \) except on a countable set (which may be finite or empty), \( f' \) is continuous on the set on which it is defined, and \( f' \) is nondecreasing on \( I \).

**Proof:** It is immediate from XIV.15.1.15. that \( D_L f \) is nondecreasing on \( I \), and hence is continuous except at countably many points \( \). If \( x \in I \), then \( D_L f(x) \leq D_R f(x) \leq D_L f(y) \) for all \( y > x \), and hence \( D_R f(x) = D_L f(x) \) if \( D_L f \) is continuous from the right at \( x \) (and only at such points). Thus \( f \) is differentiable at any point where \( D_L f \) is continuous, hence at all but countably many points. 

We then get the following “geometrically obvious” consequence:

XIV.15.1.17. **Corollary.** Let \( f \) be convex and continuous on an interval \( I \). Then one of the following holds:

(i) \( D_L f(x) \geq 0 \) for all \( x \in I \).

(ii) \( D_L f(x) \leq 0 \) for all \( x \in I \).

(iii) There are unique \( c, d \in I \), \( c \leq d \), with \( D_L f(x) < 0 \) for all \( x \in I \), \( x < c \), \( D_L f(x) > 0 \) for all \( x \in I \), \( x > d \), and, if \( c < d \), \( D_L f(x) = 0 \) for \( c < x \leq d \).

Thus either \( f \) is nondecreasing on \( I \), \( f \) is nonincreasing on \( I \), or there are unique \( c, d \in I \), \( c \leq d \), such that \( f \) is strictly decreasing on \( I \cap (-\infty, c] \), strictly increasing on \( I \cap [d, +\infty) \), and, if \( c < d \), constant on \( [c, d] \).

In fact, if \( D_L f \) takes both positive and negative values on \( I \), then \( c = \sup\{x \in I : D_L f(x) < 0\} \) and \( d = \inf\{x \in I : D_L f(x) > 0\} \). Note that we often have \( c = d \); this will happen unless \( f \) is constant on a subinterval.

XIV.15.1.18. **Corollary.** Let \( f \) be convex on an interval \( I \). Then for each \( c \) in the interior of \( I \) there is a linear function \( L \) on \( I \) with \( L(c) = f(c) \) and \( L(x) \leq f(x) \) for all \( x \in I \).

**Proof:** We can take for \( L \) the linear function with \( L(c) = f(c) \) and with slope \( m \), for any \( m \) satisfying

\[
D_L f(c) \leq m \leq D_R f(c).
\]

XIV.15.1.19. Conversely, if \( f \) is a continuous function on an interval \( I \) with the property that for each \( c \) in the interior of \( I \), there is a linear function \( L_c \) on \( I \) with \( L_c(c) = f(c) \) and \( L_c(x) \leq f(x) \) for all \( x \in I \), then \( f = \sup_c(L_c) \), and each \( L_c \) is convex on \( I \), so \( f \) is convex on \( I \) by XIV.15.1.12..

Let \( I \) be an interval, and \( g : I \to \mathbb{R} \) a nondecreasing function. Then \( g \) is Riemann integrable over every closed bounded subset of \( I \). Fix \( c \in I \), and for \( x \in I \) define

\[
f(x) = \int_c^x g(t) \, dt.
\]

1679
XIV.15.1.20. Proposition. $f$ is convex on $I$.

Proof: Let $x, y, z \in I$, $x < y < z$. Then

$$\frac{f(y) - f(x)}{y - x} = \frac{1}{y - x} \int_x^y g(t) \, dt$$

is the average value of $g$ on $[x, y]$, and similarly $\frac{f(z) - f(y)}{z - y}$ is the average value of $g$ on $[y, z]$. Since $g$ is nondecreasing,

$$\frac{f(y) - f(x)}{y - x} \leq g(y) \leq \frac{f(z) - f(y)}{z - y}.$$

Apply XIV.15.1.3.

XIV.15.1.21. We will show that the converse is true, i.e. that every convex function on an open interval is the primitive of a nondecreasing function. This follows immediately from XIV.15.1.13. along with () and (), using the theory of Lebesgue integration and absolute continuity. However, it is not necessary to use Lebesgue integration since bounded nondecreasing functions are Riemann integrable on closed bounded intervals:

XIV.15.1.22. Theorem. Let $f$ be convex on an open interval $I$. Then $f'$ is Riemann integrable over every closed bounded subinterval of $I$. If $a \in I$ is fixed, then, for every $x \in I$,

$$f(x) = f(a) + \int_a^x f'(t) \, dt.$$

Proof: This is a special case of (). We have that $D_L f$ is increasing on $I$, hence Riemann integrable over every closed bounded subinterval of $I$, and equal to $f'$ except at countably many points of $I$.

XIV.15.1.23. Corollary. Let $f$ be a function on an open interval $I$. Then $f$ is convex on $I$ if and only if $f$ is absolutely continuous on every closed bounded subinterval of $I$ and $f'$ is increasing on a subset $A$ of $I$ with $\lambda(I \setminus A) = 0$.

XIV.15.1.24. Corollary. Let $f$ and $g$ be nonnegative, nondecreasing, and convex on an open interval $I$. Then $fg$ is convex on $I$.

Proof: Let $[a, b] \subseteq I$. Then $f$ and $g$ are bounded and Lipschitz on $[a, b]$ (XIV.15.1.13.), and hence $fg$ is also Lipschitz and thus absolutely continuous on $[a, b]$. Let $A$ be the set of points where $f$ and $g$ are both differentiable; then $I \setminus A$ is countable. By the product rule, if $x \in A$, then $fg$ is differentiable at $x$ and

$$(fg)'(x) = f(x)g'(x) + f'(x)g(x).$$
Since $f$, $g$, $f'$, and $g'$ are all nonnegative and nondecreasing on $A$, $(fg)'$ is nondecreasing on $A$.

*** Is there an elementary proof of this? ***

Here is a generalization of the last sentence of XIV.15.1.7. (cf. [?, p. 39]; [HS75, 17.37(c)]). Recall (1) that

$$
\mathcal{D}^{(2)}_S(f)(x) = \limsup_{h \to 0} \frac{f(x + h) + f(x - h) - 2f(x)}{h^2}
$$

$$
\mathcal{D}^{(2)}_S(f)(x) = \liminf_{h \to 0} \frac{f(x + h) + f(x - h) - 2f(x)}{h^2}
$$

XIV.15.1.25.\ Prop. Let $f$ be a function on an open interval $I$. Then the following are equivalent:

(i) $f$ is convex on $I$.

(ii) $f$ is continuous on $I$ and $\mathcal{D}^{(2)}_S(f)(x) \geq 0$ for all $x \in I$.

(iii) $f$ is continuous on $I$ and $\mathcal{D}^{(2)}_S(f)(x) \geq 0$ for all $x \in I$.

Proof: (i) $\Rightarrow$ (iii): If $f$ is convex on $I$ and $x \in I$, then there is an $\epsilon > 0$ such that $(x - \epsilon, x + \epsilon) \subseteq I$. Then, if $|h| < \epsilon$,

$$f(x) \leq \frac{1}{2}f(x - h) + \frac{1}{2}f(x + h)$$

and hence $f(x + h) + f(x - h) - 2f(x) \geq 0$. Thus $\mathcal{D}^{(2)}_S(f)(x) \geq 0$. And $f$ is continuous on $I$ by XIV.15.1.14.

(iii) $\Rightarrow$ (ii) is trivial.

(ii) $\Rightarrow$ (i): Suppose $f$ is continuous and $\mathcal{D}^{(2)}_S(f) \geq 0$ on $I$, and let $[a, b] \subseteq I$, and $\epsilon > 0$. Set

$$\phi(x) = f(x) - \left[ f(a) + \frac{f(b) - f(a)}{b - a} (x - a) \right] + \epsilon(x - a)(x - b)$$

for $a \leq x \leq b$. Then $\phi$ is continuous on $[a, b]$, $\phi(a) = \phi(b) = 0$, and $\mathcal{D}^{(2)}_S(\phi) \geq 2\epsilon$ on $[a, b]$. If $\max_{[a, b]} \phi > 0$, then $\phi$ has a local maximum at some $x_0 \in (a, b)$, and we would have $\mathcal{D}^{(2)}_S(\phi)(x_0) \leq 0$, a contradiction. Thus $\phi(x) \leq 0$ on $[a, b],

$$f(x) \leq f(a) + \frac{f(b) - f(a)}{b - a} (x - a) - \epsilon(x - a)(x - b)$$

for all $x \in [a, b]$. Since $\epsilon > 0$ is arbitrary, we have

$$f(x) \leq f(a) + \frac{f(b) - f(a)}{b - a} (x - a)$$

for all $x \in [a, b]$. Since $[a, b]$ is arbitrary, $f$ is convex on $I$. \hfill \Box
XIV.15.2. Midpoint-Convex Functions

There is a weaker condition which almost implies convexity:

XIV.15.2.1. Definition. A real-valued function $f$ on an interval $I$ is midpoint-convex if, for every $x,y \in I$, we have

$$f\left(\frac{x+y}{2}\right) \leq \frac{f(x) + f(y)}{2}.$$ 

A convex function is midpoint-convex. The converse is false (assuming the Axiom of Choice – Exercise XIV.15.7.2.), but is “almost true” (i.e. true under very mild additional hypotheses), as the results of this subsection show. These results are quite useful since midpoint-convexity is often much easier to check than convexity.

This exposition is adapted from [...].

XIV.15.2.2. Proposition. Let $f$ be a midpoint-convex function on an interval $I$. Then, for every $x,y \in I$ and dyadic rational $t \in [0,1]$,

$$f(tx + (1-t)y) \leq tf(x) + (1-t)f(y).$$

Proof: We prove this for $t$ of the form $\frac{p}{2^n}$ by induction on $n$. The case $n = 1$ holds by definition. Suppose it is true for $n$, and let $t = \frac{p}{2^{n+1}}$. Since the condition is symmetric in $t$ and $1-t$, we may assume $p < 2^n$, so $q := 2^{n+1} - p > 2^n$. Set $r = q - 2^n$, so $p + r = 2^n$. Then

$$z := \frac{p}{2^{n+1}}x + \frac{q}{2^{n+1}}y = \frac{1}{2} \left[ \frac{p}{2^n}x + \frac{r}{2^n}y + y \right]$$

so we have

$$f(z) \leq \frac{1}{2} \left[ f\left( \frac{p}{2^n}x + \frac{r}{2^n}y \right) + f(y) \right] \leq \frac{1}{2} \left[ \frac{p}{2^n}f(x) + \frac{r}{2^n}f(y) + f(y) \right] = \frac{p}{2^{n+1}}f(x) + \frac{q}{2^{n+1}}f(y).$$

XIV.15.2.3. Corollary. If $f$ is continuous and midpoint-convex on an interval $I$, then $f$ is convex on $I$.

Proof: For fixed $x,y \in I$, the inequality

$$f(tx + (1-t)y) \leq tf(x) + (1-t)f(y)$$

for arbitrary $t \in [0,1]$ follows from the inequality for dyadic rational $t$ by continuity and density of the dyadic rationals.

We can say much more. A midpoint-convex function which is not convex must be not only discontinuous, but rather bizarre:
XIV.15.2.4. Theorem. Let \( f \) be a midpoint-convex function on an open interval \( I \). If \( f \) is not convex on \( I \), then \( f \) is not bounded above in any subinterval. If \( c \in I \), then there is a sequence \( (x_n) \) in \( I \) with \( x_n \to c \) and \( \lim_{n \to \infty} f(x_n) = +\infty \). In particular, \( f \) is discontinuous everywhere on \( I \).

Proof: By XIV.15.2.3., \( f \) is discontinuous at some \( x_0 \in I \). By translation and adding a constant, we may assume \( x_0 = 0 \) and that \( f(0) = 0 \) for ease of notation. There is a sequence \( (y_n) \) in \( I \) with \( y_n \to 0 \) and \( f(y_n) \to m \neq 0 \). If \( f(y_n) < 0 \), we have that \( f(-y_n) \geq -f(y_n) > 0 \) since \( 0 = f(0) \leq \frac{1}{2} (f(y_n) + f(-y_n)) \). Thus, by replacing \( (y_n) \) by a subsequence of \( (-y_n) \) if necessary, we may assume \( m > 0 \). If \( m = +\infty \), we are done. Otherwise, we have

\[
2f(y_n) \leq f(0) + f(2y_n) = f(2y_n)
\]

and so \( \liminf_{n \to \infty} f(2y_n) \geq 2m \). Continuing inductively, for each \( k \) we have

\[
f(2^k y_n) \geq 2^k f(y_n)
\]

for all \( n \) large enough that \( 2^k y_n \in I \), and hence \( \liminf_{n \to \infty} f(2^k y_n) \geq 2^k m \). Since for fixed \( k \) we have \( 2^k y_n \to 0 \), we have that \( f \) is unbounded above in every neighborhood of 0, and there is a sequence \( (z_n) \in I \) with \( z_n \to 0 \) and \( f(z_n) \to +\infty \).

Now let \( a \) be the largest number (or \(+\infty\)) for which \((-a, a) \subseteq I \), and let \( c \in (-a, a) \). We have that \( x_n := c + z_n \to c \), so \( x_n \in I \) for sufficiently large \( n \). Also,

\[
f(z_n) = f \left( c + \frac{2z_n - c}{2} \right) \leq \frac{f(c + 2z_n) + f(-c)}{2} = \frac{f(x_n) + f(-c)}{2}
\]

and, since \( f(z_n) \to +\infty \), it follows that \( f(x_n) \to +\infty \). Thus \( f \) is unbounded above in every subinterval of \((-a, a)\) and discontinuous everywhere on \((-a, a)\).

We end up with an open subinterval \( J \) of \( I \), extending to at least one end of \( I \), such that \( f \) is unbounded above on every subinterval of \( J \) and hence discontinuous everywhere on \( J \). If \( J \neq I \), repeat the argument with an \( x_0 \in J \) near the endpoint of \( J \) not exhausting \( I \) to get another such interval \( J_2 \) centered at \( x_0 \). If \( J \cup J_2 \neq I \), then \( J \subseteq J_2 \), and \( J_2 \) is approximately twice the length of \( J \), with the same properties. Repeating the process, in finitely many steps we cover any bounded subinterval of \( I \), which suffices to prove the result. 

XIV.15.2.5. A midpoint-convex function which is not convex can be bounded below: in fact, if \( f \) is midpoint-convex, so is \( \max(f, 0) \).

XIV.15.2.6. Corollary. A midpoint-convex function on an interval \( I \) which is bounded on at least one subinterval of \( I \) is convex.

This result considerably extends XIV.15.2.3.

We can extend XIV.15.2.4. even further. A midpoint-convex function which is not convex cannot even be bounded on a set of positive Lebesgue measure. The next result is due to Ostrowski [?].
XIV.15.2.7. Theorem. Let \( f \) be midpoint-convex on an interval \( I \). If there is a Lebesgue-measurable subset \( E \) of \( I \) with \( \lambda(E) > 0 \) on which \( f \) is bounded, then \( f \) is convex on \( I \).

Proof: Assume \( f \) is not convex on \( I \). By replacing \( I \) by \( I \cap (-n,n) \) and \( E \) by \( E \cap (-n,n) \) for some sufficiently large \( n \), we may assume \( I = (a,b) \) is bounded. There is an open set \( U \subseteq (a,b) \) with \( E \subseteq U \) and \( \lambda(U) < \frac{4}{3}\lambda(E) \). \( U \) is a disjoint union of finitely or countably many open intervals \( J_n \), and we have

\[
\lambda(E) = \sum_n \lambda(E \cap J_n) \leq \sum_n \lambda(J_n) < \frac{4}{3} \sum_n \lambda(E \cap J_n)
\]

so there is an \( n \) such that

\[
0 < \lambda(E \cap J_n) < \frac{4}{3} \lambda(E \cap J_n)
\]

and replacing \( I \) by \( J_n \) and \( E \) by \( E \cap J_n \) we may assume \( \lambda(I) = \frac{4}{3}\lambda(E) \).

Suppose \( f(x) \leq M \) for all \( x \in E \). The set

\[
S = \{ x \in I : f(x) > M \}
\]

is dense in \( I \) by XIV.15.2.4., so by contracting \( I \) slightly we may assume the midpoint of \( I \) is in \( S \). By translating, we may assume \( I = (-c,c) \) and that \( 0 \in S \), to simplify notation. Set

\[
\tilde{S} = \{ -x : x \in S \}.
\]

For any \( x \in I \), we have

\[
M < f(0) \leq \frac{f(x) + f(-x)}{2}
\]

so either \( x \) or \( -x \) is in \( S \), i.e. \( S \cup \tilde{S} = I \). The set \( S \) is not obviously Lebesgue measurable, but in any case we have \( \lambda^*(S) = \lambda^*(\tilde{S}) \), where \( \lambda^* \) denotes Lebesgue outer measure (). We have \( E \cap S = \emptyset \), so \( E \subseteq \tilde{S} \) and \( S \subseteq (I \setminus E) \). Then

\[
\lambda(E) \leq \lambda^*(S) = \lambda^*(\tilde{S}) \leq \lambda(I \setminus E) = \lambda(I) - \lambda(E)
\]

\[
2\lambda(E) \leq \lambda(I) < \frac{4}{3}\lambda(E)
\]

which is a contradiction (to the assumption that \( f \) is not convex on \( I \)).

We then obtain the following corollary, due to Sierpiński:

XIV.15.2.8. Corollary. Let \( f \) be a midpoint-convex function on an interval \( I \). If \( f \) is a Lebesgue measurable function, then \( f \) is convex on \( I \).

Proof: We have that \( E_n = f^{-1}([-n,n]) \) is a Lebesgue measurable subset of \( I \) for all \( n \), and \( \cup_n E_n = I \), so \( \sup_n \lambda(E_n) = \lambda(I) > 0 \), and \( f \) is bounded on each \( E_n \).

Summarizing, and combining with XIV.15.1.13., we have:
XIV.15.2.9. Theorem. Let \( f \) be a midpoint-convex function on an interval \( I \), and \([a, b]\) a closed bounded interval in the interior of \( I \). The following are equivalent:

(i) \( f \) is convex on \([a, b]\).
(ii) \( f \) is Lipschitz on \([a, b]\).
(iii) \( f \) is continuous on \([a, b]\).
(iv) \( f \) is bounded on \([a, b]\).
(v) \( f \) is Lebesgue measurable on \([a, b]\).

XIV.15.3. Convergence of Sequences of Convex Functions

Pointwise convergence of a sequence of convex functions implies several much stronger types of convergence. We describe some of the rather remarkable consequences of pointwise convergence in this subsection.

XIV.15.3.1. Theorem. Let \( I \) be an interval, and \((f_n)\) a sequence of convex functions on \( I \) converging pointwise on \( I \) to a function \( f \). Then \( f \) is convex on \( I \), and the convergence is uniform on any closed bounded interval contained in \( I \) on which \( f \) is continuous (e.g. any closed bounded interval contained in the interior of \( I \)).

Proof: It has been noted in XIV.15.1.11. that \( f \) is convex.

If \([a, b]\) is a closed bounded interval in \( I \), suppose the convergence is not uniform on \([a, b]\). Then there is an \( \eta > 0 \) such that, for infinitely many \( n \), there is a \( c_n \in [a, b] \) with \( |f_n(c_n) - f(c_n)| \geq \eta \). Passing to a subsequence, we may assume we have such a \( c_n \) for all \( n \).

The sequence \((c_n)\) cannot have any eventually constant subsequences, which would contradict the pointwise convergence \( f_n \to f \). Thus \((c_n)\) has a strictly monotone subsequence. Passing to this subsequence, we may assume \((c_n)\) is strictly monotone. In the rest of the argument, we will assume \((c_n)\) is strictly increasing; the strictly decreasing case is essentially identical, interchanging the roles of \( a \) and \( b \).

We have \( c_n \to c \) for some \( c, a < c < b \). There are two cases to consider:

Case 1. \( f_n(c_n) \geq f(c_n) + \eta \) for infinitely many \( n \). Again passing to a subsequence, in this case we may assume \( f_n(c_n) \geq f(c_n) + \eta \) for all \( n \). Fix \( \epsilon > 0 \). Choose \( n_0 \) so that, for all \( n \geq n_0 \), we have \( c_n > c - \epsilon \), \( |f_n(c) - f(c)| < \frac{\eta}{2} \), and \( |f_n(a) - f(a)| < \frac{\eta}{2} \). Then, for \( n \geq n_0 \), we have

\[
\frac{f(c) - f(a) - \eta}{c - a} < \frac{f_n(c) - f_n(a)}{c - a} \leq \frac{f_n(c) - f_n(c_n)}{c - c_n} < -\frac{\eta/2}{\epsilon}.
\]

This is a contradiction if \( f(c) - f(a) - \eta \geq 0 \), or if \( f(c) - f(a) - \eta < 0 \) and \( \epsilon \) is sufficiently small, specifically if

\[
\epsilon < \frac{\eta(c - a)}{2[\eta + f(a) - f(c)]}.
\]
Case 2. \( f_n(c_n) \leq f(c_n) - \eta \) for infinitely many \( n \); we may again assume this holds for all \( n \). Fix \( z \) with \( a < z < c \) and let \( \lambda > 0 \) with

\[
-\lambda < \frac{f(z) - f(a) - \eta}{z - a}.
\]

Fix \( d \) with \( a < d < c \) such that \( d > c - \frac{\eta}{4\lambda} \) and \( |f(x) - f(c)| < \frac{\eta}{4} \) for all \( x \in [d, c] \) (this is possible since \( f \) is continuous at \( c \)). Choose \( n_0 \) such that, for all \( n \geq n_0 \), \( c_n > d \), \( |f_n(a) - f(a)| < \frac{\eta}{4} \), \( |f_n(z) - f(z)| < \frac{\eta}{4} \), and \( |f_n(d) - f(d)| < \frac{\eta}{4} \). Then, for \( n \geq n_0 \), we have \( f_n(d) > f(c) - \frac{\eta}{2} \) and \( f_n(c_n) < f(c_n) - \eta < f(c) - \frac{3\eta}{4} \). Thus \( f_n(c_n) - f_n(d) < -\frac{\eta}{4} \). We also have

\[
\frac{f_n(c_n) - f_n(d)}{c_n - d} \geq \frac{f_n(z) - f_n(a)}{z - a} \geq \frac{f(z) - f(a) - \eta}{z - a} > -\lambda.
\]

Then, since \( 0 < c_n - d < \frac{n}{4\lambda} \), we get

\[
\frac{4\lambda}{\eta} (f_n(c_n) - f_n(d)) > -\lambda
\]

which is a contradiction.

(If \( c < b \) in Case 2, a contradiction can be obtained somewhat more simply using an argument similar to the one in Case 1.)

The first statement of this result which I have found is in [Con74]; however, the proof there is incorrect. A stronger assertion, which is incorrect (see the following example), is made in [? IX, Book IV, Chapter I, §4, p. 52]; the proof outlined there only gives a slightly weaker conclusion than XIV.15.3.1. (cf. XIV.15.7.6.(a)-(b)), but can be adapted to give the full result (XIV.15.7.6.(c)-(d)).

XIV.15.3.2. **Example.** If \( f \) is not continuous on \( I \), we do not have uniform convergence on all of \( I \) in general, even if \( I \) is closed and bounded. If \( f_n(x) = x^n \), then \( f_n \) is convex on \([0, 1]\) and converges pointwise on \([0, 1]\) to the function of XIV.15.1.8.(v). But the convergence is not uniform on \([0, 1]\).

If \( I \) is not closed and bounded, simple examples show that we do not have uniform convergence on all of \( I \) in general, even if \( f \) is continuous on \( I \): if \( I \) is unbounded, consider \( f_n(x) = \frac{x}{n} \), and if \( I = (0, 1] \), consider \( f_n(x) = \frac{1}{x+\pi} \).

Here is a closely related result:

XIV.15.3.3. **Theorem.** Let \( (f_n) \) be a sequence of convex functions on an interval \( I \), converging pointwise on \( I \) to a (convex) function \( f \). Then

(i) If \( x \) is not a left endpoint of \( I \), then

\[
\liminf_{n \to \infty} D_L f_n(x) \geq D_L f(x).
\]

(ii) If \( x \) is not a right endpoint of \( I \), then

\[
\limsup_{n \to \infty} D_R f_n(x) \leq D_R f(x).
\]
In particular, if \( x \) is an interior point of \( I \) and \( f \) is differentiable at \( x \), then

\[
\lim_{n \to \infty} D_L f_n(x) = \lim_{n \to \infty} D_R f_n(x) = f'(x)
\]

(i.e. the limits both exist and equal \( f'(x) \)).

**Proof:** We prove only (i); the proof of (ii) is entirely symmetric and is left to the reader. So suppose \( x \) is not a left endpoint of \( I \), and fix \( m < D_L f(x) \) (note that \( D_L f(x) \neq -\infty \)). Then there is a \( y \in I \), \( y < x \), such that

\[
\frac{f(y) - f(x)}{y - x} > m
\]

and thus there is an \( \epsilon > 0 \) such that

\[
m' := \frac{f(y) - f(x) + 2\epsilon}{y - x} > m
\]

(note that \( y - x < 0 \)). There is an \( N \) such that \( |f_n(x) - f(x)| < \epsilon \) and \( |f_n(y) - f(y)| < \epsilon \) for all \( n \geq N \). Then, for \( n \geq N \), we have \( f_n(y) < f(y) + \epsilon \) and \( f_n(x) > f(x) - \epsilon \), and thus, for any \( z \), \( y \leq z < x \), we have, using convexity of \( f_n \),

\[
\frac{f_n(z) - f_n(x)}{z - x} \geq \frac{f_n(y) - f_n(x)}{y - x} > \frac{[f(y) + \epsilon] - [f(x) - \epsilon]}{y - x} = m'
\]

so \( D_L f_n(x) \geq m' > m \) for \( n \geq N \), and hence \( \lim \inf_{n \to \infty} D_L f_n(x) \geq m' > m \).

For the final statement, since \( D_L f_n(x) \leq D_R f_n(x) \) for all \( n \), we have

\[
f'(x) \leq \lim \inf_{n \to \infty} D_L f_n(x) \leq \lim \sup_{n \to \infty} D_L f_n(x) \leq \lim \sup_{n \to \infty} D_R f_n(x) \leq f'(x)
\]

\[
f'(x) \leq \lim \inf_{n \to \infty} D_L f_n(x) \leq \lim \inf_{n \to \infty} D_R f_n(x) \leq \lim \sup_{n \to \infty} D_R f_n(x) \leq f'(x)
\]

so all the inequalities are equalities.

XIV.15.3.4. **Corollary.** Let \((f_n)\) be a sequence of convex functions on an interval \( I \) converging pointwise on \( I \) to a (convex) function \( f \). Then \( f_n' \to f' \) pointwise almost everywhere.

This corollary can also be proved by combining the next theorem with (\).

XIV.15.3.5. **Theorem.** [Con74] Let \((f_n)\) be a sequence of convex functions on a closed bounded interval \([a, b]\), converging pointwise on \([a, b]\) to a continuous (convex) function \( f \). Then \( f_n' \to f' \) in the \( L^1 \)-norm (\), i.e.

\[
\lim_{n \to \infty} \|f_n' - f'\|_1 = \lim_{n \to \infty} \int_a^b |f_n'(x) - f'(x)| \, dx = 0 .
\]

1687
**XIV.15.3.6.** Corollary. Let \((f_n)\) be a sequence of convex functions on a closed bounded interval \([a, b]\), converging pointwise on \([a, b]\) to a continuous (convex) function \(f\). Then \(f_n \to f\) in the total variation norm (\(\|\cdot\|_{TV}\)).

To see this, we may assume that each \(f_n\) is continuous on \([a, b]\) by redefining it at the endpoints. Then \(f\) and each \(f_n\) is absolutely continuous on \(I\), and by (\(\|\cdot\|_1\)) the total variation norm of an absolutely continuous function \(g\) on \([a, b]\) is

\[
\|g\|_{TV} = |g(a)| + \int_a^b |g'(x)| \, d\lambda(x).
\]

To prove XIV.15.3.5., we need a lemma:

**XIV.15.3.7.** Lemma. Let \(f\) and \(g\) be convex functions on an interval \(I\), and \(P(x) = f(a) + \frac{f(b) - f(a)}{b - a} (x - a)\). Then

\[
\|f' - P'\|_1 = 2\|f - P\|_{\infty}
\]

\[
\|g' - P'\|_1 \leq \|f' - P'\|_1 + 4\|f - g\|_{\infty}
\]

where \(\|\phi\|_{\infty} = \sup\{|\phi(x)| : a \leq x \leq b\}\) is the uniform norm.

**Proof:** For the equality, note that \(f - P\) is convex and is 0 at \(a\) and \(b\), and there is a \(c \in (a, b)\) such that \(f\) is nonincreasing on \([a, c]\) and nondecreasing on \([c, b]\), so the total variation \(\|f' - P'\|_1\) is \(2|m|\), where \(m = f(c)\) is the minimum of \(f - P\) on \([a, b]\); and we also have \(|m| = \|f - P\|_{\infty}\).

For the inequality, \(g - P\) is convex on \([a, b]\), so either \(g - P\) is monotone on \([a, b]\), in which case

\[
\|g' - P'\|_1 = \|[g(b) - P(b)] - [g(a) - P(a)]\| = \|[g(b) - f(b)] - [g(a) - f(a)]\| \leq 2\|f - g\|_{\infty}
\]

or there is a \(d \in (a, b)\) with \(g - P\) nonincreasing on \([a, d]\) and nondecreasing on \([d, b]\), in which case

\[
\|g' - P'\|_1 = ([g(a) - P(a)] - [g(d) - P(d)]) + ([g(b) - P(b)] - [g(d) - P(d)])
\]

\[
= ([g(a) - f(a)] - [g(d) - P(d)]) + ([g(b) - f(b)] - [g(d) - P(d)]) = 2[P(d) - g(d)] + |g(a) - f(a)| + |g(b) - f(b)|
\]

\[
\leq 2|g(d) - P(d)| + 2\|g - f\|_{\infty} \leq 2(|g(d) - f(d)| + |f(d) - P(d)|) + \|g - f\|_{\infty}
\]

\[
\leq 2\|f - P\|_{\infty} + 4\|g - f\|_{\infty} = \|f' - P'\|_1 + 4\|f - g\|_{\infty}.
\]

\(\circ\)

We now give the proof of XIV.15.3.5.

**Proof:** Let \(\epsilon > 0\). Using (\(\|\cdot\|_1\)), fix a partition \(\mathcal{P} = \{a = t_0 < t_1 < \cdots < t_m = b\}\) of \([a, b]\) for which

\[
\|f' - (\mathcal{P}f)'\|_1 < \frac{\epsilon}{4}
\]

where \(\mathcal{P}f\) is the polygonal function whose graph has vertices \((t_k, f(t_k))\) for \(0 \leq k \leq m\). Since \(f_n \to f\) uniformly, choose \(N\) such that

\[
\|f_n - f\|_{\infty} < \frac{\epsilon}{8m}
\]

1688
for all $n \geq N$. For such an $n$, by Lemma XIV.15.3.7, we have, for each $k$,

$$\int_{t_{k-1}}^{t_k} |f'_n - (Pf)'| \leq \int_{t_{k-1}}^{t_k} |f' - (Pf)'| + 4\|f_n - f\|_\infty < \int_{t_{k-1}}^{t_k} |f' - (Pf)'| + \frac{\epsilon}{2m}.$$  

Thus we have

$$\int_a^b |f'_n - f'| \leq \int_a^b |f'_n - (Pf)'| + \int_a^b |(Pf)' - f'|$$

$$\leq \sum_{k=1}^m \int_{t_{k-1}}^{t_k} |f'_n - (Pf)'| + \frac{\epsilon}{4}$$

$$< \sum_{k=1}^m \left( \int_{t_{k-1}}^{t_k} |f' - (Pf)'| + \frac{\epsilon}{2m} \right) + \frac{\epsilon}{4}$$

$$= \int_a^b |f' - (Pf)'| + \frac{\epsilon}{2} + \frac{\epsilon}{4} < \frac{\epsilon}{2} + \frac{\epsilon}{4} = \epsilon.$$

If the limit function is differentiable on $I$, we can say something stronger:

**XIV.15.3.8. Proposition.** Let $(f_n)$ be a sequence of convex functions on a closed bounded interval $[a, b]$, converging pointwise on $[a, b]$ to a (convex) function $f$. If $f$ is differentiable on $[a, b]$, then $(D_L f_n)$ and $(D_R f_n)$ converge uniformly to $f'$ on $[a, b]$ (i.e. $(f'_n)$ “converges uniformly” to $f'$ on $[a, b]$).

Indeed, under the hypotheses, $f'$ is continuous on $[a, b]$, so the proposition follows from the next more general result, which is strongly reminiscent of Dini’s Theorem (\():\)

**XIV.15.3.9. Proposition.** Let $(g_n)$ be a sequence of nondecreasing functions on a closed bounded interval $[a, b]$ converging pointwise on $[a, b]$ to a (necessarily nondecreasing) continuous function $g$. Then $g_n \to g$ uniformly on $[a, b]$.

**Proof:** Let $\epsilon > 0$. By continuity of $g$, choose a partition $\{a = t_0 < t_1 < \cdots < t_m = b\}$ of $[a, b]$ such that $g(t_k) - g(t_{k-1}) < \frac{\epsilon}{2}$ for $1 \leq k \leq m$. Choose $N$ such that $|g_n(t_k) - g(t_k)| < \frac{\epsilon}{2}$ for all $n \geq N$ and $0 \leq k \leq m$. Then, if $t_{k-1} \leq x \leq t_k$, we have, for $n \geq N$,

$$g(t_k) - \epsilon < g(t_k) - \frac{\epsilon}{2} \leq g_n(t_{k-1}) \leq g_n(x) \leq g_n(t_k) \leq g(t_k) + \frac{\epsilon}{2}$$

and we also have

$$g(t_k) - \frac{\epsilon}{2} < g(t_{k-1}) \leq g(x) \leq g(t_k)$$

and thus it follows that $|g_n(x) - g(x)| < \epsilon$. This is true for every $k$, i.e. for every $x \in [a, b]$.

If $f$ is not differentiable everywhere, we do not have $f'_n \to f'$ uniformly in general, even on closed bounded intervals contained in the interior of $I$:

1689
XIV.15.3.10. Example. Let \( f(x) = |x| \), and for each \( n \) let \( f_n(x) = |x|^{1+1/n} \). Then \( f \) and each \( f_n \) are convex, \( f_n \) is differentiable everywhere, with \( f'_n \) continuous, and \( f_n \to f \) pointwise on \( \mathbb{R} \) (and uniformly on any bounded subinterval). But \( f'_n \) does not converge uniformly to \( f' \) on any (deleted) interval around 0.

XIV.15.4. Jensen’s Inequality

A simple induction on \( n \), beginning with \( n = 2 \), shows:

XIV.15.4.1. Proposition. If \( f \) is convex on an interval \( I \), \( x_1, \ldots, x_n \in I \), and \( t_1, \ldots, t_n \geq 0 \), \( t_1 + \cdots + t_n = 1 \), then

\[
f(t_1 x_1 + \cdots + t_n x_n) \leq t_1 f(x_1) + \cdots + t_n f(x_n).
\]

The inequality is strict if the \( x_k \) are distinct and the \( t_k \) nonzero, unless \( f \) is linear on an interval containing the \( x_k \).

This can be rephrased:

XIV.15.4.2. Corollary. Let \( f \) be convex on an interval \( I \), \( x_1, \ldots, x_n \in I \), and \( s_1, \ldots, s_n \geq 0 \). Then

\[
\frac{s_1 x_1 + \cdots + s_n x_n}{s_1 + \cdots + s_n} \in I
\]

and

\[
f \left( \frac{s_1 x_1 + \cdots + s_n x_n}{s_1 + \cdots + s_n} \right) \leq \frac{s_1 f(x_1) + \cdots + s_n f(x_n)}{s_1 + \cdots + s_n}.
\]

The inequality is strict if the \( x_k \) are distinct and the \( s_k \) nonzero, unless \( f \) is linear on an interval containing the \( x_k \).

For the proof, just set \( t_k = \frac{s_k}{s_1 + \cdots + s_n} \).

A particularly important sample application is:

XIV.15.4.3. Corollary. Let \( x_1, \ldots, x_n \) be positive numbers, and \( \lambda_1, \ldots, \lambda_n \) positive numbers with \( \lambda_1 + \cdots + \lambda_n = 1 \). Then

\[
x_1^{\lambda_1} x_2^{\lambda_2} \cdots x_n^{\lambda_n} \leq \lambda_1 x_1 + \cdots + \lambda_n x_n
\]

with strict inequality unless all the \( x_k \) are equal.

Proof: Note that \( f(x) = e^x \) is convex on \( \mathbb{R} \). Set \( y_k = \log x_k \), so \( x_k = e^{y_k} \). We then have

\[
(e^{y_1})^{\lambda_1} \cdots (e^{y_n})^{\lambda_n} = e^{\lambda_1 y_1 + \cdots + \lambda_n y_n} \leq \lambda_1 e^{y_1} + \cdots + \lambda_n e^{y_n}
\]

which is the desired inequality.

The special case where all \( \lambda_k = \frac{1}{n} \) is
Corollary. Let \( x_1, \ldots, x_n \) be positive numbers. Then the geometric mean of \( \{x_1, \ldots, x_n\} \) is less than or equal to the arithmetic mean, i.e.

\[
[x_1 x_2 \cdots x_n]^{1/n} \leq \frac{1}{n} [x_1 + \cdots + x_n]
\]

with strict inequality unless all the \( x_k \) are equal.

Jensen’s Inequality is a generalization of XIV.15.4.2. If \( (X, \mathcal{A}, \mu) \) is a finite measure space and \( f \) is a \( \mu \)-integrable function, recall () that the average value of \( f \) is

\[
av(f) = \frac{1}{\mu(X)} \int_X f \, d\mu.
\]

Theorem. [Jensen’s Inequality] Let \( (X, \mathcal{A}, \mu) \) be a finite measure space, \( f \) a \( \mu \)-integrable function taking values in an interval \( I \), and \( \phi \) a convex function on \( I \). Let \( c = \text{av}(f) \). Then \( c \in I \), and if either \( \phi \) is nonnegative on \( I \) or \( \phi \circ f \) is \( \mu \)-integrable, then

\[
\phi(c) \leq \frac{1}{\mu(X)} \int_X \phi \circ f \, d\mu.
\]

The inequality is strict unless \( f \) is constant a.e. or \( \phi \) is linear on a subinterval containing the essential range of \( f \).

The condition that \( \phi \) is nonnegative or that \( \phi \circ f \) is integrable is simply needed to define the right side of the inequality. (Integrability of \( \phi \circ f \) is not automatic; cf. Exercise XIV.15.7.3.) Actually, in general it turns out that \( (\phi \circ f)_- \) is always integrable (Exercise XIV.15.7.4), so \( \phi \circ f \) is integrable in the extended sense of () and the right side is well defined as \( +\infty \) if \( \phi \circ f \) is not integrable, even if \( \phi \) is not nonnegative.

Proof: If \( \phi \) is nonnegative but \( \phi \circ f \) is not integrable, the inequality is trivial, so it only needs proof in the case where \( \phi \circ f \) is integrable. Let us assume this.

To see that \( c \in I \), it suffices to show that if \( a < f(x) < b \) for all \( x \in X \), then \( a < c < b \). But in this case the function \( g(x) = f(x) - a \) is strictly positive on \( X \), so \( \int_X g \, d\mu > 0 () \), and similarly \( h(x) = b - f(x) \) has \( \int_X h \, d\mu > 0 \). In fact \( c \) is in the interior of \( I \) unless \( f(x) \) is equal almost everywhere to one of the endpoints of \( I \), in which case the inequality is a trivial equality.

Let \( m \) be any number between \( D_L \phi(c) \) and \( D_R \phi(c) () \), and let \( L(t) = \phi(c) + m(t - c) \) for \( x \in I \). Then \( L \) is a linear function, and \( L(t) \leq \phi(t) \) for all \( t \in I \). Thus we have

\[
\phi(c) \mu(X) = \int_X [\phi(c) + m(f(x) - c)] \, d\mu(x) = \int_X L(f(x)) \, d\mu(x) \leq \int_X \phi(f(x)) \, d\mu(x).
\]

We have equality if and only if \( L \circ f = \phi \circ f \) \( \mu \text{-a.e.} \), which is equivalent to the condition in the last line of the statement.

The inequality XIV.15.4.2. can be regarded as a special case of Jensen’s Inequality, where \( X \) is an \( n \)-point space and \( \{s_1, \ldots, s_n\} \) are the masses of the points.

Here are some of the other most commonly stated special cases of Jensen’s Inequality:
**XIV.15.4.7. Corollary.** Let $f$ be integrable on $[a, b]$ with values in an interval $I$, and let $\phi$ be convex on $I$. Let

$$c = \frac{1}{b-a} \int_a^b f \, d\lambda .$$

Then $c \in I$, and if $\phi$ is nonnegative or $\phi \circ f$ is integrable on $[a, b]$, then

$$\phi(c) \leq \frac{1}{b-a} \int_a^b \phi \circ f \, d\lambda .$$

A slightly more general version allows a weight function:

**XIV.15.4.8. Corollary.** Let $f$ be Lebesgue measurable on $[a, b]$ with values in an interval $I$, and let $\phi$ be convex on $I$. Let $\omega$ be a nonnegative Lebesgue integrable function on $[a, b]$, with $f \omega$ integrable on $[a, b]$. Set

$$c = \frac{1}{\int_a^b \omega \, d\lambda} \int_a^b f \omega \, d\lambda .$$

Then $c \in I$, and if $\phi$ is nonnegative or $(\phi \circ f) \omega$ is integrable on $[a, b]$, then

$$\phi(c) \leq \frac{1}{\int_a^b \omega \, d\lambda} \int_a^b (\phi \circ f) \omega \, d\lambda .$$

If $f$ is continuous, then everything can be stated and proved in terms of Riemann integration:

**XIV.15.4.9. Corollary.** Let $f$ be continuous on $[a, b]$ with values in an interval $I$, and let $\phi$ be convex and continuous on $I$. Let

$$c = \frac{1}{b-a} \int_a^b f(x) \, dx .$$

Then $c \in I$, and

$$\phi(c) \leq \frac{1}{b-a} \int_a^b \phi(f(x)) \, dx .$$

An examination of the proof of XIV.15.4.5. shows that only Riemann integrals need be considered in this case. Without the continuity assumption on $\phi$, $\phi \circ f$ can fail to be Riemann-integrable on $[a, b]$ (Exercise XIV.15.7.5.).

**XIV.15.5. Log-Convex Functions**

**XIV.15.5.1. Definition.** If $I$ is an interval, a function $g : I \to (0, \infty)$ is log-convex on $I$ if $\log g$ is convex on $I$. 

1692
XIV.15.5.2. Alternatively, a positive function $g$ on an interval $I$ is log-convex on $I$ if, for all $a, b \in I$, $0 \leq \lambda \leq 1$,

$$g(\lambda a + (1 - \lambda)b) \leq g(a)^\lambda g(b)^{1-\lambda}.$$  

The right-hand side is a sort of weighted geometric mean of $g(a)$ and $g(b)$. If $g$ is continuous, then by XIV.15.2.3. $g$ is log-convex if and only if, for every $a, b \in I$,

$$g \left( \frac{a + b}{2} \right) \leq \sqrt{g(a) g(b)}.$$  

XIV.15.5.3. Proposition. A log-convex function is convex.

Proof: This follows immediately from XIV.15.5.2. and XIV.15.4.3. &

XIV.15.5.4. The converse is false. $g(x) = x^2$ is convex on $(0, \infty)$, but not log-convex on any subinterval. In fact, an increasing log-convex function on an interval $(a, \infty)$ must grow at least exponentially as $x \to +\infty$.

XIV.15.5.5. Since a sum of convex functions is convex, it is obvious that a product of log-convex functions is log-convex. It is also clear that a positive scalar multiple of a log-convex function is log-convex. It is less obvious, but true, that a sum of log-convex functions is log-convex (XIV.15.5.7.).

XIV.15.5.6. Lemma. Let $a_1, a_2, b_1, b_2, c_1, c_2$ be positive real numbers. If $a_1 c_1 - b_1^2 \geq 0$ and $a_2 c_2 - b_2^2 \geq 0$, then

$$(a_1 + a_2)(c_1 + c_2) - (b_1 + b_2)^2 \geq 0.$$  

Proof: If $a, b, c$ are positive real numbers, then the polynomial $f(x) = ax^2 + 2bx + c$ takes only nonnegative real values (for $x$ real) if and only if $ac - b^2 \geq 0$. By assumption, the polynomials $f_1(x) = a_1 x^2 + 2b_1 x + c_1$ and $f_2(x) = a_2 x^2 + 2b_2 x + c_2$ take only nonnegative real values, and hence

$$f_1(x) + f_2(x) = (a_1 + a_2)x^2 + 2(b_1 + b_2)x + (c_1 + c_2)$$

also takes only nonnegative real values. &

XIV.15.5.7. Proposition. A sum of log-convex functions on an interval $I$ is log-convex on $I$.

Proof: Since log-convex functions are continuous, by XIV.15.5.2. it suffices to show that if $f$ and $g$ are log-convex on $I$ and $x, y \in I$, then

$$\left[ f \left( \frac{x + y}{2} \right) + g \left( \frac{x + y}{2} \right) \right]^2 \leq (f(x) + g(x))(f(y) + g(y)).$$

Apply XIV.15.5.6. with $a_1 = f(x)$, $a_2 = g(x)$, $b_1 = f \left( \frac{x+y}{2} \right)$, $b_2 = g \left( \frac{x+y}{2} \right)$, $c_1 = f(y)$, $c_2 = g(y).$ &

1693
XIV.15.5.8. The conclusion of XIV.15.5.7. extends to arbitrary finite sums. Since a positive pointwise limit of log-convex functions is obviously log-convex, it also extends to a positive pointwise limit of finite sums of log-convex functions, e.g. a pointwise-convergent infinite series. By approximating the integrals by Riemann sums, we also obtain:

XIV.15.5.9. PROPOSITION. Let \( f \) be a function on \( I \times [a,b] \) for some interval \( I \) and \( a, b \in \mathbb{R}, a < b \). If \( f(x, t) \) is log-convex on \( I \) for each fixed \( t \), and \( f(x, t) \) is continuous on \( [a,b] \) for each fixed \( x \), then

\[
g(x) = \int_a^b f(x, t) \, dt
\]

is log-convex on \( I \).

PROOF: Let \( n \in \mathbb{N} \) and \( h = \frac{b-a}{n} \). Then \( g_n(x) = h(f(x,a) + f(x,a+h) + \cdots + f(x,a+(n-1)h) \) is log-convex, and \( g_n \to g \) pointwise. Since \( f \) is strictly positive, it is obvious that \( g \) is also strictly positive. 

This result extends to improper integrals:

XIV.15.5.10. COROLLARY. Let \( f \) be a function on \( I \times (a,b) \) for some interval \( I \) and \( a, b \in [-\infty, \infty], a < b \). If \( f(x, t) \) is log-convex on \( I \) for each fixed \( t \), \( f(x, t) \) is continuous on \( (a,b) \) for each fixed \( x \), and the improper Riemann integral \( \int_a^b f(x, t) \, dt \) converges for all \( x \in I \), then

\[
g(x) = \int_a^b f(x, t) \, dt
\]

is log-convex on \( I \).

PROOF: Let \( (a_n) \) be a decreasing sequence with \( a_n \to a \), \( (b_n) \) an increasing sequence with \( b_n \to b \), \( a_n < b_n \) for all \( n \). Set

\[
g_n(x) = \int_{a_n}^{b_n} f(x, t) \, dt .
\]

Then \( g_n \) is log-convex on \( I \) for all \( n \) by XIV.15.5.9., and \( g_n \to g \) pointwise on \( I \). It is also clear that \( g \) is strictly positive.

XIV.15.6. Higher-Dimensional Versions of Convexity

XIV.15.7. Exercises

XIV.15.7.1. Let \( f : \mathbb{R} \to \mathbb{R} \) be an additive function, i.e. \( f(x+y) = f(x) + f(y) \) for all \( x, y \in \mathbb{R} \). Show that if there is any nontrivial closed bounded interval \([a,b]\) on which \( f \) is bounded or Lebesgue measurable, then \( f \) is linear on \( \mathbb{R} \), i.e. there is an \( m \in \mathbb{R} \) with \( f(x) = mx \) for all \( x \in \mathbb{R} \). [Show that \( f \) and \( -f \) are midpoint-convex, and use XIV.15.2.7.]

1694
**XIV.15.7.2.** Let \( \{x_i : i \in I\} \) be a Hamel basis () for \( \mathbb{R} \) over \( \mathbb{Q} \), i.e. for each \( x \in \mathbb{R} \) there is a unique representation
\[
    x = \sum_{i \in I} c_i(x)x_i
\]
where \( c_i(x) \in \mathbb{Q} \) for each \( i \) and only finitely many \( c_i(x) \) are nonzero. (The Axiom of Choice is needed here.)

(a) Show that each function \( c_i \) is \( \mathbb{Q} \)-linear, i.e. \( c_i(x + y) = c_i(x) + c_i(y) \) and \( c_i(ax) = ac_i(x) \) for all \( x, y \in \mathbb{R}, a \in \mathbb{Q} \).

(b) Show that each \( c_i \) is a midpoint-convex function on \( \mathbb{R} \) (and that \(-c_i \) is also midpoint-convex).

(c) Conclude that \( c_i \) is discontinuous everywhere. [If \( j \neq i \), then \( \mathbb{Q}x_j \) and \( x_i + \mathbb{Q}x_j \) are both dense in \( \mathbb{R} \).]

(d) Conclude that \( c_i \) is not convex on any interval. It then follows from XIV.15.2.4. that \( c_i \) is unbounded on every interval (this can be seen directly by noting that if \( j \neq i \), then \( nx_i + \mathbb{Q}x_j \) is dense in \( \mathbb{R} \) for each \( n \in \mathbb{Z} \)). Conclude also that the restriction of \( c_i \) to any interval is not Lebesgue measurable.

**XIV.15.7.3.** Let \( X = (0, 1) \) with Lebesgue measure. Let \( f(x) = x, I = (0, 1), \phi(x) = e^{1/x} \). Show that \( X, f, I, \phi \) satisfy the hypotheses of Jensen’s Inequality, but that \( \phi \circ f \) is not integrable on \( X \).

**XIV.15.7.4.** Let \( (X, A, \mu) \) be a finite measure space, \( f \) a \( \mu \)-integrable function on \( X \) taking values in an integral \( I \), and \( \phi \) a convex function on \( I \). Show that \( \phi \circ f \) is \( \mu \)-integrable. [There is a linear function \( L \) such that \( \phi \geq L \) on \( I \).]

**XIV.15.7.5.** Let \( K \) be a Cantor set of positive measure (), and \( f \) a continuous function from \([0, 1]\) to \([0, 1]\) which takes the value 1 precisely on \( K \), e.g. \( f(x) = 1 - \text{dist}(x, K) \). Let \( \phi \) be the convex function on \([0, 1]\) defined in XIV.15.1.8.(v). Then \( \phi \circ f \) is not Riemann-integrable on \([0, 1]\).

**XIV.15.7.6.** Let \( \mathcal{F} \) be a collection of convex functions on an interval \([a, b]\), and \([c, d]\) a closed bounded subinterval of \((a, b)\).

(a) If the functions in \( \mathcal{F} \) are uniformly bounded above at \( a \) and \( b \), and there is an \( x_0 \in (a, b) \) such that the functions in \( \mathcal{F} \) are uniformly bounded below at \( x_0 \), show that \( \mathcal{F} \) is uniformly bounded on \([a, b]\).

(b) Under the hypotheses of (a), show that there are real numbers \( m \) and \( M \) such that
\[
    m \leq D_L f(x) \leq D_R f(x) \leq M
\]
for all \( f \in \mathcal{F} \) and all \( x \in [c, d] \). Conclude that \( \mathcal{F} \) is uniformly equicontinuous () on \([c, d]\). In particular, \( \mathcal{F} \) is equicontinuous on \((a, b)\).

(c) If \( (f_n) \) is a sequence of convex functions on \([a, b]\) converging pointwise on \([a, b]\) to a (convex) function \( f \), use (a), (b), and the Arzela-Ascoli Theorem () to conclude that \( f_n \to f \) uniformly on \([c, d]\) (cf. XIV.15.3.1.).

(d) If \( (f_n) \) is a sequence of continuous convex functions on \([a, b]\) converging pointwise on \([a, b]\) to a continuous (convex) function \( f \), show that the set
\[
    \mathcal{F} = \{f_n : n \in \mathbb{N}\}
\]
is uniformly bounded and equicontinuous on \([a, b]\).

(e) If \( (f_n) \) is a sequence of convex functions on \([a, b]\) converging pointwise on \([a, b]\) to a function \( f \), use (d) and the Arzela-Ascoli Theorem () to give an alternate proof of XIV.15.3.1..
XIV.15.7.7. Let $f$ be convex on an interval $I$ with right endpoint $b$, and suppose $f$ is continuous at $b$. Show that if $\sup_{x<b} D_L f(x) = m < \infty$, then $D_L f(b) = m$.

XIV.15.7.8. Let $f$ be convex on $[a, +\infty)$ for some $a$. Show that

$$\lim_{x \to +\infty} \frac{f(x)}{x}$$

exists (possibly as $+\infty$, but not $-\infty$) and equals

$$\lim_{x \to +\infty} D_L f(x) = \lim_{x \to +\infty} D_R f(x) = \sup_{x > a} D_L f(x) = \sup_{x \geq a} D_R f(x).$$

Prove a similar statement for $-\infty$.

XIV.15.7.9. Let $f$ be a function on an interval $I$ taking only positive values, with $f''$ defined everywhere on $I$.

(a) Show that $f$ is log-convex on $I$ if and only if

$$f(x)f''(x) \geq [f'(x)]^2$$

for all $x \in I$. [Set $g(x) = \log f(x)$, and compute $g''$.]

(b) What if $f''$ is only defined on the complement of a countable set? What if $f''$ is only defined almost everywhere?

XIV.15.7.10. Let $f$ and $g$ be convex functions on an interval of the form $(a, +\infty)$ for some $a$. Show that if

$$\lim_{n \to \infty} [f(n) - g(n)] = 0$$

(limit for $n \in \mathbb{N}$), then

$$\lim_{x \to +\infty} [f(x) - g(x)] = 0$$

(limit for $x \in \mathbb{R}$).
XIV.16. Functions of Bounded Variation

Functions of bounded variation are ones which vary in a controlled way. Geometrically, a function has bounded variation on an interval if its graph has finite arc length. Functions of bounded variation are well-behaved, with perhaps unexpectedly nice properties which are technically useful.

XIV.16.1. The Total Variation of a Function

XIV.16.1.1. In the definition, we will use the positive and negative part notation: if \( x \) is a real number, write \( x^+ = \max(x, 0) = \frac{|x| + x}{2} \) and \( x^- = \max(-x, 0) = \frac{|x| - x}{2} \), so that \( x = x^+ - x^- \) and \( |x| = x^+ + x^- \). Thus if \( y \) and \( z \) are real numbers, we will write \( (y + z)^+ = \max(y + z, 0) \) and \( (y + z)^- = \max(z - y, 0) \). Thus \( (y - z)^+ = y - z \) if \( y \geq z \) and 0 otherwise, and \( (y - z)^- = |y - z| \) if \( y \leq z \) and 0 otherwise. We always have \( (y - z)^+ - (y - z)^- = y - z \) and \( (y - z)^+ + (y - z)^- = |y - z| \).

XIV.16.1.2. Proposition. If \( x, y \in \mathbb{R} \), then \( (x + y)^+ \leq x^+ + y^+ \) and \( (x + y)^- \leq x^- + y^- \).

This can be proved brute-force on a case-by-case basis, or using the triangle inequality (Exercise (1)).

XIV.16.1.3. Definition. Let \( f \) be a real-valued function on an interval \([a, b]\). If

\[
P = \{ a = x_0, x_1, \ldots, x_n = b \}
\]

is a partition of \([a, b]\), set

\[
V^+(f, P) = \sum_{k=1}^{n} [f(x_k) - f(x_{k-1})]^+
\]

\[
V^-(f, P) = \sum_{k=1}^{n} [f(x_k) - f(x_{k-1})]^-
\]

\[
V(f, P) = V^+(f, P) + V^-(f, P) = \sum_{k=1}^{n} |f(x_k) - f(x_{k-1})|
\]

\(V^+(f, P), V^-(f, P),\) and \(V(f, P)\) are respectively the positive variation, negative variation, and total variation of \( f \) over the partition \( P \).

These numbers of course depend on the interval \([a, b]\), which is implicitly coded in the partition \( P \).

XIV.16.1.4. Proposition. If \( P \) is any partition of \([a, b]\), then \( V^+(f, P) \) and \( V^-(f, P) \) are nonnegative real numbers, and

\[
V^+(f, P) - V^-(f, P) = f(b) - f(a).
\]

Proof: The sums are obviously nonnegative and finite. We have

\[
V^+(f, P) - V^-(f, P) = \sum_{k=1}^{n} ([f(x_k) - f(x_{k-1})]^+ - [f(x_k) - f(x_{k-1})]^-) \]

1697
The function $f$ has bounded variation on $[a, b]$ if $V_{[a,b]}(f) < +\infty$.

**Examples.** (i) Any monotone function on an interval $[a, b]$ has bounded variation. If $f$ is nondecreasing on $[a, b]$, then $V_{[a,b]}^+(f) = V_{[a,b]}(f) = f(b) - f(a)$ and $V_{[a,b]}^-(f) = 0$; if $f$ is nonincreasing on $[a, b]$, then $V_{[a,b]}^-(f) = V_{[a,b]}(f) = f(a) - f(b)$ and $V_{[a,b]}^+(f) = 0$.

(ii) A Lipschitz function on $[a, b]$ has bounded variation. If $f$ is Lipschitz with Lipschitz constant $M$, i.e., $|f(x) - f(y)| \leq M|x - y|$ for all $x, y \in [a, b]$, then if $\mathcal{P} = \{a = x_0, x_1, \ldots, x_n = b\}$ is any partition of $[a, b]$, we have

$$V(f, \mathcal{P}) = \sum_{k=1}^{n} |f(x_k) - f(x_{k-1})| \leq \sum_{k=1}^{n} M|x_k - x_{k-1}| = M(b - a)$$

so $V_{[a,b]}(f) \leq M(b - a)$. In particular, if $f$ is differentiable on $[a, b]$ and $f'$ is bounded, then $f$ has bounded variation on $[a, b]$.
(iii) A continuous function need not have bounded variation. Continuous but everywhere non-differentiable functions cannot have bounded variation (XIV.16.2.4(iv)). Even a function which is differentiable everywhere need not have bounded variation. Let

\[ f(x) = x^2 \sin \left( \frac{1}{x^2} \right) \]

for \( x \neq 0 \), \( f(0) = 0 \) (Figure V.4). Then \( f \) is differentiable everywhere, but not of bounded variation on \([0, 1]\).

For each \( n \), let \( x_n = \frac{1}{\sqrt{2} + \pi(n - 1)} \).

Then

\[ f(x_n) = \pm \frac{1}{\sqrt{2} + \pi(n - 1)} \]

where the signs alternate, so

\[ |f(x_{n+1}) - f(x_n)| = \frac{1}{\sqrt{2} + \pi n} + \frac{1}{\sqrt{2} + \pi(n - 1)} \geq \frac{1}{\pi n} \]

so if \( P \) runs over partitions containing large initial finite segments of \( \{x_n : n \in \mathbb{N}\} \), \( V(f, P) \) is arbitrarily large since the harmonic series diverges (IV.2.2.11.). Thus \( V_{[0,1]}(f) = +\infty \). The problem is, roughly speaking (even precisely speaking; cf. XIV.16.2.5.), that \( f' \) is not Lebesgue integrable on \([0, 1]\).

It turns out that if \( f \) is differentiable everywhere on \([a, b]\) and \( f' \) is Lebesgue integrable on \([a, b]\), then \( f \) has bounded variation on \([a, b]\), but this requires considerable work to prove (). This cannot, however, be relaxed to just requiring that \( f \) be continuous, differentiable almost everywhere, and with integrable derivative ()

Example (i) shows that a function of bounded variation need not be continuous. But it must be “almost continuous”: it can have only countably many discontinuities, each of which is a jump discontinuity (XIV.16.2.4.).

XIV.16.1.8. PROPOSITION. Let \( f \) be a real-valued function on an interval \([a, b]\), and let \( \Gamma_f \) be its graph

\[ \Gamma_f = \{(x, f(x)) : a \leq x \leq b\} \]

Then \( f \) has bounded variation on \([a, b]\) if and only if the arc length () \( \ell(\Gamma_f) \) of \( \Gamma_f \) is finite. In fact,

\[ V_{[a,b]}(f) \leq \ell(\Gamma_f) \leq (b - a) + V_{[a,b]}(f) \]

Proof: We have that

\[ \ell(\Gamma_f) = \sup_P \left\{ \sum_{k=1}^{n} ||(x_k, f(x_k)) - (x_{k-1}, f(x_{k-1}))|| \right\} \]

\[ = \sup_P \left\{ \sum_{k=1}^{n} \sqrt{|x_k - x_{k-1}|^2 + |f(x_k) - f(x_{k-1})|^2} \right\} \]

1699
\[
\leq \sup_{\mathcal{P}} \left\{ \sum_{k=1}^{n} (|x_k - x_{k-1}| + |f(x_k) - f(x_{k-1})|) \right\} \\
= \sup_{\mathcal{P}} \left\{ (b-a) + \sum_{k=1}^{n} |f(x_k) - f(x_{k-1})| \right\} \\
= \sup_{\mathcal{P}} \{ (b-a) + V(f, \mathcal{P}) \} = (b-a) + V_{[a,b]}(f)
\]

where the suprema are over all partitions \( \mathcal{P} = \{a = x_0, \ldots, x_n = b\} \) of \([a,b]\). The first inequality is evident. \( \Box \)

The first inequality is always strict if \( f \) has bounded variation, but the second inequality can be an equality (\( \cdot \)).

**XIV.16.1.9.** Since a function \( f \) of bounded variation need not be continuous, the graph of \( f \) need not be an arc (a homeomorphic image of \([0,1]\)). We normally only consider arc length for arcs. But since a function of bounded variation has only jump discontinuities, and only finitely many jumps of length more than \( \epsilon \) for any \( \epsilon > 0 \), the graph of \( f \) can be expanded to an arc by adding vertical line segments across the jumps. The arc length of this arc is still no more than \( (b-a) + V_{[a,b]}(f) \).

We now explore properties of the variations of a function.

**XIV.16.1.10.** **Proposition.** Let \( f \) be a real-valued function on an interval \([a,b]\). Then

\[
V_{[a,b]}^+(f) + V_{[a,b]}^-(f) = V_{[a,b]}(f)
\]

and, if \( f \) has bounded variation on \([a,b]\), then

\[
V_{[a,b]}^+(f) - V_{[a,b]}^-(f) = f(b) - f(a).
\]

If \( f \) does not have bounded variation, then \( V_{[a,b]}^+(f) = V_{[a,b]}^-(f) = +\infty \).

**Proof:** If \( \mathcal{P} \) is any partition of \([a,b]\), we have

\[
V(f, \mathcal{P}) = V^+(f, \mathcal{P}) + V^-(f, \mathcal{P}) \leq V_{[a,b]}^+(f) + V_{[a,b]}^-(f)
\]

and thus \( V_{[a,b]}(f) \leq V_{[a,b]}^+(f) + V_{[a,b]}^-(f) \). For the opposite inequality, there is nothing to prove if \( V_{[a,b]}(f) = +\infty \), so assume \( V_{[a,b]}(f) \) is finite. Since \( V_{[a,b]}^+(f) \leq V_{[a,b]}(f) \) and \( V_{[a,b]}^-(f) \leq V_{[a,b]}(f) \), they are both also finite. Let \( \epsilon > 0 \). Choose a partition \( \mathcal{P} \) fine enough that \( V^+(f, \mathcal{P}) \geq V_{[a,b]}^+(f) - \epsilon \) and \( V^-(f, \mathcal{P}) \geq V_{[a,b]}^-(f) - \epsilon \). Then

\[
V_{[a,b]}^+(f) + V_{[a,b]}^-(f) - 2\epsilon \leq V^+(f, \mathcal{P}) + V^-(f, \mathcal{P}) = V(f, \mathcal{P}) \leq V_{[a,b]}(f)
\]

and since \( \epsilon > 0 \) is arbitrary, \( V_{[a,b]}^+(f) + V_{[a,b]}^-(f) \leq V_{[a,b]}(f) \).

For the last equation, suppose \( f \) has bounded variation. Let \( \epsilon > 0 \), and fix a partition \( \mathcal{P} \) fine enough that \( |V_{[a,b]}^+(f) - V^+(f, \mathcal{P})| < \frac{\epsilon}{2} \) and \( |V_{[a,b]}^-(f) - V^-(f, \mathcal{P})| < \frac{\epsilon}{2} \). Since by XIV.16.1.4. we have \( V^+(f, \mathcal{P}) - V^-(f, \mathcal{P}) = f(b) - f(a) \), we have

\[
||V_{[a,b]}^+(f) - V_{[a,b]}^-(f)| - (f(b) - f(a))||
\]

1700
This is a contradiction since \( \frac{V}{P} \) over then \( BV \).

XIV.16.1.14. **Proposition.** Let \( f \) be a real-valued function on \([a, b]\), and \( c \in (a, b) \). Then \( V^{+}_{[a, b]}(f) = V^{+}_{[a, b]}(f) + V^{-}_{[a, b]}(f) \), \( V^{-}_{[a, b]}(f) = V^{-}_{[a, b]}(f) + V^{+}_{[a, b]}(f) \), and \( V^{+}_{[a, b]}(f) = V^{+}_{[a, c]}(f) + V^{-}_{[c, b]}(f) \).

**Proof:** Since \( V^{+}(f, P) \) increases as \( P \) becomes finer, in computing \( V^{+}_{[a, b]}(f) \) we may restrict to partitions of \([a, b]\) containing \( c \). Any such \( P \) splits into a partition \( P_1 \) of \([a, c]\) and a partition \( P_2 \) of \([c, b]\). Conversely, any partitions \( P_1 \) of \([a, c]\) and \( P_2 \) of \([c, b]\) combine into a partition \( P \) of \([a, b]\) containing \( c \). For any such \( P \), we have \( V^{+}(f, P) = V^{+}(f, P_1) + V^{+}(f, P_2) \). Taking suprema over \( P_1 \) and \( P_2 \) corresponds to taking supremum over \( P \). The argument for \( V^{-} \) and \( V \) is identical.

The next simple result is used repeatedly.

XIV.16.1.11. **Proposition.** Let \( f \) be a real-valued function on \([a, b]\), and \( c \in (a, b) \). Then \( V^{+}_{[a, b]}(f) = V^{+}_{[a, c]}(f) + V^{-}_{[c, b]}(f) \), \( V^{-}_{[a, b]}(f) = V^{-}_{[a, c]}(f) + V^{+}_{[c, b]}(f) \), and \( V^{+}_{[a, b]}(f) = V^{+}_{[a, c]}(f) + V^{-}_{[c, b]}(f) \).

**Proof:** Since \( V^{+}(f, P) \) increases as \( P \) becomes finer, in computing \( V^{+}_{[a, b]}(f) \) we may restrict to partitions of \([a, b]\) containing \( c \). Any such \( P \) splits into a partition \( P_1 \) of \([a, c]\) and a partition \( P_2 \) of \([c, b]\). Conversely, any partitions \( P_1 \) of \([a, c]\) and \( P_2 \) of \([c, b]\) combine into a partition \( P \) of \([a, b]\) containing \( c \). For any such \( P \), we have \( V^{+}(f, P) = V^{+}(f, P_1) + V^{+}(f, P_2) \). Taking suprema over \( P_1 \) and \( P_2 \) corresponds to taking supremum over \( P \). The argument for \( V^{-} \) and \( V \) is identical.

XIV.16.1.12. **Corollary.** If \( f \) has bounded variation on \([a, b]\), and \([c, d]\) is any (closed) subinterval of \([a, b]\), then \( f \) has bounded variation on \([c, d]\), and \( V^{+}_{[c, d]}(f) \leq V^{+}_{[a, b]}(f) \), \( V^{-}_{[c, d]}(f) \leq V^{-}_{[a, b]}(f) \), \( V^{+}_{[c, d]}(f) \leq V^{-}_{[a, b]}(f) \).

XIV.16.1.13. **Proposition.** Let \( f \) and \( g \) be real-valued functions on \([a, b]\), and \( \alpha \in \mathbb{R} \). Then

(i) \( V^{+}_{[a, b]}(f + g) \leq V^{+}_{[a, b]}(f) + V^{+}_{[a, b]}(g) \), \( V^{-}_{[a, b]}(f + g) \leq V^{-}_{[a, b]}(f) + V^{-}_{[a, b]}(g) \), \( V^{+}_{[a, b]}(f + g) \leq V^{+}_{[a, b]}(f) + V^{+}_{[a, b]}(g) \).

(ii) \( V^{+}_{[a, b]}(\alpha f) = |\alpha| V^{+}_{[a, b]}(f) \). If \( \alpha \geq 0 \), then \( V^{+}_{[a, b]}(\alpha f) = \alpha V^{+}_{[a, b]}(f) \) and \( V^{-}_{[a, b]}(\alpha f) = \alpha V^{-}_{[a, b]}(f) \); if \( \alpha < 0 \), then \( V^{+}_{[a, b]}(\alpha f) = |\alpha| V^{-}_{[a, b]}(f) \) and \( V^{-}_{[a, b]}(\alpha f) = |\alpha| V^{+}_{[a, b]}(f) \).

Part (i) follows immediately from XIV.16.1.2., and the simple proof of (ii) is left as an exercise.

This result shows that if \( BV[a, b] \) is the set of functions of bounded variation on \([a, b]\), then \( BV[a, b] \) is a vector space of functions and \( ||f||_{BV} = |f(a)| + V_{[a, b]}(f) \) is a norm on \( BV[a, b] \). In fact, \( BV[a, b] \) is a Banach space under this norm (.).

1701
XIV.16.2. The Total Variation Functions

We can use the results of the previous section to define positive, negative, and total variation functions for any function of bounded variation, which yield strong structure results about such functions.

XIV.16.2.1. Definition. Let $f$ be a function of bounded variation on $[a,b]$. For $x \in [a,b]$, define

- $T^+ f(x) = V_{[a,x]}^+(f)$
- $T^- f(x) = V_{[a,x]}^-(f)$
- $T_f(x) = V_{[a,x]}(f) = T^+ f(x) + T^- f(x)$

$T^+ f$, $T^- f$, and $T_f$ are called the positive variation function, the negative variation function, and the total variation function of $f$ on $[a,b]$.

These functions depend (up to constants) on the choice of left endpoint of the interval $[a,b]$; when it is necessary to specify the starting point $a$, we will write $T^+_a f$, $T^-_a f$, $T_a f$.

XIV.16.2.2. The functions $T^+ f$, $T^- f$, $T_f$ are nonnegative and nondecreasing by XIV.16.1.12. We define all to be 0 at $a$. By XIV.16.1.4., $T^+ f(x) - T^- f(x) = f(x) - f(a)$ for all $x \in [a,b]$. Thus we obtain the following important consequence:

XIV.16.2.3. Theorem. Every function of bounded variation on an interval $[a,b]$ can be written as a difference of two nondecreasing functions on $[a,b]$.

In fact, if $f$ has bounded variation, then $f = (f(a) + T^+ f) - T^- f$.

Because of the known properties of nondecreasing functions, we obtain:

XIV.16.2.4. Corollary. Let $f$ be a function of bounded variation on an interval $[a,b]$. Then

(i) $f$ is Borel measurable.
(ii) $f$ has left and right limits at every point of $[a,b]$.
(iii) $f$ has only countably many discontinuities on $[a,b]$, each of which is a jump discontinuity.
(iv) $f$ is differentiable a.e. on $[a,b]$. 

1702
XIV.16.2.5. Proposition. Let \( f \) be a function of bounded variation on \([a, b]\). Then \( f' \) (which is defined a.e. on \([a, b]\)) is integrable on \([a, b]\), and

\[
\int_a^b |f'| \, d\lambda \leq V_{[a,b]}(f) .
\]

Proof: Extend \( f \) to \([a, b + 1]\) by setting \( f(x) = f(b) \) for \( x \in [b, b + 1] \). For each \( n \) define

\[
f_n(x) = n \left[ f \left( x + \frac{1}{n} \right) - f(x) \right].
\]

Then each \( f_n \) is (Borel) measurable, and \( f_n(x) \to f'(x) \) for any \( x \in (a, b) \) for which \( f \) is differentiable at \( x \). Thus \( f_n \to f' \) pointwise a.e., so \( f' \) is measurable. Also, since \( T^+f, T^-f, Tf \) are nondecreasing, they are differentiable a.e., with nonnegative derivatives, and since \( f = (f(a) + T^+f) - T^-f \), we have \( f' = (T^+f)' - (T^-f)' \) a.e., and thus

\[
|f'| \leq (T^+f)' + (T^-f)' = (Tf)' \text{ a.e.}
\]

By XIV.14.2.13,

\[
\int_a^b |f'| \, d\lambda \leq \int_a^b (Tf)' \, d\lambda \leq Tf(b) - Tf(a) = V_{[a,b]}(f) .
\]

XIV.16.2.6. Proposition. Let \( f \) be a function of bounded variation on \([a, b]\). Then the variation functions \( T^+f, T^-f, Tf \) are continuous wherever \( f \) is continuous.

XIV.16.2.7. Corollary. If \( f \) is a continuous function of bounded variation on \([a, b]\), then \( T^+f, T^-f, Tf \) are also continuous on \([a, b]\). Thus \( f \) can be written as a difference of two continuous nondecreasing functions on \([a, b]\).

XIV.16.3. Banach’s Multiplicity Theorem

For continuous real-valued functions on a closed bounded interval, there is a close relationship between the notion of bounded variation and the Multiplicity Function (XII.2.5.1.): a function is informally of bounded variation if its graph does not “wiggle up and down” too much, hence the function does not take “too many values too many times.” This theorem is due to Banach ( ).
XIV.16.3.1. **Theorem.** Let $f$ be a continuous function from a closed bounded interval $[a, b]$ to $\mathbb{R}$. Then $N_f$ is finite a.e. and (Lebesgue) integrable on $[c, d] = f([a, b])$ if and only if $f$ has bounded variation on $[a, b]$, and in any case
\[
\int_c^d N_f \, d\lambda = V_{[a,b]}(f) .
\]

**Proof:** Recall (XII.2.5.4.) that $N_f$ is nonnegative and (Borel) measurable, so $\int_c^d N_f \, d\lambda$ makes sense. For each $n$ let $\phi_n$ be the function defined in the proof of XII.2.5.4.. Then we have
\[
\int_c^d \phi_n \, d\lambda = \sum_{k=1}^{2^n} \lambda(f(J_k)) = \sum_{k=1}^{2^n} \lambda(f(J_k)) \leq \sum_{k=1}^{2^n} V_{[x_{k-1}, x_k]}(f) = V_{[a,b]}(f)
\]
(where the $x_k$ are the numbers from the proof of XII.2.5.4., i.e. the endpoints of the intervals $J_k$). We have $\int_c^d \phi_n \, d\lambda \to \int_c^d N_f \, d\lambda$ by the Monotone Convergence Theorem. So if $f$ has bounded variation on $[a, b]$, we have that $N_f$ is integrable on $[c, d]$ and in particular finite a.e. on $[c, d]$, and
\[
\int_c^d N_f \, d\lambda \leq V_{[a,b]}(f) .
\]

Conversely, suppose $N_f$ is finite a.e. and integrable on $[c, d]$. For $a \leq x \leq b$, let $f_x$ be the restriction of $f$ to $[a, x]$, and set $S(x) = \int_c^d N_{f_x} \, d\lambda$. We have $N_{f_x} \leq N_f$, and for $a \leq x_1 \leq x_2 \leq b$ we have
\[
0 = S(a) \leq S(x_1) \leq S(x_2) \leq S(b) = \int_c^d N_f \, d\lambda
\]
and, furthermore, since $f$ takes every value between $f(x_1)$ and $f(x_2)$ on $[x_1, x_2]$ by the Intermediate Value Theorem (), we have $N_{f_{x_2}}(y) \geq N_{f_{x_1}}(y) + 1$ for all $y$ between $f(x_1)$ and $f(x_2)$ and thus we have
\[
S(x_2) - S(x_1) = \int_c^d (N_{f_{x_2}} - N_{f_{x_1}}) \, d\lambda \geq \int_{f(x_1)}^{f(x_2)} 1 \, d\lambda = |f(x_2) - f(x_1)| .
\]

So if $a \leq x_0 < x_1 < \cdots < x_n \leq b$, we have
\[
\int_c^d N_f \, d\lambda = S(b) - S(a) \geq \sum_{k=1}^n (S(x_k) - S(x_{k-1})) \geq \sum_{k=1}^n |f(x_k) - f(x_{k-1})|
\]
and taking the supremum over all such finite subsets of $[a, b]$ we obtain
\[
\int_c^d N_f \, d\lambda \geq V_{[a,b]}(f)
\]
and thus $f$ has bounded variation, and the opposite inequality holds by the first part of the proof, giving equality.

If $f$ does not have bounded variation, equality still holds since both sides are $+\infty$. \(\diamondsuit\)
XIV.16.4. Extensions of Bounded Variation

Noncompact Intervals

We can extend the notion of bounded variation to noncompact intervals:

**XIV.16.4.1. Definition.** Let $I$ be an interval, and $f$ a real-valued function on $I$. Define

$$V^+_I(f) = \sup_{[a,b]} V^+_{[a,b]}(f)$$
$$V^-_I(f) = \sup_{[a,b]} V^-_{[a,b]}(f)$$
$$V_I(f) = \sup_{[a,b]} V_{[a,b]}(f)$$

where the suprema are taken over all closed bounded subintervals $[a,b]$ of $I$.

The function $f$ has **bounded variation on $I$** if $V_I(f) < +\infty$.

Most properties of bounded variation for closed bounded intervals carry over directly. We list some without proof; proofs are similar to the earlier ones and are left to the reader.

**XIV.16.4.2. Proposition.**

(i) $V_I(f) = V^+_I(f) + V^-_I(f)$.

(ii) If $f$ has bounded variation on $I$, then $f$ is bounded on $I$ and

$$\sup_{x \in I} f(x) - \inf_{x \in I} f(x) \leq V_I(f).$$

(iii) If $J$ is a subinterval of $I$, then $V^+_J(f) \leq V^+_I(f)$, $V^-_J(f) \leq V^-_I(f)$, $V_J(f) \leq V_I(f)$. If $f$ has bounded variation on $I$, then $f$ has bounded variation on $J$.

(iv) If $f$ is bounded variation on $I$, and $a$ and $b$ are the left and right endpoints of $I$ (we do not necessarily have $a, b \in I$; we can have $a = -\infty$ and/or $b = +\infty$), then $\lim_{x \to a^+} f(x)$ and $\lim_{x \to b^-} f(x)$ exist.

(v) If $f$ has bounded variation on $I$, then $f$ is Borel measurable, has left and right limits at every point, has only countably many discontinuities each of which is a jump discontinuity, and is differentiable a.e. on $I$.

(vi) If $f$ has bounded variation on $I$, then $f'$ is Lebesgue integrable on $I$ and

$$\int_I |f'| \, d\lambda \leq V_I(f).$$

We can also define variation functions for a function of bounded variation:
**XIV.16.4.3. Definition.** Let \( I \) be an interval, and \( a \) the left endpoint of \( I \) (we do not necessarily have \( a \in I \); \( a \) can be \(-\infty\)). Define

\[
T^+ f(x) = \begin{cases} \mathcal{V}_{[a,x]}(f) & \text{if } a \in I \\ \mathcal{V}^+_{[a,x]}(f) & \text{if } a \notin I \end{cases}
\]

\[
T^- f(x) = \begin{cases} \mathcal{V}_{[a,x]}(f) & \text{if } a \in I \\ \mathcal{V}_{(a,x]}(f) & \text{if } a \notin I \end{cases}
\]

\[
T f(x) = \begin{cases} \mathcal{V}_{[a,x]}(f) & \text{if } a \in I \\ \mathcal{V}_{(a,x]}(f) & \text{if } a \notin I \end{cases}
\]

for \( x \in I \).

\( T^+ f, \ T^- f, \ Tf \) are nonnegative and nondecreasing; \( Tf = T^+ f + T^- f \), \( T^+ f - T^- f = f - C \), where \( C = f(a) \) if \( a \in I \) and \( C = \lim_{x \rightarrow a^+} f(x) \) if \( a \notin I \).

**Complex-Valued Functions**

**XIV.16.4.4.** We can also define bounded variation for complex-valued functions. If \( f \) is a complex-valued function on \( [a,b] \) and \( P = \{a = x_0, \ldots, x_n = b\} \), then \( V^+(f, P) \) and \( V^-(f, P) \) do not make sense, but we can still define

\[
V(f, P) = \sum_{k=1}^{n} |f(x_k) - f(x_{k-1})|
\]

\[
V_{[a,b]}(f) = \sup_P V(f, P)
\]

as before. Then \( f \) has bounded variation on \( [a,b] \) if \( V_{[a,b]}(f) < +\infty \).

**XIV.16.4.5.** If \( g \) and \( h \) are the real and imaginary parts of \( f \), i.e. \( f = g + ih \) with \( g, h \) real-valued, then we have

\[
V_{[a,b]}(g), V_{[a,b]}(h) \leq V_{[a,b]}(f) \leq V_{[a,b]}(g) + V_{[a,b]}(h)
\]

so \( f \) has bounded variation if and only if both \( g \) and \( h \) have bounded variation. (There is, however, no simple formula for \( V_{[a,b]}(f) \) in terms of \( V_{[a,b]}(g) \) and \( V_{[a,b]}(h) \).) We still have:

**XIV.16.4.6. Proposition.** Let \( f \) be a complex-valued function on \( [a,b] \), and \( c \in (a,b) \). Then

\[
V_{[a,b]}(f) = V_{[a,c]}(f) + V_{(c,b]}(f)
\]

**XIV.16.4.7. Proposition.** If \( f \) is a complex-valued function of bounded variation on \( [a,b] \), then \( f \) is differentiable a.e. on \( [a,b] \), \( f' \) is integrable on \( [a,b] \), and

\[
\int_a^b |f'| d\lambda \leq V_{[a,b]}(f)
\]
XIV.16.4.8. We can also define the total variation function \( T_f \) as in the real case, which is nonnegative and nondecreasing, and continuous wherever \( f \) is continuous. If \( g \) and \( h \) are the real and imaginary parts of \( f \), then
\[
T_g, Th \leq T_f \leq Tg + Th
\]
but there is no simple formula for \( T_f \) in terms of \( Tg \) and \( Th \).

XIV.16.5. Exercises

XIV.16.5.1. Let \( f \) be a function of bounded variation on \([a, b]\). Show directly that \( f \) has one-sided limits at every point of \([a, b]\), as follows:
(a) Let \( c \in (a, b) \). Suppose
\[
\liminf_{x \to c-} f(x) < \limsup_{x \to c-} f(x).
\]
Choose \( \alpha, \beta \in \mathbb{R} \) such that
\[
\liminf_{x \to c-} f(x) < \alpha < \beta < \limsup_{x \to c-} f(x).
\]
Choose an increasing sequence \((x_n)\) in \((a, c)\) converging to \( c \) such that \( f(x_n) < \alpha \) for \( n \) odd and \( f(x_n) > \beta \) for \( n \) even.
(b) If \( \mathcal{P} = \{a = x_0, x_1, \ldots, x_{n+1}, b\} \), show that \( V(f, \mathcal{P}) > n(\beta - \alpha) \). Conclude that \( V_{[a,b]}(f) \) must be \(+\infty\).
(c) Give a similar argument for limits from the right.
(d) Conclude from V.8.6.7.(a) that \( f \) has only countably many discontinuities, each of which is a jump discontinuity.

XIV.16.5.2. Let \( f \) be the function of XIV.2.9.10.(i). Show that \( f \) does not have bounded variation on \([0, 1]\) (or on \([0, b]\) for any \( b > 0 \)). Note that \( f \) is differentiable everywhere, and \( f' \) is continuous except at 0.
XIV.17. Absolute Continuity and Lebesgue Density

A function which is differentiable everywhere on an interval \([a, b]\) need not have a (Lebesgue) integrable derivative, hence may not be the integral of its derivative (XIV.2.9.10.(i)); the problem is that such a function need not have bounded variation. But even bounded variation is not sufficient to insure that a continuous function can be recovered from its derivative by integration if it is only differentiable almost everywhere. The Cantor function is the prototype example of a continuous monotone function (hence of bounded variation) which is differentiable almost everywhere, yet is not the integral of its derivative. In this section we discuss conditions which do suffice to recover a function by integration.

Applications of the results to indicator functions demonstrate a remarkable density property of Lebesgue measurable sets: such sets cannot be too uniformly distributed in the real line and must be either thick or sparse almost everywhere.

XIV.17.1. Luzin’s Property \((N)\)

XIV.17.1.1. The principal property of the Cantor function \(f\) which causes difficulties in the context of this section is that there are null sets \(N\) for which \(f(N)\) is not a null set. In fact, the Cantor set \(K\) is a null set and \(f(K)\) is the entire interval \([0, 1]\).

From the point of view of Borel measures, the measure on \([0, 1]\) whose cdf is the Cantor function is a probability measure which is continuous, but concentrated on \(K\), and hence is not absolutely continuous with respect to Lebesgue measure.

We thus make the following definition. This condition was first defined and studied by N. Luzin, who appreciated its importance and relevance to the problem of reconstructing a function by integration.

XIV.17.1.2. Definition. Let \(I\) be an interval, and \(f : I \to \mathbb{R}\). Then \(f\) has Property \((N)\) (or Luzin’s Property \((N)\)) on \(I\) if, whenever \(N\) is a subset of \(I\) with \(\lambda(N) = 0\), we have \(\lambda(f(N)) = 0\) (i.e. \(f\) sends \(\lambda\)-null sets to \(\lambda\)-null sets).

The next result is an immediate rephrasing of the definition.

XIV.17.1.3. Proposition. Let \(\mu\) be a continuous finite signed Borel measure on \([a, b]\), with cdf \(F\). Then \(\mu \ll \lambda\) if and only if \(F\) has property \((N)\).

XIV.17.1.4. Proposition. [?] Let \(I\) be an interval, and \(f : I \to \mathbb{R}\) a continuous function. Then \(f\) has property \((N)\) if and only if, whenever \(A\) is a Lebesgue measurable subset of \(I\), \(f(A)\) is Lebesgue measurable.

Proof: Suppose \(f\) has property \((N)\). If \(A \subseteq I\) is Lebesgue measurable, then \(A = E \cup N\), where \(E\) is an \(F_\sigma\) and \(N\) a null set (XIII.3.4.5.(iv)). Then \(f(E)\) is an \(F_\sigma\) since \(f\) is continuous (XI.11.7.11.), and \(f(N)\) is a null set since \(f\) has Property \((N)\); hence \(f(A) = f(E) \cup f(N)\) is Lebesgue measurable. Conversely, if \(N\) is a null set and \(f(N)\) is not a null set (i.e. \(f(N)\) has positive Lebesgue outer measure), then \(f(N)\) contains a nonmeasurable set \(B\) (XIII.3.9.7.). If \(A = f^{-1}(B)\), then \(A \subseteq N\) and hence \(A\) is Lebesgue measurable, and \(f(A) = B\) is nonmeasurable.

\(\Box\)
XIV.17.1.5. Property \((N)\) is complementary to bounded variation, even for continuous functions: the Cantor function is continuous and monotone, hence has bounded variation, but not Property \((N)\), and there are continuous functions with Property \((N)\) which do not have bounded variation, and are even not differentiable a.e. (XIV.17.5.1).

There is an interesting variation on Property \((N)\), due to Banach:

XIV.17.1.6. Definition. Let \(I\) be an interval, and \(f : I \to \mathbb{R}\). Then \(f\) has Property \((S)\) (or Banach’s Property \((S)\)) on \(I\) if for every \(\epsilon > 0\) there is a \(\delta > 0\) such that, whenever \(A\) is a Lebesgue measurable subset of \(I\) with \(\lambda(A) < \delta\), we have \(\lambda^*(f(A)) < \epsilon\).

XIV.17.1.7. A function with Property \((S)\) obviously has Property \((N)\); hence, if \(f\) is continuous with Property \((S)\), it sends measurable sets to measurable sets, and \(\lambda^*\) can be replaced by \(\lambda\) in the definition. There are continuous functions with Property \((N)\) which do not have Property \((S)\) (XIV.17.5.2).

In fact, we have:

XIV.17.1.8. Theorem. Let \(I\) be an interval, and \(f : I \to \mathbb{R}\) a continuous function. Then \(f\) has property \((S)\) if and only if it has Property \((N)\) and \(N_f()\) is finite a.e.

Combining this with XIV.16.3.1, we obtain:

XIV.17.1.9. Corollary. Let \(I\) be an interval, and \(f : I \to \mathbb{R}\) a continuous function of bounded variation. Then \(f\) has property \((S)\) if and only if it has Property \((N)\).

XIV.17.1.10. There are continuous functions with Property \((S)\) which do not have bounded variation, and are even not differentiable a.e. (XIV.17.5.1).

XIV.17.1.11. Banach said a function \(f\) satisfies Property \((T_1)\) if \(N_f\) is finite a.e., and Property \((T_2)\) if \(N_f\) is countable a.e. (i.e. \(f\) takes almost all values only countably many times). We will avoid this terminology since it could be confused with separation axioms of topology.

The next goal is to show that differentiable functions have Property \((N)\). The next lemma is crucial.

XIV.17.1.12. Lemma. Let \(A\) be a Lebesgue measurable subset of \(\mathbb{R}\), and \(f : A \to \mathbb{R}\) a function. Suppose there is a constant \(M\) such that, for every \(x \in A\), there is a \(\delta > 0\) such that \(|f(y) - f(x)| \leq M(y - x)\) for all \(y \in A \cap (x, x + \delta)\). Then \(\lambda^*(f(A)) \leq M\lambda(A)\).

Proof: We first make a reduction. For each \(n\), let \(B_n = \{x \in A : |f(y) - f(x)| \leq M(y - x)\} \) for all \(y \in A \cap (x, x + 1/n)\).

If \(x \in A \cap B_n\), there is a monotone sequence \((x_k)\) in \(B_n\) with \(x_k \to x\), so for sufficiently large \(k\) we have \(|f(x) - f(x_k)| \leq M|x - x_k|\). Thus \(f(x) = \lim_{k \to \infty} f(x_k)\) and, if \(y \in A \cap (x, x + 1/n)\), then for
sufficiently large \( k \) we have \( y \in (x_k, x_k + 1/n) \), so \( |f(y) - f(x_k)| \leq M(y - x_k) \). Taking \( k \to \infty \), we conclude \( x \in B_n \). Thus \( B_n = A \cap B_n \), and in particular \( B_n \) is measurable. We have that \( A = \cup_n B_n \), so \( \lambda(A) = \sup_n \lambda(B_n) \) and \( \lambda^*(f(A)) = \sup_n \lambda^*(f(B_n)) \). Thus it suffices to show \( \lambda^*(f(B_n)) \leq M\lambda(B_n) \) for each \( n \). Fix \( n \); write \( B_n \) as a disjoint union of measurable sets \( A_{nm} \) of diameter \( < 1/n \). Then \( \lambda(B_n) = \sum_m \lambda(A_{nm}) \) and \( \lambda^*(f(B_n)) \leq \sum_m \lambda^*(f(A_{nm})) \). Thus it suffices to show that \( \lambda^*(f(A_{nm})) \leq M\lambda(A_{nm}) \) for all \( n, m \). But \( A_{nm} \) has the property that if \( x, y \in A_{nm}, x < y \), then \( |f(y) - f(x)| \leq M(y - x) \). Replacing \( A \) by \( A_{nm} \), we may assume \( A \) has the property that \( |f(y) - f(x)| \leq M|y - x| \) for all \( x, y \in A \). We may also assume \( \lambda(A) < \infty \).

Let \( \epsilon > 0 \). Fix a sequence \( (I_n) \) of open intervals covering \( A \) with \( \sum_n \ell(I_n) < \lambda(A) + \epsilon \). If \( x, y \in A \cap I_n \), then \( |f(y) - f(x)| \leq M|y - x| \), so \( f(A \cap I_n) \) is contained in an interval \( J_n \) of length \( \leq M\ell(I_n) \). We then have

\[
\lambda^*(f(A)) \leq \sum_{n=1}^{\infty} \lambda^*(f(A \cap I_n)) \leq \sum_{n=1}^{\infty} \ell(J_n) \leq M \sum_{n=1}^{\infty} \ell(I_n) \leq M(\lambda(A) + \epsilon).
\]

This is true for all \( \epsilon > 0 \), and the result follows. \( \diamond \)

**XIV.17.1.13.** **Corollary.** Let \( A \) be a Lebesgue measurable subset of \( \mathbb{R} \), and \( f : A \to \mathbb{R} \) a function. Suppose there is a constant \( M \) such that, for every \( x \in A \), \( f \) is differentiable at \( x \) and \( |f'(x)| \leq M \). Then \( \lambda^*(f(A)) \leq M\lambda(A) \).

**Proof:** Let \( \epsilon > 0 \). For each \( x \in A \), since

\[
\lim_{y \to x} \frac{|f(y) - f(x)|}{|y - x|} \leq M
\]

there is a \( \delta > 0 \) such that

\[
\frac{|f(y) - f(x)|}{|y - x|} \leq M + \epsilon
\]

whenever \( 0 < |y - x| < \delta \). Thus \( \lambda^*(f(A)) \leq (M + \epsilon)\lambda(A) \). Since \( \epsilon > 0 \) is arbitrary, the result follows. \( \diamond \)

As a special case, we obtain the general one-dimensional version of Sard’s Theorem (.), due to LUZIN:

**XIV.17.1.14.** **Corollary.** Let \( I \) be an interval, and \( f : I \to \mathbb{R} \) a function. Set

\[
A = \{ x \in I : f'(x) \text{ exists and equals } 0 \}.
\]

Then \( f(A) \) is a null set.

**Proof:** \( A \) is Lebesgue measurable by (.). We may write \( A = \cup_n A_n \), where \( \lambda(A_n) < \infty \). Then \( \lambda^*(f(A_n)) = 0 \) for all \( n \), and hence \( \lambda^*(f(A)) \leq \sum_n \lambda^*(f(A_n)) = 0 \). \( \diamond \)

Our main result then is:
XIV.17.15. **Theorem.** Let \( B \) be a Lebesgue measurable set, and \( f : B \to \mathbb{R} \) a function which is differentiable on \( B \) except possibly at countably many points of \( B \). If \( A \) is a subset of \( B \) with \( \lambda(A) = 0 \), then \( \lambda(f(A)) = 0 \).

**Proof:** Let \( C \) be a countable subset of \( B \) such that \( f \) is differentiable on \( B \setminus C \). For each \( n \) let
\[
D_n = \{ x \in B \setminus C : |f'(x)| \leq n \} .
\]
Each \( D_n \) is measurable. If \( A \) is a measurable subset of \( B \) with \( \lambda(A) = 0 \), then \( f(A) \) is the union of \( f(A \cap C) \) and \( f(A \cap D_n) \) for all \( n \). \( f(A \cap C) \) is countable, hence has measure 0; and by XIV.17.13. we have \( \lambda^*(f(A \cap D_n)) \leq n \lambda(A \cap D_n) = 0 \). Thus
\[
\lambda^*(f(A)) \leq \lambda^*(A \cap C) + \sum_{n=1}^{\infty} \lambda(A \cap D_n) = 0 .
\]

XIV.17.16. **Corollary.** Let \( I \) be an interval, and \( f : I \to \mathbb{R} \) a function. If \( f \) is differentiable on \( I \) except possibly at countably many points of \( I \), then \( f \) has Property (N) on \( I \).

Property (N) is relevant in extending consequences of the Mean Value Theorem:

XIV.17.17. **Theorem.** Let \( I \) be an interval, and \( f : I \to \mathbb{R} \) a continuous function with Property (N) on \( I \). If \( f \) is differentiable a.e. and \( f' \geq 0 \) a.e. on \( I \), then \( f \) is nondecreasing on \( I \) (and hence \( f' \geq 0 \) everywhere it is defined). Similarly, if \( f' \leq 0 \) a.e. on \( I \), then \( f \) is nonincreasing on \( I \).

**Proof:** If \( f' > 0 \) a.e., the proof is identical to the proof of V.8.4.1 (i), since if \( f \) is differentiable except on a null set \( A \), then \( f(A) \) is also a null set since \( f \) has Property (N) and thus contains no interval (cf. V.8.4.4.). In the general case, we proceed as follows. Set
\[
A = \{ x \in I : f \text{ is not differentiable at } x \}
\]
\[
B = \{ x \in I : f'(x) < 0 \}
\]
\[
C = \{ x \in I : f'(x) = 0 \}
\]
Then \( A \) and \( B \) are null sets by assumption, so \( f(A) \) and \( f(B) \) are null sets since \( f \) has Property (N). And \( f(C) \) is a null set by XIV.17.14. Thus \( f(A \cup B \cup C) \) is a null set, and contains no interval.

Suppose there are \( a, b \in I \) with \( a < b \) and \( f(a) > f(b) \). Then there is an \( r \notin f(A \cup B \cup C) \) with \( f(a) > r > f(b) \). There is an \( x \in [a, b] \) with \( f(x) = r \) by the Intermediate Value Theorem. Set
\[
c = \sup \{ x \in [a, b] : f(x) = r \} .
\]
Then \( f(c) = r \) by continuity, and \( c < b \). Then \( c \notin A \cup B \cup C \) since \( r = f(c) \notin f(A \cup B \cup C) \), so \( f \) is differentiable at \( c \) and \( f'(c) > 0 \). We have \( c < b \) since \( f(b) < r \), and if \( c < x \leq b \) we have \( f(x) < f(c) = r \), so \( \frac{f(x) - f(c)}{x - c} < 0 \). Thus
\[
f'(c) = \lim_{x \to c^+} \frac{f(x) - f(c)}{x - c} \leq 0
\]

1711
contradicting that $f'(c) > 0$.

Combining this result with XIV.17.16., we obtain:

**XIV.17.18. Corollary.** Let $I$ be an interval, and $f : I \to \mathbb{R}$ a continuous function, which is differentiable on $I$ except possibly at countably many points. If $f' \geq 0$ a.e. on $I$, then $f$ is nondecreasing on $I$ (and hence $f' \geq 0$ everywhere it is defined). Similarly, if $f' \leq 0$ a.e. on $I$, then $f$ is nonincreasing on $I$. If $f' = 0$ a.e. on $I$, then $f$ is constant on $I$.

Here is an interesting consequence of XIV.17.14.:

**XIV.17.19. Corollary.** Let $[a, b]$ be a closed bounded interval, and $f : [a, b] \to \mathbb{R}$ a continuous function. If $f$ is differentiable on $[a, b]$ except possibly at countably many points, then $N_f$ is finite a.e. on $[a, b]$, so $f$ has Property (S) on $[a, b]$.

**Proof:** Let $C$ be a countable set such that $f$ is differentiable on $[a, b] \setminus C$. Let

$$A = \{x \in [a, b] : f'(x) = 0\}.$$ 

By XIV.17.14., $f(A)$ has measure 0. Since $C$ is countable, $f(A \cup C)$ has measure 0.

Suppose $N_f(y) = \infty$. Then $f^{-1}(\{y\})$ is an infinite subset of $[a, b]$, hence has an accumulation point $x$. If $f'(x)$ exists, it must be zero; so $x \in A \cup C$, and hence $y \in f(A \cup C)$. So if $B = \{y : N_f(y) = \infty\}$, then $B \subseteq f(A \cup C)$, $\lambda(B) = 0$. The last statement follows from XIV.17.18.

**XIV.17.2. Absolutely Continuous Functions**

Our basic definition is a refinement of uniform continuity:

**XIV.17.2.1. Definition.** Let $[a, b]$ be a closed bounded interval, and $f : [a, b] \to \mathbb{R}$ a function. Then $f$ is absolutely continuous on $[a, b]$ if for every $\epsilon > 0$ there is a $\delta > 0$ such that, whenever $[a_1, b_1], \ldots, [a_n, b_n]$ are finitely many nonoverlapping intervals in $[a, b]$ (nonoverlapping means distinct intervals may have endpoints but not interior points in common) with total length $< \delta$, i.e.

$$\sum_{k=1}^{n} (b_k - a_k) < \delta$$

we have

$$\sum_{k=1}^{n} |f(b_k) - f(a_k)| < \epsilon .$$

Note that the definition of uniform continuity is the same, but with only one subinterval allowed.
**XIV.17.2.2.** Although it will not be necessary, we may assume the intervals \([a_1, b_1], \ldots, [a_n, b_n]\) are in increasing order. The nonoverlapping condition then means
\[
a \leq a_1 < b_1 \leq a_2 < b_2 \leq \cdots < b_n \leq b .
\]
There is also no harm, and some technical advantage, in allowing some intervals to be degenerate, i.e. \(a_k = b_k\), since such degenerate intervals make no contribution to the sums \(\sum_{k=1}^{n} (b_k - a_k)\) and \(\sum_{k=1}^{n} |f(b_k) - f(a_k)|\).
We may also allow infinite collections of subintervals:

**XIV.17.2.3.** Proposition. Let \([a, b]\) be a closed bounded interval, and \(f : [a, b] \to \mathbb{R}\) a function. Then \(f\) is absolutely continuous on \([a, b]\) if and only if for every \(\epsilon > 0\) there is a \(\delta > 0\) such that, whenever \(\{[a_k, b_k] : k \in \mathbb{N}\}\) is a sequence of pairwise nonoverlapping subintervals (not necessarily nondegenerate) of \([a, b]\) with
\[
\sum_{k=1}^{\infty} (b_k - a_k) < \delta
\]
we have
\[
\sum_{k=1}^{\infty} |f(b_k) - f(a_k)| < \epsilon .
\]

**Proof:** If \(f\) satisfies this condition, it is clearly absolutely continuous (take all but finitely many of the intervals to be degenerate). Conversely, suppose \(f\) is absolutely continuous. Let \(\epsilon > 0\), and choose \(\delta > 0\) corresponding to \(\frac{\epsilon}{2}\) in the definition of absolute continuity. If \(\{[a_k, b_k] : k \in \mathbb{N}\}\) is a sequence of pairwise nonoverlapping subintervals (not necessarily nondegenerate) of \([a, b]\) with
\[
\sum_{k=1}^{\infty} (b_k - a_k) < \delta
\]
we have, for each \(n\),
\[
\sum_{k=1}^{n} (b_k - a_k) < \delta
\]
and therefore
\[
\sum_{k=1}^{n} |f(b_k) - f(a_k)| < \frac{\epsilon}{2} .
\]
Thus
\[
\sum_{k=1}^{\infty} |f(b_k) - f(a_k)| \leq \frac{\epsilon}{2} < \epsilon .
\]
\(\Diamond\)
Our main result, which will be proved in stages, is the following theorem giving various characterizations of absolute continuity, which shows that absolutely continuous functions are precisely the functions which can be recovered from their derivatives by integration.

**XIV.17.2.4. Theorem.** Let \([a, b]\) be a closed bounded interval, and \(F : [a, b] \rightarrow \mathbb{R}\) a function. The following are equivalent:

(i) \(F\) is absolutely continuous on \([a, b]\).

(ii) \(F\) is continuous, has bounded variation, and property \((N)\) on \([a, b]\).

(iii) There is a Lebesgue integrable function \(f : [a, b] \rightarrow \mathbb{R}\) such that \(F\) is the indefinite integral of \(f\) on \([a, b]\), i.e.

\[
F(x) = F(a) + \int_a^x f \, d\lambda
\]

for all \(x \in [a, b]\).

(iv) \(F\) is differentiable a.e. on \([a, b]\), \(F'\) is integrable on \([a, b]\), and \(F\) is the indefinite integral of \(F'\) on \([a, b]\), i.e.

\[
F(x) = F(a) + \int_a^x F' \, d\lambda
\]

for all \(x \in [a, b]\).

(v) \(F\) has bounded variation and is right continuous on \([a, b]\), and the signed Borel measure on \([a, b]\) with cdf \(F()\) is absolutely continuous with respect to Lebesgue measure.

**XIV.17.2.5. Corollary.** [Fundamental Theorem of Calculus, Lebesgue Version I] Let \([a, b]\) be a closed bounded interval, and \(f : [a, b] \rightarrow \mathbb{R}\) a Lebesgue integrable function. Let

\[
F(x) = \int_a^x f \, d\lambda
\]

for all \(x \in [a, b]\). Then \(F\) is differentiable a.e. and \(F' = f\) a.e. on \([a, b]\).

**XIV.17.2.6. Corollary.** Let \([a, b]\) be a closed bounded interval, and \(F : [a, b] \rightarrow \mathbb{R}\) a function. Then \(F\) is Lipschitz on \([a, b]\) if and only if \(F\) is absolutely continuous and \(F'\) is bounded on \([a, b]\). More precisely, \(F\) is Lipschitz on \([a, b]\) with Lipschitz constant \(M\) if and only if \(F\) is absolutely continuous, hence differentiable a.e., on \([a, b]\) and \(|F'(x)| \leq M\) for all \(x \in [a, b]\) for which \(F'(x)\) exists.

In fact, the smallest Lipschitz constant for \(F\) on \([a, b]\) is exactly \(\sup_{a \leq x \leq b} |F'(x)|\) (supremum over those \(x\) where \(F\) is differentiable).
XIV.17.2.7. Corollary. Let $F$ be continuous on $[a, b]$ and differentiable except possibly on a countable subset of $[a, b]$. Then the following are equivalent:

(i) $F$ is absolutely continuous on $[a, b]$.

(ii) $F$ has bounded variation on $[a, b]$.

(iii) $F'$ is Lebesgue integrable on $[a, b]$.

XIV.17.2.8. In XIV.17.2.7., “differentiable except possibly on a countable subset” cannot be weakened to “differentiable a.e.” The Cantor function is a counterexample. The conditions can fail, even if $F$ is differentiable everywhere on $[a, b]$ (XIV.2.9.10.(i)).

Characterizing Functions as Derivatives

Theorem XIV.17.2.4. has another interesting consequence: integrable functions can be characterized without any explicit reference to integration.

XIV.17.2.9. Corollary. Let $f$ be a Lebesgue measurable real-valued function on an interval $[a, b]$. Then $f$ is Lebesgue integrable on $[a, b]$ if and only if there is an absolutely continuous function $F$ on $[a, b]$ with $F' = f$ a.e. on $[a, b]$.

If the word “absolutely” is removed from the statement, the result is false. In fact, it is remarkable that every Lebesgue measurable function is a.e. the derivative of a continuous function. This result is due to Luzin; our proof is adapted from \cite{Sak64}.

XIV.17.2.10. Theorem. Let $f$ be a Lebesgue measurable real-valued function on an interval $[a, b]$. Then there is a continuous function $F$ on $[a, b]$ which is differentiable a.e. and $F' = f$ a.e. In fact, if $G$ is any continuous function on $[a, b]$, for any $\epsilon > 0$ there is a continuous function $F$ on $[a, b]$ which is differentiable a.e., $F' = f$ a.e., and $|F(x) - G(x)| < \epsilon$ for all $x \in [a, b]$.

The proof is a little complicated technically; we begin with an observation and two lemmas.

XIV.17.2.11. Let $\epsilon > 0$. If $G$ is continuous on $[a, b]$, there is a continuous function $H$ on $[a, b]$ which is differentiable a.e. and $H' = 0$ a.e. which is uniformly within \(\frac{\epsilon}{2}\) of $G$ (XV.8.3.6.). If $F_0$ is a continuous function on $[a, b]$ which is differentiable a.e. with $F_0' = f$ a.e., with $|F_0(x)| < \frac{\epsilon}{2}$ for all $x \in [a, b]$, then $F = F_0 + H$ is the desired function. Thus it suffices to show that if $\epsilon > 0$, there is a continuous function $F$ on $[a, b]$ which is differentiable a.e., with $F' = f$ a.e. and $|F(x)| < \epsilon$ for all $x \in [a, b]$.

If $f$ is integrable, this is fairly easily accomplished with judicious use of the Cantor function (this is essentially an explicit version of XV.8.3.6., cf. Exercise XIV.17.5.4.).
**XIV.17.2.12. Lemma.** Let \( \phi \) be an integrable function on an interval \([a,b]\). Then for any \( \epsilon > 0 \) there is a continuous function \( \Phi \) on \([a,b]\) with the following properties:

(i) \( \Phi \) is differentiable a.e. and \( \Phi' = \phi \) a.e. on \([a,b]\).

(ii) \( \Phi(a) = \Phi(b) = 0 \).

(iii) \( |\Phi(x)| < \epsilon \) for all \( x \in [a,b] \).

**Proof:** For \( x \in [a,b] \), set \( \Psi(x) = \int_a^x \phi \, d\lambda \). Then \( \Psi \) is absolutely continuous on \([a,b]\), \( \Psi' = \phi \) a.e. on \([a,b]\), and \( \Psi(a) = 0 \). Fix \( \epsilon > 0 \). Since \( \Psi \) is uniformly continuous on \([a,b]\), there is a \( \delta > 0 \) such that \( |\Psi(x) - \Psi(y)| < \epsilon \) whenever \( x, y \in [a,b] \) and \( |x - y| < \delta \). Let \( P = \{a = x_0, \ldots, x_n = b\} \) be a partition of \([a,b]\) into subintervals of length \( < \delta \). On \([x_{k-1}, x_k]\), let \( H_k \) be a copy of the Cantor Function scaled to \([x_{k-1}, x_k]\) with \( H_k(x_{k-1}) = \Psi(x_{k-1}) \) and \( H_k(x_k) = \Psi_k(x_k) \). Define \( \Phi(x) = \Psi(x) - H_k(x) \) if \( x_{k-1} \leq x \leq x_k \). Then \( \Phi(x_k) = 0 \) for all \( k \), and hence \( \Phi \) is well defined and continuous; and \( \Phi' = \Psi' = \phi \) a.e. since \( H'_k = 0 \) a.e. for each \( k \). If \( x \in [x_{k-1}, x_k] \), we have \( |\Psi(x) - \Psi(x_{k-1})| < \epsilon \) and \( |\Psi(x) - \Psi(x_k)| < \epsilon \); since \( H_k(x) \) is between \( H_k(x_{k-1}) = \Psi(x_{k-1}) \) and \( H_k(x_k) = \Psi(x_k) \), we also have \( |\Phi(x)| = |\Psi(x) - H_k(x)| < \epsilon \).

To handle the more difficult case where \( f \) is not integrable, we need the following technical lemma:

**XIV.17.2.13. Lemma.** Let \( \phi \) be an integrable function on an interval \([a,b]\), and \( C \) a closed subset of \([a,b]\). Then for any \( \epsilon > 0 \) there is a continuous function \( \Phi \) on \([a,b]\) with the following properties:

(i) \( \Phi \) is differentiable a.e. and \( \Phi' = \phi \) a.e. on \([a,b] \setminus C\).

(ii) \( \Phi(x) = \Phi'(x) = 0 \) for all \( x \in C \).

(iii) \( |\Phi(x + h)| = |\Phi(x) + h - \Phi(x)| < \epsilon |h| \) whenever \( x \in C \) and \( x + h \in [a,b] \).

**Proof:** Fix \( \epsilon > 0 \). The open set \((a,b) \setminus C\) is a disjoint union of open intervals \((a_k, b_k)\). For each \( k \), fix a set \( \{x_{k,n} : n \in \mathbb{Z}\} \) with \( x_{k,n} < x_{k,n+1} \) for all \( n \), \( \lim_{n \to -\infty} x_{k,n} = a_k \), and \( \lim_{n \to +\infty} x_{k,n} = b_k \). For each \( k \) and \( n \), let \( \Phi_{k,n} \) be a continuous function on \([x_{k,n}, x_{k,n+1}]\) such that

(i) \( \Phi_{k,n} \) is differentiable a.e. and \( \Phi'_{k,n} = \phi \) a.e. on \([x_{k,n}, x_{k,n+1}]\).

(ii) \( \Phi_{k,n}(x_{k,n}) = \Phi_{k,n}(x_{k,n+1}) = 0 \).

(iii) \( |\Phi_{k,n}(x)| < \min \left( \frac{\epsilon (x_{k,n} - a_k)}{|k| + |n|}, \frac{\epsilon (b_k - x_{k,n+1})}{|k| + |n|} \right) \) for all \( x \in [x_{k,n}, x_{k,n+1}] \).

(Lemma XIV.17.2.12). Define \( \Phi \) on \([a,b]\) by \( \Phi(a) = \Phi(b) = 0 \), \( \Phi(x) = 0 \) for \( x \in C \), and \( \Phi(x) = \Phi_{k,n}(x) \) if \( x \in [x_{k,n}, x_{k,n+1}] \). Then \( \Phi \) is well defined and continuous, and it is routine to check it has the other required properties (Exercise XIV.17.5.3.).

1716
XIV.17.2.14. We now prove the theorem (in the reduced form $G = 0$). Fix $\epsilon > 0$. Inductively for $n \geq 0$ construct continuous functions $\Phi_n$ which are differentiable a.e. and closed subsets $(C_n)$ of $[a, b]$ with $C_n \subseteq C_{n+1}$ for all $n$, such that, with $F_n = \sum_{k=1}^{n} \Phi_k$, the following conditions are satisfied for $n \geq 1$:

(i) $F_n$ is differentiable at all points of $C_n$ and $F_n' = f$ on $C_n$.

(ii) $\Phi_n(x) = \Phi_n'(x) = 0$ for all $x \in C_{n-1}$.

(iii) $|\Phi_n(x + h)| = |\Phi_n(x) - \Phi_n(x)| \leq \frac{\epsilon |h|}{2^n(b-a)}$ whenever $x \in C_{n-1}$ and $x + h \in [a, b]$.

(iv) $\lambda([a, b] \setminus C_n) < \frac{1}{n}$.

Begin with $C_0 = \emptyset$ and $\Phi_0 = 0$. Suppose $\Phi_k$ and $C_k$ have been chosen for $k \leq n$. Since $F_n'$ and $f$ are defined a.e., for some sufficiently large $M$ the measurable set

$$A_n = \{x \in [a, b] \setminus C_n : F_n'(x) \text{ and } f(x) \text{ exist and } |F_n'(x)|, |f(x)| \leq M\}$$

satisfies $\lambda([a, b] \setminus C_n) < \frac{1}{n+1}$.

Define $\phi_n$ on $[a, b]$ by $\phi_n = f - F_n'$ on $A_n$ and $\phi_n = 0$ on $[a, b] \setminus A_n$. Then $\phi_n$ is bounded, hence integrable, so by Lemma XIV.17.2.13. there is a continuous function $\Phi_{n+1}$ on $[a, b]$ which is differentiable a.e., $\Phi_{n+1}'(x) = f(x) - F_n'(x)$ for almost all $x \in A_n$, $\Phi_{n+1}(x) = \Phi_{n+1}'(x) = 0$ for all $x \in C_n$, and

$$|\Phi_{n+1}(x + h)| < \frac{\epsilon |h|}{2^{n+1}(b-a)}$$

if $x \in C_n$ and $x + h \in [a, b]$.

By (), there is a closed subset $B_n$ of $A_n$ such that $\Phi_{n+1}'(x) = f(x) - F_n'(x)$ for all $x \in B_n$ and $\lambda([0, 1] \setminus (C_n \cup B_n)) < \frac{1}{n+1}$. Set $C_{n+1} = C_n \cup B_n$. This completes the inductive construction, and properties (i)–(iv) obviously hold.

From (iii), we have $|\Phi_n(x)| < \frac{\epsilon}{2^n}$ for all $x \in [a, b]$; thus the series

$$\sum_{n=1}^{\infty} \Phi_n$$

converges uniformly to a continuous function $F$ on $[a, b]$ and $|F(x)| < \epsilon$ for all $x \in [a, b]$. Set $C = \cup_{n=1}^{\infty} C_n$. Then $\lambda([a, b] \setminus C) = 0$, and if $x \in C$, then $x \in C_n$ for sufficiently large $n$; thus for any $h$ with $x + h \in [a, b]$ we have

$$\left| \frac{F(x + h) - F(x)}{h} - \frac{F_n(x + h) - F_n(x)}{h} \right| = \left| \sum_{k=n+1}^{\infty} \frac{\Phi_k(x + h) - \Phi_k(x)}{h} \right| < \frac{\epsilon}{2^n(b-a)}$$

for sufficiently large $n$, and hence

$$\limsup_{h \to 0} \left| \frac{F(x + h) - F(x)}{h} - f(x) \right| \leq \frac{\epsilon}{2^n(b-a)}$$

for all sufficiently large $n$, i.e. $F'(x) = f(x)$.

This completes the proof of Theorem XIV.17.2.10. \( \square \)
XIV.17.3. $L^p$ Versions, $p > 1$

There is an $L^p$ analog of absolute continuity for $p > 1$. Surprisingly, the distinction between absolute continuity and bounded variation disappears in this case. This section is adapted from [?].

XIV.17.3.1. **Theorem.** Let $F$ be a function from $[a, b]$ to $\mathbb{R}$, and $p > 1$. The following are equivalent:

(i) There is a measurable function $f$ on $[a, b]$ with $\int_a^b |f|^p \, d\lambda < \infty$ (i.e. $f \in L^p([a, b])$) and

$$F(x) = F(a) + \int_a^x f \, d\lambda$$

for all $x \in [a, b]$.

(ii) There is a constant $M$ such that whenever $[a_1, b_1], \ldots, [a_n, b_n]$ are nonoverlapping subintervals of $[a, b]$, with $h_k = b_k - a_k$ for each $k$, we have

$$\sum_{k=1}^n |F(b_k) - F(a_k)|^p h_k^{1-p} \leq M.$$

(iii) There is a constant $M$ such that whenever $[a_1, b_1], \ldots, [a_n, b_n]$ are nonoverlapping subintervals of $[a, b]$, with $h_k = b_k - a_k$ for each $k$, we have

$$\sum_{k=1}^n |F(b_k) - F(a_k)|^p h_k^{1-p} \leq M$$

and, for every $\epsilon > 0$, there is a $\delta > 0$ such that whenever $[a_1, b_1], \ldots, [a_n, b_n]$ are nonoverlapping subintervals of $[a, b]$, with $h_k = b_k - a_k$ for each $k$ and $\sum_{k=1}^n h_k < \delta$,

$$\sum_{k=1}^n |F(b_k) - F(a_k)|^p h_k^{1-p} < \epsilon.$$

If these conditions are satisfied, the smallest $M$ in (ii) and (iii) is precisely $\int_a^b |f|^p \, d\lambda$.

XIV.17.3.2. The conditions in (iii) are apparently more restrictive than in (ii). The condition in (i) implies that $f$ is integrable on $[a, b]$, and hence that $F$ is absolutely continuous on $[a, b]$.

If $p = 1$, the condition in (ii) is precisely that $F$ have bounded variation on $[a, b]$, and the second condition in (iii) is that $F$ be absolutely continuous on $[a, b]$, which implies that $F$ has bounded variation and hence satisfies the first condition of (iii). Thus Theorem XIV.17.2.4. says that (i) and (iii) are equivalent also if $p = 1$; however, (ii) is not equivalent to (i) and (iii) in general if $p = 1$ (the Cantor function is a counterexample).
XIV.17.3.3. We now give the proof of XIV.17.3.1.

Proof: (iii) ⇒ (ii) is trivial.

(i) ⇒ (iii): By (), for each \( k \) we have

\[ |F(b_k) - F(a_k)| = \left| \int_{a_k}^{b_k} f \, d\lambda \right| \leq \left[ \int_{a_k}^{b_k} |f|^p \, d\lambda \right]^{1/p} \left[ \int_{a_k}^{b_k} 1 \, d\lambda \right]^{1-1/p} = h_k^{1-1/p} \left[ \int_{a_k}^{b_k} |f|^p \, d\lambda \right]^{1/p} \]

so

\[ \sum_{k=1}^{n} |F(b_k) - F(a_k)| h_k^{-p} \leq \sum_{k=1}^{n} h_k^{1-p} \left[ h_k^{1-1/p} \right]^{p} \left[ \int_{a_k}^{b_k} |f|^p \, d\lambda \right] = \sum_{k=1}^{n} \left[ \int_{a_k}^{b_k} |f|^p \, d\lambda \right] \leq \int_{a}^{b} |f|^p \, d\lambda. \]

Also, by (), for any \( \epsilon > 0 \) there is a \( \delta > 0 \) such that if \( \sum_{k=1}^{n} h_k < \delta \),

\[ \sum_{k=1}^{n} \left[ \int_{a_k}^{b_k} |f|^p \, d\lambda \right] < \epsilon \]

so condition (iii) is satisfied with \( M = \int_{a}^{b} |f|^p \, d\lambda \).

(ii) ⇒ (i): Let \([a_1, b_1], \ldots, [a_n, b_n]\) be nonoverlapping subintervals of \([a, b]\). Then, by Hölder’s Inequality (), we have

\[ \sum_{k=1}^{n} |F(b_k) - F(a_k)| = \sum_{k=1}^{n} \left[ |F(b_k) - F(a_k)| h_k^{-p+1} \right]^{1/p} h_k^{1-1/p} = \sum_{k=1}^{n} \left[ |F(b_k) - F(a_k)| h_k^{1-1/p} \right]^{1/p} h_k^{1-1/p} \]

\[ \leq \left( \sum_{k=1}^{n} \left[ |F(b_k) - F(a_k)| h_k^{1-1/p} \right] \right)^{1/p} \left( \sum_{k=1}^{n} h_k \right)^{1-1/p} \leq M^{1/p} \left( \sum_{k=1}^{n} h_k \right)^{1-1/p} \]

and thus, for any \( \epsilon > 0 \), there is a \( \delta > 0 \) such that if \( \sum_{k=1}^{n} h_k < \delta \), \( \sum_{k=1}^{n} |F(b_k) - F(a_k)| < \epsilon \). Thus \( F \) is absolutely continuous. Hence there is an integrable function \( f \) on \([a, b]\) with

\[ F(x) = F(a) + \int_{a}^{x} f \, d\lambda \]

for all \( x \in [a, b] \). It remains to show that \( \int_{a}^{b} |f|^p \, d\lambda \leq M \).

For each \( n \) let \( \mathcal{P}_n = \{ a = x_{n,0}, x_{n,1}, \ldots, x_{n,n} = b \} \) be a partition of \([a, b]\) into \( n \) subintervals of equal length. For \( x_{n,k} \leq x < x_{n,k+1} \), set

\[ f_n(x) = \frac{F(x_{n,k+1}) - F(x_{n,k})}{x_{n,k+1} - x_{n,k}}. \]

Since \( F \) is absolutely continuous, it is differentiable a.e. and \( F' = f \) a.e. Suppose \( x_{n,k} < x < x_{n,k+1} \) and \( F' \) is differentiable at \( x \). Then

\[ f_n(x) = \frac{F(x_{n,k+1}) - F(x)}{x_{n,k+1} - x} \cdot \frac{x_{n,k+1} - x}{x_{n,k+1} - x_{n,k}} + \frac{F(x) - F(x_{n,k})}{x - x_{n,k}} \cdot \frac{x - x_{n,k}}{x_{n,k+1} - x_{n,k}} \]

\[ = (F'(x) + \eta_1) \frac{x_{n,k+1} - x}{x_{n,k+1} - x_{n,k}} + (F'(x) + \eta_2) \frac{x - x_{n,k}}{x_{n,k+1} - x_{n,k}} = F'(x) + \eta_3 \]

1719
where \( \eta_1, \eta_2, \eta_3 \) depend on \( x \) and \( n \); for fixed \( x \) and \( n \) we have \( |\eta_3| \leq |\eta_1| + |\eta_2| \), and for fixed \( x \) we have \( \eta_1, \eta_2 \to 0 \) as \( n \to \infty \). So if \( x \) is not one of the \( x_{n,k} \) for any \( n \) and \( F \) is differentiable at \( x \), \( f_n(x) \to F'(x) \).

Thus \( f_n \to f \) a.e. By Fatou’s Lemma (),

\[
\int_a^b |f|^p \, d\lambda \leq \liminf_{n \to \infty} \int_a^b |f_n|^p \, d\lambda = \liminf_{n \to \infty} \sum_{k=1}^n \frac{|F(x_{n,k}) - F(x_{n,k-1})|^p}{(x_{n,k} - x_{n,k-1})^p} (x_{n,k} - x_{n,k-1}) \leq M.
\]

\[\blacklozenge\]

**XIV.17.4. The Lebesgue Density Theorem**

If \( A \) and \( B \) are Lebesgue measurable subsets of \( \mathbb{R} \), with \( 0 < \lambda(B) < \infty \), it makes sense to interpret \( \frac{\lambda(A \cap B)}{\lambda(B)} \) as the “fraction of the points of \( B \) which are in \( A \).” We will particularly make this interpretation when \( B \) is a finite interval.

If \( A \) is a measurable subset of \( \mathbb{R} \) and \( c \in \mathbb{R} \), we similarly want to carefully define “the fraction of points near \( c \) which are in \( A \).” There is a way to do this, and it leads to a remarkable result (XIV.17.4.3.): for almost all points \( x \) of \( A \), almost all points near \( x \) are in \( A \), and for almost all points \( y \) of \( A^c \), almost all points near \( y \) are in \( A^c \). As a consequence, a Lebesgue measurable subset of \( \mathbb{R} \) is “lumpy” and cannot be distributed very evenly throughout \( \mathbb{R} \), or an interval in \( \mathbb{R} \), unless it is very densely or very sparsely distributed in that interval in a measure-theoretic sense.

**XIV.17.4.1. Definition.** Let \( A \) be a Lebesgue measurable subset of \( \mathbb{R} \). If \( c \in \mathbb{R} \), define the left and right upper and lower densities of \( A \) at \( c \) to be

- The left lower density \( d_- (A, c) = \liminf_{x \to c^-} \frac{\lambda([x, c] \cap A)}{\lambda([x, c])} \).
- The left upper density \( d^- (A, c) = \limsup_{x \to c^-} \frac{\lambda([x, c] \cap A)}{\lambda([x, c])} \).
- The right lower density \( d_+ (A, c) = \liminf_{x \to c^+} \frac{\lambda([c, x] \cap A)}{\lambda([c, x])} \).
- The right upper density \( d^+ (A, c) = \limsup_{x \to c^+} \frac{\lambda([c, x] \cap A)}{\lambda([c, x])} \).

If \( d_- (A, c) = d^- (A, c) \), the left density \( d_l (A, c) \) is defined and equals the common value.

If \( d_+ (A, c) = d^+ (A, c) \), the right density \( d_r (A, c) \) is defined and equals the common value.

If \( d_l (A, c) = d_r (A, c) \), the density \( d(A, c) \) is defined and equals the common value.

Note that the left and right upper and lower densities are always defined and are between 0 and 1. It should not be expected that left or right densities, much less densities, always exist (indeed, see XIV.17.5.5.); in fact, it is remarkable that the density exists for almost all \( c \) (and even more is true).

Comparing definitions, we immediately get the following characterization of densities as Dini derivatives:
**XIV.17.4.2.** Proposition. Let $A \subseteq \mathbb{R}$ be Lebesgue measurable, and $c \in \mathbb{R}$. Fix $a < c$, and define

$$F(x) = \int_a^x \chi_A \, d\lambda$$

for $x \geq a$. Then $d_-(A, c)$, $d^-(A, c)$, $d_+(A, c)$, $d^+(A, c)$ are the Dini derivatives ($D_- F(c)$, $D^- F(c)$, $D_+ F(c)$, $D^+ F(c)$) respectively. Thus $d_l(A, c) [d_r(A, c)]$ is defined if and only if $F$ is left [right] differentiable at $c$, and $d_l(A, c) = D_L F(c)$ [$d_r(A, c) = D_R F(c)$]. The density $d(A, c)$ is defined if and only if $F$ is differentiable at $c$, and $d(A, c) = F'(c)$.

**XIV.17.4.3.** Theorem. (Lebesgue Density Theorem) Let $A$ be a Lebesgue measurable subset of $\mathbb{R}$. Then the density of $A$ exists and is 1 for almost all points of $A$, and exists and is 0 for almost all points of $A^c$.

Proof: This is an almost immediate corollary of XIV.17.2.5. We may assume $A$ is bounded, since for $x \in (a, b)$ the density of $A$ at $x$ is the same as the density of $A \cap (a, b)$ at $x$. So suppose $A \subseteq (a, b)$. Set

$$F(x) = \int_a^x \chi_A \, d\lambda$$

for $x \in [a, b]$. Then $F$ is differentiable a.e. and $F' = \chi_A$ a.e. on $[a, b]$, i.e. $F'(x) = 1$ for almost all $x \in A$ and $F'(x) = 0$ for almost all $x \in [a, b] \setminus A$.

The next Corollary makes precise the statement that Lebesgue measurable sets are “lumpy” and cannot be evenly distributed.

**XIV.17.4.4.** Corollary. Let $A$ be a measurable subset of $\mathbb{R}$, and $I$ a bounded interval in $\mathbb{R}$.

(i) If $\lambda(A \cap I) > 0$, then for every $\epsilon > 0$ there is a subinterval $J$ of $I$ such that

$$\frac{\lambda(A \cap J)}{\lambda(J)} \geq 1 - \epsilon.$$ 

(ii) If $\lambda(A \cap I) < \lambda(I)$, then for every $\epsilon > 0$ there is a subinterval $J$ of $I$ such that

$$\frac{\lambda(A \cap J)}{\lambda(J)} \leq \epsilon.$$ 

**XIV.17.4.5.** Thus, for example, there cannot be a Lebesgue measurable set $A$ such that $\lambda(A \cap I) = \frac{1}{2} \lambda(I)$ for every bounded interval $I$, i.e. such that $A$ contains “half” the points in every interval. In fact, if $A$ is Lebesgue measurable, there is no $\epsilon > 0$ such that

$$\epsilon < \frac{\lambda(A \cap I)}{\lambda(I)} < 1 - \epsilon$$

for every bounded interval $I$.

**XIV.17.4.4.** does not hold for $\epsilon = 0$ in general (XIV.17.5.7.)

1721
XIV.17.5. Exercises

XIV.17.5.1. [Sak64] Let $A$ be a Cantor set of positive measure in $[0, 1]$, containing 0 and 1. Let $\{I_n : n \in \mathbb{N}\}$ be the open intervals in $[0, 1] \setminus A$, in decreasing order of length, and $c_n$ the midpoint of $I_n$. Let $\ell_n$ be the length of $I_n$, and $r_n$ the length of the longest subinterval of $[0, 1]$ disjoint from $I_1, \ldots, I_n$. Define a continuous function $f : [0, 1] \to \mathbb{R}$ by letting $f$ be identically zero on $A$, $f(c_n) = \ell_n + r_n$, and $f$ piecewise-linear on $I_n$.

(a) Show that $r_n \to 0$ (obviously $\ell_n \to 0$), and hence $f$ is indeed continuous.

(b) Show that $f$ is absolutely continuous on each $I_n$.

(c) Show that $f$ has Property (N). [If $N$ is a null set in $[0, 1]$, write $N = \bigcup_{k=0}^{\infty} N_k$, where $N_0 = N \cap A$ and $N_k = N \cap I_k$ for $k \geq 1$. Show that $\lambda(f(N_k)) = 0$ for all $k$.] This $f$ is an ACG function in the language of [Sak64].

(d) If $x \in A$, show that $D_-f(x) \leq 0$ and $D^+f(x) \geq 0$, and either $D_-f(x) \leq -1$ or $D^+f(x) \geq 1$ (or both). Hence $f$ fails to be differentiable anywhere on $A$, i.e. on a set of positive measure. Conclude that $f$ does not have bounded variation.

(e) Show that if $x > 0$, then $N_f(x)$ is finite. Thus $f$ has Property (S) by XIV.17.1.8.

XIV.17.5.2. Let $f$ be as in XIV.17.5.1., and set $g(x) = x + f(x)$.

(a) Show that $g$ has property (N). [See XIV.17.5.1 (c).]

(b) Show that for almost all $x \in A$, $N_g(x) = +\infty$. Thus $N_g$ is not finite a.e.

(c) By Theorem XIV.17.1.8., $g$ also does not satisfy property (S).

XIV.17.5.3. Verify that the function $\Phi$ defined in the proof of Lemma XIV.17.2.13. has all the required properties.

XIV.17.5.4. Show that Lemma XIV.17.2.12. is essentially an explicit version of XV.8.3.6., as follows.

(a) Deduce XIV.17.2.12. from XV.8.3.6. by taking $H$ to be a singular function approximating $\Psi$. [One additional correction with a scaled Cantor function is needed to make $H(a) = \Psi(a)$ and $H(b) = \Psi(b)$.

(b) Slightly modify the proof of XIV.17.2.12. to obtain XV.8.3.6.. [If $G$ is any continuous function, construct $H$ to approximate $\Psi - G$.]

XIV.17.5.5. Fix $c \in \mathbb{R}$ and $m, M$ with $0 \leq m \leq M \leq 1$. Show that a sequence

$$a_1 < b_1 < a_2 < b_2 < \cdots < c$$

of real numbers converging to $c$ can be constructed so that, if $A = \{c\} \cup \bigcup_{n=1}^{\infty} [a_n, b_n]$, then $d_-(A, c) = m$ and $d^-(A, c) = M$. Do the same for right densities. Thus the four densities at a given point can be arbitrary within the obvious constraints, even if $A$ is a closed set (or open set).

XIV.17.5.6. Let $A$ and $B$ be Lebesgue measurable subsets of $\mathbb{R}$. If $\lambda(A \Delta B) = 0$, show that $d_-(A, x) = d_-(B, x)$ for all $x \in \mathbb{R}$, and similarly for $d^-, d_+, d^+$. 

1722
XIV.17.5.7. Construct a Lebesgue measurable subset $A$ of $\mathbb{R}$ such that

$$0 < \frac{\lambda(A \cap I)}{\lambda(I)} < 1$$

for every bounded interval $I$ in $\mathbb{R}$. (Note that these numbers cannot be bounded away from 0 or 1 by XIV.17.4.4.) [Let $f$ be a differentiable function which is not monotone on any interval (V.12.1.7., XI.12.5.7.), and let $A = \{x : f'(x) > 0\}$. Use XIV.17.1.18..]
Chapter XV

Functional Analysis

Functional analysis is, in a nutshell, the study of topological vector spaces and operators on them. The name arose in part because historically (and still today), many of the most important topological vector spaces are function spaces. Another reason for the name is that one of the main underlying philosophies of functional analysis is that spaces can be studied by means of real- or complex-valued functions \((\text{functionals})\) on them.

Functional analysis combines linear algebra with analysis and topology. The interaction makes for a rich and powerful theory that has many applications in both pure and applied mathematics.

If a scientist wants to study a forest, there are two principal ways to examine it. First, one can walk through the forest. In this way, the small-scale properties can be studied in detail: the individual trees and the local ecosystems. But it is not easy to determine the large-scale structure of the forest this way, its overall extent and shape, the relative distribution of tree species and open spaces, etc. The other way is to fly over the forest. If you do this, the small-scale structure is not easily seen: individual trees are almost reduced to points in the overall picture; but the large-scale structure can be easily seen at a glance. A full study of the forest would undoubtedly include both methods.

Calculus and traditional elementary analysis give the basic tools necessary to do small-scale analysis of spaces of functions. Functional analysis provides the way to do large-scale analysis. Individual functions, although they have a rich internal structure of their own, are just points in an overall space from the functional analysis point of view. Flying over the function space using functional analysis is often a powerful way of easily establishing properties or solving problems related to function spaces.

Functional analysis reaches its full development and power in combination with measure theory, and many if not most texts assume familiarity with measure theory. But the essentials of functional analysis can be done without measure theory, so we will go as far as possible without weaving measure theory into the picture.
XV.1. Normed Vector Spaces

XV.1.1. Completeness

XV.1.1.1. Proposition. Let $X$ be a normed vector space and $Y$ a (necessarily closed) subspace of $X$. If $Y$ is complete, and $X/Y$ is complete in the quotient norm, then $X$ is complete.

Proof: Let $\hat{X}$ be the completion of $X$. Then $Y$ is closed in $\hat{X}$ since $Y$ is complete. Thus the quotient map from $X$ to $X/Y$ extends to a (bounded) quotient map $\pi$ from $\hat{X}$ to $\hat{X}/Y$; so $X/Y$ is naturally a subspace of $\hat{X}/Y$. On the one hand, $X/Y$ is dense in $\hat{X}/Y$ since $X$ is dense in $\hat{X}$ and $\pi$ is continuous; on the other hand, $X/Y$ is complete, hence closed in $\hat{X}/Y$. Thus $X/Y = \hat{X}/Y$, and hence $X = \hat{X}$ [if $z \in \hat{X}$, let $x \in X$ with $\pi(x) = \pi(z)$; then $z - x \in Y \subseteq X$, so $z = x + (z - x) \in X$].

Since finite-dimensional normed spaces are complete, we obtain:

XV.1.1.2. Corollary. Let $X$ be a normed vector space and $Y$ a (necessarily closed) subspace of $X$. If $Y$ is complete, and $X/Y$ is finite-dimensional, then $X$ is complete.

XV.1.2. Isometries of Normed Vector Spaces

In this section, we prove the following theorem due to Mazur and Ulam []:

XV.1.2.1. Theorem. Let $V$ and $W$ be normed vector spaces over $\mathbb{R}$. Then any isometry from $V$ onto $W$ is an $\mathbb{R}$-affine function.

XV.1.2.2. This result is false if $\mathbb{R}$ is replaced by $\mathbb{C}$. For example, $\alpha \mapsto \bar{\alpha}$ is an isometry on the complex vector space $\mathbb{C}$ which is not $\mathbb{C}$-affine (it is, of course, $\mathbb{R}$-affine).

We begin with a simple observation:

XV.1.2.3. Proposition. Let $V$ and $W$ be Hausdorff topological vector spaces over $\mathbb{R}$, and $f : V \to W$ a continuous function. Then $f$ is $\mathbb{R}$-affine if and only if, for every $x, y \in V$, we have

$$f \left( \frac{x + y}{2} \right) = \frac{f(x) + f(y)}{2}$$

(i.e. $f$ preserves midpoints).

Proof: It is obvious that an affine function preserves midpoints. Conversely, suppose $f$ preserves midpoints. By composing $f$ with a translation, we may assume $f(0) = 0$. It then follows that

$$f \left( \frac{x}{2} \right) = \frac{f(x)}{2}$$
for every \( x \in \mathcal{V} \) by taking \( y = 0 \) in the midpoint property. Thus \( f(2x) = 2f(x) \) for every \( x \in \mathcal{V} \), and thus, for any \( x,y \in \mathcal{V} \), we have

\[
f(x+y) = f\left(\frac{2x+2y}{2}\right) = \frac{f(2x) + f(2y)}{2} = \frac{2f(x) + 2f(y)}{2} = f(x) + f(y)
\]

so \( f \) is additive. Then by iteration we get that \( f(\alpha x) = \alpha f(x) \) for any dyadic rational \( \alpha \) and any \( x \). If \( \alpha \in \mathbb{R} \) is arbitrary, let \( (\alpha_n) \) be a sequence of dyadic rationals converging to \( \alpha \). Then, for any \( x \),

\[
f(\alpha x) = \lim_{n \to \infty} f(\alpha_n x) = \lim_{n \to \infty} \alpha_n f(x) = \alpha f(x)
\]

since \( \mathcal{W} \) is Hausdorff, i.e. the (translated) function \( f \) is linear.

The special case of XV.1.2.1. for \( \mathcal{V} = \mathcal{W} = \mathbb{R}^n \) follows almost immediately:

**XV.1.2.4. Theorem.** Every isometry of \( \mathbb{R}^n \) (with the usual Euclidean norm) is affine.

**Proof:** Let \( f \) be an isometry of \( \mathbb{R}^n \), and let \( x,y \in \mathbb{R}^n \). Let \( z = \frac{x+y}{2} \) be the midpoint of \( x \) and \( y \). Then \( z \) is the unique point of \( \mathbb{R}^n \) with the property that

\[
2(\rho_2(x,z) - \rho_2(z,y)) = \frac{1}{2} \rho_2(x,y)
\]

where \( \rho_2 \) is the standard metric coming from the norm. It follows that \( f(z) \) must satisfy

\[
\rho_2(f(x), f(z)) = \frac{1}{2} \rho_2(f(x), f(y))
\]

since \( f \) is an isometry. Thus \( f(z) \) must be the midpoint of \( f(x) \) and \( f(y) \). Since \( f \) is continuous, it is affine by XV.1.2.3.

**XV.1.2.5.** This proof works more generally for XV.1.2.1. if \( \mathcal{V} \) and \( \mathcal{W} \) are strictly convex (\( \rho \)). For the general case of XV.1.2.1., we need a subtler argument:

**Proof:** Write \( \rho \) and \( \sigma \) for the norm metrics on \( \mathcal{V} \) and \( \mathcal{W} \) respectively. Fix \( x \) and \( y \) in \( \mathcal{V} \), and set \( z = \frac{x+y}{2} \). By XV.1.2.3. it suffices to show that

\[
f(z) = f\left(\frac{x+y}{2}\right)
\]

Let \( A_1 \) be the set of all \( a \in \mathcal{V} \) such that

\[
\rho(x,a) = \rho(a,y) = \frac{1}{2} \rho(x,y)
\]

Then \( A_1 \) is a subset of \( \mathcal{V} \) containing \( z \). We show that \( A_1 \) is symmetric around \( z \), i.e. if \( a \in A_1 \), then \( b = a + 2(z - a) = 2z - a \) is also in \( A_1 \) (\( b \) is the point for which \( z \) is the midpoint of \( a \) and \( b \)). We have \( 2z = x + y \), and thus \( b - x = y - a \) and \( b - y = x - a \), so

\[
\rho(x, b) = \rho(y, a) = \rho(a, x) = \rho(b, y) = \frac{1}{2} \rho(x, y)
\]
and \( b \in A_1 \).

Let \( \delta_1 \) be the diameter of \( A_1 \). Then \( \delta_1 \) is finite since if \( a, b \in A_1 \), we have

\[
\rho(a, b) \leq \rho(a, x) + \rho(x, b) = \rho(x, y).
\]

For any \( a \in A_1 \), set \( b = 2z - a \in A_1 \). Since \( z \) is the midpoint of \( a \) and \( b \), we have

\[
\rho(a, z) = \frac{1}{2} \rho(a, b) \leq \delta_1.
\]

Now let \( A_2 \) be the set of \( c \in A_1 \) such that \( \rho(a, c) \leq \frac{1}{2} \delta_1 \) for all \( a \in A_1 \). Then \( z \in A_2 \). If \( c \in A_2 \), set \( d = 2z - c \). If \( a \in A_1 \), set \( b = 2z - a \in A_1 \). We then have \( 2z = a + b \), so \( d - a = c - b \) and hence

\[
\rho(a, d) = \rho(b, c) \leq \frac{1}{2} \delta_1,
\]

so \( d \in A_2 \) and \( A_2 \) is also symmetric around \( z \). Also, if \( c, d \in A_2 \), then \( c \in A_1 \) so

\[
\rho(c, d) \leq \frac{1}{2} \delta_1.
\]

Thus the diameter \( \delta_2 \) of \( A_2 \) satisfies \( \delta_2 \leq \frac{1}{2} \delta_1 \).

If \( c \in A_2 \), then \( d = 2z - c \in A_2 \), so we have

\[
\rho(c, z) = \rho(z, d) = \frac{1}{2} \rho(c, d) \leq \frac{1}{2} \delta_2.
\]

Let \( A_3 \) be the set of \( v \in A_2 \) for which \( \rho(c, v) \leq \frac{1}{2} \delta_2 \) for all \( c \in A_2 \). Then \( z \in A_3 \) and, as before, \( A_3 \) is symmetric around \( z \) and the diameter \( \delta_3 \) of \( A_3 \) satisfies \( \delta_3 \leq \frac{1}{2} \delta_2 \).

Iterating the process, we obtain a decreasing sequence \((A_n)\) of sets containing \( z \), symmetric around \( z \), with diameter

\[
\delta_n \leq \frac{1}{2} \delta_{n-1} \leq \frac{1}{2^n} \delta_1
\]

and hence \( \cap_n A_n = \{ z \} \).

Let \( w \) be the midpoint of \( f(x) \) and \( f(y) \) in \( W \). Similarly, using \( \sigma \) construct a decreasing sequence \((B_n)\) of subsets of \( W \) containing \( w \). Since the \( A_n \) and \( B_n \) are constructed using just the metrics \( \rho \) and \( \sigma \), and \( f \) is an isometry, we must have \( f(A_n) = B_n \) for all \( n \). Thus we have that

\[
f(\{ z \}) = f(\cap_n A_n) = \cap_n B_n = \{ w \}.
\]

\( \diamond \)

### XV.1.3. Exercises

#### XV.1.3.1. Use the Baire Category Theorem to give an alternate proof that that no Banach space has vector space dimension \( \aleph_0 \) ([If \( \{ \xi_n : n \in \mathbb{N} \} \) is a Hamel basis for \( X \), consider \( X_n = \text{span}\{\xi_1, \ldots, \xi_n\} \).]
XV.2. Topological Vector Spaces

XV.2.1. Basic Definitions and Properties

XV.2.2. Locally Convex Topological Vector Spaces

As pointed out in [KN76], the main extra feature in topological vector spaces distinguishing them from general topological groups is convexity.

Convexity is hard to categorize mathematically. It is essentially a purely algebraic concept; but it is defined only in vector spaces, or affine spaces, over the real numbers (or over a field containing the real numbers), and the primary applications are in analysis.

XV.2.2.1. Definition. Let $C$ and $D$ be convex sets in vector spaces $X$ and $Y$ respectively. An affine map from $C$ to $D$ is a function $f : C \to D$ such that

$$f(tx + (1-t)y) = tf(x) + (1-t)f(y)$$

for all $x, y \in C$ and all $t, 0 \leq t \leq 1$.

XV.2.2.2. An affine map from $C$ to $D$ is a function which preserves the convex structure. If $f$ is an affine map from $X$ to $Y$ in the usual sense of $()$, and $f(C) \subseteq D$, then $f|_C$ is an affine map from $C$ to $D$ in the sense of XV.2.2.1. It can be shown that every affine map from $C$ to $D$ arises in this way $()$, so the terminology is consistent.

XV.2.2.3. Definition. Let $C$ and $D$ be convex sets in topological vector spaces $X$ and $Y$ respectively. An isomorphism from $C$ to $D$ is an affine homeomorphism from $C$ to $D$.

Thus an isomorphism from $C$ to $D$ is a bijection which preserves both the convex structure and the topology.

XV.2.3. Metrizability and Normability
XV.3. Bounded Operators

When considering normed vector spaces, or more generally topological vector spaces, the most natural and important functions between them should preserve both the algebraic structure, i.e. be linear, and the topological structure, i.e. be continuous. Thus we usually want to work with continuous linear operators. In the case of normed vector spaces, continuity is equivalent to another property, boundedness, which is usually easier to work with directly.

XV.3.1. Bounded Operators on Normed Vector Spaces

XV.3.1.1. Definition. Let $X$ and $Y$ be vector spaces over $F$. A (linear) operator from $X$ to $Y$ is a linear transformation () from $X$ to $Y$. Thus operator and linear transformation are synonymous. The term operator is primarily used in the case $X = Y$, in which case we call it an operator on $X$. If $T : X \to Y$ is an operator, we usually write $Tx$ instead of $T(x)$ for the image of $x \in X$ under $T$.

XV.3.1.2. Definition. Let $(X, \| \cdot \|_X)$ and $(Y, \| \cdot \|_Y)$ be normed vector spaces over $F$, and $T : X \to Y$ an operator (linear transformation). Then $T$ is bounded, or a bounded operator, if there is a constant $M$ such that

$$\|Tx\|_Y \leq M\|x\|_X$$

for all $x \in X$. The smallest such $M$ is called the operator norm of $T$, written $\|T\|_{op}$ or usually just $\|T\|$ when there is no possibility of confusion.

Although the notation does not reflect it, boundedness of $T$ and its operator norm depend on the choices of norms on $X$ and $Y$. Thus, although we often write $T : X \to Y$ by slight abuse of notation, there must be understood norms on $X$ and $Y$.

XV.3.1.3. If $T$ is a bounded operator from $X$ to $Y$, we have

$$\|T\| = \sup_{x \neq 0} \frac{\|Tx\|_Y}{\|x\|_X} = \sup_{\|x\|_X = 1} \|Tx\|_Y$$

since $T$ is linear and any vector is a scalar multiple of a unit vector. The 0 operator is bounded, and $\|0\| = 0$; if $T$ is bounded, then $\|T\| \geq 0$, and $\|T\| = 0$ if and only if $T = 0$.

The most important feature of boundedness is that it is equivalent to continuity:

XV.3.1.4. Proposition. Let $(X, \| \cdot \|_X)$ and $(Y, \| \cdot \|_Y)$ be normed vector spaces over $F$, and $T : X \to Y$ a linear transformation. The following are equivalent:

(i) $T$ is continuous at 0.

(ii) $T$ is continuous.

(iii) $T$ is uniformly continuous.

(iv) $T$ is bounded.
Proof: (iii) ⇒ (ii) ⇒ (i) is trivial.
(iv) ⇒ (iii): Suppose $T$ is bounded. We may assume $T \neq 0$, so $\|T\| > 0$. Let $\epsilon > 0$, and set $\delta = \frac{\epsilon}{\|T\|}$. If $x_1, x_2 \in X$ with $\|x_2 - x_1\|_X < \delta$, then

$$\|Tx_2 - Tx_1\|_Y = \|T(x_2 - x_1)\|_Y \leq \|T\|\|x_2 - x_1\|_X < \|T\|\delta = \epsilon.$$ 

Thus $T$ is uniformly continuous.

(i) ⇒ (iv): Suppose $T$ is not bounded. Then for every $n$ there is a $v_n \in X$, $v_n \neq 0$, with $\|Tv_n\|_Y > n\|v_n\|_X$. Set $x_n = \frac{1}{n\|v_n\|_X}v_n$. Then $\|x_n\|_X = \frac{1}{n}$ and

$$\|Tx_n\|_Y = \left\|T\left(\frac{1}{n\|v_n\|_X}v_n\right)\right\|_Y = \frac{1}{n\|v_n\|_X}\|Tv_n\|_Y > 1$$

for all $n$. Thus $x_n \to 0$ in $X$ but $Tx_n \not\to 0$ in $Y$, so $T$ is not continuous at 0. \qed

**XV.3.1.5.** Let $X$ and $Y$ be vector spaces over $\mathbb{F}$. The set $\mathcal{L}(X,Y)$ of linear transformations from $X$ to $Y$ is a vector space over $\mathbb{F}$ under the usual operations $()$.

**XV.3.1.6.** Proposition. Let $(X, \|\cdot\|_X)$ and $(Y, \|\cdot\|_Y)$ be normed vector spaces over $\mathbb{F}$, and $S$ and $T$ bounded operators from $X$ to $Y$. Then

(i) $S + T$ is a bounded operator from $X$ to $Y$, and $\|S + T\| \leq \|S\| + \|T\|$.

(ii) If $\alpha \in \mathbb{F}$, then $\alpha T$ is bounded and $\|\alpha T\| = |\alpha|\|T\|$.

Proof: (i): If $x \in X$, we have

$$\|(S + T)x\|_Y = \|Sx + Tx\|_Y \leq \|Sx\|_Y + \|Tx\|_Y \leq \|S\|\|x\|_X + \|T\|\|x\|_X = (\|S\| + \|T\|)\|x\|_X.$$ 

(ii): We have

$$\|\alpha T\| = \sup_{\|x\|_X = 1} \|\alpha(Tx)\|_Y = \sup_{\|x\|_X = 1} \|\alpha(Tx)\|_Y = \sup_{\|x\|_X = 1} |\alpha|\|Tx\|_Y = |\alpha| \sup_{\|x\|_X = 1} \|Tx\|_Y = |\alpha|\|T\|.$$ 

\qed

**XV.3.1.7.** Corollary. Let $X$ and $Y$ be normed vector spaces over $\mathbb{F}$. Then the set $\mathcal{B}(X,Y)$ of bounded operators from $X$ to $Y$ is a vector subspace of $\mathcal{L}(X,Y)$, and the operator norm is a norm on $\mathcal{B}(X,Y)$.

The operator norm has one more simple but important property:
**XV.3.1.8.** Proposition. Let \( X, Y, Z \) be normed vector spaces over \( F \), \( T \in \mathcal{B}(X, Y) \), \( S \in \mathcal{B}(Y, Z) \). Then \( ST = S \circ T \in \mathcal{B}(X, Z) \) and \( \| ST \| \leq \| S \| \| T \| \).

Proof: If \( x \in X \), we have
\[
\| (ST)x \|_Z = \| S(Tx) \|_Z \leq \| S \| \| Tx \|_Y \leq \| S \| \| T \| \| x \|_X.
\]

Simple examples with \( 2 \times 2 \) matrices show that the inequality can be strict; if fact, we can have \( ST = 0 \) even if \( S \) and \( T \) are both nonzero, if the range of \( T \) is contained in the null space of \( S \).

Completeness

**XV.3.1.9.** Theorem. Let \( X \) and \( Y \) be normed vector spaces over \( F \). If \( Y \) is complete (a Banach space), then \( \mathcal{B}(X, Y) \) is complete (a Banach space) in the operator norm.

Proof: The proof follows the standard pattern of completeness proofs. Suppose \((T_n)\) is a Cauchy sequence in \( \mathcal{B}(X, Y) \). We first find a candidate for the limit \( T \).

Fix \( x \in X \). We have, for \( n, m \in \mathbb{N} \),
\[
\| T_n x - T_m x \|_Y = \| (T_n - T_m) x \|_Y \leq \| T_n - T_m \| \| x \|_X
\]
so the sequence \((T_n x)\) is a Cauchy sequence in \( Y \). Since \( Y \) is complete, the sequence \((T_n x)\) converges to an element of \( Y \) we may call \( T x \). As \( x \) varies over \( X \), this procedure defines a function \( T : X \to Y \), and \( T_n \to T \) pointwise.

We must show that \( T \) is a bounded operator and that \( T_n \to T \) in operator norm. If \( x_1, x_2 \in X \), then \( T_n x_1 \to T x_1, T_n x_2 \to T x_2 \), and \( T_n (x_1 + x_2) \to T (x_1 + x_2) \). But \( T_n (x_1 + x_2) = T_n x_1 + T_n x_2 \) by linearity, and \( T_n x_1 + T_n x_2 \to T x_1 + T x_2 \) by continuity of addition in \( Y \). Thus \( T(x_1 + x_2) = T x_1 + T x_2 \) by uniqueness of limits in \( Y \). Similarly, if \( \alpha \in F \), we have \( T_n (\alpha x) \to T (\alpha x) \) and \( T_n (\alpha x) = \alpha T_n x \to \alpha (T x) \), so \( T (\alpha x) = \alpha (T x) \). Thus \( T \) is linear.

To show that \( T \) is bounded, note that the sequence \((T_n)\), being a Cauchy sequence, is bounded, say \( \| T_n \| \leq M \) for all \( n \). Fix \( x \) with \( \| x \| = 1 \). Then \( \| T_n x \|_Y \leq M \| x \|_X = M \), and since \( T_n x \to T x \), we also have \( \| T x \|_Y \leq M \). This is true for every \( x \) of norm 1, so \( T \) is bounded and \( \| T \| \leq M \).

Finally, let \( \epsilon > 0 \). Since \((T_n)\) is a Cauchy sequence, there is an \( N \) such that \( \| T_n - T_m \| < \epsilon \) for all \( n, m \geq N \). Fix \( x \in X \), \( \| x \|_X = 1 \). Then
\[
\| T_n x - T_m x \|_Y = \| (T_n - T_m) x \|_Y \leq \| T_n - T_m \| \| x \|_X < \epsilon
\]
for all \( n, m \geq N \). Fix \( n \geq N \); since \( T_n x \to T x \), we have \( \| (T_n - T) x \|_Y = \| T_n x - T x \|_Y \leq \epsilon \). This is true for all such \( x \), so \( \| T_n - T \| \leq \epsilon \). This is true for all \( n \geq N \), so \( T_n \to T \) in operator norm.

**XV.3.1.10.** Note that completeness of \( X \) is not needed for this result. But if \( Y \) is complete, any bounded operator from \( X \) to \( Y \) extends uniquely to a bounded operator from the completion \( \bar{X} \) to \( Y \) with the same norm, so \( \mathcal{B}(X, Y) \cong \mathcal{B}(\bar{X}, Y) \):
**XV.3.1.11.** PROPOSITION. Let $X$ and $Y$ be normed vector spaces, with $Y$ complete, and let $Z$ be a dense subspace of $X$. If $T$ is a bounded operator from $Z$ to $Y$, then $T$ extends uniquely to a bounded operator $\hat{T} : X \to Y$, and $\|\hat{T}\| = \|T\|$.

PROOF: Since $T$ is uniformly continuous (XV.3.1.4.), and $Y$ is complete, $T$ extends uniquely to a continuous function $\hat{T}$ from $X$ to $Y$. If $x_1, x_2 \in X$, there are sequences $(z_{n1})$ and $(z_{n2})$ in $Z$ converging to $x_1$ and $x_2$ respectively. Then $z_{n1} + z_{n2} \to x_1 + x_2$, so $\hat{T}(z_{n1} + z_{n2}) = T(z_{n1} + z_{n2}) \to \hat{T}(x_1 + x_2)$. On the other hand, $Tz_{n1} = \hat{T}z_{n1} \to \hat{T}x_1$ and $Tz_{n2} = \hat{T}z_{n2} \to \hat{T}x_2$, so

$$\hat{T}(z_{n1} + z_{n2}) = T(z_{n1} + z_{n2}) = Tz_{n1} + Tz_{n2} \to \hat{T}x_1 + \hat{T}x_2$$

so $\hat{T}(x_1 + x_2) = \hat{T}x_1 + \hat{T}x_2$ by uniqueness of limits in $Y$. Similarly, if $\alpha \in F$, $\hat{T}(\alpha z_{n1})$ converges to both $T(\alpha x_1)$ and $\alpha(Tx_1)$, so $\hat{T}(\alpha z_{n1}) = \alpha(Tx_1)$ and $\hat{T}$ is linear.

Let $x \in X$, $\|x\| = 1$. There is a sequence $(z_n)$ in $Z$ converging to $x$. Then $\|z_n\|_X \to \|x\|_X = 1$, so if $w_n = \frac{z_n}{\|z_n\|_X}$, then $w_n \in Z$ for all $n$, $\|w_n\|_X = 1$ for all $n$, and $w_n \to x$ by joint continuity of scalar multiplication. We have $\|T w_n\|_Y \leq \|T\|$ for all $n$, and since $\hat{T} w_n = T w_n \to \hat{T} x$, we also have $\|\hat{T} x\|_Y \leq \|T\|$. This is true for all such $x$, so $\hat{T}$ is bounded and $\|\hat{T}\| \leq \|T\|$.

For the opposite inequality, let $\epsilon > 0$. There is a $z \in \hat{Z}$ with $\|z\|_X = 1$ and $\|Tz\|_Y > \|T\| - \epsilon$. We then have

$$\|T\| - \epsilon < \|\hat{T} z\|_Y = \|\hat{T} z\|_Y \leq \|\hat{T}\| \|z\|_X = \|\hat{T}\|.$$

The extreme inequality is true for all $\epsilon > 0$, and thus $\|T\| \leq \|\hat{T}\|$.

** XV.3.2. Bounded Linear Functionals **

**XV.3.2.12.** DEFINITION. Let $X$ be a vector space over $\mathbb{F}$. A linear functional on $X$ is a linear transformation from $X$ to $\mathbb{F}$. If $X$ is a normed vector space, a linear functional $\phi$ on $X$ is bounded if it is bounded as a linear transformation (regarding $\mathbb{F}$ as a normed vector space with norm $|\cdot|$), i.e. if there is a constant $M$ such that $|\phi(x)| \leq M \|x\|$ for all $x \in X$. The smallest such $M$ is the norm of $\phi$, denoted $\|\phi\|$.

**XV.3.2.13.** NOTATION: If $X$ is a vector space over $\mathbb{F}$, we will write $X'$ for the set $\mathcal{L}(X, \mathbb{F})$ of linear functionals on $X$. If $X$ is normed, write $X^*$ for the set $\mathcal{B}(X, \mathbb{F})$ of bounded linear functionals on $X$. Then $X'$ is a vector space over $\mathbb{F}$, and by XV.3.1.7., $X^*$ is a subspace which is normed by $\|\cdot\|_X$; $X^*$ is a Banach space by XV.3.1.9.. $X'$ is called the algebraic dual space of $X$, and $X^*$ the (topological) dual space of $X$.

There is no uniformity of notation for dual spaces. Many authors use $X'$ for the topological dual space, and some of these (e.g. [?]) even use $X^*$ to denote the algebraic dual. We use what seems to be the most common notation. We usually use $\phi$, $\psi$, etc. to denote linear functionals; some authors use $x^*$ to denote a general element of $X^*$, leading to poor and confusing expressions like $x^*(x)$ where $x$ denotes a general element of $X$ and $x^*$ a general element of $X^*$, with no relation between them.

**XV.3.2.14.** By XV.3.1.4., a linear functional on a normed vector space is continuous if and only if it is bounded. The null space of any bounded operator is closed () . The converse does not hold in general, e.g. there are unbounded one-to-one linear transformations. However:
**Proposition.** Let $X$ be a normed vector space over $F$, and $\phi : X \to F$ a linear functional on $X$. If the null space $N_\phi$ is closed in $X$, then $\phi$ is bounded.

**Proof:** Suppose $\phi$ is unbounded. Then for each $n \in \mathbb{N}$ there is a $y_n \in X$ with $\|y_n\| = 1$ but $|\phi(y_n)| > n$. Set $x_n = \frac{1}{\phi(y_n)}y_n$. Then $\|x_n\| < 1/n$ and $\phi(x_n) = 1$ for all $n$. Fix $v \in X$ with $\phi(v) = 1$. We have $x_n \to 0$, so $v - x_n \to v$. But $v - x_n \in N_\phi$ for all $n$, so $v \in \overline{N_\phi} \setminus N_\phi$, and $N_\phi$ is not closed.

In fact, this argument shows that if $\phi$ is unbounded, then $N_\phi$ is dense in $X$. (Actually it would have to be either closed or dense since it has codimension 1.)

**XV.3.3. Operators on Finite-Dimensional Normed Spaces**

**XV.3.4. Bounded Operators on Hilbert Spaces**

**XV.3.5. Algebras of Operators**

**XV.3.5.1. Definition.** A (concrete) operator algebra is a *-subalgebra of $B(\mathcal{H})$ which is topologically closed in a suitable sense (there is also a subject of non-self-adjoint operator algebras, but it is outside the scope of this volume.) A von Neumann algebra is a (necessarily unital) *-subalgebra $M$ of $B(\mathcal{H})$ such that $M = M''$.

A von Neumann algebra is weakly (hence strongly, norm-, ...) closed, and in particular is a concrete C*-algebra (XV.14.1.3.), albeit of a very special kind.

**Commutant and Bicommutant**

One of the first, yet still one of the most crucial basic theorems of operator algebra theory is von Neumann’s Bicommutant Theorem [?]. We say a *-algebra $A$ of operators on a Hilbert space $\mathcal{H}$ acts nondegenerately if $T \xi = 0$ for all $T \in A$ implies $\xi = 0$. Since $A$ is a *-algebra, this is equivalent to the condition that the subspace $A\mathcal{H} = \text{span}\{T \xi : T \in A, \xi \in \mathcal{H}\}$

is dense in $\mathcal{H}$. If $I \in A$, then $A$ obviously acts nondegenerately.

**Theorem. [Bicommutant Theorem]** Let $A$ be a *-subalgebra of $B(\mathcal{H})$ acting nondegenerately. Then $A$ is $\sigma$-strongly dense in $A''$.

**Proof:** Using ?, the proof reduces to showing that if $\xi \in \mathcal{H}$ and $T \in A''$, there is a sequence $(T_n)$ in $A$ with $T_n \xi \to T \xi$. If $\mathcal{X} = \{S \xi : S \in A\}^\perp$, then $P_X \in A'$ (since both $\mathcal{X}$ and $\mathcal{X}^\perp$ are invariant under $A$), so $T$ commutes with $P_X$, i.e. $T$ leaves $\mathcal{X}$ invariant. It remains to show that $\xi \in \mathcal{X}$, so that $T \xi \in \mathcal{X}$. This is trivial if $I \in A$. In the general nondegenerate case, for each $S \in A$,

$$S[(I - P_X)\xi] = (I - P_X)[S\xi] = 0$$

since $S\xi \in \mathcal{X}$, so $(I - P_X)\xi = 0$.

The Bicommutant Theorem relates a topological closure property with the simple, natural, and purely algebraic property of being the bicommutant (or just commutant) of a *-closed set of operators.
XV.3.5.3. Corollary. Let $A$ be a unital (or just nondegenerate) $*$-subalgebra of $\mathcal{B}(\mathcal{H})$. The following are equivalent:

(i) $A$ is strongly closed.

(ii) $A$ is $\sigma$-strongly closed.

(iii) $A$ is weakly closed.

(iv) $A$ is $\sigma$-weakly closed.

(v) $A$ is a von Neumann algebra, i.e. $A''$. 

XV.4. Dual Spaces and Weak Topologies

One of the core tenets of functional analysis is that spaces can be studied via the scalar-valued continuous functions on them. This section describes the linear version of this philosophy.

XV.4.1. Bounded Linear Functionals

XV.4.1.4. Definition. Let $X$ be a vector space over $F$. A linear functional on $X$ is a linear transformation from $X$ to $F$. If $X$ is a normed vector space, a linear functional $\phi$ on $X$ is bounded if it is bounded as a linear transformation, i.e. if there is a constant $M$ such that $|\phi(x)| \leq M\|x\|$ for all $x \in X$. The smallest such $M$ is the norm of $\phi$, denoted $\|\phi\|$.

XV.4.1.5. Notation: If $X$ is a vector space over $F$, we will write $X'$ for the set of linear functionals on $X$. If $X$ is normed, write $B(X;F)$ for the set of bounded linear functionals on $X$. We have that $X'$ is a vector space over $F$ in the obvious way, and by ( ), $X'$ is a subspace which is normed by $\|\cdot\|$; $X^*$ is a Banach space by ( ). $X'$ is called the algebraic dual space of $X$, and $X^*$ the (topological) dual space of $X$.

There is no uniformity of notation for dual spaces. Many authors use $X'$ for the topological dual space, and some of these (e.g. [?]) even use $X^*$ to denote the algebraic dual. We use what seems to be the most common notation. We usually use $\phi$, $\psi$, etc. to denote linear functionals; some authors use $x^*$ to denote a general element of $X^*$, leading to poor and confusing expressions like $x^*(x)$ where $x$ denotes a general element of $X$ and $x^*$ a general element of $X^*$, with no relation between them.

XV.4.1.6. By ( ), a linear functional on a normed vector space is continuous if and only if it is bounded. The null space of any bounded operator is closed ( ). The converse does not hold in general, e.g. there are unbounded one-to-one linear transformations. However:

XV.4.1.7. Proposition. Let $X$ be a normed vector space over $F$, and $\phi : X \to F$ a linear functional on $X$. If the null space $N_\phi$ is closed in $X$, then $\phi$ is bounded.

Proof: Suppose $\phi$ is unbounded. Then for each $n \in \mathbb{N}$ there is a $y_n \in X$ with $\|y_n\| = 1$ but $|\phi(y_n)| > n$. Set $x_n = \frac{1}{\phi(y_n)}y_n$. Then $\|x_n\| < 1/n$ and $\phi(x_n) = 1$ for all $n$. Fix $v \in X$ with $\phi(v) = 1$. We have $x_n \to 0$, so $v - x_n \to v$. But $v - x_n \in N_\phi$ for all $n$, so $v \in \overline{N_\phi} \setminus N_\phi$, and $N_\phi$ is not closed.

In fact, this argument shows that if $\phi$ is unbounded, then $N_\phi$ is dense in $X$. (Actually it would have to be either closed or dense since it has codimension 1.)
XV.5. The Hahn-Banach Theorem

The Hahn-Banach Theorem is one of the most fundamental results of functional analysis. In various forms it asserts the existence of “many” linear functionals on real or complex vector spaces. Indeed, this theorem underlies and justifies the whole philosophy of functional analysis: that a space can be completely studied via the scalar-valued functionals on the space.

There are many slightly different forms in which this theorem is commonly expressed. All the general versions require use of some form of the Axiom of Choice, but versions for vector spaces which are “not too large” can be proved directly without using the AC.

XV.5.1. Sublinear Functionals and Version 1

The first version of the Hahn-Banach Theorem concerns existence of linear functionals on a real vector space which are trapped between a sublinear functional and a superlinear functional, and more generally extensions to the whole vector space of such a linear functional already defined on a subspace.

**XV.5.1.1. Definition.** Let $V$ be a real vector space. A function $p : V \to (-\infty, +\infty]$ is a *sublinear functional* on $V$ if

(i) $p(x + y) \leq p(x) + p(y)$ for all $x, y \in V$.

(ii) $p(\alpha x) = \alpha p(x)$ for all $\alpha > 0$.

A function $q : V \to [-\infty, +\infty)$ is a *superlinear functional* on $V$ if

(i) $q(x + y) \geq q(x) + q(y)$ for all $x, y \in V$.

(ii) $q(\alpha x) = \alpha q(x)$ for all $\alpha > 0$.

A sublinear or superlinear functional taking only real values is called *finite*.

Note that a sublinear functional can take the value $+\infty$ but not $-\infty$, and a superlinear functional can take the value $-\infty$ but not $+\infty$. In most applications, sublinear or superlinear functionals are finite.

**XV.5.1.2. Examples.** (i) Any linear functional is both sublinear and superlinear.

(ii) The function $p(x) = +\infty$ for all $x$ is sublinear; the function $q(x) = -\infty$ for all $x$ is superlinear.

(iii) Any seminorm () is a finite sublinear functional taking only nonnegative values.

(iv) Let $C$ be a convex set in $V$ containing $0$. For $x \in V$, set

$$p(x) = \inf\{\alpha > 0 : \alpha^{-1}x \in C\}$$

(where $\inf(\emptyset) = +\infty$). It is easily checked () that $p$ is a sublinear functional on $V$, called the *Minkowski functional* of $C$. It takes only nonnegative values, and is finite if and only if $C$ is absorbing ().

(v) If $p$ is a sublinear functional, then $-p$ is a superlinear functional, and vice versa.

The first version of the Hahn-Banach Theorem is:
Theorem. [Hahn-Banach Theorem, Version 1] Let \( V \) be a real vector space, \( p \) a sublinear functional on \( V \), and \( q \) a superlinear functional on \( V \) satisfying \( q(x) \leq p(x) \) for all \( x \in V \). Assume at least one of \( p \) and \( q \) is finite. Let \( W \) be a subspace of \( V \), and \( \psi \) a linear functional on \( W \) satisfying \( q(y) \leq \psi(y) \leq p(y) \) for all \( y \in W \). Then there is a linear functional \( \phi \) on \( V \) extending \( \psi \) with
\[
q(x) \leq \phi(x) \leq p(x)
\]
for all \( x \in V \).

Taking \( q(x) = -\infty \) for all \( x \), we get the following commonly-stated version of the theorem:

Corollary. [Hahn-Banach Theorem, Version 1A] Let \( V \) be a real vector space, and \( p \) a finite sublinear functional on \( V \). Let \( W \) be a subspace of \( V \), and \( \psi \) a linear functional on \( W \) satisfying \( \psi(y) \leq p(y) \) for all \( y \in W \). Then there is a linear functional \( \phi \) on \( V \) extending \( \psi \) with
\[
\phi(x) \leq p(x)
\]
for all \( x \in V \).

There is an analogous result with inequalities reversed for a superlinear functional.

If \( p \) is a sublinear functional on \( V \), then \( p(0) = \alpha p(0) \) for all \( \alpha > 0 \). Thus \( p(0) \) is either 0 or \( +\infty \). Similarly, if \( q \) is superlinear, then \( q(0) \) is either 0 or \( -\infty \). Thus, if \( p \) is sublinear and \( q \) superlinear, then \( q(0) \leq 0 \leq p(0) \), so the hypotheses of XV.5.1.3. and XV.5.1.4. are automatically satisfied if \( W \) is the zero subspace and \( \psi \) the zero functional. Thus we obtain:

Corollary. Let \( V \) be a real vector space, \( p \) a sublinear functional on \( V \), and \( q \) a superlinear functional on \( V \) satisfying \( q(x) \leq p(x) \) for all \( x \in V \). Assume at least one of \( p \) and \( q \) is finite. Then there is a linear functional \( \phi \) on \( V \) with
\[
q(x) \leq \phi(x) \leq p(x)
\]
for all \( x \in V \).

There are also one-sided versions of this result.

The proof of Theorem XV.5.1.3. consists of two steps:

1. Show that \( \psi \) can be extended to a subspace spanned by \( W \) and one additional element.
2. “Iterate” step 1 to extend \( \psi \) all the way to \( V \).

The first step is elementary and straightforward, but takes some work. The second step in general requires some form of the Axiom of Choice.

We begin with step 1.
XV.5.1.8. **Lemma.** Let $V$ be a real vector space, $p$ a sublinear functional on $V$, and $q$ a superlinear functional on $V$ satisfying $q(x) \leq p(x)$ for all $x \in V$. Assume at least one of $p$ and $q$ is finite. Let $W$ be a subspace of $V$, and $\psi$ a linear functional on $W$ satisfying $q(y) \leq \psi(y) \leq p(y)$ for all $y \in W$. Let $x_0 \in V \setminus W$, and let $X$ be the subspace of $V$ spanned by $W$ and $x_0$. Then there is a linear functional $\theta$ on $X$ extending $\psi$ with

$$q(x) \leq \theta(x) \leq p(x)$$

for all $x \in X$.

**Proof:** Every $x \in X$ can be uniquely written as $y + \alpha x_0$, where $y \in W$ and $\alpha \in \mathbb{R}$. Any linear functional on $X$ extending $\psi$ is of the form

$$\theta(y + \alpha x_0) = \psi(y) + \alpha c$$

for some $c \in \mathbb{R}$, so we must choose $c$ so that $q(x) \leq \theta(x) \leq p(x)$ for all $x \in X$, i.e.

$$q(y + \alpha x_0) \leq \psi(y) + \alpha c \leq p(y + \alpha x_0)$$

for all $y \in W$ and $\alpha \in \mathbb{R}$. To show this is possible, we obtain some inequalities.

First, if $y, z \in W$, we have

$$\psi(y) - \psi(z) = \psi(y - z) \leq p(y - z) = p([y + x_0] + [-x_0 - z]) \leq p(y + x_0) + p(-x_0 - z)$$

and similarly we obtain

$$p(-x_0 - z) - \psi(z) \leq q(-x_0 - z) - \psi(z)$$

Finally, we have

$$\psi(y) - \psi(z) = \psi(y + x_0) - \psi(x_0 + z) \leq p(y + x_0) - q(x_0 + z)$$

and we similarly obtain

$$p(-x_0 - z) - \psi(z) \leq q(-x_0 - y) - \psi(y)$$

Now define

$$\sigma_1 = \sup\{-p(-x_0 - y) - \psi(y) : y \in W\}$$
$$\sigma_2 = \sup\{q(x_0 + y) - \psi(y) : y \in W\}$$
$$\tau_1 = \inf\{p(x_0 + y) - \psi(y) : y \in W\}$$
$$\tau_2 = \inf\{-q(-x_0 - y) - \psi(y) : y \in W\}$$

We have $\sigma_1 \leq \tau_1$ by XV.1, $\sigma_2 \leq \tau_2$ by XV.2, $\sigma_2 \leq \tau_1$ by XV.3, and $\sigma_1 \leq \tau_2$ by XV.4. Thus

$$\max(\sigma_1, \sigma_2) \leq \min(\tau_1, \tau_2)$$

If there is a $y \in W$ with $p(x_0 + y) < +\infty$, then $\tau_1$ is not $+\infty$, so $\sigma_1$ and $\sigma_2$ are not $+\infty$; if there is a $y \in W$ with $p(-x_0 - y) < +\infty$, then $\sigma_1$ is not $-\infty$, so $\tau_1$ and $\tau_2$ are not $-\infty$. A similar statement holds for $q$. Thus, if $p$ or $q$ is finite, we have that $\max(\sigma_1, \sigma_2) \neq +\infty$ and $\min(\tau_1, \tau_2) \neq -\infty$.

Choose any $c \in \mathbb{R}$ such that

$$\max(\sigma_1, \sigma_2) \leq c \leq \min(\tau_1, \tau_2)$$

1738
We will show that this $c$ works, i.e. that $\theta(y + \alpha x_0) = \psi(y) + \alpha c$ satisfies
\[
q(y + \alpha x_0) \leq \psi(y) + \alpha c \leq p(y + \alpha x_0)
\]
for all $y \in W$ and $\alpha \in \mathbb{R}$.

Let $x \in X$. Write $x = y + \alpha x_0$. If $\alpha = 0$, then $x = y \in W$ and $q(x) \leq \theta(x) = \psi(x) \leq p(x)$ by assumption. If $\alpha > 0$, we have $\alpha^{-1}y \in W$, so
\[
c \leq \tau_1 \leq p(x_0 + \alpha^{-1}y) - \psi(\alpha^{-1}y)
\]
\[
\alpha c \leq \alpha p(x_0 + \alpha^{-1}y) - \alpha \psi(\alpha^{-1}y) = p(\alpha x_0 + y) - \psi(y) = p(x) - \psi(y)
\]
\[
\theta(x) = \psi(y) + \alpha c \leq p(x).
\]
Similarly using $\sigma_2$ we obtain $q(x) \leq \theta(x)$.

If $\alpha < 0$, we similarly have
\[
-p(-x_0 - \alpha^{-1}y) - \psi(\alpha^{-1}y) \leq \sigma_1 \leq c
\]
\[
-q(x) + \psi(y) = -p(\alpha x_0 + y) + \psi(y) = (-\alpha)[-p(-x_0 - \alpha^{-1}y)] - (-\alpha)\psi(\alpha^{-1}y) \leq -\alpha c
\]
\[
\theta(x) = \psi(y) + \alpha c \leq p(x).
\]
In the same manner using $\tau_2$ we have $q(x) \leq \theta(x)$.

\[\boxdot\]

XV.5.1.9. In the case of XV.5.1.3, where $V/W$ is countably generated, we can iterate XV.5.1.8 inductively to extend $\psi$ to all of $V$ (the Countable AC is technically needed to do this; if $V$ itself is countably generated, the countable AC can be dispensed with). The same construction can be done transfinitely if a set of generators for $V/W$ can be well ordered; assuming the Well-Ordering Principle (i.e. assuming AC: cf. ()), the proof of the general version of XV.5.1.3. can be completed this way.

XV.5.1.10. We will give an alternate argument using Zorn’s Lemma to finish the proof of XV.5.1.3. in the general case. Let $\mathcal{E}$ be the set of pairs $(X, \theta)$, where $X$ is a subspace of $V$ containing $W$ and $\theta$ is a linear functional on $X$ extending $\psi$, with $q(x) \leq \theta(x) \leq p(x)$ for all $x \in X$. Put a partial ordering $\preceq$ on $\mathcal{E}$ by setting $(X_1, \theta_1) \preceq (X_2, \theta_2)$ if and only if $X_1 \subseteq X_2$ and $\theta_2$ extends $\theta_1$.

If $\mathcal{C} = \{(X_i, \theta_i) : i \in I\}$ is a chain in $\mathcal{E}$, set $X = \bigcup_i X_i$. If $x, y \in X$, then $x \in X_i$ and $y \in X_j$ for some $i, j$; but either $X_i \subseteq X_j$ or $X_j \subseteq X_i$ since $\mathcal{C}$ is a chain, so either $x, y \in X_i$ or $x, y \in X_j$; in either case $x + y \in X$, so $X$ is closed under addition. $X$ is obviously closed under scalar multiplication, so $X$ is a subspace of $V$. Define $\theta : X \to \mathbb{R}$ by $\theta(x) = \theta_i(x)$ if $x \in X_i$: this function is well defined since the $\theta_i$ all agree wherever they are defined. It is routine to check that $\theta$ is linear. Thus $(X, \theta)$ is an upper bound for $\mathcal{C}$ in $\mathcal{E}$.

Thus Zorn’s lemma applies to give a maximal element $(X, \theta)$ in $\mathcal{E}$. But we must have $X = V$, for otherwise if $x_0 \in V \setminus X$ Lemma XV.5.1.8. gives an extension of $\theta$ to the span of $X$ and $x_0$ with the right properties, contradicting maximality of $(X, \theta)$. Then $\phi = \theta$ is the desired extension.

This completes the proof of Theorem XV.5.1.3..

XV.5.1.11. The proof we have given of the Hahn-Banach Theorem uses the AC. But the full AC is not necessary; one can get away with weaker assumptions such as the BPI ( ). Even this assumption is not necessary: the Hahn-Banach Theorem is logically equivalent (over ZF) to the Measure Extension Property ( ), which is strictly weaker than the BPI [ ]. The Hahn-Banach Theorem is not a theorem of ZF, i.e. some form of Choice is necessary.

1739
**XV.5.2. Extension of Bounded Linear Functionals**

One of the most common special cases of XV.5.1.4. is extension of bounded linear functionals from subspaces of normed vector spaces without increasing the norm:

**XV.5.2.1. Theorem.** [Hahn-Banach Theorem, Version 2] Let $V$ be a real vector space, and $\| \cdot \|$ a norm on $V$. Let $W$ be a subspace of $V$, and $\psi$ a bounded linear functional on $W$. Then there is a bounded linear functional $\phi$ on $V$ extending $\psi$ with $\| \phi \| = \| \psi \|$.

**Proof:** Apply XV.5.1.4. with $p(x) = \| \psi \| \| x \|$.

**XV.5.2.2. Note** that no completeness is assumed in this result, and the subspace $W$ need not be closed in $V$. (This is not a significant observation, though, since a bounded linear functional can automatically be extended to the completion or closure without increase in norm by uniform continuity.)

**XV.5.2.3. Corollary.** Let $V \neq \{0\}$ be a normed real vector space, and $x \in V$. Then there is a bounded linear functional $\phi$ of norm 1 on $V$ with $\phi(x) = \| x \|$. In particular,

$$\| x \| = \max\{\| \phi(x) \| : \phi \in V^*, \| \phi \| = 1\} = \sup\{\| \phi(x) \| : \phi \in V^*, \| \phi \| = 1\}.$$  

**Proof:** Suppose $x \neq 0$. Let $W$ be the one-dimensional subspace of $V$ spanned by $x$. Define $\psi : W \to \mathbb{R}$ by $\psi(\alpha x) = \alpha \| x \|$. Then $\psi$ is a bounded linear functional of norm 1 on $W$ with $\psi(x) = \| x \|$. Extend $\psi$ to a bounded linear functional of norm 1 on $V$.

If $x = 0$, let $\phi$ be any bounded linear functional on $V$ of norm 1 (such a linear functional exists by the first part of the proof applied to any nonzero vector in $V$).

**XV.5.2.4. This result shows** that if $V$ is a normed vector space, then $V^*$ is “large” (large enough to determine the norm on $V$). Without this result it is not obvious that a normed vector space has any nonzero bounded linear functionals.

**The Canonical Embedding into the Second Dual**

**XV.5.2.5. If** $V$ is a normed (real) vector space, then $V^*$ is a Banach space ($\cdot$). $V^*$ itself has a dual space $V^{**} = (V^*)^*$. If $x \in V$, then there is a canonically associated $\hat{x} \in V^{**}$ defined by

$$\hat{x}(\phi) = \phi(x)$$

for $\phi \in V^*$. It is easily checked that $\hat{x}$ is a linear functional on $V^*$, and that $x \mapsto \hat{x}$ is linear in $x$. Since $|\hat{x}(\phi)| = |\phi(x)| \leq \| x \| \| \phi \|$ for any $\phi \in V^*$, $\hat{x}$ is bounded and $\| \hat{x} \| \leq \| x \|$. By XV.5.2.3., we actually have $\| \hat{x} \| = \| x \|$. So:
XV.5.2.6. **Corollary.** Let $V$ be a normed real vector space. The map $x \mapsto \hat{x}$ is an isometric linear embedding of $V$ into $V^{**}$, called the canonical embedding.

XV.5.2.7. $V$ is said to be reflexive if the canonical map from $V$ to $V^{**}$ is surjective. Since $V^{**}$ is a Banach space, if $V$ is reflexive it must be complete (a Banach space). Some Banach spaces are reflexive (), (1) while others are not ()

XV.5.3. The Complex Hahn-Banach Theorem

XV.5.4. Separation of Convex Sets

XV.5.4.1. **Example.** Here is an interesting “folklore” example of a pair of convex sets which cannot be separated by a linear functional.

Let $X = c_{00} ()$. Let $A$ be the set of nonzero sequences in $X$ whose last nonzero term is positive. It is obvious that $A$ is convex. Similarly, let $B = -A$ be the set of nonzero sequences whose last nonzero term is negative. Then $B$ is convex, and $X$ is the disjoint union of $A$, $B$, and $\{0\}$.

If $X$ is given the uniform norm () (or any vector space topology), then $A$ and $B$ are dense in $X$: if $x \in X$, fix a $k$ larger than the index of the last nonzero term in $x$, and then $x + \epsilon e_k \in A$ for any $\epsilon > 0$, where $e_k$ is the $k$th standard basis vector (). A similar argument shows that $A$ and $B$ have no interior points.

Since $A$ and $B$ are dense in $X$, it is obvious they cannot be separated by a bounded linear functional. But in fact they cannot be separated by any nonzero linear functional, bounded or not, i.e. there is no nonzero linear functional $\phi$ on $X$ such that $\phi(x) \geq 0$ for all $x \in A$ (a separating linear functional or its negative would have to have this property). For if $\phi$ is such a linear functional, and $x \in X$ is arbitrary, fix $k$ larger than the index of the last nonzero term in $x$. Then $x + \epsilon e_k \in A$ for any $\epsilon > 0$, so

$$0 \leq \phi(x + \epsilon e_k) = \phi(x) + \epsilon \phi(e_k)$$

for any $\epsilon > 0$. Letting $\epsilon \to 0$, we obtain $\phi(x) \geq 0$. Since $x \in X$ is arbitrary, we also have $\phi(-x) \geq 0$, so $\phi(x) = 0$ for any $x$ and $\phi$ is the zero linear functional.

Note that we have referred to a norm topology on $X$, but actually this example is purely algebraic and can be written (except for the density of $A$ and $B$) without any reference to a topology on $X$.

XV.5.5. **Exercises**

XV.5.5.1. Here are two natural separation properties between separation and strict separation.

(a) If $X$ is a topological vector space and $A$ and $B$ disjoint convex sets in $X$, then $A$ and $B$ are completely separated if there is a hyperplane $H$ such that $A$ and $B$ are contained in distinct open half-spaces for $H$.

(b) If $X$ is a topological vector space and $A$ and $B$ disjoint convex sets in $X$, then $A$ and $B$ are fully separated if there is a hyperplane $H$ such that one of $A$ and $B$ is contained in an open half-space for $H$ and the other in the complementary closed half-space.

(c) Observe that strict separation $\Rightarrow$ complete separation $\Rightarrow$ full separation $\Rightarrow$ separation.

(d) Show that $A$ and $B$ are fully separated if and only if there is a continuous linear functional $\phi$ on $X$ such that $\phi(a) < \phi(b)$ for all $a \in A$, $b \in B$, and that $A$ and $B$ are completely separated if and only if there is a continuous linear functional $\phi$ and a real number $m$ such that $f(a) < m < f(b)$ for all $a \in A$, $b \in B$.
(e) Show that if $A$ and $B$ are convex sets in a topological vector space, and if one is open, then $A$ and $B$ are fully separated. If both are open, then they are completely separated. If $A$ and $B$ are not disjoint, then $A$ and $B$ cannot be completely separated, and if $A$ and $B$ are also not disjoint, then $A$ and $B$ cannot be fully separated.

(f) Let $X = \mathbb{R}^2$, $A$ the open upper half-plane along with the positive $x$-axis, and $B$ the lower half-plane along with the negative $x$-axis. Show that $A$ and $B$ are disjoint, convex, separated, but not fully separated.

(g) Let $X = \mathbb{R}^2$, $A$ the $x$-axis, and $B = \{(x, y) : x > 0, y \geq \frac{1}{2}\}$. Show that $A$ and $B$ are disjoint closed convex sets which are fully separated but not completely separated.

(h) Show that if $A$ and $B$ are disjoint closed convex subsets of $\mathbb{R}^2$, then $A$ and $B$ are fully separated.

(i) [KN76, 3G] Let $X = \mathbb{R}^3$,

$$A = \{(x, y, z) : x \geq 0, y \geq 0, z \geq 0, z^2 \leq xy\}$$

$$B = \{(0, y, 1) : y \in \mathbb{R}\}.$$

Show that $A$ and $B$ are disjoint, closed, convex, and separated, but not fully separated.

Thus full or complete separation is not always possible, even in finite-dimensional spaces.
XV.6. The Open Mapping Theorem, Closed Graph Theorem, and Uniform Boundedness Theorem

These are three of the most basic theorems of functional analysis. The first two are essentially one theorem, in the sense that either of them can be derived relatively easily from the other. The Uniform Boundedness Theorem is a consequence of the other two, or can be proved independently (it is apparently a “lower-level theorem” since the other two theorems cannot be obviously deduced from Uniform Boundedness). All of them are a consequence of the Baire Category Theorem, although they are not immediate corollaries and take some considerable additional work to prove.

XV.6.1. Open Mappings

XV.6.1.1. Recall () that if \( f \) is a function from a topological space \( X \) to a topological space \( Y \), then \( f \) is an **open mapping** if \( f(U) \) is open in \( Y \) for every open set \( U \) in \( X \). An open mapping does not have to be continuous. It is unusual for a continuous function, even a surjective one, to be an open mapping; however, we will show that a surjective bounded linear transformation between Banach spaces is an open mapping.

In this subsection, we give alternate characterizations of when linear transformations are open mappings. The arguments make repeated use of the following principle which is an immediate result of linearity:

**XV.6.1.2. [Basic Principle of Open Balls]** Let \( X \) and \( Y \) be normed vector spaces, and \( T : X \to Y \) a linear transformation. Then the images under \( T \) of all open balls in \( X \) look essentially the same, up to scaling and translation.

**XV.6.1.3. Proposition.** Let \( X \) and \( Y \) be normed vector spaces, and \( T : X \to Y \) a linear transformation (not necessarily bounded). The following are equivalent:

(i) \( T \) is an open mapping.

(ii) The image under \( T \) of some open ball in \( X \) contains an open ball in \( Y \).

(iii) The image under \( T \) of every open ball in \( X \) contains an open ball in \( Y \).

(iv) The image under \( T \) of some open ball in \( X \) centered at 0 contains an open ball in \( Y \) centered at 0.

(v) The image under \( T \) of every open ball in \( X \) centered at 0 contains an open ball in \( Y \) centered at 0.

**Proof:** (i) \(\Rightarrow\) (iii) \(\Rightarrow\) (ii) and (i) \(\Rightarrow\) (iv) \(\Rightarrow\) (ii) are trivial (since \( T(0) = 0 \)). (ii) \(\Rightarrow\) (iii) is an instance of the Basic Principle of Open Balls: if \( T(B_r(x_0)) \) contains \( B_r(y_0) \), then for any \( x_1 \) we have that \( T(B_r(x_1)) \) contains \( B_r(y_1) \), where \( y_1 = y_0 + T(x_1 - x_0) \). In particular, \( T(B_r(0)) \) contains \( B_r(y_2) \), where \( y_2 = y_0 - T(x_0) \). Then, for any \( s \), we have \( T(B_s(0)) \) contains \( B_{s\delta}(\tfrac{\delta}{s}y_2) \), where \( \delta = \frac{s}{r} \varepsilon \), and, for any \( x_1 \), \( T(B_s(x_1)) \) contains \( B_{s\delta}(T(x_1) + \tfrac{\delta}{s}y_2) \). The proof of (iv) \(\Rightarrow\) (v) is similar but easier.

To prove (iii) \(\Rightarrow\) (iv), suppose \( T(B_r(0)) \) contains \( B_{\varepsilon}(y_0) \). Then there is an \( x_0 \in B_r(0) \) with \( T(x_0) = y_0 \). Then \( T(B_r(-x_0)) \) contains \( B_r(0) \). If \( s = r + ||x_0|| \), then \( B_{r}(x_0) \subseteq B_s(0) \), so \( T(B_s(0)) \) contains \( B_{\varepsilon}(0) \).

To finish the proof, it suffices to show (v) \(\Rightarrow\) (i). Let \( U \) be an open set in \( X \), and \( y_0 \in T(U) \). Let \( x_0 \in U \) with \( T(x_0) = y_0 \), and \( \delta > 0 \) for which \( B_{\delta}(x_0) \subseteq U \). There is an \( \varepsilon > 0 \) such that \( T(B_{\delta}(0)) \) contains \( B_{\varepsilon}(0) \) by
(v). Then $T(B_{\delta}(x_0))$ contains $B_\epsilon(y_0)$, so $T(U)$ contains $B_\epsilon(y_0)$. Since $y_0 \in T(U)$ is arbitrary, $T(U)$ is open.

A slight modification of a subset of the proof of XV.6.1.3. (adding the words “the closure of” in a few places) gives the following:

**XV.6.1.4. PROPOSITION.** Let $X$ and $Y$ be normed vector spaces, and $T : X \to Y$ a linear transformation (not necessarily bounded). The following are equivalent:

(ii) The closure of the image under $T$ of some open ball in $X$ contains an open ball in $Y$.

(iii) The closure of the image under $T$ of every open ball in $X$ contains an open ball in $Y$.

(iv) The closure of the image under $T$ of some open ball in $X$ centered at 0 contains an open ball in $Y$ centered at 0.

(v) The closure of the image under $T$ of every open ball in $X$ centered at 0 contains an open ball in $Y$ centered at 0.

**XV.6.2. The Open Mapping Theorem**

The main result of this subsection is:

**XV.6.2.1. THEOREM.** [OPEN MAPPING THEOREM] Let $X$ and $Y$ be Banach spaces, and $T : X \to Y$ a surjective bounded operator. Then $T$ is an open mapping.

A crucial special case is when $T$ is injective as well as surjective:

**XV.6.2.2. COROLLARY.** [BOUNDED INVERSE THEOREM] Let $X$ and $Y$ be Banach spaces, and $T : X \to Y$ a bijective bounded operator. Then $T^{-1} : Y \to X$ is also bounded. Equivalently, $T$ is bounded below, i.e. a homeomorphism.

**Proof:** $T^{-1}$ is continuous, hence bounded by (), if and only if $T$ is an open mapping, which follows from the Open Mapping Theorem.
We can derive the Open Mapping Theorem from the Bounded Inverse Theorem, as follows. Let $X$ and $Y$ be Banach spaces and $T : X \rightarrow Y$ a surjective bounded operator. Let $N$ be the null space of $T$; then $N$ is a closed subspace of $X$, so we may form the quotient space $X/N$ which is a Banach space under the quotient norm. Let $P : X \rightarrow X/N$ be the projection map. Then there is an injective bounded operator $\tilde{T} : X/N \rightarrow Y$ with $T = \tilde{T} \circ P$. $\tilde{T}$ is an open mapping by the Bounded Inverse Theorem. $P$ is also an open mapping: this is a general fact about quotient spaces, but in this instance it is also an immediate corollary of XV.6.1.3., since it follows from the definition of the quotient norm that the image of the open unit ball in $X$ is exactly the open unit ball in $X/N$. Thus $T$ is a composition of two open mappings, hence also an open mapping. Hence the Open Mapping Theorem and the Bounded Inverse Theorem are equivalent.

Although the Open Mapping Theorem can be easily deduced from the Bounded Inverse Theorem, there does not appear to be a proof of the Bounded Inverse Theorem which is simpler than the proof of the Open Mapping Theorem.

Examples. All the hypotheses of the Open Mapping Theorem are necessary in general, as the following examples show. These examples illustrate that the statement of the Open Mapping Theorem is a nontrivial assertion which may even be considered somewhat surprising.

(i) Let $X = Y = \ell^2$, and define $T : X \rightarrow Y$ by

$$T((\xi_1, \xi_2, \ldots)) = \left(\xi_1, \frac{1}{2}\xi_2, \ldots, \frac{1}{n}\xi_n, \ldots\right).$$

Then $T$ is injective and has dense range, but is not surjective. $T$ is bounded ($\|T\| = 1$). $T$ is not an open map since no positive scalar multiple of $(1, \frac{1}{2}, \ldots)$ is in the range. Thus the hypothesis that $T$ is surjective is necessary. (In fact, a linear map which is not surjective can never be an open map, since the range is a subspace and a proper subspace can never be an open set.)

(ii) Take the same example as in (i) but let $Y$ be the range of $T$. $Y$ is a dense subspace of $\ell^2$ and inherits a norm from $\ell^2$, but is not complete. $T$ is now a bijection from $X = \ell^2$ to $Y$, but $T^{-1}$ is not bounded since $T$ is not bounded below. Thus the hypothesis that $Y$ be complete is necessary. (In fact, a linear map which is not surjective can never be an open map, since the range is a subspace and a proper subspace can never be an open set.)

(iii) It is trickier to give an example showing that the hypothesis that $X$ be a Banach space is necessary. Let $Z$ be a Banach space and $N$ a closed subspace of $Z$. Set $Y = Z/N$ with the quotient norm, and $P : Z \rightarrow Z/N$ the quotient map. Suppose $X$ is a subspace of $Z$ complementary to $N$ which is not closed (e.g. $X$ is the null space of a discontinuous linear functional on $Z$ and $N$ a complementary one-dimensional subspace; cf. also ). $X$ is a normed vector space with norm inherited from $Z$, and $T = P|_X$ is an injective bounded operator from $X$ onto $Y$. But $T^{-1} : Y \rightarrow X$ cannot be bounded, since if it were $X$ would be complete, hence closed in $Z$.

(iv) The hypothesis that $T$ be bounded is also necessary. Expand the standard orthonormal basis of $\ell^2$ to a Hamel basis, and take a permutation of the Hamel basis interchanging the orthonormal basis with a subset of the remaining Hamel basis vectors. This permutation extends to a bijective but unbounded operator $T$ from $\ell^2$ to $\ell^2$. If $T$ were an open mapping, then $T^{-1}$ would be continuous, hence bounded, so $T$ would be bounded by the Bounded Inverse Theorem, a contradiction.

Note that some form of the Axiom of Choice is needed in (iii) and (iv). (Actually, some form of Choice is even needed for the Open Mapping Theorem, since the Baire Category Theorem depends on DC.)
We now give the proof of the Open Mapping Theorem.

**Proof:** Write $B^X_r$ and $B^Y_r$ for the open balls of radius $r$ around 0 in $X$ and $Y$ respectively. We have that

$$
\bigcup_{n=1}^{\infty} T(B^X_n) = T(X) = Y
$$

since $T$ is surjective. Thus, since $Y$ is a Banach space, by the Baire Category Theorem $T(B^X_n)$ is not nowhere dense in $Y$ for some $n$, i.e. $\overline{T(B^X_n)}$ contains an open ball in $Y$. Thus by XV.6.1.4., $T(B^X_r)$ contains an open ball around 0 in $Y$ for any $r$. In particular, there is an $\epsilon > 0$ such that $T(B^X_1)$ contains $B^Y_\epsilon$. We will show that $T(B^X_n)$ contains $B^Y_\epsilon$; it will then follow from XV.6.1.3. that $T$ is an open mapping.

Let $y \in B^Y_\epsilon$; we will construct an $x \in X$ with $\|x\| < 2$ and $Tx = y$. A key observation is that $\overline{T(B^X_1)}$ contains $B^Y_r$ for every $r > 0$. Since $y$ is in the closure of $T(B^X_1)$, for any $\delta > 0$ we can find an $x_0 \in X$, $\|x_0\| < 1$, with $\|y - Tx_0\| < \delta$. Let $x_1 \in X$, $\|x_1\| < 1$, with

$$
\|y - Tx_1\| < \frac{\epsilon}{2}.
$$

Since $y - Tx_1$ is in the closure of $T(B^X_{1/2})$, there is an $x_2 \in X$, $\|x_2\| < \frac{1}{2}$, with

$$
\| (y - Tx_1) - Tx_2 \| < \frac{\epsilon}{4}.
$$

Continuing inductively, we obtain for each $n$ an $x_n \in X$ with $\|x_n\| < 2^{-n+1}$ and

$$
\| y - Tx_1 - Tx_2 - \cdots - Tx_n \| < 2^{-n} \epsilon.
$$

The infinite series

$$
\sum_{k=1}^{\infty} x_k
$$

converges absolutely, hence converges to some $x \in X$ since $X$ is a Banach space (). We have

$$
\|x\| < \sum_{k=1}^{\infty} 2^{-k+1} = 2.
$$

Since $T$ is continuous, we have

$$
Tx = \sum_{k=1}^{\infty} Tx_k
$$

in $Y ()$. But we have

$$
\left\| y - \sum_{k=1}^{n} Tx_k \right\| < 2^{-n} \epsilon
$$

for all $n$, and thus the infinite series

$$
\sum_{k=1}^{\infty} Tx_k
$$

converges to $y$, i.e. $Tx = y$, completing the proof.

$\blacksquare$
XV.6.3. The Closed Graph Theorem
XV.6.3.1. Recall () that if \( X \) and \( Y \) are sets and \( f : X \to Y \) is a function, the set
\[
\Gamma(f) = \{(x,y) \in X \times Y : y = f(x)\}
\]
is the graph of \( f \). (Technically, using the ordered pair definition of function, a function is its graph.) If \( X \) and \( Y \) are topological spaces, then \( f \) has closed graph if \( \Gamma(f) \) is closed in \( X \times Y \).

XV.6.3.2. Proposition. If \( X \) and \( Y \) are topological spaces and \( f : X \to Y \) is a function, then \( f \) has closed graph if and only if, whenever \((x_i)\) is a net in \( X \) with \( x_i \to x \) and \( f(x_i) \to y \) for some \( x \in X \) and \( y \in Y \), we have \( y = f(x) \).

Proof: By definition, \( f \) has closed graph if and only if, whenever \((x_i, y_i)\) is a net in \( \Gamma(f) \) converging to \((x,y) \in X \times Y \), we have \((x,y) \in \Gamma(f)\). The statement of the proposition is a simple rephrasing.

A continuous function between Hausdorff spaces has closed graph (), but a function between Hausdorff spaces which has closed graph need not be continuous (). However, we have the following, which is the main result of this subsection:

XV.6.3.3. Theorem. [Closed Graph Theorem] Let \( X \) and \( Y \) be Banach spaces, and \( T : X \to Y \) be a linear transformation. Then \( T \) is bounded (continuous) if and only if \( T \) has closed graph.

Proof: If \( T \) is continuous, it has closed graph by (). Conversely, suppose \( T \) has closed graph. We have that \( X \times Y \) is a Banach space under a number of equivalent norms (). Fix one of these norms, say
\[
\|(x,y)\| = \max(\|x\|, \|y\|)
\]
Since \( T \) is linear, \( \Gamma(T) \) is a subspace of \( X \times Y \); by assumption, it is closed, hence a Banach space under the induced norm. The map \( S : \Gamma(T) \to X \) given by \( S((x,Tx)) = x \) is bijective and linear, and bounded (\( \|S\| \leq 1 \)). Thus by the Bounded Inverse Theorem \( S^{-1} : X \to \Gamma(T) \) is bounded. If \( P \) is the projection from \( X \times Y \) to \( Y \), then \( P \) is bounded, and hence \( T = P \circ S^{-1} \) is also bounded.

XV.6.3.4. The proof shows that the Closed Graph Theorem is a simple corollary of the Bounded Inverse Theorem. The converse is true too: if \( X \) and \( Y \) are Banach spaces and \( T : X \to Y \) is a continuous (bounded) bijection, then \( \Gamma(T) \) is closed. Thus \( \Gamma(T^{-1}) \) is also closed since it is essentially the same as \( \Gamma(T) \) with coordinates reversed. So \( T^{-1} \) is bounded by the Closed Graph Theorem.

We thus obtain that the Open Mapping Theorem, the Bounded Inverse Theorem, and the Closed Graph Theorem are equivalent statements by simple arguments.

XV.6.3.5. The importance of the Closed Graph Theorem is that it is often much easier to prove that a map \( T : X \to Y \) has closed graph than to directly prove that it is continuous or bounded. To prove directly that \( T \) is continuous, it must be shown that if \((x_n)\) is a sequence in \( X \) with \( x_n \to x \), then the sequence \((Tx_n)\) converges to \( Tx \). The sequence \((Tx_n)\) cannot be assumed to converge or even to have a convergent subsequence. But to show that \( T \) has closed graph, one only needs to show that if \((x_n)\) is a sequence in \( X \) with \( x_n \to x \), and \( Tx_n \to y \) for some \( y \in Y \), then \( y = Tx \), i.e. the sequence \((Tx_n)\) can be assumed to converge to something. The next result is a good illustration of the use of the Closed Graph Theorem.
XV.6.3.6. **Proposition.** Let $H_1$ and $H_2$ be Hilbert spaces, and $T : H_1 \to H_2$ a linear operator. If $T$ has an adjoint $T^* : H_2 \to H_1$, i.e. $T^*$ is a function (which is automatically a linear operator) satisfying

$$\langle x, T^*y \rangle_{H_1} = \langle Tx, y \rangle_{H_2}$$
for all $x \in H_1$, $y \in H_2$, then $T$ is bounded (and hence $T^*$ is also bounded).

**Proof:** We need only show that $T$ has closed graph. Suppose $(x_n)$ is a sequence in $H_1$ with $x_n \to x$ and $Tx_n \to y$ for some $y \in H_2$. Then, for any $z \in H_2$, we have

$$\langle Tx_n, z \rangle_{H_2} \to \langle y, z \rangle_{H_2}$$
by continuity of the inner product in $H_2$ (iii). On the other hand, we have

$$\langle Tx_n, z \rangle_{H_2} = \langle x_n, T^*z \rangle_{H_1} \to \langle x, T^*z \rangle_{H_1} = \langle Tx, z \rangle_{H_2}$$
by continuity of the inner product in $H_1$. Thus by uniqueness of limits we have

$$\langle y, z \rangle_{H_2} = \langle Tx, z \rangle_{H_2}$$
for every $z \in H_2$, and so $y = Tx$ by (iii).

XV.6.3.7. **Caution:** Our convention is that “$T$ is a linear map from $X$ to $Y$” means that the domain of $T$ is all of $X$. In some references, this phrase means only that the domain of $T$ is a subspace (usually dense) of $X$. The Closed Graph Theorem does not apply in this situation; in fact, such an operator can be unbounded but have closed graph. Densely defined unbounded operators with closed graph, called **closed operators**, are very important; see section (iii). Proposition XV.6.3.6. is also false in general for operators which are just densely defined (with densely defined adjoint); cf. (iv).

XV.6.3.8. Since in the statement of the Closed Graph Theorem $T$ is not required to be surjective, one might think the hypothesis that $Y$ be complete is unnecessary: $Y$ could just be replaced by its completion $\hat{Y}$. But this is incorrect. The graph of $T$ can be a closed subset of $X \times Y$ but not closed in $X \times \hat{Y}$.

For a counterexample, let $X$, $Y$, $T$ be as in XV.6.2.4.(iii). Then the graph of $T$ is closed in $X \times Y$ since $T$ is continuous, so the graph of $T^{-1} : Y \to X$ is closed in $Y \times X$. But $T^{-1}$ is not bounded.

XV.6.4. **The Uniform Boundedness Theorem**

The Uniform Boundedness Theorem is a theorem which states that a family of bounded operators on a Banach space which is “pointwise bounded” is actually uniformly bounded. This result, like the Open Mapping Theorem and Closed Graph Theorem, has many uses. It can be obtained as a simple consequence of the Closed Graph Theorem or proved directly from scratch; we will give three arguments.

1748
XV.6.4.1. **Theorem.** [Uniform Boundedness Theorem] Let \( X \) be a Banach space, \( \{Y_i : i \in I\} \) a collection of normed vector spaces, and \( T_i : X \to Y_i \) a bounded operator for each \( i \). Suppose, for each \( x \in X \), the set
\[
\{\|T_i(x)\| : i \in I\}
\]
is bounded (the bound may depend on \( x \)). Then the set
\[
\{\|T_i\| : i \in I\}
\]
is bounded.

XV.6.4.2. In other words, if for each \( x \in X \) there is a constant \( M_x \) such that \( \|T_i x\| \leq M_x \) for all \( i \in I \), then there is a single constant \( M \) such that \( \|T_i\| \leq M \) for all \( i \in I \).

The theorem is commonly applied in the case where all the \( Y_i \) are the same, and/or when \( I = \mathbb{N} \), but these restrictions do not make the proof any easier.

XV.6.4.3. **Proof:** Our first proof deduces the theorem from the Closed Graph Theorem.

First note that since the \( T_i \) are not assumed to be surjective, there is no harm in replacing \( Y_i \) by its completion. Thus we may assume without loss of generality that each \( Y_i \) is a Banach space.

Let \( Y \) be the \( \ell^\infty \) product of the \( Y_i \). Then \( Y \) is a Banach space. Define \( T : X \to Y \) by
\[
T(x) = (\cdots T_i(x) \cdots)
\]
(the pointwise boundedness hypothesis exactly means that \( T(x) \in Y \) for all \( x \in X \)). Then \( T \) is a linear operator; \( T \) is bounded if and only if the \( T_i \) are uniformly bounded (in fact, \( \|T\| = \sup_i \|T_i\| \)).

To show \( T \) is bounded, it suffices to show that \( T \) has closed graph. But this is easy. Suppose \( (x_n) \) is a sequence in \( X \) and \( x_n \to x \) and \( T x_n \to y \) for some \( x \in X \), \( y \in Y \). Set \( y = (\cdots y_i \cdots) \). Since convergence in \( Y \) implies coordinatewise convergence, we have \( T_i x_n \to y_i \) for all \( i \). But since \( T_i \) is bounded, we have \( T_i x_n \to T_i x \), i.e. \( y_i = T_i x \) for all \( i \), and thus \( y = T x \).

XV.6.4.4. **Proof:** We give a second direct proof from the Baire Category Theorem.

For \( n \in \mathbb{N} \), define
\[
A_n = \{x \in X : \|T_i x\| \leq n \text{ for all } i \in I\}
\]
and note that \( A_n \) is a closed subset of \( X \) (\( A_n = \bigcap_{i \in I} T_i^{-1}(\{y \in Y_i : \|y\| \leq n\}) \)).

By the pointwise boundedness assumption, \( \cup_n A_n = X \), so by the Baire Category Theorem some \( A_n \) has nonempty interior. Thus there is an \( x_0 \in X \) and \( \epsilon > 0 \) such that \( \|T_i x\| \leq n \) whenever \( \|x - x_0\| < \epsilon \). Let \( m \) be a number such that \( \|T_i(x_0)\| \leq m \) for all \( i \in I \). Then, if \( \|x\| < \epsilon \), we have \( \|x + x_0 - x_0\| < \epsilon \), so, for all \( i \),
\[
\|T_i(x + x_0)\| \leq n
\]
\[
\|T_i(x + x_0) - T_i(x_0)\| = \|T_i(x + x_0) - T_i(x_0)\| \leq \|T_i(x + x_0)\| + \|T_i(x_0)\| \leq n + m
\]
which implies that
\[
\|T_i\| \leq \frac{n + m}{\epsilon}
\]
for all \( i \).
**XV.6.4.5.** Proof: Our third proof is the most elementary, using a “gliding hump” argument. This proof is due to Hausdorff [Hau32] (cf. [Hen80]).

Suppose \( \{\|T_i\| : i \in I\} \) is unbounded. Inductively define sequences \((x_n)\) in \( X \) and \( i_n \in I \) as follows. Suppose \( x_k \) and \( i_k \) have been defined for \( k < n \). Set \( M_0 = 0 \), and if \( n > 1 \) set \( M_{n-1} = \sup_i \{T_i(x_1 + \cdots + x_{n-1})\} \).

Now choose \( i_n \) such that
\[
\|T_{i_n}\| > 3 \cdot 4^n |n + M_{n-1}|
\]
and \( x_n \) such that
\[
\|x_n\| = 4^{-n} \quad \text{and} \quad \|T_{i_n}x_n\| > \frac{2}{3} \|T_{i_n}\| \|x_n\|.
\]

Set
\[
x_n = \sum_{n=1}^{\infty} x_n
\]
(note that the series converges absolutely, hence converges since \( X \) is complete). For each \( n \) set
\[
z_n = x_1 + \cdots + x_{n-1}
\]
(set \( z_1 = 0 \))
\[
y_n = \sum_{k=n+1}^{\infty} x_k
\]
and note that \( \|y_n\| \leq \frac{4^{-n}}{3} = \frac{1}{3} \|x_n\| \). We then have
\[
\|T_{i_n}x_n\| > 2 |n + M_{n-1}|
\]
\[
\|T_{i_n}y_n\| \leq \|T_{i_n}\| \|y_n\| \leq \frac{1}{3} \|T_{i_n}\| \|x_n\| < \frac{1}{2} \|T_{i_n}x_n\|
\]
for each \( n \). Thus for each \( n \) we have
\[
\|T_{i_n}x\| = \|T_{i_n}(x_n + y_n + z_n)\| \geq \|T_{i_n}x_n\| - \|T_{i_n}y_n\| - \|T_{i_n}z_n\| > |n + M_n| - M_n = n
\]
which contradicts that \( \{\|T_ix\| : i \in I\} \) is bounded.

**XV.6.5. Exercises**

**XV.6.5.1.** Let \( X \) and \( Y \) be normed vector spaces, with \( X \) complete, and \( T : X \rightarrow Y \) a linear operator.

(a) Show that \( T \) is bounded if and only if \( T^{-1}(B_Y) \) is closed, where \( B_Y \) is the closed unit ball of \( Y \). (One direction is trivial from continuity. Conversely, suppose \( T^{-1}(B_Y) \) is closed. Then \( T^{-1}(B) \) is closed for every closed ball \( B \) in \( Y \). Apply the Baire Category Theorem to conclude that \( T^{-1}(B_Y) \) contains an open ball.)

(b) Let \( T : c_00 \rightarrow c_00 \) be defined by \( T(\xi_1, \xi_2, \ldots) = (\xi_1, 2\xi_2, \ldots, n\xi_n, \ldots) \).

Show that \( T^{-1}(B_{c_00}) \) is closed. Thus the result does not necessarily hold if \( X \) is not complete.

(c) What is the relation between this property of \( T \) and having closed graph?
XV.7. Compact Convex Sets

A fairly detailed analysis can be given of the structure of compact convex sets in locally convex topological vector spaces. We describe the basics of this theory in this section; for more detailed analyses, see [Alf71], [?].

We will work throughout this section with real topological vector spaces. The results will immediately apply also to complex topological vector spaces, since a complex topological vector space has an underlying structure as a real topological vector space and none of the statements or proofs of the results make use of complex scalar multiplication. To avoid unnecessary subscripts, if \( K \) is a compact Hausdorff space, in this section write \( C(K) \) for the set \( C_{\mathbb{R}}(K) \) of real-valued continuous functions on \( K \).

XV.7.1. Faces and Extreme Points

The crucial notion underlying the whole analysis of compact convex sets is that of a face.

XV.7.1.1. Definition. Let \( K \) be a convex set in a vector space. A nonempty convex subset \( F \) of \( K \) is a face of \( K \) if, whenever \( x, y \in K \) and \( tx + (1 - t)y \in F \) for some \( t, 0 < t < 1 \), then both \( x \) and \( y \) are in \( F \). A one-point face is called an extreme point of \( K \). More precisely, \( p \) is an extreme point of \( K \) if \( \{p\} \) is a face of \( K \). Thus an extreme point of \( K \) is a point which cannot be written as a nontrivial convex combination of two distinct points in \( K \).

Note that this definition makes no use of any topology. However, faces and extreme points are most interesting for closed convex sets in topological vector spaces.

In some references, faces are called extreme subsets or supports.

XV.7.1.2. \( K \) itself is a face of \( K \); we are mainly interested in proper faces of \( K \). Roughly (imprecisely, and not quite correctly) speaking, a proper face of \( K \) is a convex subset of the “boundary” of \( K \).

XV.7.1.3. Examples. (i) In \( \mathbb{R} \), convex subsets are intervals. If \( I \) is an interval, the only faces are the extreme points; the extreme points of \( I \) are the endpoints of \( I \) which are contained in \( I \) (by definition, a face of a convex set is a subset of the convex set). Thus a nondegenerate closed bounded interval has two extreme points, an open interval has no extreme points, and other intervals have one extreme point.

(ii) Let \( K \) be a closed convex (solid) polygon in \( \mathbb{R}^2 \), e.g. a (solid) triangle or rectangle. Each closed edge of \( K \) is a face of \( K \), and each vertex is an extreme point, and these are all the proper faces.

(iii) Let \( K \) be a closed convex (solid) polyhedron in \( \mathbb{R}^3 \), e.g. a tetrahedron or cube. There are two-dimensional faces, the closed bounding (solid) polygons (which are usually called the “faces” of the polyhedron); one-dimensional faces, the closed edges; and 0-dimensional faces (extreme points), the vertices. These are all the proper faces. This example is undoubtedly the origin of the term “face” for general convex sets.

(iv) Let \( K \) be the closed unit ball in \( \mathbb{R}^n \). Then the only proper faces of \( K \) are the extreme points, which are precisely all the points on the unit sphere. Thus if \( n > 1 \) there are uncountably many extreme points.

(v) An open ball in \( \mathbb{R}^n \) has no extreme points. A nontrivial subspace of \( \mathbb{R}^n \) has no extreme points.

1751
**XV.7.1.4.** PROPOSITION. Let $K$ be a convex set in a vector space.

(i) Let \( \{ F_i : i \in I \} \) be a collection of faces of $K$. If \( \cap_i F_i \neq \emptyset \), then it is a face of $K$.

(ii) A face of a face of $K$ is a face of $K$.

(iii) If $C$ is a convex subset of $K$, $F$ is a face of $K$, and \( F \cap C \neq \emptyset \), then $F \cap C$ is a face of $C$.

**PROOF:** Straightforward and left to the reader.

**XV.7.1.5.** Thus, if $S$ is any nonempty subset of $K$, there is a smallest face $F(S)$ containing $S$, called the **face generated by** $S$. $F(S)$ is the intersection of all faces containing $S$.

We can define an **interior point** of $K$ to be any point $p$ of $K$ such that $F(p) = K$. Note that such a $p$ is not necessarily an interior point in the topological sense in general (indeed, there may be no topology in the picture!); but if $K$ is a convex set in a topological vector space which has a nonempty interior, then points in the topological interior are interior points in this sense.

**XV.7.1.6.** PROPOSITION. Let $X$ and $Y$ be vector spaces, and $T : X \to Y$ a linear transformation. If $K$ is a convex set in $Y$ and $F$ is a face of $K$, then $T^{-1}(F)$ is a face in $T^{-1}(K)$.

The simple proof is again left to the reader.

**XV.7.1.7.** The same result does not hold for images in general: if $T : X \to Y$ is linear, $K$ is a convex set in $X$, and $F$ is a face in $K$, then $T(F)$ is not necessarily a face in $T(K)$ (consider the case where $Y$ is one-dimensional).

**XV.7.1.8.** A particularly important case of XV.7.1.6. is when $Y = \mathbb{R}$. If $\phi$ is a linear functional on $X$, $K$ is a convex subset of $X$, $I = \phi(K)$ (an interval in $\mathbb{R}$), and $c$ is an endpoint of $I$ contained in $I$, then the intersection of $K$ with the hyperplane $\phi^{-1}(\{c\})$ is a face of $K$ (cf. XV.7.1.4.(iii)). In other words, if $\phi(x) \geq c$ (or $\phi(x) \leq c$) for all $x \in K$, and there is an $x \in K$ with $\phi(x) = c$, then the set

\[
\{x \in K : \phi(x) = c\}
\]

is a face of $K$. In this case, the hyperplane $\phi^{-1}(\{c\})$ is called a **support hyperplane** for $K$, and the intersection with $K$ a **support face**. Such a support face is frequently, although far from always, an extreme point of $K$.

**Closed Faces**

Now let $X$ be a topological vector space, and $K$ a convex subset of $X$. The faces of $K$ which are relatively closed in $K$ are particularly important, and are called the **closed faces** of $K$. This situation is especially important if $K$ is closed in $X$, although we do not make this assumption in the definition. Note that (if $X$ is Hausdorff) every extreme point is a closed face.

**XV.7.1.9.** It looks at first from the definition that a face should be closed; in fact, if $F$ is a face in $K$ and $Y$ is a one-dimensional (more generally, finite-dimensional) affine subspace of $X$, then $F \cap Y$ is always relatively closed in $K \cap Y$. However, a face of a convex set, even a compact convex set (Choquet simplex), need not be closed in general, and the closure of a face is not necessarily a face (XV.7.7.2.).
As in XV.7.1.4 (i), an arbitrary intersection of closed faces of a convex set \( K \), if nonempty, is a closed face (the other parts of XV.7.1.4. have straightforward analogs for closed faces too, with “face” replaced by “closed face” throughout). Thus if \( S \) is an arbitrary nonempty subset of \( K \), there is a smallest closed face \( F(S) \) of \( K \) containing \( S \), the intersection of all closed faces containing \( S \).

Similarly, if \( K \) is a convex set in a topological vector space \( X \), and \( \phi \) is a continuous linear functional on \( X \) (XV.7.1.8.) is a support face for \( K \) from \( \phi \).

### Convex Hulls and Extreme Points

**Proposition.** Let \( X \) be a topological vector space, and \( K_1, \ldots, K_n \) a finite collection of compact convex sets in \( X \). Let \( K \) be the convex hull of \( \bigcup_{j=1}^n K_j \). Then \( K \) is compact.

**Proof:** Since each \( K_j \) is convex, it is easy to check that

\[
\left\{ \sum_{j=1}^n \alpha_j x_j : x_j \in K_j, \alpha_j \geq 0, \sum_{j=1}^n \alpha_j = 1 \right\}
\]

is convex; since it is contained in \( K \) and contains each \( K_j \), it equals \( K \). Set

\[
S = \left\{ (\alpha_1, \ldots, \alpha_n) : \alpha_j \geq 0, \sum_{j=1}^n \alpha_j = 1 \right\}.
\]

Then \( S \) is a compact subset of \( \mathbb{R}^n \) (it is an \((n-1)\)-simplex), so the map

\[
(\alpha_1, \ldots, \alpha_n, x_1, \ldots, x_n) \mapsto \sum_{j=1}^n \alpha_j x_j
\]

is a continuous function from the compact set \( S \times K_1 \times \cdots \times K_n \) onto \( K \). Thus \( K \) is compact by (i).

The next result is known as Milman’s (partial) converse to the Krein-Milman Theorem. Our proof is adapted from [SW99].

**Theorem.** Let \( S \) be a subset of a locally convex (Hausdorff) topological vector space \( X \) such that the closed convex hull \( K \) of \( S \) is compact. Then all extreme points of \( K \) lie in \( S \).

**Proof:** Since \( \bar{S} \) is a subset of \( K \), it is compact. Let \( U \) be an open convex neighborhood of 0 in \( X \). For \( x \in \bar{S} \), set \( U_x = x + U \). The \( U_x \) form an open cover of \( \bar{S} \), so there is a finite subcover \( \{U_{x_1}, \ldots, U_{x_n}\} \). Let \( K_j \) be the closed convex hull of \( S \cap U_{x_j} \). Then \( K_j \subset K \) for all \( j \). The convex hull \( K' \) of \( \bigcup_{j=1}^n K_j \) contains \( S, K' \subset K \), and \( K' \) is compact by XV.7.1.12.; thus \( K' = K \). So if \( p \) is an extreme point of \( K \), we have \( p = \sum_{j=1}^n \alpha_j y_j \) for some \( \alpha_j \)'s in \( S \) and \( y_j \in K_j \); since \( p \) is extreme, we must have \( p = y_j \) for some \( j \), i.e. \( p \in K_j \). Since \( U_{x_j} \) is closed and convex, \( K_j \subset U_{x_j} \subset \bar{S} + U \). Thus \( p \in \bar{S} + U \). This is true for every \( U \), so \( p \in \bar{S} \).
XV.7.2. Compact Convex Sets in Finite-Dimensional Spaces

We now look at compact convex sets in finite-dimensional topological vector spaces. A finite-dimensional real vector space has a unique topology making it a Hausdorff topological vector space, which can be identified with $\mathbb{R}^n$ for some $n$. So without loss of generality we will work in Euclidean space. We can thus use geometric arguments in our analysis.

XV.7.2.1. If $K$ is a convex set in $\mathbb{R}^n$, then $K$ spans an $m$-dimensional affine subspace of $\mathbb{R}^n$ for some $m \leq n$; we say $K$ is $m$-dimensional (this terminology is justified in ??). By replacing $\mathbb{R}^n$ with this subspace and identifying it with $\mathbb{R}^m$, we may if desired for analysis of $K$ assume it spans all of $\mathbb{R}^n$ as an affine space (i.e. is $n$-dimensional), although we will not routinely make this restriction. Dimension in this sense is an isomorphism invariant of $K$.

XV.7.2.2. Proposition. If $K$ is an $n$-dimensional convex set in $\mathbb{R}^n$, then $K$ has nonempty (topological) interior $K^\circ$; in fact $K^\circ$ is an open convex set in $\mathbb{R}^n$ which is dense in $K$.

Proof: $K$ contains $n + 1$ points $x_0, \ldots, x_n$ which span $\mathbb{R}^n$ as an affine space (any set which spans $\mathbb{R}^n$ as an affine space contains $n + 1$ points which also span it). Set $x = \frac{1}{n+1} \sum_{k=0}^n x_k$. Every point $y$ of $\mathbb{R}^n$ can be uniquely written as $\sum_{k=0}^n \alpha_k x_k$ for $\alpha_k \in \mathbb{R}$, $\sum_{k=0}^n \alpha_k = 1$; if $y$ is sufficiently close to $x$, each $\alpha_k$ is close to $\frac{1}{n+1}$ and is hence positive. Thus $y \in K$ if $y$ is sufficiently close to $x$, i.e. $K$ contains an open ball around $x$. Thus $x$ is in $K^\circ$, so $K^\circ \neq \emptyset$. The density and convexity of $K^\circ$ follow from ()

This result fails for infinite-dimensional compact convex sets, since it implies that the spanned affine subspace contains a nonempty open set with compact closure.

Combining this with the geometric version of the Hahn-Banach Theorem in () (which is elementary in a finite-dimensional vector space, not requiring any form of Choice), we obtain:

XV.7.2.3. Proposition. Let $K$ be an $n$-dimensional convex set in $\mathbb{R}^n$. If $x \in K$ is in the topological boundary of $K$, then $x$ is contained in a proper face of $K$, and hence is not an interior point in the sense of XV.7.1.5.

Proof: By () applied to $K^\circ$ and $x$, there is a linear functional $\phi$ on $\mathbb{R}^n$, which is automatically continuous, and a number $r$ such that $\phi(x) \geq r$ and $\phi(y) < r$ for all $y \in K^\circ$. Since $\phi$ is continuous, $\phi(y) \leq r$ for all $y \in K^\circ$, and in particular $\phi(x) = r$ and $\phi(y) \leq r$ for all $y \in K$ since $K^\circ$ is dense in $K$. The set $F = \{ y \in K : \phi(y) = r \}$ is thus a proper face of $K$ containing $x$.

This result fails in the infinite-dimensional case, and even in the finite-dimensional case if the dimension of the convex set is strictly smaller than the dimension of the space.

Extreme Points

Our next goal is to show that a compact convex set $K$ in a finite-dimensional vector space has “many” extreme points, enough that $K$ is the convex hull of its extreme points. This result is a special case of the Krein-Milman Theorem, although we will obtain a sharper result with a more elementary proof in the finite-dimensional case.
**XV.7.2.4.**  Example. It can be shown that if $K$ is a compact convex set in $\mathbb{R}^2$, then the set of extreme points of $K$ is closed in $K$, hence also compact. But this fails in $\mathbb{R}^3$. Let $K$ be the convex hull of the points of $C = \{(x, y, 0) : (x-1)^2 + y^2 = 1\}$ and the points $(0, 0, 1)$ and $(0, 0, -1)$; see Fig. (). The extreme points of $K$ are the points of $C$ except the origin, and the points $(0, 0, 1)$ and $(0, 0, -1)$. The origin is in the closure of the set of extreme points but is not itself an extreme point.

**XV.7.2.5.**  Proposition. An $n$-dimensional compact convex set $K$ has at least $n + 1$ extreme points. The extreme points of $K$ span the same affine subspace as $K$.

**XV.7.2.6.**  Lemma. A nonempty compact convex set in $\mathbb{R}^n$ has an extreme point.

**Proof:** Let $K$ be a compact convex set in $\mathbb{R}^n$, and $x \in K$. There is a point $y \in K$ of maximum distance $d$ from $x$ by compactness ($y$ is not necessarily unique). Then $y$ is an extreme point of the ball $B_d(x)$, which contains $K$, so $y$ is an extreme point of $K$.

This result and proof hold more generally in any strictly convex Banach space. The result is true in much greater generality (XV.7.3.1), but requires a different proof.

**Proof:** Proof of XV.7.2.5: let $K$ be an $n$-dimensional compact convex subset of $\mathbb{R}^n$. Let $A$ be the affine subspace spanned by the extreme points of $K$ (there is at least one extreme point by XV.7.2.6). If $A$ does not contain $K$, then there is a point $x$ of $K$ of maximum distance $d > 0$ from $A$. If $S$ is the set of points of $K$ of distance $d$ from $A$, then the face $F(\{x\})$ of $K$ generated by $x$ is contained in $S$. $F(\{x\})$ is a compact convex set and thus has an extreme point $y$ (XV.7.2.6), which must be an extreme point of $K$ also. But $y \in S$, so $y \notin A$, a contradiction. The first statement then follows since the affine subspace spanned by $m$ points has dimension $\leq m - 1$.

The next result is the main theorem of this subsection, due first to MINKOWSKI without the $n + 1$, and in the sharp form with $n + 1$ by CARATHÉODORY.

**XV.7.2.7.**  Theorem. Let $K$ be a compact convex set in $\mathbb{R}^n$. Then every point of $K$ is a convex combination of at most $n + 1$ extreme points of $K$.

**Proof:** By complete induction on the dimension $m$ of $K$. If $m = 1$, $K$ is isomorphic to a closed bounded interval and is the convex hull of its two endpoints (and the case $m = 0$ is trivial). For a general $K$ of dimension $m$, let $x \in K$. If $x$ is in the topological boundary of $K$, then $x$ lies in a proper face $F$ of $K$ (XV.7.2.3), and thus $x$ is a convex combination of at most $m$ extreme points of $F$ by the inductive hypothesis, all of which are extreme points of $K$. If $x$ is an interior point of $K$, let $y$ be an extreme point of $K$. The ray from $y$ through $x$ intersects the boundary of $K$ in a (unique) point $z$, which is in $K$ since $K$ is compact. Then as before $z$ is a convex combination of at most $m$ extreme points in a proper face of $K$. Since $x$ is a convex combination of $z$ and $y$, $x$ is a convex combination of $y$ and these at most $m$ other extreme points of $K$.

Combining this result with XV.7.1.13, we get:
XV.7.2.8. Corollary. Let $E$ be a compact subset of $\mathbb{R}^n$. Then the convex hull $K$ of $E$ is also compact.

Proof: Let

$$S = \left\{ (\alpha_0, \ldots, \alpha_n) : \alpha_j \geq 0, \sum_{j=0}^n \alpha_j = 1 \right\} \subseteq \mathbb{R}^{n+1}$$

and consider the map $f : S \times \mathbb{R}^{n+1} \to K$ defined by

$$f(\alpha_0, \ldots, \alpha_n, x_0, \ldots, x_n) = \sum_{j=0}^n \alpha_j x_j.$$ 

Then $f$ is continuous. Each extreme point of $K$ is in $E$ by XV.7.1.13., and every element of $K$ is a convex combination of at most $n + 1$ extreme points by XV.7.2.7., so $f$ is surjective. $S \times \mathbb{R}^{n+1}$ is compact, so $K$ is compact by (1).

XV.7.3. The Krein-Milman Theorem

XV.7.3.1. Theorem. [Krein-Milman Theorem] Let $K$ be a nonempty compact convex set in a locally convex (Hausdorff) topological vector space $X$. Then $K$ is the closed convex hull of its extreme points (and in particular has extreme points).

Proof: Recall that we regard $X$ as a real topological vector space by ignoring the complex structure if necessary, since all relevant notions (convexity, compactness, etc.) depend only on the real topological vector space structure. Let $F$ be the collection of all closed faces of $K$. Partially order $F$ by reverse inclusion: if $E, F \in F$, then $E \leq F$ if $F \subseteq E$. If $C = \{ F_i : i \in I \}$ is a chain in $F$, then $C$ has an upper bound, namely $F = \bigcap_i F_i$, which is a closed face (XV.7.1.10.) since it is nonempty because $C$ is a nested family of compact subsets of $K$ (this is the first of several places compactness of $K$ is used).

Thus, by Zorn’s Lemma, $F$ has a maximal element, i.e. $K$ has a minimal closed face $E$. We must have that $E$ is a singleton: if $x, y \in E$, $x \neq y$, there is a continuous linear functional $\phi$ on $X$ with $\phi(x) \neq \phi(y)$ (this is the first place where we need that $X$ is locally convex and Hausdorff). Then $\{ \phi(z) : z \in E \}$ is a compact subset of $\mathbb{R}$ (actually a closed bounded interval) since $E$ is compact. If $\lambda$ is the largest number in this set, then $F = \{ z \in E : \phi(z) = \lambda \}$ is a closed face of $E$ and hence of $K$, and is a proper subset of $E$ since $x$ and $y$ cannot both be in $F$, contradicting that $E$ is a minimal closed face of $K$. Thus $E = \{ p \}$ for an extreme point $p$ of $K$, and $K$ has an extreme point. A stronger conclusion also holds: if $F$ is any closed face of $K$, then $\tilde{F}$ is itself a nonempty compact convex set in $X$, and so has a point which is an extreme point of $F$ and thus an extreme point of $K$. Therefore every closed face of $K$ contains an extreme point of $K$.

Now let $L$ be the closed convex hull of the extreme points of $K$. If $L \neq K$, let $x \in K \setminus L$. Then, since $L$ is compact and convex, there is a continuous linear functional $\psi$ on $X$ with

$$\psi(x) > \sup \{ \psi(y) : y \in L \}$$

by the geometrical Hahn-Banach Theorem (1) (we again use that $X$ is locally convex and Hausdorff). The set $\{ \psi(z) : z \in K \}$ is a compact subset of $\mathbb{R}$ (actually a closed bounded interval), so has a largest number $\mu$. Then $F = \{ z \in K : \psi(z) = \mu \}$ is a closed face in $K$ disjoint from $L$. But $F$ contains an extreme point of $K$ by the previous proof, contradicting that all extreme points of $K$ are in $L$. Thus $L = K$. \( \diamond \)
XV.7.3.2. The local convexity hypothesis in the Krein-Milman Theorem is to insure that there are sufficiently many continuous linear functionals, or equivalently enough closed supporting hyperplanes. There exists a compact convex set in a topological vector space which is complete and metrizable, but not locally convex, which has no extreme points [Rob77]. (In a non-Hausdorff topological vector space, there is a trivial counterexample: the closure of \( \{0\} \).)

XV.7.3.3. The hypotheses of the Krein-Milman Theorem are not necessary. If \( A \) is a unital C*-algebra (), then every element of the open unit ball of \( A \) is a convex combination of unitaries, which are extreme points of the closed unit ball [Bla06]. Thus the closed unit ball of a unital C*-algebra is the closed convex hull of its extreme points, even though there is no (Hausdorff) topological vector space topology on \( A \) in general under which the closed unit ball is compact. (The closed unit ball of a nonunital C*-algebra has no extreme points.) A closed bounded set in a Banach space with the Radon-Nikodym Property () is the closed convex hull of its extreme points ([Phe74], [Edg75]).

XV.7.4. Choquet’s Theorem

There is an important sharpening of the Krein-Milman Theorem for metrizable compact convex sets, due to G. Choquet [Cho56]. Our exposition is adapted from [Phe66].

Representing Measures

XV.7.4.1. Definition. Let \( X \) be a topological vector space, and \( E \) a compact subset of \( X \). Let \( \mu \) be a Borel probability measure on \( E \), and \( x \in X \). Then \( \mu \) represents \( x \), or \( x \) is the barycenter, resultant, or moment of \( \mu \), if for every continuous linear functional \( \phi \) on \( X \) we have

\[
\phi(x) = \mu(\phi) := \int_E \phi \, d\mu
\]

(note that \( \phi \) is Borel measurable and bounded on \( E \), so the integral is defined; the notation \( \mu(\phi) \) comes from regarding \( \mu \) as a bounded linear functional on \( C(E) \) by the Riesz Representation Theorem ()).

The point \( x \), if it exists, is the weak integral \( \int_E \iota \, d\mu \), where \( \iota \) is the identity map on \( E \), regarded as a continuous function from \( E \) to \( X \).

XV.7.4.2. Examples. (i) If \( x \in X \) and \( E \) is any compact subset of \( X \) containing \( x \), then the point mass \( \delta_x \) (regarded as a Borel probability measure on \( E \)) represents \( x \). The measure \( \delta_x \) is called \( \epsilon_x \) in some references.

(ii) Let \( K \) be the convex hull of \( n \) extreme points \( \{p_1, \ldots, p_n\} \) in a Hausdorff topological vector space \( X \). Then \( K \) is compact. If \( x \in K \), then \( x = \sum_{j=1}^{n} \alpha_j p_j \) for some \( \alpha_1, \ldots, \alpha_n \geq 0 \) with \( \sum_{j=1}^{n} \alpha_j = 1 \). If \( \mu \) is the purely atomic Borel probability measure on \( K \) with \( \mu(p_j) = \alpha_j \) (i.e. \( \mu = \sum_{j=1}^{n} \alpha_j \delta_{p_j} \)), then \( \mu \) represents \( x \) (\( x \) is the barycenter of \( \mu \)). Thus every point of \( K \) is the barycenter of a Borel probability measure on \( K \) supported on the extreme points of \( K \). (Since the convex combination giving \( x \) is not necessarily unique, the representing measure for \( x \) is not unique in general.)

Choquet’s Theorem extends (ii) to an arbitrary metrizable compact convex set \( K \), giving a representing measure (not unique in general) for any point of \( K \) which is supported on the extreme points of \( K \).
XV.7.4.3. **Proposition.** If $X$ is locally convex (Hausdorff), and $\mu$ is a Borel probability measure on a compact subset $E$ of $X$, then $\mu$ represents at most one point of $X$.

**Proof:** If $\mu$ represents $x$ and $y$, then $\phi(x) = \mu(\phi) = \phi(y)$ for all $\phi \in X^*$. Thus $x = y$ since $X^*$ separates the points of $X$.

XV.7.4.4. **Proposition.** If $K$ is a compact convex set in a topological vector space $X$, and $\mu$ is a Borel probability measure on $K$, of $X$, then $\mu$ represents at least one point of $X$ (exactly one point $x_\mu$ if $X$ is locally convex), and the barycenter is in $K$. If $X$ is locally convex, the function $\mu \mapsto x_\mu$ is weak-* continuous, i.e. if $\mu_i \to \mu$ weak-* in $C(K)^*$, then $x_{\mu_i} \to x_\mu$ in $K$.

**Proof:** If $x \in X$ is represented by $\mu$, then for any $\phi \in X^*$,

$$\phi(x) = \mu(\phi) \leq \sup \{ \phi(y) : y \in K \}$$

and thus by the geometrical Hahn-Banach Theorem (X.7.4.3) $x \in K$ since it is closed and convex.

For existence, for each $\phi \in X^*$ let $H_\phi = \{ x \in K : \phi(x) = \mu(\phi) \}$. Then $H_\phi$ is a closed hyperplane in $X$, and we wish to show that

$$\bigcap_{\phi} H_\phi \cap K \neq \emptyset.$$ 

Since these sets are compact, it suffices to show that for any $\phi_1, \ldots, \phi_n \in X^*$,

$$(\bigcap_{\phi_i} H_{\phi_i}) \cap K \neq \emptyset.$$ 

Define a bounded linear map $T : X \to \mathbb{R}^n$ by

$$T(x) = (\phi_1(x), \ldots, \phi_n(x)).$$

Then $T(K)$ is a compact convex subset of $\mathbb{R}^n$. Set $y = (\mu(\phi_1), \ldots, \mu(\phi_n)) \in \mathbb{R}^n$. It suffices to show $y \in T(K)$.

If $y \notin T(K)$, there is a linear functional $\psi$ on $\mathbb{R}^n$ with $\psi(y) > \sup \{ \psi(z) : z \in T(K) \}$. There is a vector $a \in \mathbb{R}^n$ such that $\psi(z) = (a, z)$ for all $z \in \mathbb{R}^n$. Set $a = (a_1, \ldots, a_n)$. We have

$$\psi(y) = \langle a, y \rangle > \sup \{ \langle a, T(x) \rangle : x \in K \}.$$ 

If $\theta \in X^*$ is defined by $\theta = \sum_{j=1}^n a_j \phi_j$, we have

$$\int_K \theta d\mu = \psi(y) > \sup \{ \theta(x) : x \in K \}.$$ 

This is impossible since $\mu$ is a probability measure. Thus $y \in T(K)$.

Now suppose $X$ is locally convex (Hausdorff), and $(\mu_i)$ is a net of Borel probability measures on $K$ with $\mu_i \to \mu$ weak-*. Set $x_i = x_{\mu_i}$ and $x = x_\mu$. To show $x_i \to x$, we use the hard-to-state criterion XI.3.2.13. Fix a subnet $(x_j)$ of $(x_i)$. Then $(x_j)$ has a convergent subnet by compactness of $K$. Fix a convergent subnet $(x_r)$, say $x_r \to y \in K$. Then, for any $\phi \in X^*$, $\phi(x_r) \to \phi(y)$ by continuity of $\phi$. On the other hand,

$$\phi(x_i) = \mu_i(\phi) \to \mu(\phi) = \phi(x)$$

and so the subnet $(\phi(x_i))$ also converges to $\phi(x)$. Thus $\phi(y) = \phi(x)$. This is true for all $\phi \in X^*$, so $y = x$ since $X^*$ separates the points of $X$. So $(x_j)$ has a subnet converging to $x$, and so $x_i \to x$ by XI.3.2.13.
XV.7.4.5. Corollary. If $E$ is a compact set in a locally convex topological vector space $X$, and the closed convex hull $K$ of $E$ is also compact (this is automatic if $X$ is topologically complete, e.g. if $X$ is a Banach space in either the norm or weak topology, or the dual of a Banach space in the weak-* topology, cf. ()), then every Borel probability measure $\mu$ on $E$ has a unique barycenter $x_\mu$ in $X$, and $x_\mu \in K$. The map $\mu \mapsto x_\mu$ is weak-* continuous.

XV.7.4.6. Proposition. If $E$ is a compact set in a locally convex topological vector space $X$, and $x \in X$, then $x$ is in the closed convex hull $\overline{co}(E)$ if and only if $x$ is represented by a Borel probability measure on $E$.

Proof: One direction generalizes part of XV.7.4.5. (since it is not assumed that $\overline{co}(E)$ is compact), and has the same proof: if $x$ is represented by $\mu$, then for any $\phi \in X^*$,

$$\phi(x) = \mu(\phi) \leq \sup\{\phi(y) : y \in E\} = \sup\{\phi(y) : y \in \overline{co}(E)\}$$

and thus $x \in \overline{co}(E)$ since it is closed and convex.

For the converse, suppose $x \in \overline{co}(E)$. Then there is a net $(x_i)$ in $co(E)$ with $x_i \to x$. Each $x_i$ can be represented by a Borel probability measure $\mu_i$ on $E$ which is a finite convex combination of point masses as in XV.7.4.2.(ii). Since the set of Borel probability measures on $E$ is a weak-* compact subset of $C(E)^*$, there is a subnet $(\mu_j)$ of the net $(\mu_i)$ which converges weak-* to a Borel probability measure $\mu$. Then $x_j \to x$, and for any $\phi \in X^*$ we have

$$\phi(x_j) \to \phi(x)$$

and thus $\phi(x) = \mu(\phi)$. Since this holds for all $\phi \in X^*$, $\mu$ represents $x$.

The Krein-Milman Theorem Revisited

The Krein-Milman Theorem can thus be rephrased using XV.7.4.6.:

XV.7.4.7. Theorem. [Krein-Milman Theorem, Representing Measure Form] Let $K$ be a compact convex set in a locally compact (Hausdorff) topological vector space $X$, and $E$ the closure of the set $\partial_e(K)$ of extreme points of $K$. Then every point of $K$ is the barycenter of a Borel probability measure on $E$.

For the proof, just note that $\overline{co}(E) = \overline{co}(\partial_e(K))$, and apply XV.7.3.1. and XV.7.4.6.. Conversely, XV.7.3.1. follows from XV.7.4.7. and XV.7.4.6., so XV.7.3.1. and XV.7.4.7. are equivalent via XV.7.4.6..

XV.7.4.8. This form of the Krein-Milman Theorem is not optimally useful, since $E$ can be a rather large subset of $K$; in fact, $E$ is “generically” the whole set $K$ (i.e. the set of extreme points of $K$ is generically dense in $K$)! [Kle59]. It would be far better to have representing measures supported on the set $\partial_e(K)$ of extreme points of $K$ itself, not just on the closure.
**XV.7.4.9.** In order for the desired statement to even make sense, we need the set \( \partial_e(K) \) to be a Borel set. Although it is not closed in general, even if \( K \) is a metrizable Choquet simplex \( (\cdot) \), in the metrizable case we do have:

**XV.7.4.10.** **Proposition.** Let \( K \) be a metrizable compact convex set in a topological vector space \( X \). Then the set \( \partial_e(K) \) of extreme points of \( K \) is a \( G_\delta \), and in particular a Borel set.

**Proof:** Fix a metric \( \rho \) giving the topology of \( K \). For \( n \in \mathbb{N} \), let \( A_n \) be the set of all \( x \in K \) such that there exist \( y, z \in K \) with \( x = \frac{1}{2}(y + z) \) and \( \rho(y, z) \geq \frac{1}{n} \). Then \( \bigcup_{n=1}^\infty A_n \) is the complement of \( \partial_e(K) \), so it suffices to show that each \( A_n \) is a closed set.

Fix \( n \in \mathbb{N} \), and let \( (x_j) \) be a sequence in \( A_n \) with \( x_j \to x \in K \). For each \( j \), there are \( y_j, z_j \in K \) with \( x_j = \frac{1}{2}(y_j + z_j) \) and \( \rho(y_j, z_j) \geq \frac{1}{n} \). By compactness of \( K \), there are convergent subsequences \( (y_{r_j}) \) and \( (z_{r_j}) \) of \( (y_j) \) and \( (z_j) \), which can be taken to have the same indices \( (\cdot) \), say \( y_{r_j} \to y \), \( z_{r_j} \to z \). Then

\[
\frac{1}{2}(y_{r_j} + z_{r_j}) \to \frac{1}{2}(y + z).
\]

But

\[
\frac{1}{2}(y_{r_j} + z_{r_j}) = x_{r_j} \to x
\]

and thus \( x = \frac{1}{2}(y + z) \) since \( K \) is Hausdorff. Since \( \rho(y, z) \geq \frac{1}{n} \) by continuity of \( \rho \), we have \( x \in A_n \) and \( A_n \) is closed.

We then have the following strengthening of **XV.7.4.7.** in the metrizable case:

**XV.7.4.11.** **Theorem.** [Choquet’s Theorem] Let \( K \) be a metrizable compact convex set in a locally convex (Hausdorff) topological vector space \( X \). Then every \( x \in K \) is represented by a measure which is supported on the set \( \partial_e(K) \) of extreme points of \( K \).

**XV.7.4.12.** We give a nice proof due to BONSALL [Bon63] (cf. [Phe66]) based on the Hahn-Banach Theorem. The argument will be a series of lemmas. To begin, fix a point \( x_0 \in K \); we will show that \( x_0 \) is represented by a measure supported on \( \partial_e(K) \). We will work with the subspace \( \text{Aff}(K) \) of \( C(K) \) of real-valued continuous affine functions on \( K \). Since \( K \) is metrizable, \( \text{Aff}(K) \) is separable; fix a sequence \( (h_n) \) which is dense in the unit sphere of \( \text{Aff}(K) \), and set

\[
f = \sum_{n=1}^\infty 2^{-n}h_n^2 \in C(K).
\]

**XV.7.4.13.** **Lemma.** The function \( f \) is strictly convex on \( K \), i.e. \( f(tx + (1-t)y) < tf(x) + (1-t)f(y) \) for \( x, y \in K \), \( x \neq y \), \( 0 < t < 1 \).

**Proof:** Each \( h_n^2 \) is clearly convex, so \( f \) is convex. If \( x \neq y \), there is an \( h_n \) with \( h_n(x) \neq h_n(y) \), so \( h_n \) is affine and not constant on the segment between \( x \) and \( y \), and therefore \( h_n^2 \) is strictly convex on this segment. Hence \( f \) is too. ☐

1760
XV.7.4.14. Definition. If \( g \in C(K) \), write
\[
\tilde{g} = \inf \{ h : h \in \text{Aff}(K), g \leq h \}.
\]
The function \( \tilde{g} \) is called the upper envelope of \( g \).

XV.7.4.15. Lemma. Let \( g, g_1, g_2 \in C(K) \). Then

(i) \( \tilde{g} \) is concave, i.e. \( \tilde{g}(tx + (1-t)y) \geq t\tilde{g}(x) + (1-t)\tilde{g}(y) \) for \( x, y \in K, 0 < t < 1 \).

(ii) \( \tilde{g} \) is bounded and upper semicontinuous, hence Borel measurable.

(iii) \( g \leq \tilde{g} \), and \( g = \tilde{g} \) if and only if \( g \) is concave.

(iv) \( \frac{1}{g_1 + g_2} \leq \frac{1}{g_1 + g_2}, \) and \( \frac{1}{g_1 + g_2} = \frac{1}{g_1 + g_2} = \frac{1}{g_1 + g_2} \) if \( g_2 \in \text{Aff}(K) \).

(v) \( |\tilde{g}_1 - \tilde{g}_2| \leq ||g_1 - g_2|| \).

(vi) If \( \alpha \geq 0 \), then \( \alpha \tilde{g} = \alpha \tilde{g} \).

The simple proof is straightforward and left to the reader.

XV.7.4.16. Let \( Y \) be the subspace of \( C(K) \) spanned by \( \text{Aff}(K) \) and \( f \) (defined above). Define a linear functional \( \psi \) on \( Y \) by \( \psi(h + \alpha f) = h(x_0) + \alpha f(x_0) \).

XV.7.4.17. Lemma. For \( g \in C(K) \), define \( p(g) = \tilde{g}(x_0) \). Then

(i) \( p \) is subadditive and positive-homogeneous.

(ii) If \( h + \alpha f \in Y \), then \( \psi(h + \alpha f) \leq p(h + \alpha f) \).

Proof: (i) follows immediately from XV.7.4.15.(iv) and (vi).

(ii): If \( \alpha \geq 0 \), then \( \frac{1}{h + \alpha f} = h + \alpha f \) by XV.7.4.15.(iv) and (vi), and in particular
\[
\psi(h + \alpha f) = p(h + \alpha f).
\]

If \( \alpha < 0 \), then \( h + \alpha f \) is concave, so \( \frac{1}{h + \alpha f} = h + \alpha f \geq h + \alpha f \) and in particular
\[
\psi(h + \alpha f) = p(h + \alpha f).
\]

XV.7.4.18. Thus by the Hahn-Banach Theorem there is a linear functional \( \phi \) on \( C(K) \) with \( \phi(g) \leq p(g) = \tilde{g}(x_0) \)

for all \( g \in C(K) \), which extends \( \psi \).
**XV.7.4.19.** Lemma. The linear functional $\phi$ is a state (positive linear functional of norm 1) on $C(K)$.

**Proof:** If $g \in C(K)$, $g \leq 0$, then since the constant function 0 is in $\text{Aff}(K)$, $\bar{g} \leq 0$, and in particular $\phi(g) \leq \mu(g) = \bar{g}(x_0) \leq 0$. Taking negatives, $\phi$ is a positive linear functional. Since the constant function 1 is in $\text{Aff}(K)$, we have $\phi(1) = \psi(1) = 1(x_0) = 1$.

**XV.7.4.20.** Thus, by the Riesz Representation Theorem, there is a Borel probability measure $\mu$ on $K$ with

$$\phi(g) = \mu(g) := \int_K g \, d\mu$$

for all $g \in C(K)$. We have $\mu(f) = \bar{f}(x_0)$. Since $f \leq \bar{f}$, $\mu(f) \leq \mu(\bar{f})$ (note that $\mu(\bar{f}) = \int_K \bar{f} \, d\mu$ is defined even though $\bar{f}$ may not be continuous, since it is bounded and Borel measurable); but if $h \in \text{Aff}(K)$, $h \geq f$, we have $h \geq \bar{f}$, so

$$h(x_0) = \psi(h) = \phi(h) = \mu(h) \geq \mu(\bar{f}) .$$

Taking the infimum over all such $h$, we get

$$\bar{f}(x_0) \geq \mu(\bar{f}) \geq \mu(f) = \bar{f}(x_0)$$

and thus equality holds, i.e.

$$\int_K \bar{f} \, d\mu = \mu(\bar{f}) = \mu(f) = \int_K f \, d\mu$$

and so

$$\int_K (\bar{f} - f) \, d\mu = 0 .$$

Thus $\mu$ vanishes on the complement of the set

$$S = \{ x \in K : f(x) = \bar{f}(x) \} .$$

**XV.7.4.21.** Lemma. The set $S$ is contained in $\partial_e(K)$.

**Proof:** If $x, y, z$ are distinct points of $K$ with $x = \frac{1}{2}(y + z)$, then by the strict convexity of $f$ we have

$$f(x) < \frac{1}{2} f(y) + \frac{1}{2} f(z) \leq \frac{1}{2} \bar{f}(y) + \frac{1}{2} \bar{f}(z) \leq \bar{f}(x)$$

since $\bar{f}$ is concave.

This completes the proof of **XV.7.4.11**.

**XV.7.4.22.** In fact, the set $S$ is exactly $\partial_e(K)$; cf. [Phe66, 3.1].

1762
The Nonmetrizable Case

XV.7.4.23. There is a generalization of Choquet’s Theorem to nonmetrizable compact convex sets, the Bishop-de Leeuw Theorem \[BdL59\]. This theorem is considerably more difficult to prove, and is even somewhat tricky to state, because (among other things) the set of extreme points in a nonmetrizable compact convex set, even a nonmetrizable Choquet simplex, need not be a Borel set. See e.g. \[Phe66\] or \[Alf71\] for details.

XV.7.4.24. The Bishop of Bishop-de Leeuw is the Errett Bishop of constructivism fame (I.6.1.20.). Karel de Leeuw is known (besides for his work) for a darker reason: he was murdered in his office by a graduate student.

XV.7.5. Regular Embeddings, Cones, and Affine Functions

XV.7.6. Choquet Simplexes

XV.7.6.1. A compact convex set can be thought of as being defined by “generators” and “relations.” The “generators” are the set of extreme points, and the “relations” are pairs of measures which represent the same point. For example, a square (or parallelogram, cf. XV.7.7.1. (b)) has four generators \(v_1, v_2, v_3, v_4\) and one relation

\[
\frac{1}{2}(v_1 + v_3) = \frac{1}{2}(v_2 + v_4).
\]

From this (somewhat imprecise) point of view, a Choquet simplex is a “free” compact convex set, i.e. one with no relations.

Bauer Simplexes

XV.7.6.2. Definition. A Choquet simplex \(\Delta\) in which the set of extreme points is closed in \(\Delta\) is a Bauer simplex.

XV.7.6.3. Since a Bauer simplex is compact, its set of extreme points is a compact Hausdorff space. Every compact Hausdorff space \(X\) is the set of extreme points of a Bauer simplex \(\Delta_X\), which is unique up to isomorphism. \(\Delta_X\) can be concretely described as the state space of \(C(X)\) (\(\cdot\)), which by the Riesz\(\) Representation Theorem can be identified with the set of Radon probability measures on \(X\). The extreme points are just the point masses, which can be identified with \(X\) (\(\cdot\)). The representing measure of a point is just the point itself; thus uniqueness is essentially tautological, so \(\Delta_X\) is a Choquet simplex. \(\Delta_X\) is metrizable if and only if \(X\) is metrizable, i.e. \(C(X)\) is separable (\(\cdot\)). All finite-dimensional simplexes are, of course, Bauer simplexes.

Other Simplexes

XV.7.6.4. “Most” Choquet simplexes are not Bauer simplexes. The simplest example of a Choquet simplex which is not a Bauer simplex is given in Exercise XV.7.7.2.. The construction can be modified to give far more complicated examples.

In fact, if \(X\) is any Polish space, there is a metrizable Choquet simplex \(\Delta\) such that \(\partial_e(\Delta)\) is homeomorphic to \(X\) (\(\cdot\); the set of extreme points of a metrizable Choquet simplex is always a \(G_\delta\), hence a Polish space in the relative topology). The simplex \(\Delta\) is highly nonunique in general; for example, the set of extreme

1763
points for each of the $\Delta_c$ ($0 < c \leq 1$) of XV.7.7.2. (f) is a countable discrete space (and there are much more complicated simplexes with the same space of extreme points).

**XV.7.6.5.** The most extreme case is the Poulsen simplex. There is a metrizable Choquet simplex $\Delta$, unique up to isomorphism, called the *Poulsen simplex*, for which the set of extreme points of $\Delta$ is dense in $\Delta$ [?]. Every metrizable Choquet simplex is isomorphic to a face of the Poulsen simplex.

The set of extreme points of the Poulsen simplex is thus a Polish space in which every Polish space can be embedded as a closed subset. It can be shown that $\partial_c(\Delta)$ is homeomorphic to $\mathbb{R}^\infty ()$, the underlying topological space of every separable infinite-dimensional Banach space ().

**XV.7.7. Exercises**

**XV.7.7.1.** (a) Show that all (solid) triangles are isomorphic as compact convex sets.

(b) Show that all parallelograms are isomorphic as convex sets. Show that a convex quadrilateral which is not a parallelogram is not isomorphic to a parallelogram. Describe the isomorphism classes of convex quadrilaterals. [Consider how the diagonals intersect.]

**XV.7.7.2.** Give $\ell^1$ the weak-* topology as $c_0^\infty ()$. Then the closed unit ball is compact (), metrizable (), and convex. Let $(e_n)$ be the standard Schauder basis. Let $\Delta$ be the set of sequences $x = (\lambda_1, \lambda_2, \ldots)$ such that $\|x\| \leq 1$, $-1 \leq \lambda_1 \leq 1$, and $\lambda_n \geq 0$ for all $n > 1$.

(a) Show that $\Delta$ is the closed convex hull of $E = \{e_1, -e_1, e_2, e_3, \ldots\}$, and that $E$ is the set of extreme points of $\Delta$. Thus $\Delta$ is compact (and metrizable).

(b) Show that $\Delta$ is a Choquet simplex. [Use ().]

(c) Show that $E$ is not closed in $\Delta$: $\bar{E} = E \cup \{0\}$. Note that $0$ is the midpoint of the segment between $e_1$ and $-e_1$.

(d) Let $F$ be the set of sequences in $\Delta$ for which $\lambda_1 = 0$ and $\sum_{k=2}^\infty \lambda_k = 1$. Show that $F$ is a face of $\Delta$.

(e) Show that $\bar{F}$ is the set of sequences in $\Delta$ with $\lambda_1 = 0$, which is not a face of $\Delta$.

(f) More generally, fix $c$, $0 \leq c \leq 1$, and let $\Delta_c$ be the closed convex hull of $\{e_1, -ce_1, e_2, e_3, \ldots\}$. Then each $\Delta_c$ is a metrizable Choquet simplex with a sequence of extreme points converging to $0$. No two of the $\Delta_c$ are isomorphic. $\Delta_0$ is a Bauer simplex ($0$ is an extreme point).

(g) In all these examples except $\Delta_0$, the relative topology on $\partial_c(\Delta_c)$ is the discrete topology. The facial topology on $\partial_c(\Delta_c)$ is the $T_1$ topology consisting of a sequence of isolated points $(e_n$ for $n \geq 2$) converging simultaneously to $e_1$ and $-ce_1$. The relative and facial topologies on $\partial_c(\Delta_0)$ coincide and consist of a sequence of isolated points (the $e_n$) converging to $0$.

**XV.7.7.3.** Let $\Delta_0$ be the simplex of XV.7.7.2. (f), and let $\pi$ be the quotient map from $\ell^1$ onto $\ell^1 / X$, where $X$ is the one-dimensional subspace of $\ell^1$ spanned by $x = (2^{-1}, 2^{-2}, 2^{-3}, \ldots)$. Set $\Delta = \pi(\Delta_0)$.

(a) Show that $\Delta$ is a Choquet simplex, and that $\partial_c(\Delta)$ consists of $\{f_n : n \in \mathbb{N}\}$, where $f_n = \pi(e_n)$.

(b) The relative topology on $\partial_c(\Delta)$ is the discrete topology, while the facial topology is the finite complement topology.

This $\Delta$ is a *prime simplex* (cf. ()).
XV.7.7.4. ([Bau61]; cf. [Phe66, 1.4], [Alf71, 1.2.4]) Let $K$ be a nonempty compact convex set in a locally convex topological vector space.

(a) If $x \in K$, show that $x$ is an extreme point of $K$ if and only if $\delta_x$ is the only Borel probability measure on $K$ representing $x$.

(b) Use (a) and XV.7.4.6. to give an alternate proof of Milman’s partial converse XV.7.1.13.

XV.7.7.5. Let $K$ be a convex set in a topological vector space $X$. A point $p$ of $K$ is an exposed point of $K$ if there is a closed hyperplane $H$ such that $H \cap K = \{p\}$, i.e. if there is a continuous linear functional $\phi$ on $X$ with $\phi(x) < \phi(p)$ for all $x \in K \setminus \{p\}$.

(a) Show that every exposed point is an extreme point.

(b) Let $K$ be the union in $\mathbb{R}^2$ of the closed unit disk and the square

$$\{(x, y) : -1 \leq x \leq 1, -2 \leq y \leq 0\}.$$ 

Then $K$ is compact and convex. Show that $(1, 0)$ and $(-1, 0)$ are extreme points of $K$ but not exposed points. Find all extreme points and exposed points of $K$.

There are other related notions: strongly exposed points, dentable points, etc. These notions are tied in with the structure theory of Banach spaces.
XV.8. The Stone-Weierstrass Theorem

The Stone-Weierstrass Theorem is one of the important theorems of functional analysis, giving a useful criterion for uniformly approximating general continuous functions by “nice” functions.

XV.8.1. The Weierstrass Approximation Theorem

The original version proved by Weierstrass in 1885 was:

**Theorem.** Let $I$ be a closed bounded interval in $\mathbb{R}$. Then every continuous function from $I$ to $\mathbb{R}$ can be uniformly approximated arbitrarily closely on $I$ by a polynomial.

**Bernstein’s Proof**

In 1912 Sergei Bernstein gave a better proof of the Weierstrass Approximation Theorem in which he gave an explicit sequence of polynomials converging uniformly to a given continuous function on an interval:

**Theorem.** If $f$ is a continuous real-valued function on $[0,1]$, define, for $0 \leq x \leq 1$,

$$B_n(f)(x) = \sum_{k=0}^{n} \binom{n}{k} f\left(\frac{k}{n}\right) x^k (1-x)^{n-k}$$

(This is the $n$'th Bernstein polynomial of $f$.) Then $(B_n(f))$ converges uniformly to $f$ on $[0,1]$.

Other intervals can be handled via an affine transformation.

**Bernstein’s probabilistic argument** (cf. [?]), which suggests that $B_n(f)$ should at least converge to $f$ pointwise.

Fix $f$ and $x \in [0,1]$. We repeatedly toss a coin with probability $x$ of heads. Suppose we toss the coin a large number $n$ of times, and receive a payoff of $f(r)$ dollars, where $r$ is the fraction of tosses which are heads. In the long run (as $n \to \infty$), $r$ will approach $x$ with probability 1, so the payoff will approach $f(x)$ since $f$ is continuous.

If we toss the coin $n$ times, we will get exactly $k$ heads with probability

$$\binom{n}{k} x^k (1-x)^{n-k}$$

so the expected payoff is

$$\sum_{k=0}^{n} \binom{n}{k} f\left(\frac{k}{n}\right) x^k (1-x)^{n-k} = B_n(f)(x).$$

A direct proof of Bernstein’s result can be found in [?] or almost any book on numerical analysis or approximation theory; a probability version of the proof can be found in [?]. In fact, books on numerical analysis prove the following sharpened form:
**Theorem.** Let $f$ be a bounded real-valued function on $[0, 1]$, and $B_n(f)$ the $n$’th Bernstein polynomial of $f$ (XV.8.1.2). Then

$$|f(x) - B_n(f)(x)| \leq \frac{3}{2} \omega\left(f, \frac{1}{\sqrt{n}}\right)$$

for all $x \in [0, 1]$, where $\omega(f, \cdot)$ is the modulus of continuity ($\cdot$) of $f$ on $[0, 1]$.

Since $\lim_{\delta \to 0} \omega(f, \delta) = 0$ if $f$ is continuous, XV.8.1.2. is a corollary of XV.8.1.4.

**Korovkin’s Theorem**

We give a proof of XV.8.1.2., and hence XV.8.1.1., based on a result of independent interest due to KOROVKIN [Kor53]:

**Theorem.** Let $I = [a, b]$ be a closed bounded interval, and $(L_n)$ a sequence of positive linear operators from $C(I)$ to $C(I)$ (i.e. if $f \geq 0$ then $L_n f \geq 0$ for all $n$). Let $p_0(x) = 1$, $p_1(x) = x$, and $p_2(x) = x^2$. If $L_n p_k \to p_k$ uniformly for $k = 0, 1, 2$, then $L_n f \to f$ uniformly for all $f \in C(I)$.

**Proof:** (cf. [Bri98]) For each $t \in I$, set $g_t(x) = (x - t)^2 = t^2 p_0(x) - 2t p_1(x) + p_2(x)$. Then

$$[L_n g_t](x) = t^2 [L_n p_0](x) - 2t [L_n p_1](x) + [L_n p_2](x)$$

for all $n, t, x$. Since $g_t \geq 0$, we have

$$0 \leq [L_n g_t](t) = t^2 ([L_n p_0](t) - 1) + 2t ([L_n p_1](t) - t) + ([L_n p_2](t) - t^2)$$

$$\leq t^2 [L_n p_0 - p_0] + 2t [L_n p_1 - p_1] + [L_n p_2 - p_2]$$

and thus, since $t^2$ and $|2t|$ are bounded on $I$, for any $\eta > 0$ there is an $N$ such that $[L_n g_t] < \eta$ for all $n \geq N$ and all $t \in I$.

Now fix $f \in C(I)$ and $\epsilon > 0$. Since $f$ is uniformly continuous on $I$, there is a $\delta > 0$ such that $|f(x) - f(y)| < \epsilon$ whenever $x, y \in I$ and $|x - y| < \delta$. Fix $t \in I$. If $x \in I$, $|x - t| \geq \delta$, we have

$$|f(t) - f(x)| \leq 2 \|f\| \leq 2 \|f\| \frac{(x - t)^2}{\delta^2} = \frac{2}{\delta^2} \|f\| g_t(x)$$

so for any $x \in I$ we have

$$|f(t) - f(x)| \leq \frac{2}{\delta^2} \|f\| g_t(x) + \epsilon.$$

Thus

$$-\epsilon p_0 - \frac{2}{\delta^2} \|f\| g_t \leq f(t)p_0 - f \leq \epsilon p_0 + \frac{2}{\delta^2} \|f\| g_t$$

and hence

$$-\epsilon L_n p_0 - \frac{2}{\delta^2} \|f\| L_n g_t \leq f(t) L_n p_0 - L_n f \leq \epsilon L_n p_0 + \frac{2}{\delta^2} \|f\| [L_n g_t]$$

$$|f(t) [L_n p_0](t) - [L_n f](t)| \leq \epsilon \|L_n p_0\| + \frac{2}{\delta^2} \|f\| [L_n g_t](t).$$

1767
Thus
\[ |f(t) - [L_n f](t)| \leq |f(t) - f(t)[L_n p_0](t)| + |f(t)[L_n p_0](t) - [L_n f](t)| \]
\[ \leq |f(t)|1 - |L_n p_0|(t)| + \epsilon |L_n p_0| + \frac{2}{\delta^2} ||f||[L_n g_k](t) \]
\[ \leq ||f|||p_0 - L_n p_0| + \epsilon (||p_0|| + ||p_0 - L_n p_0||) + \frac{2\eta}{\delta^2} ||f||L_n g_k(t) . \]
so if \( \eta > 0 \) and \( n \) is large enough,
\[ |f(t) - [L_n f](t)| \leq ||f|||p_0 - L_n p_0| + \epsilon (||p_0|| + ||p_0 - L_n p_0||) + \frac{2\eta}{\delta^2} ||f|| . \]
The right side is independent of \( t \) and can be made less than \( 2\epsilon \) by choosing \( \eta \) small enough and then \( n \) large enough. Since \( \epsilon > 0 \) is arbitrary, we have \( L_n f \to f \) uniformly on \( I \).

\[ \text{(XV.8.1.6.)} \]

To prove XV.8.1.2., and hence XV.8.1.1., it thus suffices to show that each \( B_n \) is a positive operator (obvious) and that \( B_n p_k \to p_k \) uniformly for \( k = 0, 1, 2 \), which is a simple calculation.

**XV.8.2. The Stone-Weierstrass Theorem**

In 1937 Marshall Stone formulated and proved a general version of Weierstrass’s Theorem, which is now known as the Stone-Weierstrass Theorem. There are several commonly stated versions of the theorem, all of which are simple consequences of the following general version. Stone also proved a lattice version (XV.8.2.14.).

**XV.8.2.1. Theorem.** [Stone-Weierstrass] Let \( X \) be a compact Hausdorff space, and \( C(X) \) the algebra of real-valued continuous functions on \( X \). Let \( A \) be a subalgebra of \( C(X) \) which is uniformly closed () and separates points (i.e. if \( x, y \in X \) with \( x \neq y \) there is an \( f \in A \) with \( f(x) \neq f(y) \)). Then either \( A = C(X) \) or there is a \( p \in X \) such that \( A \) consists of all \( f \in C(X) \) with \( f(p) = 0 \).

Here is the most commonly stated version of the Stone-Weierstrass Theorem (to prove it, consider the uniform closure of \( A \), which is also an algebra):

**XV.8.2.2. Corollary.** Let \( X \) be a compact Hausdorff space, and \( A \) a subalgebra of \( C(X) \) which separates points and contains the constant functions. Then \( A \) is dense in \( C(X) \) for the uniform norm.

Weierstrass’s Theorem is an immediate corollary of this, applied to \( X = I \) and \( A \) the algebra of polynomials.

There is also a complex version:

**XV.8.2.3. Theorem.** [Complex Stone-Weierstrass] Let \( X \) be a compact Hausdorff space, and \( C(X) \) the algebra of complex-valued continuous functions on \( X \). Let \( A \) be a (complex) subalgebra of \( C(X) \) which is closed under complex conjugation, uniformly closed, and separates points. Then either \( A = C(X) \) or there is a \( p \in X \) such that \( A \) consists of all \( f \in C(X) \) with \( f(p) = 0 \).

A complex version of XV.8.2.2. follows immediately:

1708
**XV.8.2.4. Corollary.** Let $X$ be a compact Hausdorff space, and $A$ a subalgebra of $C(X)$ which separates points, contains the constant functions, and is closed under complex conjugation. Then $A$ is dense in $C(X)$ for the uniform norm.

To prove XV.8.2.3. from XV.8.2.1., note that if $A$ is closed under complex conjugation and $f \in A$, then the real and imaginary parts $Re(f) = (f + \bar{f})/2$ and $Im(f) = (f - \bar{f})/2i$ are also in $A$ (the converse is also true). The real-valued functions in $A$ thus satisfy the hypotheses of XV.8.2.1.

**XV.8.2.5.** The hypothesis that $A$ be closed under complex conjugation, or something similar, is necessary; see Exercise XV.8.3.10.

**XV.8.2.6.** Here is an important observation for the proof of XV.8.2.1. If $A$ is an algebra of real-valued functions on a space $X$, $f \in A$, and $p$ is a polynomial with real coefficients and no constant term, then $p \circ f \in A$: if $p(t) = a_1t + a_2t^2 + \cdots + a_nt^n$, then $p \circ f = a_1f + a_2f^2 + \cdots + a_nf^n \in A$. If $A$ contains the constant functions, the same is true if $p$ is a polynomial with constant term. If $(p_n)$ is a sequence of polynomials (without constant term) which converge uniformly on the range of $f$ to a function $g$, then $p_n \circ f \to g \circ f$ uniformly on $X$, so if $A$ is uniformly closed, $g \circ f \in A$. Here is an important application:

**XV.8.2.7. Lemma.** Let $A$ be a uniformly closed algebra of real-valued bounded functions on a set $X$. If $f \in A$, then $|f| \in A$.

Since $|f| = g \circ f$, where $g(t) = |t|$, this follows from the next lemma:

**XV.8.2.8. Lemma.** For any $m \in \mathbb{N}$ there is a sequence of polynomials without constant term converging uniformly to $g(t) = |t|$ on $[-m, m]$.

**Proof:** This can be quickly deduced from XV.8.1.1., but we give a simple direct argument. First consider the interval $[-1, 1]$. By V.17.7.9., the Taylor polynomials $q_n(t)$ around 0 converge uniformly to $h(t) = (1 + t)^{1/2}$ on $[-1, 1]$. Set $r_n(t) = q_n(t^2 - 1)$; then $r_n$ is a polynomial, and $r_n(t)$ converges uniformly to $h(t^2 - 1) = g(t)$ on $[-1, 1]$ (since $t^2 - 1$ maps $[-1, 1]$ into $[-1, 1]$). It is unclear whether $r_n$ has a nonzero constant term; but if $c_n$ is the constant term of $r_n$, then $c_n = r_n(0) \to g(0) = 0$, so if $p_n(t) = r_n(t) - c_n$, then $p_n$ is a polynomial without constant term, and $p_n \to g$ uniformly on $[-1, 1]$.

For $[-m, m]$, set $\phi_n(t) = mp_n(t/m)$. Then $\phi_n$ is a polynomial without constant term, and $\phi_n \to g$ uniformly on $[-m, m]$.

**XV.8.2.9. Lemma.** Let $A$ be a uniformly closed algebra of real-valued bounded functions on a set $X$. If $f, g \in A$, then $f \vee g = \max(f, g)$ and $f \wedge g = \min(f, g)$ are in $A$.

**Proof:** $f \vee g = \frac{1}{2}(f + g + |f - g|)$ and $f \wedge g = \frac{1}{2}(f + g - |f - g|)$.

By induction, if $f_1, \ldots, f_n \in A$, then $f_1 \vee \cdots \vee f_n$ and $f_1 \wedge \cdots \wedge f_n$ are in $A$.  

1769
**XV.8.2.10. Lemma.** Let $A$ be an algebra of real-valued functions on $X$ which separates the points of $X$, and $x, y \in X$. If there are $f, g \in A$ with $f(x) \neq 0$ and $g(y) \neq 0$, then for any $a, b \in \mathbb{R}$ there is an $h \in A$ with $h(x) = a$ and $h(y) = b$.

**Proof:** If $\phi = f^2 + g^2$, then $\phi(x) > 0$ and $\phi(y) > 0$. If $\phi(x) = \phi(y)$, let $\psi$ be a function in $A$ with $\psi(x) \neq \psi(y)$. Then for some (almost any) $r \in \mathbb{R}$ the function $\theta = \phi + r\psi$ has $c = \theta(x)$ and $d = \theta(y)$ distinct nonzero numbers. It is easy to find a quadratic polynomial $p$ with no constant term such that $p(c) = a$ and $p(d) = b$ by solving two linear equations for the coefficients. Then $h = p \circ \theta$ is the desired element of $A$. $\blacksquare$

We are thus in the situation where the following definition applies (for a more general version, see ()):

**XV.8.2.11. Definition.** Let $X$ be a compact Hausdorff space. A subspace $L$ of $C_R(X)$ is a lattice if $f \land g \in L$ for all $f, g \in L$.

A lattice $L$ in $C_R(X)$ has the strong separation property if, whenever $x, y \in X$, $x \neq y$, and $a, b \in \mathbb{R}$, there is an $f \in L$ with $f(x) = a$ and $f(y) = b$.

Since $f \lor g = -[(-f) \land (-g)]$, if $L$ is a lattice and $f, g \in L$, then $f \lor g \in L$.

**XV.8.2.12.** A uniformly closed subalgebra $A$ of $C_R(X)$ is a lattice by XV.8.2.9., and, if $A$ separates points and there is no point of $X$ at which all the functions in $A$ vanish, $A$ has the strong separation property by XV.8.2.10.. Note also:

**XV.8.2.13. Proposition.** Let $X$ be a compact Hausdorff space, and $L$ a lattice in $C_R(X)$. If $L$ separates points and the constant functions are in $L$, then $L$ has the strong separation property.

**Proof:** Let $x, y \in A$, $x \neq y$, and $a \leq b \in \mathbb{R}$. There is an $f \in L$ with $f(x) \neq f(y)$. Replacing $f$ by $-f$ if necessary, we may assume $f(x) < f(y)$, and multiplying $f$ by a scalar we may assume $f(y) - f(x) \geq b - a$. Adding a constant to $f$, we may assume $f(x) = a$, and thus $f(y) \geq b$. If $g = f \land (b1)$, then $g \in L$, $g(x) = a$, and $g(y) = b$. The case $a \geq b$ is obtained by interchanging $x$ and $y$. $\blacksquare$

We then have the lattice version of XV.8.2.2:

**XV.8.2.14. Theorem.** [STONE] Let $X$ be a compact Hausdorff space, and $L$ a lattice in $C_R(X)$ with the strong separation property. Then $L$ is uniformly dense in $C_R(X)$.

**Proof:** Let $f \in C_R(X)$. By the strong separation property, for each $x, y \in X$ there is a $g_{xy} \in L$ with $g_{xy}(x) = f(x)$ and $g_{xy}(y) = f(y)$. Let $\epsilon > 0$. Fix $x$. Since $f$ and $g_{xy}$ are continuous, for each $y$ there is a neighborhood $U_y$ of $y$ such that $g_{xy}(z) < f(z) + \epsilon$ for all $z \in U_y$. Since $X$ is compact, there are finitely many of these sets which cover $X$, say $U_{y_1}, \ldots, U_{y_n}$. Set $h_x = g_{xy_1} \land \cdots \land g_{xy_n}$. Then $h_x \in L$, $h_x(x) = f(x)$, and $h_x(z) < f(z) + \epsilon$ for all $z \in X$. There is such an $h_x$ for every $x \in X$. For each $x$, there is a neighborhood $V_x$ of $x$ such that $h_x(z) > f(z) - \epsilon$ for all $z \in V_x$. Choose a finite subcover $\{V_{x_1}, \ldots, V_{x_m}\}$. If $\phi = h_{x_1} \lor \cdots \lor h_{x_m}$, then $\phi \in L$ and $\|\phi - f\|_{\infty} < \epsilon$. There is such a $\phi$ for every $\epsilon$, so $f \in \bar{L}$. (The proof uses the AC.) $\blacksquare$
**XV.8.2.15.** Corollary. Let $X$ be a compact Hausdorff space, and $L$ a lattice in $C_R(X)$ which separates points and contains the constant functions. Then $L$ is uniformly dense in $C_R(X)$.

**XV.8.2.16.** We now prove XV.8.2.1. Suppose first that for every $x \in X$ there is a $g \in A$ with $g(x) \neq 0$. Then the hypotheses of XV.8.2.14. hold (XV.8.2.12.), so $A$ is uniformly dense in $C_R(X)$, and since $A$ is uniformly closed, $A = C_R(X)$.

Now suppose there is a $p \in X$ such that $g(p) = 0$ for all $g \in A$. (There cannot be more than one such $p$ since $A$ separates points.) Let $B$ be the set of all functions of the form $f = g + c$, where $g \in A$ and $c$ is a constant. Note that for such an $f$, $c = f(p)$. It is clear that $B$ is an algebra of functions. Suppose $(f_n)$ is a sequence in $B$, and $f_n \to f$ uniformly. Write $f_n = g_n + c_n$, with $g_n \in A$ and $c_n = f_n(p)$ a constant. Then $c_n \to c = f(p)$, and hence $g_n \to g = f - c$ uniformly. Thus $g \in A$ since $A$ is uniformly closed, and $f = g + c \in B$. Thus $B$ is uniformly closed. By the first part of the proof, $B = C_R(X)$. Now suppose $f \in C_R(X)$ with $f(p) = 0$. Then $f \in B$, so $f = g + c$ for some $g \in A$ and constant $c$. But $0 = f(p) = g(p) + c = 0 + c = c$, so $f = g \in A$.

This completes the proof of XV.8.2.1. (The proof uses the AC.)

**XV.8.3. Exercises**

**XV.8.3.1.** Prove the following corollary of XV.8.2.1.:

**Theorem.** Let $X$ be a locally compact Hausdorff space. Let $A$ be a uniformly closed subalgebra of $C_R^0(X)$ which separates points of $X$, such that there is no point of $X$ at which all the functions in $A$ vanish. Then $A = C_R^0(X)$.

[Regard $A$ as a subalgebra of $C_R(X)$.]

**XV.8.3.2.** Let $X$ be a locally compact, $\sigma$-compact Hausdorff space. Let $A$ be an algebra of real-valued continuous functions on $X$ which separate points of $X$, such that there is no point of $X$ at which all the functions in $A$ vanish. Show that if $f$ is any real-valued continuous function on $X$, then there is a sequence $(f_n)$ of functions in $A$ converging u.c. to $f$ on $X$.

**XV.8.3.3.** General Weierstrass Approximation Theorem. Let $X$ be a compact subset of $\mathbb{R}^n$ for some $n$.

(a) Show that any continuous function from $X$ to $\mathbb{R}$ can be uniformly approximated arbitrarily closely by a polynomial in the coordinates (in $\mathbb{R}^n$).

(b) Show that any continuous function from $X$ to $\mathbb{R}^m$ for any $m$ can be uniformly approximated arbitrarily closely by a function whose $m$ coordinate functions are all polynomials in the coordinates (in $\mathbb{R}^n$).

**XV.8.3.4.** Let $X$ be a compact subset of $\mathbb{C}$. Let $A$ be the subalgebra of $C(X)$ consisting of all functions of the form $g(z) = p(z,)$, where $p$ is a polynomial of two variables with complex coefficients. Then $A$ separates points of $X$ and contains the constant functions. Show that $A$ is closed under complex conjugation and hence is dense in $C(X)$ by XV.8.2.4.
XV.8.3.5. (a) Let $X$ and $Y$ be compact Hausdorff spaces. Show that every real-valued continuous function on $X \times Y$ can be uniformly approximated arbitrarily closely by (finite) sums of functions of the form $f \otimes g$, where $f \in C_R(X)$, $g \in C_R(Y)$, and

$$(f \otimes g)(x, y) = f(x)g(y).$$

(b) Prove a similar result for complex-valued continuous functions. In fact, every complex-valued continuous function on $X \times Y$ is a uniform limit of finite sums of functions of the form $\lambda(f \otimes g)$, where $\lambda$ is 1 or $i$ and $f$ and $g$ are real-valued continuous functions on $X$ and $Y$ respectively.

(c) Use (a) to give an alternate proof of Fubini’s Theorem for continuous functions (XIV.3.4.7.):

**Theorem.** Let $R = [a, b] \times [c, d]$ be a rectangle in $\mathbb{R}^2$, and $h : R \to \mathbb{R}$ a continuous function. Then

$$\int \int_{R} h \, dA = \int_{a}^{b} \int_{c}^{d} h(x, y) \, dy \, dx = \int_{c}^{d} \int_{a}^{b} h(x, y) \, dx \, dy.$$

[First prove the theorem if $h = f \otimes g$, and take uniform limits.] Generalize to Radon measures on general compact Hausdorff spaces.

XV.8.3.6. Let $a, b \in \mathbb{R}$, $a < b$. Let $C_{sing}([a, b])$ be the set of all continuous functions $f : [a, b] \to \mathbb{R}$ such that $f$ is differentiable a.e. and $f' = 0$ a.e. on $[a, b]$.

(a) Show that $C_{sing}([a, b])$ is a subalgebra of $C_R([a, b])$ containing the constant functions.

(b) By scaling the Cantor function, show that $C_{sing}([a, b])$ separates points of $[a, b]$.

(c) Conclude that $C_{sing}([a, b])$ is uniformly dense in $C_R([a, b])$.

There is an explicit proof of this result not using the Stone-Weierstrass Theorem; cf. XIV.17.5.4..

XV.8.3.7. Let $f$ be a continuous function on an interval $[a, b]$, and suppose that all the moments

$$\int_{a}^{b} f(x)x^n \, dx$$

$(n \in \mathbb{N}_0)$ of $f$ are zero. Prove that $f$ is identically zero on $[a, b]$. [It suffices to show that

$$\int_{a}^{b} [f(x)]^2 \, dx = 0.$$

Show that

$$\int_{a}^{b} f(x)p(x) \, dx = 0$$

for any polynomial $p$, and apply the Weierstrass Approximation Theorem.]
XV.8.3.8. Here is an “integral” version of Weierstrass’s Theorem.
(a) If \( f \) is a polynomial with integer coefficients, regarded as an element of \( C([0, 1]) \), then of course \( f(0) \) and \( f(1) \) are integers. The rest of the problem will show that if \( f \) is an element of \( C([0, 1]) \) such that \( f(0) \) and \( f(1) \) are integers, then \( f \) is a uniform limit on \([0, 1]\) of polynomials with integer coefficients.
(b) Let \( g(x) = x + x(1 - 2x)(1 - x) = 2x - 3x^2 + 2x^3 \). Show that \( g \) is a strictly increasing function from \([0, 1]\) onto \([0, 1]\). The function \( g \) has fixed points 0, 1/2, and 1; if 0 < \( x \) < 1/2, then \( x < g(x) < 1/2 \); if 1/2 < \( x \) < 1, then 1/2 < \( g(x) \) < \( x \).
(c) Show that the iterates \( (g_i) \) of \( g \) converge pointwise on \((0, 1)\) to the constant function 1/2, and that the convergence is uniform on compact subsets (i.e. on subintervals of the form \([\epsilon, 1 - \epsilon]\) for \( \epsilon > 0 \)). Such iterates are strictly increasing.
(d) Show by induction on \( n \) that if \( k \) is any integer, 1 ≤ \( k \) ≤ 2\( n \) − 1, and \( \epsilon > 0 \), then there are integer linear combinations \((\phi_m)\) of powers of the \( g_i \) and \( 1 - g_i \) such that 0 ≤ \( \phi_m \) ≤ 1 on \([0, 1]\) and such that \((\phi_m)\) converges uniformly to the constant function \( \frac{1}{2n} \) on \([\epsilon, 1 - \epsilon]\).
(e) If \( p \) is a polynomial with integer coefficients and \( p(0) = p(1) = 0 \), and \( \lambda \in \mathbb{R} \), show that there is a sequence of polynomials with integer coefficients converging uniformly to \( \lambda p \) on \([-1, 1]\).
(f) If \( f \) is a continuous function on \([0, 1]\) such that \( f(0) \) and \( f(1) \) are integers, then there is a linear polynomial \( q \) with integer coefficients with \( q(x) = f(x) \) for \( x = 0, 1 \). Apply the Stone-Weierstrass Theorem and (e) to conclude that \( f - q \), and hence \( f \), can be approximated uniformly on \([0, 1]\) by polynomials with integer coefficients.

XV.8.3.9. This problem is an extension of Exercise XV.8.3.8.
(a) Let \( f \) be a polynomial with integer coefficients, regarded as an element of \( C([-1, 1]) \). Show that \( f(-1) \), \( f(0) \), and \( f(1) \) are integers, and that \( f(-1) \equiv f(1) \mod 2 \) (i.e. both are even or both odd). The rest of the problem will show that if \( f \) is an element of \( C([-1, 1]) \) such that \( f(-1), f(0) \), and \( f(1) \) are integers, and \( f(-1) \equiv f(1) \mod 2 \), then \( f \) is a uniform limit on \([-1, 1]\) of polynomials with integer coefficients.
(b) If \( p \) is a polynomial with integer coefficients and \( p(-1) = p(0) = p(1) = 0 \), and \( \lambda \in \mathbb{R} \), show that there is a sequence of polynomials with integer coefficients converging uniformly to \( \lambda p \) on \([-1, 1]\). [Consider functions of the form \( \psi(x) = \phi(1 - x^2) \), where \( \phi \) is one of the \( \phi_m \) from (d).]
(c) If \( f \) is a continuous function on \([-1, 1]\) such that \( f(-1), f(0), \) and \( f(1) \) are integers and \( f(-1) \equiv f(1) \mod 2 \), then there is a quadratic polynomial \( q \) with integer coefficients with \( q(x) = f(x) \) for \( x = -1, 0, 1 \). Apply the Stone-Weierstrass Theorem and (b) to conclude that \( f - q \), and hence \( f \), can be approximated uniformly on \([-1, 1]\) by polynomials with integer coefficients.

XV.8.3.10. (a) Let \( T \) be the unit circle in \( \mathbb{C} \). Each polynomial with complex coefficients can be regarded as a continuous function from \( T \) to \( \mathbb{C} \), and this set of polynomials forms a subalgebra \( P \) of \( C(T) \). \( P \) contains the constant functions and separates points of \( T \). But \( P \) is not closed under complex conjugation (in fact, if \( p \) and \( \bar{p} \) are both in \( P \), then \( p \) is a constant function).
(b) Regard \( T \) alternatively as \([0, 2\pi]\) with the endpoints identified, and \( C(T) \) as the algebra of continuous functions \( f : [0, 2\pi] \to \mathbb{C} \) with \( f(2\pi) = f(0) \). \( P \) then becomes an algebra of “trigonometric polynomials” on \([0, 2\pi]\) (but not all trigonometric polynomials), functions of the form

\[
f(t) = \sum_{k=0}^{n} c_k e^{ikt}
\]

1773
for some $n \in \mathbb{N}$ (depending on $f$) and $\{c_k\}$ in $\mathbb{C}$.

(c) If $f \in P$, then $\int_0^{2\pi} f(t) e^{it} \, dt = 0$. The same holds if $f$ is in the uniform closure $\tilde{P}$ of $P$ in $C(\mathbb{T})$.

(d) For $z \in \mathbb{T}$, let $f(z) = \bar{z}$. Alternatively, if $t \in [0, 2\pi]$, let $f(t) = e^{-it}$. Then $f \in C(\mathbb{T})$, and $\int_0^{2\pi} f(t) e^{it} \, dt = 2\pi$. Thus $f$ is not in $\tilde{P}$.

(e) Let $D$ be the open unit disk in $\mathbb{C}$. Each $f \in P$ defines an analytic function on $D$. If $(f_n)$ is a sequence in $P$ converging uniformly on $T$ to a function $f \in \mathbb{P}$, then, by the Maximum Modulus Theorem, $(f_n)$ also converges uniformly on $D$ to a function which is continuous on $\overline{D}$ and analytic on $D$. Conversely, if $f$ is continuous on $D$ and analytic on $D$, the Taylor polynomials (partial sums of the Taylor series) for $f$ around 0 converge uniformly to $f$ on $\overline{D}$ (and, in particular, on $T$), so $f$ is in $\tilde{P}$. Thus $\tilde{P}$ consists precisely of the complex-valued continuous functions on $T$ which extend to a function continuous on $D$ and analytic on $D$.

(f) $\tilde{P}$ also consists precisely of the functions in $C(T)$ whose negative Fourier coefficients vanish.

(g) A trigonometric polynomial on $[0, 2\pi]$ is a function of the form

$$f(t) = \sum_{k=-n}^{n} c_k e^{ikt}$$

for some $n \in \mathbb{N}$ (depending on $f$) and $\{c_k\}$ in $\mathbb{C}$. Then $f \in C(\mathbb{T})$. A trigonometric polynomial can also be written

$$f(t) = \sum_{k=0}^{n} a_k \cos kt + i \sum_{k=1}^{n} b_k \sin kt$$

for $n \in \mathbb{N}$ and $a_k, b_k \in \mathbb{C}$. Show that the trigonometric polynomials are dense in $C(T)$.

See books on function algebras, e.g. [Bro69], for a thorough study of more sophisticated examples of this type.

XV.8.3.11. Let $X$ be a compact Hausdorff space, and let $P$ be a set of nonnegative real-valued continuous functions on $X$ with the following properties:

(i) $f + g \in P$ for all $f, g \in P$.

(ii) $\alpha f \in P$ for all $f \in P$, $\alpha > 0$.

(iii) Either

(1) $f \land g \in P$ for all $f, g \in P$

or

(2) $f \lor g \in P$ for all $f, g \in P$

Let $L = P - P = \{f - g : f, g \in P\}$.

(a) Show that $L$ is a lattice in $C_{\mathbb{R}}(X)$. Use

$$(f_1 - g_1) \land (f_2 - g_2) = [(f_1 + g_2) \land (f_2 + g_1)] - (g_1 + g_2)$$

$$(f_1 - g_1) \lor (f_2 - g_2) = [(f_1 + g_2) \lor (f_2 + g_1)] - (g_1 + g_2)$$

1774
and $f \vee g = -[(-f) \wedge (-g)]$.]

(b) Conclude from XV.8.2.15. that if $P$ separates points and contains a nonzero constant function, then $L$ is uniformly dense in $C_\mathbb{R}(X)$.

Examples of sets $P$ satisfying the hypotheses are the set of nonnegative continuous convex functions on an interval $[a, b]$ and the set of nonnegative continuous concave functions on $[a, b]$. Thus every continuous function on $[a, b]$ can be uniformly approximated arbitrarily closely by the sum of a continuous convex function and a continuous concave function (difference of two continuous convex functions).

**XV.8.3.12.** Use the Stone-Weierstrass Theorem to give another proof of the Tietze Extension Theorem (X) for compact Hausdorff spaces: let $X$ be a compact Hausdorff space, and $Z$ a closed subset of $X$. Let $A$ be the subalgebra of $C_\mathbb{R}(Z)$ consisting of the restrictions to $Z$ of continuous functions from $X$ to $\mathbb{R}$.

(a) Use Urysohn’s Lemma to show that $A$ is uniformly closed in $C_\mathbb{R}(Z)$. (This is a bit tricky.)

(b) Conclude from the Stone-Weierstrass Theorem that $A = C_\mathbb{R}(Z)$, i.e. that every continuous function from $Z$ to $\mathbb{R}$ extends to $X$.

This proof is not easier than the proof in (X), and the result is less general, but it is a different approach. A simpler argument for (a) can be given using C*-algebra theory (XV.14.2.3.).
XV.9. Hilbert Spaces

A Hilbert space is a vector space over \( \mathbb{R} \) or \( \mathbb{C} \) with an inner product or “dot product” which is complete with respect to the norm induced by the inner product. A Hilbert space can be thought of as a special kind of Banach space which has an intrinsic Euclidean geometry; in fact, every finite-dimensional subspace of a Hilbert space is a Euclidean space.

Hilbert spaces are the nicest kinds of topological vector spaces, essentially Euclidean spaces which are allowed to be infinite-dimensional. They share many pleasant properties with Euclidean spaces. In fact, they are so nice they are not themselves very interesting mathematically: there is up to isometric isomorphism exactly one of each dimension, finite or infinite. Like vector spaces, they are mainly important not in and of themselves, but as the setting for operators, which are highly nontrivial and very important.

Hilbert spaces can be either real or complex. The theories of real and complex Hilbert spaces are essentially identical and can be done in parallel. When we get to operators, however, the theories diverge somewhat, and for technical reasons (e.g. the Fundamental Theorem of Algebra) operator theory works better on complex Hilbert spaces. Thus in applications and more advanced work on operators, complex Hilbert spaces are used almost exclusively. Adhering to custom, we will take the default meaning of the term “Hilbert space” to be “complex Hilbert space.”

XV.9.1. Inner Products

Although a unified treatment can be given (XV.9.1.10.), it is clearer to separately define inner products in real and complex vector spaces.

Real Inner Products

XV.9.1.1. Definition. Let \( \mathcal{V} \) be a vector space over \( \mathbb{R} \). A bilinear form on \( \mathcal{V} \) is a function

\[
\langle \cdot, \cdot \rangle : \mathcal{V} \times \mathcal{V} \rightarrow \mathbb{R}
\]

(i.e. a function which assigns to each ordered pair of vectors a scalar) which is linear in each entry when the other entry is fixed, i.e.

(i) \( \langle x_1 + x_2, y \rangle = \langle x_1, y \rangle + \langle x_2, y \rangle \) for all \( x_1, x_2, y \in \mathcal{V} \).

(i') \( \langle x, y_1 + y_2 \rangle = \langle x, y_1 \rangle + \langle x, y_2 \rangle \) for all \( x, y_1, y_2 \in \mathcal{V} \).

(ii) \( \langle \alpha x, y \rangle = \alpha \langle x, y \rangle \) for all \( x, y \in \mathcal{V}, \alpha \in \mathbb{R} \).

(ii') \( \langle x, \alpha y \rangle = \alpha \langle x, y \rangle \) for all \( x, y \in \mathcal{V}, \alpha \in \mathbb{R} \).

A bilinear form is symmetric if

(iii) \( \langle y, x \rangle = \langle x, y \rangle \) for all \( x, y \in \mathcal{V} \).

A symmetric bilinear form is positive (or positive semidefinite) if

(iv) \( \langle x, x \rangle \geq 0 \) for all \( x \in \mathcal{V} \).

A positive symmetric bilinear form is definite (or positive definite) if

(v) \( \langle x, x \rangle = 0 \) for \( x \in \mathcal{V} \) if and only if \( x = 0 \).

A positive symmetric bilinear form is called a real pre-inner product.

A positive definite symmetric bilinear form is called a real inner product.
XV.9.1.2. Remarks. (i) Note that the inner product of two vectors is a *scalar*. Thus an inner product is not really a “multiplication” on the vector space, although it has some flavor of a product.

(ii) In a symmetric form, properties (i′) and (ii′) follow automatically from (i) and (ii) respectively. Since most forms we consider are symmetric (or hermitian in the complex case), we will rarely have to separately consider (i′) and (ii′).

XV.9.1.3. Notation. The notation \( \langle x; y \rangle \) is probably the most common notation for an inner product. Other common notations are \((x; y), \langle x|y \rangle, \text{ and } (x|y)\). Additional notations are also occasionally used.

XV.9.1.4. Examples. (i) On \( \mathbb{R}^n \), the usual dot product is a real inner product: if \( x = (x_1, \ldots, x_n) \) and \( y = (y_1, \ldots, y_n) \), then

\[
\langle x, y \rangle = x_1y_1 + \cdots + x_ny_n = \sum_{k=1}^{n} x_ky_k.
\]

This is the *standard inner product* on \( \mathbb{R}^n \).

(ii) On \( C_\mathbb{R}([a,b]) \), the real vector space of continuous real-valued functions on \([a,b]\), define

\[
\langle f, g \rangle = \int_{a}^{b} f(t)g(t) \, dt.
\]

then \( \langle \cdot, \cdot \rangle \) is a real inner product on \( C_\mathbb{R}([a,b]) \).

These two examples obviously have considerable similarity, and can be adapted to a wide range of settings. In fact, these are the “generic” examples; every inner product looks essentially like them (XV.9.5.21.).

(iii) Write elements of \( \mathbb{R}^n \) as column vectors. If \( A \) is an \( n \times n \) matrix over \( \mathbb{R} \), for \( x, y \in \mathbb{R}^n \) define

\[
\langle x, y \rangle = (Ax, y) = y^tAx
\]

where \( \langle \cdot, \cdot \rangle \) is the standard inner product. Then \( \langle \cdot, \cdot \rangle \) is a bilinear form on \( \mathbb{R}^n \). We have

\[
\langle y, x \rangle = x^tAy = [y^tA^tx]^t = y^tA^tx = (A^t x, y)
\]

since transpose is the identity on \( \mathbb{R} \); thus \( \langle \cdot, \cdot \rangle \) is symmetric if and only if \( A \) is symmetric (i.e. \( A^t = A \)). The form is a pre-inner product if and only if \( A \) is positive \( () \), or equivalently if \( A = A^t \) and all eigenvalues of \( A \) are nonnegative; it is an inner product if and only if \( A \) is positive definite, i.e. positive and invertible (i.e. \( A = A^t \) and all eigenvalues of \( A \) are strictly positive).

We can recover \( A \): if \( A_{jk} \) is the \((j,k)\) entry of \( A \), then \( A_{jk} = \langle e_k, e_j \rangle \), where \( e_i \) is the \( i \)'th standard basis vector. Conversely, if \( [\cdot, \cdot] \) is any bilinear form on \( \mathbb{R}^n \), set \( B_{jk} = \langle e_k, e_j \rangle \); then a simple calculation shows that

\[
[x, y] = \langle Bx, y \rangle
\]

for any \( x, y \in \mathbb{R}^n \), where \( B = (B_{jk}) \), so every bilinear form on \( \mathbb{R}^n \) is of this type. The matrix \( B \) is called the *matrix of the bilinear form* with respect to the standard basis of \( \mathbb{R}^n \).
Complex Inner Products

XV.9.1.5. The definitions in XV.9.1. make sense if \( \mathbb{R} \) is merely replaced by \( \mathbb{C} \). However, they are not very interesting. In fact, bilinearity is essentially incompatible with positivity: if \( \alpha \in \mathbb{C} \) with \( \alpha \not\in \mathbb{R} \), and \( x \in V \), if \( \langle \cdot, \cdot \rangle \) is bilinear we have

\[
\langle \alpha x, \alpha x \rangle = \alpha^2 \langle x, x \rangle
\]

and since \( \alpha^2 \) is not a nonnegative real number, \( \langle x, x \rangle \) and \( \langle \alpha x, \alpha x \rangle \) cannot both be nonnegative unless they are zero.

Fortunately, there is a fairly simple way around the difficulty, based on the fact that if \( \alpha \in \mathbb{C} \), then \( \alpha \bar{\alpha} \geq 0 \). We replace bilinearity by “sesquilinearity” (sesqui- is a Latin prefix meaning “one and a half”):

XV.9.1.6. Definition. Let \( V \) be a vector space over \( \mathbb{C} \). A sesquilinear form on \( V \) is a function

\[
\langle \cdot, \cdot \rangle : V \times V \to \mathbb{C}
\]

(i.e. a function which assigns to each ordered pair of vectors a scalar) which is linear in the first entry when the second entry is fixed and conjugate-linear in the second entry when the first entry is fixed, i.e.

(i) \( \langle x_1 + x_2, y \rangle = \langle x_1, y \rangle + \langle x_2, y \rangle \) for all \( x_1, x_2, y \in V \).

(i') \( \langle x, y_1 + y_2 \rangle = \langle x, y_1 \rangle + \langle x, y_2 \rangle \) for all \( x, y_1, y_2 \in V \).

(ii) \( \langle \alpha x, y \rangle = \alpha \langle x, y \rangle \) for all \( x, y \in V \), \( \alpha \in \mathbb{C} \).

(ii') \( \langle x, \alpha y \rangle = \bar{\alpha} \langle x, y \rangle \) for all \( x, y \in V \), \( \alpha \in \mathbb{C} \).

A sesquilinear form is hermitian if

(iii) \( \langle y, x \rangle = \overline{\langle x, y \rangle} \) for all \( x, y \in V \).

A hermitian sesquilinear form is positive (or positive semidefinite) if

(iv) \( \langle x, x \rangle \geq 0 \) for all \( x \in V \).

A positive hermitian sesquilinear form is definite (or positive definite) if

(v) \( \langle x, x \rangle = 0 \) for \( x \in V \) if and only if \( x = 0 \).

A positive hermitian sesquilinear form is called a pre-inner product.

A positive definite hermitian sesquilinear form is called a (complex) inner product.

XV.9.1.7. Notation: We have made the convention that sesquilinear forms and inner products are linear in the first variable and conjugate-linear in the second, the usual convention in mathematics. For obscure reasons, the opposite convention is common in mathematical physics, so readers should be aware of the convention used in any reference. The difference will have no practical effect, and a trivial notational change (reversing order in the inner product) will convert to the opposite convention.

1778
XV.9.1.8. Examples. (i) On \(\mathbb{C}^n\), if \(x = (x_1, \ldots, x_n)\) and \(y = (y_1, \ldots, y_n)\), define
\[
\langle x, y \rangle = x_1\overline{y_1} + \cdots + x_n\overline{y_n} = \sum_{k=1}^{n} x_k\overline{y_k}.
\]
This is an inner product, called the standard inner product on \(\mathbb{C}^n\).

(ii) On \(C([a, b])\), the complex vector space of continuous complex-valued functions on \([a, b]\), define
\[
\langle f, g \rangle = \int_{a}^{b} f(t)\overline{g(t)} \, dt.
\]
then \(\langle \cdot, \cdot \rangle\) is an inner product on \(C([a, b])\).

These two examples obviously have considerable similarity, and can be adapted to a wide range of settings. In fact, these are the “generic” examples; every inner product looks essentially like them (XV.9.5.21.).

(iii) Write elements of \(\mathbb{C}^n\) as column vectors. If \(A\) is an \(n \times n\) matrix over \(\mathbb{C}\), for \(x, y \in \mathbb{C}^n\) define
\[
(x, y) = \langle Ax, y \rangle = y^*Ax
\]
where \(\langle \cdot, \cdot \rangle\) is the standard inner product and, for a matrix \(B\),
\[
B^* = \overline{B^t}
\]
is the complex conjugate of the transpose. Then \(\langle \cdot, \cdot \rangle\) is a sesquilinear form on \(\mathbb{C}^n\). We have
\[
(y, x) = x^*Ay = [y^*A^*x]^* = \overline{y}^*A^*x = \overline{\langle Ax, y \rangle}
\]
and thus \(\langle \cdot, \cdot \rangle\) is hermitian if and only if \(A\) is hermitian (i.e. \(A^* = A\)). The form is a pre-inner product if and only if \(A\) is positive (\(\langle x, x \rangle \geq 0\)), or equivalently if \(A = A^*\) and all eigenvalues of \(A\) are nonnegative; it is an inner product if and only if \(A\) is positive definite, i.e. positive and invertible (i.e. \(A = A^*\) and all eigenvalues of \(A\) are strictly positive).

We can recover \(A\): if \(A_{jk}\) is the \((j, k)\) entry of \(A\), then \(A_{jk} = (e_k, e_j)\), where \(e_i\) is the \(i^{th}\) standard basis vector. Conversely, if \([\cdot, \cdot]\) is any sesquilinear form on \(\mathbb{C}^n\), set \(B_{jk} = [e_k, e_j]\); then a simple calculation shows that
\[
[x, y] = \langle Bx, y \rangle
\]
for any \(x, y \in \mathbb{C}^n\), where \(B = (B_{jk})\), so every sesquilinear form on \(\mathbb{C}^n\) is of this type. The matrix \(B\) is called the matrix of the sesquilinear form with respect to the standard basis of \(\mathbb{C}^n\).

XV.9.1.9. If \(V\) is a complex vector space, then \(V\) can be regarded as a real vector space by restricting scalar multiplication. However, if \(\langle \cdot, \cdot \rangle\) is a (complex) inner product on \(V\), it does not become a real inner product by simply restricting scalar multiplication (for one thing, it is complex-valued, not real-valued). But there is a simple conversion: if we define
\[
(x, y) = \text{Re} \langle x, y \rangle
\]
then it is easily checked that \(\langle \cdot, \cdot \rangle\) is a real inner product on \(V\) satisfying \(\langle x, x \rangle = \langle x, x \rangle\) for all \(x \in V\).
A Unified Treatment

A unified treatment of real and complex inner products can be given by making the convention that “complex conjugation” $\alpha \mapsto \bar{\alpha}$ is the identity map on $\mathbb{R}$. With this convention, we may meld the two definitions:

**XV.9.1.10.** Definition. Let $\mathbb{F}$ be $\mathbb{R}$ or $\mathbb{C}$, and $V$ a vector space over $\mathbb{F}$. A pre-inner product on $V$ is a function

$$\langle \cdot, \cdot \rangle : V \times V \to \mathbb{F}$$

satisfying

(i) $\langle x_1 + x_2, y \rangle = \langle x_1, y \rangle + \langle x_2, y \rangle$ for all $x_1, x_2, y \in V$.

(ii) $\langle \alpha x, y \rangle = \alpha \langle x, y \rangle$ for all $x, y \in V$, $\alpha \in \mathbb{F}$.

(iii) $\langle y, x \rangle = \overline{\langle x, y \rangle}$ for all $x, y \in V$.

(iv) $\langle x, x \rangle \geq 0$ for all $x \in V$.

The pre-inner product is an inner product if it additionally satisfies

(v) $\langle x, x \rangle = 0$ for $x \in V$ if and only if $x = 0$.

It is automatic that such a pre-inner product also satisfies

(i') $\langle x_1 + y_1 + y_2, x \rangle = \langle x_1, x \rangle + \langle y_1, x \rangle + \langle y_2, x \rangle$ for all $x, y_1, y_2 \in V$.

(ii') $\langle x, \alpha y \rangle = \bar{\alpha} \langle x, y \rangle$ for all $x, y \in V$, $\alpha \in \mathbb{F}$.

**XV.9.1.11.** Definition. A (real or complex) inner product space is a pair $(V, \langle \cdot, \cdot \rangle)$, where $V$ is a vector space over $\mathbb{R}$ or $\mathbb{C}$ and $\langle \cdot, \cdot \rangle$ is an inner product on $V$.

An inner product space is a vector space $V$ with specified inner product on $V$. As usual, we will sometimes abuse language by saying “Let $V$ be an inner product space.” There will then implicitly be a specified inner product on $V$. (By convention, we will take “inner product space” to mean “complex inner product space” unless otherwise qualified.)

**XV.9.2.** The CBS Inequality and the Norm

An inner product on a real or complex vector space defines a “norm”

$$\| x \| = \sqrt{\langle x, x \rangle}$$

but to prove that this is truly a norm, specifically to prove the triangle inequality, requires a preliminary inequality which is itself extremely important.
**XV.9.2.1.** **Theorem.** [CBS Inequality] Let $(\cdot,\cdot)$ be a pre-inner product on a real or complex vector space $V$. Then

$$|\langle x, y \rangle|^2 \leq \langle x, x \rangle \langle y, y \rangle$$

for all $x, y \in V$. If the pre-inner product is an inner product, we have equality if and only if $\{x, y\}$ is linearly dependent.

**Proof:** Fix $x, y \in V$. Suppose first that $\langle y, y \rangle \neq 0$ and set

$$\alpha = -\frac{\langle x, y \rangle}{\langle y, y \rangle}.$$

We then have

$$0 \leq \langle x + \alpha y, x + \alpha y \rangle = \langle x, x \rangle + \alpha \langle y, x \rangle + \alpha \langle x, y \rangle + \alpha^2 \langle y, y \rangle$$

$$= \langle x, x \rangle - \left(\frac{\langle x, y \rangle}{\langle y, y \rangle}\right) \langle y, x \rangle + \frac{\langle x, y \rangle \langle y, x \rangle}{\langle y, y \rangle} + \alpha^2 \langle y, y \rangle$$

$$= \langle x, x \rangle - \frac{|\langle x, y \rangle|^2}{\langle y, y \rangle}.$$

and putting the second term on the left and multiplying by $\langle y, y \rangle$ gives the inequality.

Now suppose $\langle y, y \rangle = 0$. If the pre-inner product is an inner product, then $y = 0$, so $\langle x, y \rangle = 0$ by (real) linearity in the second variable and there is nothing to prove. For the general case, set $\beta = -n \langle x, y \rangle$ for $n \in \mathbb{N}$. Then

$$0 \leq \langle x + \beta y, x + \beta y \rangle = \langle x, x \rangle + \beta \langle y, x \rangle + \beta \langle x, y \rangle + \beta^2 \langle y, y \rangle$$

$$= \langle x, x \rangle + \beta \langle y, x \rangle + \beta \langle x, y \rangle = \langle x, x \rangle - 2n |\langle x, y \rangle|^2.$$

This must be true for all $n \in \mathbb{N}$, so $\langle x, y \rangle = 0$.

If $x$ or $y$ is zero, we clearly have equality. Suppose $x$ and $y$ are nonzero and we have equality, and the pre-inner product is an inner product. Then there are suitable scalar multiples $z$ and $w$ of $x$ and $y$ respectively with

$$\langle z, z \rangle = \langle w, w \rangle = \langle z, w \rangle = 1.$$

We then have

$$\langle z - w, z - w \rangle = \langle z, z \rangle - 2\langle z, w \rangle + \langle w, w \rangle = 0$$

so $z = w$, i.e. $x$ and $y$ are scalar multiples of each other. $\blacktriangle$

**XV.9.2.2.** The name “CBS inequality” is not the one most commonly used, but is the most appropriate. The names CAUCHY, BUNYAKOVSKII, and SCHWARZ are associated with the inequality, and it is commonly called by various subsets of these names (most commonly the “Cauchy-Schwarz inequality.”) Here is a summary of the history:

(i) The first version of the CBS inequality to appear in print was for the standard inner product in $\mathbb{R}^n$, by CAUCHY in [Cau21] in 1821. See Exercise XV.9.10.1. for CAUCHY’s proof.

(ii) In 1859, V. BUNYAKOVSKII stated and indicated a proof of the inequality for the inner product of XV.9.1.4.(ii) [Bun59]. This paper, although written in French and not Russian (BUNYAKOVSKII was actually...
Ukrainian and studied in Paris), was published in Russia and was apparently little noticed in Western Europe. See Exercise XV.9.10.3. for BUNYAKOVSKIĬ’s statement and argument.

(iii) In 1885, H. SCHWARZ published an important and influential paper on minimal surfaces [Sch88] in which he proved, as a relatively minor technical result, a slightly more general integral version of the inequality. He was apparently unaware of BUNYAKOVSKIĬ’s paper. Because SCHWARZ’s paper was widely read and studied, the inequality became known and was often called the “Schwarz inequality.” SCHWARZ did make a substantive contribution: although he only stated the result for integrals, he gave a simple and elegant proof which works verbatim for any real inner product. See Exercise XV.9.10.4. for SCHWARZ’S proof.

(iv) It is unclear who first stated the inequality for complex inner products, or who first discovered the proof given above. The arguments of CAUCHY, BUNYAKOVSKIĬ, and SCHWARZ do not work directly for complex inner products, although the complex case can be easily derived from the real case; see Exercise XV.9.10.5.

The website http://www-stat.wharton.upenn.edu/~steele/Publications/Books/CSMC/CSMC_index. html for the book [Ste04] contains more information and links to electronic copies of the papers by BUNYAKOVSKIĬ and SCHWARZ. The book itself has a thorough study of the CBS inequality and many related inequalities.

The Norm

XV.9.2.3. If $(\mathcal{V}, \langle \cdot, \cdot \rangle)$ is an inner product space over $F = \mathbb{R}$ or $\mathbb{C}$, for $x \in \mathcal{V}$ define

$$\|x\| = \sqrt{\langle x, x \rangle}.$$ 

Whenever we refer to a norm on an inner product space, we mean this induced norm unless otherwise specified.

With this notation, the CBS inequality can be rephrased:

$$|\langle x, y \rangle| \leq \|x\| \|y\|$$

for $x, y \in \mathcal{V}$. A useful consequence is:

XV.9.2.4. Proposition. Let $(\mathcal{V}, \langle \cdot, \cdot \rangle)$ be an inner product space, and $x \in \mathcal{V}$. Then

$$\|x\| = \max_{\|y\|=1} |\langle x, y \rangle| = \sup_{\|y\|=1} |\langle x, y \rangle|.$$ 

In particular, if $\langle x, y \rangle = 0$ for all $y$ with $\|y\| = 1$, then $x = 0$.

Proof: We have $\|x\| \geq |\langle x, y \rangle|$ for $\|y\| = 1$ by the CBS inequality, and equality is obtained for $y = \frac{x}{\|x\|}$ if $x \neq 0$ and for any $y$ if $x = 0$.

XV.9.2.5. Proposition. $\| \cdot \|$ is a norm on $\mathcal{V}$.

Proof: It is clear that $\|x\| \geq 0$ for all $x$ and $\|x\| = 0$ if and only if $x = 0$. We have

$$\|\alpha x\| = \sqrt{\langle \alpha x, x \rangle} = \sqrt{\alpha \overline{\alpha} \langle x, x \rangle} = |\alpha| \sqrt{\langle x, x \rangle} = |\alpha| \|x\|$$
for \( x \in \mathcal{V}, \alpha \in \mathbb{F} \) since \(|\alpha| = \sqrt{\alpha \bar{\alpha}}\). For the triangle inequality,
\[
\|x + y\|^2 = \langle x + y, x + y \rangle = \langle x, x \rangle + \langle x, y \rangle + \langle y, x \rangle + \langle y, y \rangle \leq \|x\|^2 + 2\|x\|\|y\| + \|y\|^2 = (\|x\| + \|y\|)^2
\]
for \( x, y \in \mathcal{V} \).

### The Parallelogram Law and Polarization Identity

The norm on an inner product space satisfies the following geometric property:

**XV.9.2.6. Proposition.** [Parallelogram Law] Let \((\mathcal{V}, \langle \cdot , \cdot \rangle)\) be an inner product space (real or complex), and \( x, y \in \mathcal{V} \). Then
\[
\|x + y\|^2 + \|x - y\|^2 = 2(\|x\|^2 + \|y\|^2).
\]

**Proof:**
\[
\|x + y\|^2 + \|x - y\|^2 = \langle x + y, x + y \rangle + \langle x - y, x - y \rangle
\]
\[
= \langle x, x \rangle + \langle x, y \rangle + \langle y, x \rangle + \langle y, y \rangle + \langle x, x \rangle - \langle x, y \rangle - \langle y, x \rangle + \langle y, y \rangle
\]
\[
= 2\langle x, x \rangle + 2\langle y, y \rangle = 2(\|x\|^2 + \|y\|^2).
\]

**XV.9.2.7.** “Most” norms on vector spaces do not satisfy the Parallelogram Law and therefore do not come from inner products. For example, on \( \mathbb{R}^2 \), the norm \( \| \cdot \|_2 \) comes from the standard inner product; but neither \( \| \cdot \|_1 \) or \( \| \cdot \|_\infty \) come from an inner product: since \( \|e_1\|_1 = \|e_2\|_1 = 1 \) but \( \|e_1 + e_2\|_1 = \|e_1 - e_2\|_1 = 2 \), the Parallelogram Law is not satisfied for \( \| \cdot \|_1 \), and similarly for \( \| \cdot \|_\infty \).

In fact, we have a converse to XV.9.2.6, sometimes called the Fréchet-von Neumann-Jordan Theorem:

**XV.9.2.8. Proposition.** [Polarization Identity] (i) Let \( \mathcal{V} \) be a real vector space, and \( \| \cdot \| \) a norm on \( \mathcal{V} \). Then \( \| \cdot \| \) is induced from a (real) inner product if and only if it satisfies the Parallelogram Law, and the inner product giving the norm is unique and satisfies
\[
\langle x, y \rangle = \frac{1}{4} (\|x + y\|^2 - \|x - y\|^2)
\]
for \( x, y \in \mathcal{V} \).

(ii) Let \( \mathcal{V} \) be a complex vector space, and \( \| \cdot \| \) a norm on \( \mathcal{V} \). Then \( \| \cdot \| \) is induced from an inner product if and only if it satisfies the Parallelogram Law, and the inner product giving the norm is unique and satisfies
\[
\langle x, y \rangle = \frac{1}{4} (\|x + y\|^2 - \|x - y\|^2 + i\|x + iy\|^2 - i\|x - iy\|^2)
\]

1783
for $x, y \in \mathcal{V}$.

**Proof:** We write the proof of (ii); the proof of (i) is nearly identical but easier. If the norm comes from an inner product, then a straightforward argument similar to the proof of XV.9.2.6. (Exercise XV.9.10.9.) shows that the inner product satisfies the Polarization Identity and is thus unique. Conversely, if the “inner product” defined by the Polarization Identity is a true inner product, then for $x \in \mathcal{V}$

$$\langle x, x \rangle = \frac{1}{4} \left( \|2x\|^2 - \|0\|^2 + i\|1 + i\|x\|^2 - i\|(1 - i)\|x\|^2 \right) = \|x\|^2$$

since $|1 + i| = |1 - i|$; so the norm it defines is the given one, which therefore satisfies the Parallelogram Law. Thus it suffices to show that if the norm satisfies the Parallelogram Law, the Polarization Identity defines an inner product on $\mathcal{V}$.

So suppose the norm satisfies the Parallelogram Law, and define $\langle \cdot, \cdot \rangle$ by the Polarization Identity. A simple straightforward calculation (not using the Parallelogram Law) shows that $\langle y, x \rangle = \overline{\langle x, y \rangle}$ and $\langle x, iy \rangle = -i \langle x, y \rangle$ for any $x, y \in \mathcal{V}$, and hence $\langle ix, y \rangle = i \langle x, y \rangle$ for $x, y \in \mathcal{V}$. Next, for $x, y, z \in \mathcal{V}$,

$$\|x + y + 2z\|^2 + \|x - y\|^2 = \|(x + z) + (y + z)\|^2 + \|(x + z) - (y + z)\|^2 = 2(\|x + z\|^2 + \|y + z\|^2)$$

by the Parallelogram Law, and similarly

$$\|x + y - 2z\|^2 + \|x - y\|^2 = 2(\|x - z\|^2 + \|y - z\|^2)$$

$$\|x + y + 2iz\|^2 + \|x - y\|^2 = 2(\|x + iz\|^2 + \|y + iz\|^2)$$

$$\|x + y - 2iz\|^2 + \|x - y\|^2 = 2(\|x - iz\|^2 + \|y - iz\|^2)$$

so we have

$$4\langle x + y, 2z \rangle = \|x + y + 2z\|^2 - \|x + y - 2z\|^2 + i\|x + y + 2iz\|^2 - i\|x + y - 2iz\|^2$$

$$= 2\|x + z\|^2 + 2\|y + z\|^2 - 2\|x - z\|^2 - 2\|y - z\|^2 + 2i\|x + iz\|^2 - 2i\||y + iz\|^2 - 2i\|x - iz\|^2 - 2i\|y - iz\|^2$$

$$= 8(\langle x, z \rangle + \langle y, z \rangle)$$

and in the special case $y = 0$,

$$\langle x, 2z \rangle = 2\langle x, z \rangle$$

and therefore, for general $x, y, z$,

$$\langle x + y, z \rangle = \frac{1}{2} \langle x + y, 2z \rangle = \langle x, z \rangle + \langle y, z \rangle$$

and $\langle \cdot, \cdot \rangle$ is additive in each variable. We have also

$$\langle 2x, y \rangle = 2\langle x, y \rangle$$

for any $x, y$ and we get by iteration that

$$\langle \alpha x, y \rangle = \alpha \langle x, y \rangle$$

for all $x, y \in \mathcal{V}$ and every dyadic rational number $\alpha$. Since

$$\langle \alpha x, y \rangle = \frac{1}{4} \left( \|\alpha x + y\|^2 - \|\alpha x - y\|^2 + i\|\alpha x + iy\|^2 - i\|\alpha x - iy\|^2 \right)$$

1784
is clearly a continuous function of $\alpha$ for fixed $x, y$, we have
\[ \langle \alpha x, y \rangle = \alpha \langle x, y \rangle \]
for all $\alpha \in \mathbb{R}$. Since it is also true for $\alpha = i$, it holds for all $\alpha \in \mathbb{C}$ and $\langle \cdot, \cdot \rangle$ is an inner product.  

Thus the norm and inner product completely determine each other. One way of phrasing this is:

**XV.9.2.9. Corollary.** Let $(\mathcal{V}, \langle \cdot, \cdot \rangle)$ and $(\mathcal{W}, \langle \cdot, \cdot \rangle)$ be inner product spaces over the same field, and $T : \mathcal{V} \to \mathcal{W}$ a linear transformation. Then $T$ is an isometry (i.e. $\|Tx\| = \|x\|$ for all $x \in \mathcal{V}$) if and only if $T$ preserves inner products (i.e. $(Tx, Ty) = \langle x, y \rangle$ for all $x, y \in \mathcal{V}$).

**XV.9.2.10. Continuity of the Inner Product**

Let $(\mathcal{V}, \langle \cdot, \cdot \rangle)$ be an inner product space. Then the inner product is **jointly continuous**: if $(x_n)$ and $(y_n)$ are sequences in $\mathcal{V}$, $x, y \in \mathcal{V}$, and $x_n \to x$, $y_n \to y$, then
\[ \langle x_n, y_n \rangle \to \langle x, y \rangle . \]
In particular, the inner product is **separately continuous**:
\[ \langle x_n, y \rangle \to \langle x, y \rangle \text{ and } \langle x, y_n \rangle \to \langle x, y \rangle . \]

**Proof:** We have
\[ |\langle x_n, y_n \rangle - \langle x, y \rangle| \leq |\langle x_n, y_n \rangle - \langle x_n, y \rangle| + |\langle x_n, y \rangle - \langle x, y \rangle| = |(x_n, y_n - y)| + |(x_n - x, y)| \leq \|x_n\|\|y_n - y\| + \|x_n - x\|\|y\| . \]
Since $(x_n)$ converges, it is bounded; hence both terms go to 0 as $n \to \infty$. 

**XV.9.3. Completeness and Hilbert Spaces**

**XV.9.3.1. Definition.** A (complex) **Hilbert space** is a complex inner product space which is complete with respect to the induced norm. A **real Hilbert space** is a real inner product space which is complete with respect to the induced norm. In light of XV.9.2.8., we can also say, by slight abuse of terminology, that a Hilbert space is a Banach space whose norm satisfies the Parallelogram Law.

In this section, the term “Hilbert space” will denote either a real or complex Hilbert space. But in the rest of this volume, the term “Hilbert space,” unless qualified with “real,” will denote a complex Hilbert space. The letter $\mathcal{H}$ will generally be used to denote a Hilbert space.

Note that specification of an inner product (or, equivalently, a norm satisfying the Parallelogram Law) is part of the definition of a Hilbert space. But we will frequently employ the usual abuse of terminology by saying “Let $\mathcal{H}$ be a Hilbert space.”
XV.9.3.2. Examples. (i) \( \mathbb{C}^n \) is a Hilbert space (with respect to the standard inner product) for any \( n \).
\( \mathbb{R}^n \) is a real Hilbert space.

(ii) \( C([a,b]) \) is not a Hilbert space with respect to the inner product of XV.9.1.8.(ii) since it is not complete (Exercise XV.9.10.11.).

(iii) The sequence space \( \ell^2 \) of square-summable sequences of complex numbers is a Hilbert space with respect to the inner product
\[
\langle x, y \rangle = \sum_{k=1}^{\infty} x_k \overline{y_k}
\]
where \( x = (x_1, x_2, \ldots), y = (y_1, y_2, \ldots) \).

(iv) More generally, \( L^2(X, \mathcal{A}, \mu) \), the space of square-integrable functions on a measure space \((X, \mathcal{A}, \mu)\) (or, more precisely, of equivalence classes of square-integrable functions, with functions agreeing almost everywhere identified), with inner product
\[
\langle f, g \rangle = \int_X f \overline{g} \, d\mu
\]
is a Hilbert space. If \( S \) is a set, let \( \mu \) be counting measure on \( S \), and denote \( L^2(S, \mu) \) by \( \ell^2(S) \). Then \( \ell^2 = \ell^2(\mathbb{N}) \).

XV.9.3.3. The definition and basic properties of \( \ell^2 \) were given in 1906 by D. Hilbert, who was the first to describe something approaching the modern notion of a “Hilbert space,” and developed by E. Schmidt, F. Riesz, and others in immediately succeeding years. According to [Jah03, p. 385], the name “Hilbert space” was first used in 1908 by A. Schönflies, apparently to refer to what we today call \( \ell^2 \). The definition of an abstract Hilbert space was, however, not given until 1928 by J. von Neumann [vN30].

Completion of an Inner Product Space

Just as with metric spaces and normed vector spaces, every inner product space can be completed to a Hilbert space:

XV.9.3.4. Theorem. Let \((V, \langle \cdot, \cdot \rangle)\) be a (real or complex) inner product space. Then \( V \) can be isometrically embedded, in a unique way up to isometric isomorphism, as a dense subspace of a (real or complex) Hilbert space, called the completion of \( V \).

Proof: This theorem can be proved directly in the same way as (i) and (ii); see Exercise XV.9.10.13.. But there is a much easier argument using XV.9.2.8.: if \( \mathcal{H} \) is the completion of \( V \) with respect to the induced norm, then the norm on \( \mathcal{H} \) satisfies the Parallelogram Law on a dense subspace, hence by continuity on the whole space. Thus it comes from an inner product which must extend the inner product on \( V \) by Polarization. 

XV.9.3.5. As usual, there is often a concrete realization of the completion of an inner product space: if it can be identified with a subspace of a Hilbert space, the closure of this subspace is the completion.
Pre-Hilbert Spaces

XV.9.3.6. Definition. A pre-Hilbert space is a complex vector space with a pre-inner product.

Real pre-Hilbert spaces can be defined accordingly, but we will stick to the complex case.

Any (complex) inner product space is a pre-Hilbert space. But there are other natural ones. Here is an example of a very common kind:

XV.9.3.7. Example. Let $PC([a; b])$ be the set of piecewise-continuous complex-valued functions on $[a; b]$. Define a sesquilinear form on $PC([a; b])$ by

$$\langle f, g \rangle = \int_a^b f(t) \overline{g(t)} \, dt.$$ 

This is a pre-inner product, but not an inner product: if $f$ is zero except at finitely many points, then $\langle f, f \rangle = 0$, but $f$ is not the zero element of $PC([a; b])$.

XV.9.3.8. Proposition. Let $(\mathcal{V}, \langle \cdot, \cdot \rangle)$ be a pre-Hilbert space. Then

(i) If $\mathcal{N} = \{ x \in \mathcal{V} : \langle x, x \rangle = 0 \}$

then $\mathcal{N}$ is a closed subspace of $\mathcal{V}$.

(ii) The pre-inner product on $\mathcal{V}$ induces an inner product on $\mathcal{V}/\mathcal{N}$ by

$$\langle [x], [y] \rangle = \langle x, y \rangle$$

for $x, y \in \mathcal{V}$.

Proof: This is more or less a special case of (i), and is proved in a similar way.

XV.9.3.9. Example. Let $PC([a; b])$ be as in XV.9.3.7. Then $\mathcal{N}$ consists of all functions which are zero except at finitely many points. If $f$ is piecewise-continuous, the equivalence class $[f]$ of $f$ consists precisely of all (necessarily piecewise-continuous) functions which agree with $f$ except at finitely many points. Let $PC([a; b])$ be the set of equivalence classes of piecewise-continuous functions. Then the pre-inner product of XV.9.3.7. gives a well-defined inner product on $PC([a; b])$. We often think of the elements of $PC([a; b])$ as functions on $[a, b]$, but they are technically equivalence classes of functions; but the distinction can often be overlooked without essential difficulty. We can naturally identify $C([a, b])$ with a (dense) subspace of $PC([a; b])$.

XV.9.3.10. Definition. Let $(\mathcal{V}, \langle \cdot, \cdot \rangle)$ be a pre-Hilbert space. The completion of $\mathcal{V}$ is the Hilbert space obtained by completing $\mathcal{V}/\mathcal{N}$. 1787
XV.9.4. Best Approximation

Hilbert spaces have a nice property not shared by general Banach spaces which is important in applications. If $A$ is a nonempty closed convex set in a Hilbert space $H$ (e.g. a closed subspace), and $x \in H$, then there is a unique vector $y \in A$ which is closest to $x$. This theorem was proved by BEPPO LEVI in 1906 [?].

We use the notation $\langle x; y \rangle = \|x - y\|$, and

$$\rho(x, A) = \inf_{y \in A} \rho(x, y) = \inf_{y \in A} \|x - y\|.$$

XV.9.4.1. Theorem. Let $H$ be a Hilbert space and $A$ a nonempty closed convex subset of $H$. For any $x \in H$, there is a unique $y \in A$ such that

$$\|x - y\| = \rho(x, y) = \rho(x, A) = \inf_{z \in A} \|x - z\| = \min_{z \in A} \|x - z\|.$$

We need a lemma which is an immediate consequence of the Parallelogram Law:

XV.9.4.2. Lemma. Let $A$ be a nonempty convex set in an inner product space $\mathcal{V}$, $x \in \mathcal{V}$, and $\epsilon > 0$. If $y, z \in A$ with $\|x - y\|^2 < \rho(x, A)^2 + \epsilon$ and $\|x - z\|^2 < \rho(x, A)^2 + \epsilon$, then $\|y - z\|^2 < 4\epsilon$.

Proof: Set $w = \frac{1}{2}(y + z)$. Then $w \in A$ since $A$ is convex, so $\|x - w\| \geq \rho(x, A)$. We have

$$x - w + \frac{1}{2}(y - z) = x - z$$

$$x - w - \frac{1}{2}(y - z) = x - y$$

so by the Parallelogram Law

$$\|x - z\|^2 + \|x - y\|^2 = \left\| x - w + \frac{1}{2}(y - z) \right\|^2 + \left\| x - w - \frac{1}{2}(y - z) \right\|^2 = 2 \left( \|x - w\|^2 + \left\| \frac{1}{2}(y - z) \right\|^2 \right)$$

$$\|y - z\|^2 = 2\|x - z\|^2 + 2\|x - y\|^2 - 4\|x - w\|^2 < 2\rho(x, A)^2 + 2\epsilon + 2\rho(x, A)^2 + 2\epsilon - 4\rho(x, A)^2 = 4\epsilon.$$

We now prove Theorem XV.9.4.1..

Proof: Let $(y_n)$ be a sequence in $A$ with $\|x - y_n\| \to \rho(x, A)$. Then Lemma XV.9.4.2. implies that $(y_n)$ is a Cauchy sequence in $\mathcal{H}$. Let $y = \lim y_n$. Then $y \in A$ since $A$ is closed, and

$$\|x - y\| = \lim_{n \to \infty} \|x - y_n\| = \rho(x, A).$$

If $z \in A$ with $\|x - z\| = \rho(x, A)$, then the hypotheses of Lemma XV.9.4.2. are satisfied for every $\epsilon > 0$, and we conclude $y = z$. 

1788
XV.9.4.3. Lemma XV.9.4.2. really says that an inner product space is uniformly convex (XV.9.10.16.). The argument above shows that the closest approximation theorem holds in any uniformly convex Banach space.

XV.9.4.4. Examples. (i) The closest approximation result does not hold in general Banach spaces. In \((\mathbb{R}^2, \| \cdot \|_\infty)\), if \(A\) is the closed unit ball and \(x = (2, 0)\), then there is a closest vector in \(A\) to \(x\) (there must be since \(A\) is compact), but it is not unique; in fact, any vector \((1, y)\) with \(|y| \leq 1\) is a closest approximation to \(x\) in \(A\).

(ii) The proof of XV.9.4.1. uses completeness. The result fails in general in an inner product space which is not complete. For example, let \(V = C([0, 1])\) with the standard inner product, and let \(A = \{ f \in C([0, 1]) : \int_0^{1/2} f(t) \, dt - \int_{1/2}^1 f(t) \, dt = 1 \} \). Then it is easily checked that \(A\) is a closed convex set in \(V\). But there is no closest vector to 0 (vector of minimum norm) in \(A\): \(\rho(0, A) = 1\), but there is no \(f\) in \(A\) of norm 1. (In the completion, the unique closest vector in \(A\) to 0 is the function which is 1 on \([0, \frac{1}{2})\) and \(-1\) on \((\frac{1}{2}, 1]\).)

XV.9.5. Orthogonality

Hilbert spaces have a geometric structure similar to that of Euclidean space. The most important geometric notion is orthogonality:

XV.9.5.1. Definition. Let \((V, \langle \cdot, \cdot \rangle)\) be an inner product space over \(F = \mathbb{R}\) or \(\mathbb{C}\). If \(x, y \in V\), then \(x\) and \(y\) are orthogonal (with respect to \(\langle \cdot, \cdot \rangle\)), written \(x \perp y\), if \(\langle x, y \rangle = 0\).

XV.9.5.2. The geometric term perpendicular is sometimes used as a synonym for orthogonal. But in functional analysis we prefer to use orthogonal, especially for complex inner product spaces. Note that in a complex inner product space, “perpendicular” and “orthogonal” do not quite have the same meaning: for example, in the one-dimensional (complex) Hilbert space \(\mathbb{C}^1\) with standard inner product, the vectors 1 and \(i\) are “perpendicular” but not orthogonal.

We have \(0 \perp y\) for every \(y\). Conversely, we have a useful rephrasing of the simple result XV.9.2.4.:

XV.9.5.3. Proposition. Let \((V, \langle \cdot, \cdot \rangle)\) be an inner product space, and \(x \in V\). Then \(x \perp y\) for all \(y \in V\) if and only if \(x = 0\).

Orthogonal Complement

XV.9.5.4. Definition. Let \((V, \langle \cdot, \cdot \rangle)\) be an inner product space, and \(S \subseteq V\). The orthogonal complement of \(S\) (in \(V\)) is \(S^\perp = \{ x \in V : \langle x, y \rangle = 0 \text{ for all } y \in S\} \).
\( S^\perp \) is a closed subspace of \( V \) (whether or not \( S \) is a subspace; in fact, \( S^\perp = (\text{span}(S))^\perp \)).

The next norm relation is fundamental.

**XV.9.5.5. Proposition.** [Pythagorean Theorem] Let \( V \) be an inner product space, and \( x, y \in V \) with \( x \perp y \). Then
\[
\|x + y\|^2 = \|x\|^2 + \|y\|^2.
\]

**Proof:** Expand \( \langle x + y, x + y \rangle \).

The converse is true in a real inner product space, but not a complex one (take 1 and \( i \) in \( \mathbb{C} \)). But there is a partial converse:

**XV.9.5.6. Proposition.** Let \( V \) be an inner product space over \( \mathbb{F} \), and \( x, y \in V \). The following are equivalent:

(i) \( x \perp y \).

(ii) \( \|x + \alpha y\|^2 = \|x\|^2 + |\alpha|^2 \|y\|^2 \) for all \( \alpha \in \mathbb{F} \).

(iii) \( \|x + \alpha y\| \geq \|x\| \) for all \( \alpha \in \mathbb{F} \).

**Proof:** (i) \( \Rightarrow \) (ii) is XV.9.5.5., and (ii) \( \Rightarrow \) (iii) is trivial. For (iii) \( \Rightarrow \) (i), we may assume \( y \neq 0 \). Set
\[
\alpha = -\frac{\langle x, y \rangle}{\langle y, y \rangle}
\]
and then a calculation as in the proof of XV.9.2.1. shows that
\[
\|x + \alpha y\|^2 = \|x\|^2 - \frac{|\langle x, y \rangle|^2}{\|y\|^2}
\]
which is only \( \geq \|x\|^2 \) if \( \langle x, y \rangle = 0 \).

If \( \mathcal{H} \) is a Hilbert space, \( \mathcal{Y} \) is a closed subspace of \( \mathcal{H} \), and \( x \in \mathcal{H} \), then there is a closest vector \( y \in \mathcal{Y} \) to \( X \). It turns out that \( z = x - y \in \mathcal{Y}^\perp \):

**XV.9.5.7. Proposition.** Let \( \mathcal{H} \) be a Hilbert space, and \( \mathcal{Y} \) a closed subspace of \( \mathcal{H} \). Then every \( x \in \mathcal{H} \) can be uniquely written as \( y + z \), where \( y \in \mathcal{Y} \) and \( z \in \mathcal{Y}^\perp \). The \( y \) is the closest vector in \( \mathcal{Y} \) to \( x \).

**Proof:** By XV.9.4.1. there is a (unique) closest vector \( y \in \mathcal{Y} \) to \( x \). Set \( z = x - y \). Let \( w \in \mathcal{Y} \). Then, for any \( \alpha \in \mathbb{C} \),
\[
\|z + \alpha w\| = \|x - (y - \alpha w)\| \geq \|x - y\| = \|z\|
\]
since \( y - \alpha w \in \mathcal{Y} \). Thus \( z \perp w \) by XV.9.5.6.. If also \( x = y' + z' \) with \( y' \in \mathcal{Y} \), \( z' \in \mathcal{Y}^\perp \), we have \( y + z - y' - z' = 0 \), so
\[
y - y' = z' - z \in \mathcal{Y} \cap \mathcal{Y}^\perp = \{0\}
\]
and \( y = y' \), \( z = z' \).

1790
XV.9.5.8. **Example.** Completeness is essential in XV.9.5.7. As a slight variation of Example XV.9.4.4., let

\[\mathcal{V} = \left\{ f \in C([0,1]) : \int_0^{1/2} f(t) \, dt - \int_{1/2}^1 f(t) \, dt = 0 \right\}.\]

Then \(\mathcal{V}\) is a closed subspace of \(C([0,1])\) (with respect to the norm induced by the standard inner product). But if \(f\) is the constant function 1, there is no decomposition \(f = g + h\) with \(g \in \mathcal{V}\) and \(h \in \mathcal{V}^\perp\). In fact, \(\mathcal{V}^\perp = \{0\}\) in \(C([0,1])\) even though \(\mathcal{V}\) is a proper subspace of \(C([0,1])\).

XV.9.5.9. If \(\mathcal{V}\) is an inner product space and \(S \subseteq \mathcal{V}\), then \(S^\perp\) is a closed subspace of \(\mathcal{V}\) containing \(S\). If \(\mathcal{V}\) is complete, then \(S^\perp\) is the smallest closed subspace containing \(S\):

**Proposition.** Let \(\mathcal{H}\) be a Hilbert space and \(S \subseteq \mathcal{H}\). Then \(S^\perp\) is the closed linear span of \(S\).

**Proof:** Let \(\mathcal{V}\) be the closed linear span of \(S\), i.e. the closure of \(\text{span}(S)\). Then \(\mathcal{V} \subseteq S^\perp\), and \(\mathcal{V}^\perp = S^\perp\). If \(x \in S^\perp\), then \(x = y + z\) with \(y \in \mathcal{V}\) and \(z \in \mathcal{V}^\perp\). But since \(x, y \in S^\perp\), \(z = x - y \in S^\perp = \mathcal{V}^\perp\). Thus \(z \in \mathcal{V}^\perp \cap \mathcal{V}^\perp = \{0\}\) so \(x = y \in \mathcal{V}\), i.e. \(\mathcal{V} = S^\perp\).

XV.9.5.11. **Corollary.** Let \(\mathcal{H}\) be a Hilbert space and \(\mathcal{V}\) a closed subspace. Then \(\mathcal{V} = \mathcal{V}^\perp\). In particular, \(\mathcal{V} = \mathcal{H}\) if and only if \(\mathcal{V}^\perp = \{0\}\), so if \(\mathcal{S} \subseteq \mathcal{H}\), then the closed linear span of \(S\) is \(\mathcal{S}\) if and only if \(S^\perp = \{0\}\).

This result can fail if the space is not complete (Example XV.9.5.8.).

**Orthonormal Sets**

XV.9.5.12. **Definition.** A set \(\{e_j : j \in J\}\) of vectors in an inner product space is orthonormal if \(\langle e_j, e_k \rangle = \delta_{jk}\) for all \(j, k \in J\), i.e. it is a mutually orthogonal set of unit vectors.

Of course, any subset of an orthonormal set is orthonormal. A set is orthonormal if and only if every finite subset (in fact, every two-element subset) is orthonormal.

XV.9.5.13. **Proposition.** An orthonormal set in an inner product space is linearly independent.

**Proof:** Suppose \(S = \{e_j : j \in J\}\) is an orthonormal set, and suppose

\[\alpha_1 e_{j_1} + \cdots + \alpha_n e_{j_n} = 0\]

for some \(j_1, \ldots, j_n\) and scalars \(\alpha_1, \ldots, \alpha_n\). Then for \(1 \leq m \leq n\)

\[0 = \langle \alpha_1 e_{j_1} + \cdots + \alpha_n e_{j_n}, e_{j_m} \rangle = \sum_{r=1}^n \alpha_r \langle e_{j_r}, e_{j_m} \rangle = \alpha_m\]

1791
so $S$ is linearly independent.

Orthonormal sets are very nice to work with. If $S$ is an orthonormal set, then it is easy to see how to explicitly write any vector in $\text{span}(S)$ as a convex combination of the vectors in $S$:

**XV.9.5.14. Proposition.** Let $S = \{e_1, \ldots, e_n\}$ be a finite orthonormal set in an inner product space, and $x \in \text{span}(S)$. Then the unique representation of $x$ as a linear combination of $\{e_1, \ldots, e_n\}$ is

$$x = \sum_{k=1}^{n} (x, e_k)e_k.$$  

We also have

$$\|x\|^2 = \sum_{k=1}^{n} |(x, e_k)|^2.$$  

**Proof:** Suppose

$$x = \sum_{k=1}^{n} \alpha_k e_k$$

is the unique expression of $x$ as a linear combination of $S$, then, for each $j$,

$$(x, e_j) = \sum_{k=1}^{n} \alpha_k (e_k, e_j) = \alpha_j.$$

The number $(x, e_j)$ is often called the *Fourier coefficient* of $x$ with respect to $e_j$ (cf. (1)).

This finite result has an important generalization to infinite orthonormal sets:

**XV.9.5.15. Theorem.** Let $S = \{e_j : j \in J\}$ be an orthonormal set in an inner product space $\mathcal{V}$, and $\mathcal{Y}$ the closed linear span of $S$ in $\mathcal{V}$. Then, for any $y \in \mathcal{Y}$:

(i) The sum

$$\sum_{j \in J} \langle y, e_j \rangle e_j$$

converges unconditionally to $y$ in $\mathcal{V}$, i.e. the net of finite subsums converges to $y$.

(ii) The unordered sum

$$\sum_{j \in J} |\langle y, e_j \rangle|^2$$

converges (absolutely) to $\|y\|^2$, i.e. the net of finite subsums converges to $\|y\|^2$.  

1792
Proof: Let $F = \{e_{j_1}, \ldots, e_{j_n}\}$ be a finite subset of $S$, and set

$$y_F = \sum_{k=1}^{n} \langle y, e_{j_k} \rangle e_{j_k}$$

and $z_F = y - y_F$. We have that $y_F \in \text{span}(F)$, and that

$$\langle z_F, e_{j_m} \rangle = \langle y, e_{j_m} \rangle - \langle y_F, e_{j_m} \rangle = 0$$

for $1 \leq m \leq n$; thus $z_F \in (\text{span}(F))^\perp$. So we have

$$\|y\|^2 = \|y_F\|^2 + \|z_F\|^2 \geq \|y_F\|^2 = \sum_{k=1}^{n} |\langle y, e_{j_k} \rangle|^2.$$  

Thus the sum in (ii) converges, and is $\leq \|y\|^2$.

On the other hand, if $\epsilon > 0$ there is an $x \in \text{span}(S)$ with $\|x - y\| < \epsilon$. We have $x \in \text{span}(E)$ for some finite subset $E$ of $S$. If $F = \{e_{j_1}, \ldots, e_{j_n}\}$ is a finite subset of of $S$ containing $E$, then

$$\|y - y_F\| \leq \|y - x\|$$

since $y_F$ is the closest vector in $\text{span}(F)$ to $y$. Thus

$$\left\| y - \sum_{k=1}^{n} \langle y, e_{j_k} \rangle e_{j_k} \right\| < \epsilon$$

and the finite subsums in (i) converge to $y$. Also,

$$\sum_{k=1}^{n} |\langle y, e_{j_k} \rangle|^2 = \|y_F\|^2 \geq (\|y\| - \|y - y_F\|)^2 \geq (\|y\| - \epsilon)^2$$

which can be made arbitrarily close to $\|y\|^2$ by choosing $\epsilon$ sufficiently small. Thus the sum in (ii) converges to $\|y\|^2$. 

\[\Box\]

XV.9.5.16. Corollary. Let $\mathcal{H}$ be a Hilbert space, $S = \{e_j : j \in J\}$ an orthonormal set in $\mathcal{H}$, and $x \in \mathcal{H}$. Then

$$\sum_{j \in J} |\langle x, e_j \rangle|^2 \leq \|x\|^2$$

(Bessel's inequality). In particular, $\langle x, e_j \rangle \neq 0$ for only countably many $j$. We have

$$\sum_{j \in J} |\langle x, e_j \rangle|^2 = \|x\|^2$$

(Parseval's relation) if and only if $x$ is in the closed linear span of $S$.

Proof: Let $\mathcal{Y}$ be the closed linear span of $S$, and write $x = y + z$ with $y \in \mathcal{Y}$, $z \in \mathcal{Y}^\perp$. Then

$$\|x\|^2 = \|y\|^2 + \|z\|^2 \geq \|y\|^2 = \sum_{j \in J} |\langle y, e_j \rangle|^2 = \sum_{j \in J} |\langle x, e_j \rangle|^2$$

with equality if and only if $z = 0$. 

\[\Box\]
Orthonormal Bases

The next result is a combination of parts of XV.9.5.11. and XV.9.5.15:

**Corollary.** Let \( \mathcal{H} \) be a Hilbert space, and \( S = \{ e_j : j \in J \} \) an orthonormal set in \( \mathcal{H} \). The following are equivalent:

(i) \( S \) is a maximal orthonormal set (not contained in any strictly larger orthonormal set).

(ii) \( S^\perp = \{ 0 \} \).

(iii) The closed linear span of \( S \) is \( \mathcal{H} \).

(iv) For every \( x \in \mathcal{H} \), there is a unique unordered sum

\[
\sum_{j \in J} \alpha_j e_j
\]

which converges to \( x \). We necessarily have that the unordered sum

\[
\sum_{j \in J} |\alpha_j|^2
\]

converges to \( \|x\|^2 \), and \( \alpha_j = \langle x, e_j \rangle \).

**Proof:** For the equivalence of (i) and (ii), note that if \( S' \) is an orthonormal set containing \( S \), then \( S' \setminus S \subseteq S^\perp \). Conversely, if \( S^\perp \neq \{ 0 \} \), let \( x \) be a unit vector in \( S^\perp \); then \( S \cup \{ x \} \) is an orthonormal set strictly larger than \( S \).

For the uniqueness in (iv), suppose the unordered sum \( \sum_j \alpha_j e_j \) converges to \( x \). Then, by linearity and continuity of the inner product, we have, for each \( k \),

\[
\langle x, e_k \rangle = \lim_{F \subseteq S} \sum_{j \in F} \langle \alpha_j e_j, e_k \rangle = \alpha_k
\]

where the limit is over the net of finite subsets \( F \) of \( S \).

---

**Definition.** If \( \mathcal{H} \) is a Hilbert space, an **orthonormal basis** for \( \mathcal{H} \) is an orthonormal set \( S \) in \( \mathcal{H} \) satisfying the equivalent conditions of XV.9.5.17.

An orthonormal basis is linearly independent (XV.9.5.13.). If \( \mathcal{H} \) is finite-dimensional, then an orthonormal basis for \( \mathcal{H} \) is finite, hence a Hamel basis. But an orthonormal basis for an infinite-dimensional Hilbert space is not a Hamel basis. For example, if \( \{ e_{j_1}, e_{j_2}, \ldots \} \) is a sequence of distinct elements of an orthonormal basis for \( \mathcal{H} \), then the series

\[
\sum_{n=1}^{\infty} \frac{1}{n} e_{j_n}
\]

converges in \( \mathcal{H} \) to a vector which cannot be written as a finite linear combination of the \( e_j \) by the uniqueness in XV.9.5.17.. A countable orthonormal basis for a Hilbert space is an unconditional Schauder basis ( ).
As with Hamel bases in vector spaces, there is nothing remotely unique about orthonormal bases for Hilbert spaces. For example, any two perpendicular unit vectors in $\mathbb{R}^2$ form an orthonormal basis for $\mathbb{R}^2$ or $\mathbb{C}^2$ (with respect to the usual inner product). $\mathbb{C}^2$ has many other orthonormal bases not contained in the subset $\mathbb{R}^2$.

If $\mathcal{H}$ is a complex Hilbert space, whether an orthonormal set is an orthonormal basis depends whether $\mathcal{H}$ is regarded as a complex Hilbert space or as a real Hilbert space with inner product $(\cdot,\cdot) = \text{Re}(\langle \cdot , \cdot \rangle)$. If $B$ is an orthonormal basis for $\mathcal{H}$ as a complex Hilbert space, it is an orthonormal set, but not an orthonormal basis, for $\mathcal{H}$ as a real Hilbert space; the set

$$B \cup iB = \{ e, ie : e \in B \}$$

is an orthonormal basis for $\mathcal{H}$ as a real Hilbert space.

We have a companion result slightly generalizing XV.9.5.17., which is an immediate corollary of XV.9.5.17., the continuity of the inner product, and the CBS inequality:

**Corollary.** Let $\mathcal{H}$ be a Hilbert space, and $\{ e_j : j \in J \}$ an orthonormal basis for $\mathcal{H}$. Let $x, y \in \mathcal{H}$. Write

$$x = \sum_{j \in J} \alpha_j e_j, \quad y = \sum_{j \in J} \beta_j e_j$$

as in XV.9.5.17.. Then the unordered sum

$$\sum_{j \in J} \alpha_j \overline{\beta_j}$$

converges absolutely to $\langle x, y \rangle$.

The next theorem is the main theoretical result about orthonormal bases:

**Theorem.** Let $\mathcal{H}$ be a Hilbert space. Then

(i) $\mathcal{H}$ has an orthonormal basis.

(ii) Every orthonormal set in $\mathcal{H}$ is contained in an orthonormal basis.

(iii) Any two orthonormal bases for $\mathcal{H}$ have the same cardinality.

**Proof:** The proof of (i) is a prototype Zorn’s Lemma argument (using the characterization of an orthonormal basis as a maximal orthonormal set), similar to the proof in III.11.2.32. (but easier), and is left to the reader. Part (ii) can be proved in a similar way: if $S$ is an orthonormal set in $\mathcal{H}$, consider only orthonormal sets containing $S$. Alternately, let $\mathcal{V}$ be the closed linear span of $S$. Then $\mathcal{V}^\perp$ is a closed subspace of $\mathcal{H}$ and thus itself a Hilbert space, so has an orthonormal basis $B'$. Then $B = S \cup B'$ is an orthonormal basis for $\mathcal{H}$ containing $S$.

To prove (iii), first note that if $\mathcal{H}$ has a finite orthonormal basis $B$ with $n$ elements, then $B$ is a Hamel basis for $\mathcal{H}$ and thus $\mathcal{H}$ is an $n$-dimensional vector space. Thus any other orthonormal basis for $\mathcal{H}$ also has exactly $n$ elements. Now assume that one (hence every) orthonormal basis for $\mathcal{H}$ is infinite. Let $\{ e_j : j \in J \}$ be an orthonormal basis for $\mathcal{H}$ of cardinality $\lambda$, and $\{ f_k : k \in K \}$ another orthonormal basis for $\mathcal{H}$ of cardinality $\kappa$. Then each $e_j$ is in the closed linear span of countably many $f_k$ ( ). Every $f_k$ occurs in one of
these, since otherwise $e_j \in \{f_k\}$ for all $j$. Thus $K$ is a union of $\lambda$ countable sets, so $\kappa \leq \aleph_0 \cdot \lambda$. Similarly, $\lambda \leq \aleph_0 \cdot \kappa$. Since $\lambda$ and $\kappa$ are infinite, $\lambda = \kappa$ (II.9.7.4.).

Note that the AC is needed for this proof; in fact, (i) and (ii) may be equivalent to the AC. (The full AC is not needed for (iii), but some weaker form is (II.9.7.4.).)

**XV.9.5.23. Definition.** Let $\mathcal{H}$ be a Hilbert space over $\mathbb{F}$ ($\mathbb{R}$ or $\mathbb{C}$). The **orthogonal dimension** (or **Hilbert dimension**) of $\mathcal{H}$ (over $\mathbb{F}$) is the cardinality of some (hence every) orthonormal basis for $\mathcal{H}$.

**XV.9.5.24.** The orthogonal dimension of $\mathcal{H}$ is finite if and only if $\mathcal{H}$ is a finite-dimensional vector space, in which case the orthogonal dimension is the same as the vector space dimension. The two dimensions do not coincide for infinite-dimensional Hilbert spaces in general ('). We usually only consider the orthogonal dimension for a Hilbert space $\mathcal{H}$; it is often just called the **dimension** of $\mathcal{H}$ and denoted $\dim(\mathcal{H})$.

The orthogonal dimension of a finite-dimensional complex Hilbert space changes (is multiplied by 2) if it is regarded as a real Hilbert space with inner product $(\cdot, \cdot) = \text{Re}(\langle \cdot, \cdot \rangle)$. The orthogonal dimension of an infinite-dimensional complex Hilbert space does not change if it is regarded as a real Hilbert space (since $2\kappa = \kappa$ for any infinite cardinal $\kappa$).

The orthogonal dimension classifies Hilbert spaces up to isometric isomorphism; thus the orthogonal dimension is the only isomorphism invariant for Hilbert spaces:

**XV.9.5.25. Theorem.** Let $\mathcal{H}$ and $\mathcal{H}'$ be Hilbert spaces over $\mathbb{F}$. Then $\mathcal{H}$ and $\mathcal{H}'$ are isometrically isomorphic (over $\mathbb{F}$) if and only if they have the same orthogonal dimension. More precisely, if $B = \{e_j : j \in J\}$ is an orthonormal basis for $\mathcal{H}$ and $B' = \{f_j : j \in J\}$ is an orthonormal basis for $\mathcal{H}'$, the map $e_j \mapsto f_j$ extends to a unique isometric isomorphism $T : \mathcal{H} \to \mathcal{H}'$.

**Proof:** It is obvious from the uniqueness of orthogonal dimension that Hilbert spaces of different orthogonal dimensions cannot be isometrically isomorphic. So we need only prove the last statement. The map $T_0 : \text{span}(B) \to \text{span}(B')$ defined by

$$T_0 \left( \sum_{j \in F} \alpha_j e_j \right) = \sum_{j \in F} \alpha_j f_j$$

(where $F$ is an arbitrary finite subset of $J$) is a well-defined linear map since $B$ is linearly independent. $T_0$ is an isometry by XV.9.5.14.. Thus $T_0$ extends uniquely to an isometric linear isomorphism $T$ from $\mathcal{H}$ onto $\mathcal{H}'$. The extension satisfies

$$T \left( \sum_{j \in J} \alpha_j e_j \right) = \sum_{j \in J} \alpha_j f_j$$

by continuity (cf. XV.9.5.17.).

Although the AC is not used in this proof, this theorem depends on the AC since we must know that $\mathcal{H}$ and $\mathcal{H}'$ have orthonormal bases. But if they are particular Hilbert spaces for which we know the existence of orthonormal bases of the same cardinality without using the AC (e.g. XV.9.5.29.), then the isomorphism also does not depend on the AC.
XV.9.5.26. For each cardinal \( \kappa \), there is a Hilbert space whose orthogonal dimension is \( \kappa \), namely \( \ell^2(X) \) for a set \( X \) of cardinality \( \kappa \) (indicator functions of singleton subsets of \( X \) form an orthonormal basis of cardinality \( \kappa \)). Thus (assuming AC) there is a precise classification of Hilbert spaces up to isometric isomorphism: there is exactly one for each cardinal. (There is, of course, a separate classification for real Hilbert spaces and complex Hilbert spaces.) This classification is analogous to, but not exactly the same as, the classification up to isomorphism of vector spaces over a fixed field by their dimension.

Separable Hilbert spaces

XV.9.5.27. Proposition. Let \( \mathcal{H} \) be a Hilbert space. Then \( \mathcal{H} \) is separable if and only if its orthogonal dimension is countable.

Proof: If \( \mathcal{H} \) has a countable orthonormal basis, then it is the closed linear span of a countable set and thus separable. Conversely, any orthonormal basis for a Hilbert space is discrete in the relative topology (the distance between any two orthogonal unit vectors is \( \sqrt{2} \)), and a separable metric space cannot have an uncountable discrete subset.

This proof depends on the existence of orthonormal bases and thus on the AC. But we will give a constructive proof that every separable Hilbert space has a (countable) orthonormal basis without using even the countable AC; thus this result does not depend on any form of Choice.

XV.9.5.28. Suppose \( \mathcal{H} \) is a separable Hilbert space. Fix a countable dense (or just total) set in \( \mathcal{H} \) and arrange it into a sequence \( (x_n) \). We will describe an explicit inductive procedure to manufacture an orthonormal basis out of the \( x_n \), called the Gram-Schmidt orthogonalization procedure.

To avoid annoying notational problems, we will first go through the sequence \( (x_n) \) to discard any \( x_n \) which is a linear combination of the previous ones. Reindexing, we may thus assume the \( x_n \) are linearly independent.

In particular, \( x_1 \neq 0 \). Set \( e_1 = \frac{x_1}{\|x_1\|} \). Then \( e_1 \) is a unit vector spanning the same one-dimensional subspace as \( x_1 \).

Now set \( y_2 = x_2 - \langle x_2, e_1 \rangle e_1 \). Then \( y_2 \neq 0 \) since \( \{x_1, x_2\} \) is linearly independent and hence \( \{e_1, x_2\} \) is linearly independent, and
\[
\langle y_2, e_1 \rangle = \langle x_2, e_1 \rangle - \langle x_2, e_1 \rangle \langle e_1, e_1 \rangle = 0
\]
So \( y_2 \perp e_1 \). Set \( e_2 = \frac{y_2}{\|y_2\|} \). Then \( e_2 \) is a unit vector orthogonal to \( e_1 \), and span\( (\{e_1, e_2\}) = \text{span}(\{x_1, x_2\}) \).

Continue in this manner, i.e.
\[
y_3 = x_3 - \langle x_3, e_1 \rangle e_1 - \langle x_3, e_2 \rangle e_2
\]
is a nonzero vector orthogonal to \( e_1 \) and \( e_2 \) (it is just the component of \( x_3 \) in the orthogonal complement of \( \text{span}(\{x_1, x_2\}) \) in \( \text{span}(\{x_1, x_2, x_3\}) \)), and if \( e_3 = \frac{y_3}{\|y_3\|} \), then \( \{e_1, e_2, e_3\} \) is an orthonormal set with the same span as \( \{x_1, x_2, x_3\} \). In this way we generate an orthonormal sequence \( (e_n) \), with
\[
\text{span}(\{e_1, \ldots, e_n\}) = \text{span}(\{x_1, \ldots, x_n\})
\]
for all \( n \). Since the sequence \( (x_n) \) is total in \( \mathcal{H} \), so is the sequence \( (e_n) \), i.e. \( \{e_n : n \in \mathbb{N}\} \) is an orthonormal basis for \( \mathcal{H} \).

The result is important enough that we state it as a theorem:

1797
XV.9.5.29. **Theorem.** [Gram-Schmidt] Let $H$ be a separable Hilbert space, and $S$ a countable total subset of $H$. Then there is a countable orthonormal basis $B$ for $H$ with $\text{span}(B) = \text{span}(S)$. The orthonormal basis $B$ is constructed from $S$ by an explicit algorithm.

XV.9.5.30. Several things to note about this process:

(i) The orthonormal basis obtained depends not only on the $x_n$, but on the order in which they are taken. Even in a two-dimensional Hilbert space the orthonormal basis is quite different in general if the order of the original vectors is changed. The reader unfamiliar with the Gram-Schmidt procedure should try some two- and three-dimensional examples to understand the process.

(ii) Nowhere in the procedure did we use that $H$ is complete. Thus the process works equally well in any separable inner product space, i.e. any dense subspace of a separable Hilbert space. The conclusion is that every dense subspace of a separable Hilbert space $H$ contains an orthonormal basis for $H$. This is useful when $H$ contains a dense subspace of nice concrete elements; cf. XV.9.5.33.

(iii) No form of Choice is used in the Gram-Schmidt process.

We thus obtain the following result without any form of AC:

XV.9.5.31. **Corollary.** Two separable Hilbert spaces over $\mathbb{F}$ are isometrically isomorphic (over $\mathbb{F}$) if and only if they have the same orthogonal dimension (over $\mathbb{F}$), which is in $\mathbb{N}_0 \cup \{ \aleph_0 \}$. Any separable infinite-dimensional Hilbert space (over $\mathbb{F}$) is isometrically isomorphic (over $\mathbb{F}$) to $\ell^2$; hence any two separable infinite-dimensional Hilbert spaces (over $\mathbb{F}$) are isometrically isomorphic (over $\mathbb{F}$).

XV.9.5.32. Topologists generally use the term “Hilbert space” to denote the unique separable infinite-dimensional Hilbert space (i.e. $\ell^2$), regarded either as a metric space or as a topological space (where it is homeomorphic to $\mathbb{R}^\infty$ with the product topology ($\_\_\_\_\_$), although there is no linear homeomorphism). Thus to a topologist there is only one “Hilbert space” (up to isometry), but to an analyst there are many.

XV.9.5.33. **Example.** [Legendre Polynomials] Let $H = L^2([-1, 1])$ (we can take this simply to be the completion of $C([-1, 1])$, $PC([-1, 1])$, or $R([-1, 1])$; cf. ($\_\_\_\_$), and we can work over either $\mathbb{R}$ or $\mathbb{C}$). The algebra $P$ of polynomials is uniformly dense in $C([-1, 1])$ by the Stone-Weierstrass Theorem ($\_\_\_\_$); since the uniform topology is stronger than the topology defined by the standard inner product

$$
\langle f, g \rangle = \int_{-1}^{1} f(t)g(t) \, dt
$$

we have that $P$ is dense in $L^2([-1, 1])$. Thus, if we take $f_n(t) = t^n$, then the sequence $(f_n)$ ($n \geq 0$) is total in $L^2([-1, 1])$.

We make an orthonormal basis for $L^2([-1, 1])$ by the Gram-Schmidt procedure. Since $\|f_0\| = \sqrt{2}$, $e_0$ is the constant function $\frac{1}{\sqrt{2}}$. We have that

$$
g_1 := f_1 - \langle f_1, e_0 \rangle e_0 = t - \frac{1}{\sqrt{2}} \int_{-1}^{1} t \frac{1}{\sqrt{2}} \, dt = f_1
$$

1798
(actually $f_1 \perp e_0$, so $e_1$ is just a unit vector in the direction of $f_1$). Since

$$
\|g_1\| = \|f_1\| = \left[ \int_{-1}^{1} |t|^2 \, dt \right]^{1/2} = \sqrt{\frac{2}{3}}
$$

we have that $e_1(t) = \sqrt{\frac{2}{3}} t$.

Continuing in this manner, we obtain

$$
e_n(t) = \sqrt{\frac{2n+1}{2}} p_n(t)
$$

where

$$
p_n(t) = \frac{1}{2^n n!} \frac{d^n}{dt^n} [(t^2 - 1)^n]
$$

is the $n$'th Legendre polynomial (this expression is called Rodrigues’s formula). The constants are chosen so that $p_n(1) = 1$ for all $n$. The polynomial $p_n$ is the solution to the Legendre differential equation

$$(1-t^2)y'' - 2ty' + n(n+1)y = 0$$

with $y(1) = 1$. See e.g. [?, 3.7] for details, and for more examples of orthonormal bases of function spaces constructed by the Gram-Schmidt procedure.

Note that, as expected, we obtain an orthonormal basis for $L^2([-1, 1])$ consisting of polynomials.

**XV.9.5.34.** The statement (XV.9.5.30.(ii)) that a dense subspace of a Hilbert space $H$ contains an orthonormal basis for $H$ can be false if $H$ is nonseparable. In fact, a Hilbert space of orthogonal dimension $2^{\aleph_0}$ has a dense subspace which does not contain any uncountable orthonormal set [Dix53].

**A Crinkled Curve**

“There’s a lot of room in Hilbert space.”

*Traditional*

**XV.9.5.35.** In an infinite-dimensional Hilbert space, even a separable one, there are continuous arcs which are “crinkled” in a way impossible in a finite-dimensional Euclidean space: curves which make a right-angled turn at every point. Such a curve cannot be differentiable anywhere in any reasonable sense.

**XV.9.5.36.** Example. In $L^2([0, 1])$ (we can avoid involving measure theory by working in the dense subspace $PC([0, 1])$, cf. ()), for $0 \leq t \leq 1$ let $f_t = \chi_{[0,t]}$, the indicator function of the subinterval $[0, t]$. It is easy to check that $t \mapsto f_t$ is a one-to-one continuous function from $[0, 1]$ into $L^2([0, 1])$. If $0 \leq a < b < c \leq 1$, then the chord $f_b - f_a$ from $f_a$ to $f_b$ is orthogonal to the chord $f_c - f_b$ from $f_b$ to $f_c$. Thus any two consecutive chords (or indeed any two nonoverlapping chords) are orthogonal!
XV.9.6. Projections

The theory of subspaces and orthogonal complements in a Hilbert space has a nice alternate description in terms of orthogonal projection operators (projections).

XV.9.6.1. Definition. Let $H$ be a Hilbert space, and $Y$ a closed subspace. For any vector $x \in H$, write $x = y + z$ with $y \in Y$ and $z \in Y^\perp$, and define $P_Y(x)$ to be $y$. Then $P_Y$ is a function from $H$ to $H$, with range $Y$. $P_Y$ is called the orthogonal projection operator, or just projection, of $H$ onto $Y$.

Note that $P_Y(x)$ is well defined by the uniqueness of the decomposition $x = y + z$ (XV.9.5.7.). We have $P_{\{0\}} = 0$ and $P_H = I$.

XV.9.6.2. Proposition. Let $H$ be a Hilbert space, and $Y$ a closed subspace. Then $P_Y$ is a bounded linear operator on $H$ with operator norm $\|P_Y\| = 1$ (unless $Y = \{0\}$), and $N(P_Y) = Y^\perp$.

Proof: If $x_1, x_2 \in H$, and $x_1 = y_1 + z_1$, $x_2 = y_2 + z_2$ with $y_j \in Y$, $z_j \in Y^\perp$, then $x_1 + x_2 = (y_1 + y_2) + (z_1 + z_2)$ must be the unique decomposition for $x_1 + x_2$, and thus

$$P_Y(x_1 + x_2) = y_1 + y_2 = P_Y(x_1) + P_Y(x_2).$$

Similarly, if $x \in H$ and $\alpha \in \mathbb{F}$, and $x = y + z$ is the decomposition of $x$, then $\alpha x = \alpha y + \alpha z$ is the decomposition of $\alpha x$, and thus

$$P_Y(\alpha x) = \alpha y = \alpha P_Y(x).$$

Thus $P_Y$ is a linear operator. If $x \in H$, $x = y + z$, then by XV.9.5.5.

$$\|P_Y(x)\|^2 = \|y\|^2 \leq \|y\|^2 + \|z\|^2 = \|x\|^2$$

so $P_Y$ is a bounded operator and $\|P_Y\| \leq 1$. But if $Y \neq \{0\}$, and $y$ is a nonzero vector in $Y$, then $P_Y(y) = y$, so $\|P_Y\| = 1$.

It is obvious that $P_Y(x) = 0$ if and only if $x \in Y^\perp$. \(\diamondsuit\)

XV.9.6.3. Orthogonal projection operators are the simplest kinds of non-scalar bounded operators on a Hilbert space. They are the “building blocks” for general self-adjoint operators via the Spectral Theorem ().

XV.9.6.4. Proposition. Let $H$ be a Hilbert space, and $Y$ a closed subspace. Then $P_Y$ is an idempotent operator on $H$, i.e. $P_Y^2 = P_Y$. Every idempotent bounded operator $P$ on $H$ with $\|P\| \leq 1$ is an orthogonal projection operator, i.e. $P = P_X$ for some closed subspace $X$ of $H$.

Proof: If $x \in H$, $x = y + z$, then

$$P_Y^2(x) = P_Y(P_Y(x)) = P_Y(y) = y = P_Y(x).$$

1800
Conversely, if $P^2 = P$, let $\mathcal{X}$ be the range of $P$. If $x \in \mathcal{X}$, then $x = P(v)$ for some $v \in \mathcal{H}$, so $P(x) = P^2(v) = P(v) = x$. If $w = v - x$, we then have $w \in \mathcal{N}(P)$ and $v = x + w$; thus, if $v$ is any vector in $\mathcal{H}$, we can write $v = P(v) + w$ with $w \in \mathcal{N}(P)$. If $x \in \mathcal{X}$ and $w \in \mathcal{N}(P)$, then, for any $v \in \mathbb{F}$,

$$\|x\| = \|P(x + \alpha w)\| \leq \|x + \alpha w\|$$

if $\|P\| \leq 1$; thus $x \perp w$ by XV.9.5.6, i.e. $\mathcal{N}(P) \subseteq \mathcal{X}^\perp$. But if $v \in \mathcal{X}^\perp$, we can write $v = P(v) + w$ with $w \in \mathcal{N}(P)$. Since $P(v) \in \mathcal{X}$ and $w \in \mathcal{X}^\perp$, we must have $v = w$ by XV.9.5.7, i.e. $v \in \mathcal{N}(P)$, $\mathcal{N}(P) = \mathcal{X}^\perp$. Thus, if $v \in \mathcal{H}$, and $v = x + w$ for $x \in \mathcal{X}$, $w \in \mathcal{X}^\perp$, we have $P(v) = x = P_X(v)$.

Thus the projections have a simple algebraic characterization: they are exactly the idempotent bounded operators on $\mathcal{H}$ of norm $\leq 1$.

Here are some other elementary properties of projections:

**XV.9.6.5.** PROPOSITION. Let $\mathcal{H}$ be a Hilbert space, and $\mathcal{Y}$ a closed subspace. Then $P_{\mathcal{Y}^\perp} = I - P_{\mathcal{Y}}$.

**XV.9.6.6.** The projection $I - P$ is often written $P^\perp$. Thus $P_{\mathcal{Y}^\perp} = P_Y^\perp$. We say two projections $P$ and $Q$ are orthogonal, written $P \perp Q$, if $PQ = 0$. We have $P_X \perp P_Y$ if and only if $\mathcal{Y} \subseteq \mathcal{X}^\perp$. Also, if $P \perp Q$, then $P + Q$ is a projection (and conversely). We have $P \perp P^\perp$ for any $P$.

**XV.9.6.7.** PROPOSITION. Let $\mathcal{X}$ and $\mathcal{Y}$ be closed subspaces of $\mathcal{H}$. The following are equivalent:

(i) $\mathcal{X} \subseteq \mathcal{Y}$.

(ii) $P_X P_Y = P_Y P_X = P_X$.

(iii) $P_Y - P_X$ is a projection (it is $P_{Y \cap \mathcal{X}^\perp}$).

**XV.9.6.8.** This result suggests that we can put a reasonable partial order on the projections on $\mathcal{H}$ by setting $P \leq Q$ if $PQ = QP = P$. Thus $P_X \leq P_Y$ if and only if $\mathcal{X} \subseteq \mathcal{Y}$, i.e. $P \leq Q$ if and only if $\mathcal{R}(P) \subseteq \mathcal{R}(Q)$. There is a “largest” projection $I$ and a “smallest” projection $0$ under this partial order. Any collection $\{P_j\}$ of projections has an infimum $P = \bigwedge P_j$ and a supremum $Q = \bigvee P_j$: if $P_j = P_{X_j}$, then $P = P_X$, where $\mathcal{X} = \bigcap \mathcal{X}_j$, and $Q = P_Y$, where $\mathcal{Y}$ is the closed linear span of $\bigcup \mathcal{X}_j$. In particular, if $P$ and $Q$ are projections, with $P = P_X$ and $Q = P_Y$, then $P \wedge Q$ is $P_{\mathcal{X} \cap \mathcal{Y}}$ and $P \vee Q$ is $P_{(\mathcal{X} + \mathcal{Y})^\perp}$. Thus the projections on $\mathcal{H}$ form a complete lattice $\bigvee$.

Using the complement $P \mapsto P^\perp = I - P$, the projections on $\mathcal{H}$ form a complete Boolean algebra.

**XV.9.6.9.** Caution: Two projections $P$ and $Q$ do not commute (i.e. $PQ \neq QP$) in general: for example, consider projections from $\mathbb{R}^2$ onto two one-dimensional subspaces which are distinct but not orthogonal. $P_X$ and $P_Y$ commute if and only if the subspaces $\mathcal{X}$ and $\mathcal{Y}$ are “nicely situated” with respect to each other. If $PQ = QP$, we have $P \wedge Q = PQ$ and $P \vee Q = P + Q - PQ$. In general, there are no simple algebraic formulas for $P \wedge Q$ or $P \vee Q$. If $P \perp Q$, i.e. if $PQ = 0$, then also $QP = 0$ and $P \wedge Q = 0$, $P \vee Q = P + Q$.

1801
XV.9.7. Dual Spaces and Weak Topology

Bounded linear functionals on a Hilbert space are easy to describe:

XV.9.7.1. Theorem. [Riesz-Fréchet] Let $H$ be a Hilbert space, and $\phi$ a bounded linear functional on $H$. Then there is a (unique) vector $\xi \in H$ with $\phi(\eta) = \langle \eta, \xi \rangle$ for all $\eta \in H$; and $\|\xi\| = \|\phi\|$.

So the dual space $H^*$ of $H$ may be identified with $H$ (the identification is conjugate-linear), and the weak (= weak-* topology is given by the inner product: $\xi_i \to \xi$ weakly if $\langle \xi_i, \eta \rangle \to \langle \xi, \eta \rangle$ for all $\eta$. In particular, a Hilbert space is a reflexive Banach space and the unit ball is therefore weakly compact. A useful way of stating this is:

XV.9.7.2. Corollary. Let $H$ be a Hilbert space. If $(\xi_i)$ is a bounded weak Cauchy net in $H$ (i.e. $(\langle \xi_i, \eta \rangle)$ is Cauchy for all $\eta \in H$), then there is a (unique) vector $\xi \in H$ such that $\xi_i \to \xi$ weakly, i.e. $\langle \xi_i, \eta \rangle \to \langle \xi, \eta \rangle$ for all $\eta \in H$.

The weak topology is, of course, distinct from the norm topology (strictly weaker) if $H$ is infinite-dimensional: for example, an orthonormal sequence of vectors converges weakly to 0. The next proposition gives a connection.

XV.9.7.3. Proposition. Let $H$ be a Hilbert space, $\xi_i, \xi \in H$, with $\xi_i \to \xi$ weakly. Then $\|\xi\| \leq \lim \inf \|\xi_i\|$, and $\xi_i \to \xi$ in norm if and only if $\|\xi_i\| \to \|\xi\|$.

Proof: $\|\xi\|^2 = \lim \langle \xi_i, \xi \rangle \leq \|\xi\| \lim \inf \|\xi_i\|$ by the CBS inequality.

$$\|\xi_i - \xi\|^2 = \langle \xi_i, \xi_i \rangle - \langle \xi_i, \xi \rangle - \langle \xi, \xi_i \rangle + \langle \xi, \xi \rangle$$

which goes to zero if and only if $\|\xi_i\| \to \|\xi\|$.

XV.9.7.4. If $H$ is infinite-dimensional, then the weak topology on $H$ is not first countable, and a weakly convergent net need not be (norm-)bounded. It is an easy consequence of Uniform Boundedness (XV.6.4.1.) that a weakly convergent sequence is bounded. For example, if $\{\xi_n\}$ is an orthonormal sequence in $H$, then 0 is in the weak closure of $\{\sqrt{n}\xi_n\}$, but no subsequence converges weakly to 0 (cf. [Hal82, Problem 28], [?]). If $H$ is separable, then the restriction of the weak topology to the unit ball of $H$, and hence to any bounded set, is metrizable [Hal82, Problem 24].

XV.9.8. Standard Constructions

There are two standard constructions on Hilbert spaces which are used repeatedly, direct sum and tensor product.
XV.9.8.1. If \( \{ \mathcal{H}_i : i \in \Omega \} \) is a set of Hilbert spaces, we can form the Hilbert space direct sum, denoted \( \bigoplus_{\Omega} \mathcal{H}_i \), as the set of “sequences” (indexed by \( \Omega \)) \( (\cdots \xi_i, \cdots) \), where \( \xi_i \in \mathcal{H}_i \) and \( \sum_i \| \xi_i \|^2 < \infty \) (so \( \xi_i \neq 0 \) for only countably many \( i \)). The inner product is given by

\[
\langle (\cdots \xi_i, \cdots), (\cdots \eta_i, \cdots) \rangle = \sum_i \langle \xi_i, \eta_i \rangle.
\]

This is the completion of the algebraic direct sum with respect to this inner product. If all \( \mathcal{H}_i \) are the same \( \mathcal{H} \), the direct sum is called the amplification of \( \mathcal{H} \) by \( card(\Omega) \). The amplification of \( \mathcal{H} \) by \( n \) (the direct sum of \( n \) copies of \( \mathcal{H} \) is denoted by \( \mathcal{H}^n \); the direct sum of countably many copies of \( \mathcal{H} \) is denoted \( \mathcal{H}^\infty \) (or sometimes \( l^2(\mathcal{H}) \)).

XV.9.8.2. If \( \mathcal{H}_1, \mathcal{H}_2 \) are Hilbert spaces, let \( \mathcal{H}_1 \odot \mathcal{H}_2 \) be the algebraic tensor product over \( \mathbb{C} \). Put an inner product on \( \mathcal{H}_1 \odot \mathcal{H}_2 \) by

\[
\langle (\xi_1 \otimes \xi_2, \eta_1 \otimes \eta_2) = \langle \xi_1, \eta_1 \rangle \langle \xi_2, \eta_2 \rangle
\]

extended by linearity, where \( \langle \cdot, \cdot \rangle \) is the inner product on \( \mathcal{H}_i \). (It is easily checked that this is an inner product, in particular that it is positive definite.) Then the Hilbert space tensor product \( \mathcal{H}_1 \otimes \mathcal{H}_2 \) is the completion of \( \mathcal{H}_1 \odot \mathcal{H}_2 \). Tensor products of finitely many Hilbert spaces can be defined similarly. (Infinite tensor products are trickier and will be discussed in ??.)

If \( \mathcal{H} \) and \( \mathcal{H}' \) are Hilbert spaces and \( \{ \eta_i : i \in \Omega \} \) is an orthonormal basis for \( \mathcal{H}' \), then there is an isometric isomorphism from \( \mathcal{H} \otimes \mathcal{H}' \) to the amplification of \( \mathcal{H} \) by \( card(\Omega) \), given by \( \sum_i \xi_i \otimes \eta_i \mapsto (\cdots \xi_i, \cdots) \). In particular, \( \mathcal{H}^n \) is naturally isomorphic to \( \mathcal{H} \otimes \mathbb{C}^n \) and \( \mathcal{H}^\infty \cong \mathcal{H} \otimes l^2 \).

If \( (X, \mu) \) is a measure space and \( \mathcal{H} \) is a separable Hilbert space, then the Hilbert space \( L^2(X, \mu) \otimes \mathcal{H} \) is naturally isomorphic to \( L^2(X, \mu, \mathcal{H}) \), the set of weakly measurable functions \( f : X \to \mathcal{H} \) (i.e. \( x \mapsto \langle f(x), \eta \rangle \) is a complex-valued measurable function for all \( \eta \in \mathcal{H} \)) such that \( \int_X \| f(x) \|^2 \, d\mu(x) < \infty \), with inner product

\[
\langle f, g \rangle = \int_X (\langle f(x), g(x) \rangle) \, d\mu(x).
\]

The isomorphism sends \( f \otimes \eta \) to \( (x \mapsto \langle f(x), \eta \rangle) \).

Unless otherwise qualified, a “direct sum” or “tensor product” of Hilbert spaces will always mean the Hilbert space direct sum or tensor product.

XV.9.9. Real Hilbert Spaces

One can also consider real inner product spaces, real vector spaces with a (bilinear, real-valued) inner product \( \langle \cdot, \cdot \rangle \) satisfying the properties of ?? for \( \alpha \in \mathbb{R} \). A real Hilbert space is a complete real inner product space. A real Hilbert space \( \mathcal{H}_R \) can be complexified to \( \mathbb{C} \otimes_{\mathbb{R}} \mathcal{H}_R \); conversely, a (complex) Hilbert space can be regarded as a real Hilbert space by restricting scalar multiplication and using the real inner product \( \langle \xi, \eta \rangle = \text{Re} \langle \xi, \eta \rangle \). (Note, however, that these two processes are not quite inverse to each other.) All of the results of this section, and many (but by no means all) results about operators, hold verbatim or have obvious exact analogs in the case of real Hilbert spaces.

Throughout this volume, the term “Hilbert space,” unless qualified with “real,” will always denote a complex Hilbert space; and “linear” will mean “complex-linear.”

1803
XV.9.10. Exercises

XV.9.10.1. Prove the CBS inequality for $\mathbb{R}^n$ as follows. Let $x = (x_1, \ldots, x_n)$ and $y = (y_1, \ldots, y_n)$.

(a) Show that
\[
\left( \sum_{k=1}^{n} x_k y_k \right)^2 + \sum_{j<k} (x_j y_k - x_k y_j)^2 = \left( \sum_{k=1}^{n} x_k^2 \right) \left( \sum_{k=1}^{n} y_k^2 \right).
\]

(b) Use that all the terms in the second sum are nonnegative to deduce the CBS inequality.

(c) Equality holds in the CBS inequality if and only if all terms in the second sum are zero. Show that this implies that $\{x, y\}$ is linearly dependent.

This was Cauchy’s proof of the CBS inequality from [Can21].

XV.9.10.2. Give another proof of the CBS inequality for $\mathbb{R}^n$ as follows.

(a) Show that for $x, y \in \mathbb{R}$, $|xy| \leq \frac{1}{2}(x^2 + y^2)$, with equality if and only if $y = \pm x$. [Use that $(x + y)^2$ and $(x - y)^2$ are nonnegative.]

(b) Show that it suffices to prove the CBS inequality for $x, y$ of norm 1.

(c) if $x = (x_1, \ldots, x_n)$ and $y = (y_1, \ldots, y_n)$ have norm 1, then
\[
\left| \sum_{k=1}^{n} x_k y_k \right| \leq \sum_{k=1}^{n} |x_k y_k| \leq \frac{1}{2} \left( \sum_{k=1}^{n} x_k^2 + \sum_{k=1}^{n} y_k^2 \right) = 1
\]
with equality if and only if $y = \pm x$.

XV.9.10.3. Let $f$ and $g$ be real-valued continuous functions on $[a, b]$. Use Riemann sums for $\int_{a}^{b} f(t)g(t) \, dt$, $\int_{a}^{b} [f(t)]^2 \, dt$, and $\int_{a}^{b} [g(t)]^2 \, dt$, and the CBS inequality for $\mathbb{R}^n$, to prove
\[
\left( \int_{a}^{b} f(t)g(t) \, dt \right)^2 \leq \left( \int_{a}^{b} [f(t)]^2 \, dt \right) \left( \int_{a}^{b} [g(t)]^2 \, dt \right)
\]
with equality if and only if $\{f, g\}$ is linearly dependent. This was Bunyakovskii’s inequality and proof from [Bun59].

XV.9.10.4. Let $(\mathcal{V}, \langle \cdot, \cdot \rangle)$ be a real inner product space, and $x, y \in \mathcal{V}$. 

(a) Write $\langle x + \alpha y, x + \alpha y \rangle$ as a quadratic function of $\alpha$.

(b) Use the quadratic formula and the fact that $\langle x + \alpha y, x + \alpha y \rangle \geq 0$ for all $\alpha$ to deduce the CBS inequality.

This was essentially Schwarz’s proof from [Sch88] (he only explicitly considered the case where the inner product was given by a (multiple) integral as in XV.9.1.4.(ii).)

XV.9.10.5. Deduce the CBS inequality for complex inner products from the inequality for real inner products. [Consider the real inner product $\langle x, y \rangle = \Re(\langle x, y \rangle)$ and suitable scalar multiples.]

XV.9.10.6. [Ste04] Prove the CBS inequality for the standard inner product on $\mathbb{R}^n$ by induction, starting with the case $n = 2$ (it is trivial for $n = 1$).
XV.9.10.7. Justify the name “Parallelogram Law” by giving a geometric interpretation in terms of the lengths of the diagonals of a parallelogram. If \( x, y \in \mathbb{R}^2 \), consider the parallelogram with vertices \( 0, x, y, x + y \). See VI.3.1.22.

XV.9.10.8. Let \( \mathcal{V} \) be a normed vector space over \( \mathbb{F} = \mathbb{R} \) or \( \mathbb{C} \). Show that the norm on \( \mathcal{V} \) comes from an inner product if and only if every two-dimensional subspace of \( \mathcal{V} \) is isometrically isomorphic to \( \mathbb{F}^2 \) with the induced norm from the standard inner product.

XV.9.10.9. Suppose \((\mathcal{V}, \langle \cdot, \cdot \rangle)\) is an inner product space. Expand the right side of the Polarization Identity (XV.9.2.8) to show that the identity is satisfied.

XV.9.10.10. (a) Show that the Parallelogram Law is equivalent to the statement that
\[
\|x + y\|^2 - \|x - y\|^2 = 2(\|x + y\|^2 - \|x\|^2 - \|y\|^2)
\]
for all \( x, y \).
(b) Show that in an inner product space,
\[
\langle x, y \rangle = \frac{1}{2}[(\|x + y\|^2 - \|x\|^2 - \|y\|^2) + i(\|x + iy\|^2 - \|x\|^2 - \|y\|^2)]
\]
for all \( x, y \). Give a similar formula for real inner products.

XV.9.10.11. (a) In \( C([0, 1]) \), let \( f_n (n \geq 2) \) be defined by
\[
f_n(t) = \begin{cases} 
0 & \text{if} \ 0 \leq t \leq \frac{1}{2} \\
\text{linear} & \text{if} \ \frac{1}{2} \leq t \leq \frac{1}{2} + \frac{1}{n} \\
1 & \text{if} \ \frac{1}{2} \frac{1}{n} \leq t \leq 1
\end{cases}
\]
Show that \((f_n)\) is a uniformly bounded sequence in \( C([0, 1]) \) which is a Cauchy sequence with respect to the norm induced by the inner product, but which does not converge in \( C([0, 1]) \) in the induced norm. (Note that we have referred here to the uniform norm \( \| \cdot \|_\infty \) as well as the norm induced by the inner product; in this problem and succeeding problems we discuss Cauchy sequences and convergence only with respect to the norm induced by the inner product. The sequence \((f_n)\) is bounded but not Cauchy in the uniform norm.)
(b) It is slightly harder to show that \( PC([0, 1]) \) is not complete. Let \( g_n (n \geq 2) \) be defined by
\[
g_n(t) = \begin{cases} 
0 & \text{if} \ 0 \leq t \leq \frac{1}{n} \\
\sin \left( \frac{\pi}{t} \right) & \text{if} \ \frac{1}{n} \leq t \leq 1
\end{cases}
\]
Show that \((g_n)\) defines a uniformly bounded Cauchy sequence in \( C([0, 1]) \) which does not converge in \( PC([0, 1]) \).
(c) It is easier to give an example of a nonconvergent Cauchy sequence which is not uniformly bounded. Let
\[
h_n(t) = \min \left( n, \frac{1}{\sqrt{n}} \right)
\]
for \( 0 \leq t \leq 1 \). Then \((h_n)\) is a Cauchy sequence in \( C([0, 1]) \) which does not converge even in \( PC([0, 1]) \).
XV.9.10.12. Let \( \mathcal{R}([a, b]) \) be the set of complex-valued Riemann-integrable functions on \([a, b]\).

(a) Show that the formula

\[
\langle f, g \rangle = \int_a^b f(t)g(t) \, dt
\]

(where the integral is a Riemann integral) defines a pre-inner product on \( \mathcal{R}([a, b]) \).

(b) Explicitly describe the space \( \mathcal{N} \).

(c) Let \( R([a, b]) = \mathcal{R}([a, b]) / \mathcal{N} \). Show that \( PC([a, b]) \) can be naturally identified with a dense subspace of \( R([a, b]) \).

(d) The Cauchy sequence \((h_n)\) of XV.9.10.11.(c) does not converge in \( R([0, 1]) \).

(e) Find a uniformly bounded Cauchy sequence in \( \mathcal{R}([a, b]) \) that does not converge. [A Cantor set of positive measure () is helpful.]

(f) Try to describe the completion of \( R([a, b]) \) (which will also be the completion of \( C([a, b]) \) and \( PC([a, b]) \)) since these are dense in \( R([a, b]) \). The example in (d) shows that we must at least add all nonnegative improperly Riemann square-integrable functions on \([a, b]\), but (e) shows that even linear combinations of these do not give enough. The answer involves Lebesgue measure and integration (); this example gives good motivation for development of the Lebesgue theory.

XV.9.10.13. Let \((V, \langle \cdot, \cdot \rangle)\) be a (real or complex) inner product space. Let \( \mathcal{H} \) be the set of equivalence classes of Cauchy sequences in \( V \) as in the proof of (). Show that

\[
\langle [(x_n)], [(y_n)] \rangle = \lim_{n \to \infty} \langle x_n, y_n \rangle
\]

gives a well-defined inner product on \( \mathcal{H} \) inducing the norm defined in ()

XV.9.10.14. Let \( \mathcal{H} \) be an infinite-dimensional Hilbert space.

(a) Show that for every \( r > 0 \), an open ball of radius \( 3r \) in \( \mathcal{H} \) contains infinitely many pairwise disjoint open balls of radius \( r \). If \( \mathcal{H} \) is nonseparable, an open ball of radius \( 3r \) contains uncountably many pairwise disjoint open balls of radius \( r \). [Consider open balls centered at points of an orthonormal basis.] This is one justification for the statement “There’s a lot of room in Hilbert space.”

(b) Use (a) to show that there is no translation-invariant Borel measure on \( \mathcal{H} \) for which open balls have finite positive measure.

(c) Show that an open ball of radius \( 2r \) in a Hilbert space (finite- or infinite-dimensional) cannot contain more than two disjoint open balls of radius \( r \). [If there are three such balls, consider the two-dimensional real affine subspace spanned by the centers.]

In (a), 3 may be replaced by \( 1 + \sqrt{2} \approx 2.414 \) and in (c), 2 may be replaced by any number less than \( 1 + \frac{2}{\sqrt{3}} \approx 2.1547 \). What about numbers in between?

XV.9.10.15. Let \( \{X_i : i \in I\} \) be an indexed collection of Banach spaces. Define the \( \ell^2 \)-direct sum \( \bigoplus_{i \in I} X_i \) to be the subset of \( \prod_{i \in I} X_i \) consisting of all elements \(( \cdots, x_i, \cdots)\) for which \( \sum_{i \in I} \|x_i\|^2 < \infty \). (Note that \( \bigoplus_{i \in I} X_i = \prod_{i \in I} X_i \) if \( I \) is finite.)
(a) Let $\mathcal{X} = \bigoplus_{i \in I} \mathcal{X}_i$. Show that $\mathcal{X}$ is a vector subspace of $\prod_{i \in I} \mathcal{X}_i$ and that $\| \cdot \|$ defined on $\mathcal{X}$ by

$$
\|(\cdots x_i \cdots)\| = \left[ \sum_{i \in I} |x_i|^2 \right]^{1/2}
$$

is a norm on $\mathcal{X}$.

(b) Show that $(\mathcal{X}, \| \cdot \|)$ is complete, i.e. a Banach space.

(c) Show that if each $\mathcal{X}_i$ is a Hilbert space (i.e. the norm satisfies the Parallelogram Law), then $\mathcal{X}$ is also a Hilbert space.

**XV.9.10.16. Uniformly Convex Banach Spaces.** Let $\mathcal{X}$ be a Banach space. $\mathcal{X}$ is **strictly convex** if, whenever $x, y \in \mathcal{X}$, $x \neq y$, $\|x\| = \|y\| = 1$, we have $\|1/2 (x + y)\| < 1$. $\mathcal{X}$ is **uniformly convex** if for every $\epsilon > 0$ there is a $\delta > 0$ such that, whenever $x, y \in \mathcal{X}$, $\|x\| = \|y\| = 1$, $\|x - y\| > \epsilon$, we have $\|1/2 (x + y)\| < 1 - \delta$. Note that a uniformly convex Banach space is strictly convex.

(a) Show that $\mathcal{X}$ is strictly convex if and only if every element of $\mathcal{X}$ of norm 1 is an extreme point of the closed unit ball of $\mathcal{X}$.

(b) Show that any (closed) subspace of a strictly [resp. uniformly] convex Banach space is strictly [resp. uniformly] convex.

(c) Use the Parallelogram Law to show that any Hilbert space is uniformly convex.

(d) Show that $(\mathbb{R}^n, \| \cdot \|_p)$ is uniformly convex for $1 < p < \infty$, but that $(\mathbb{R}^n, \| \cdot \|_1)$ and $(\mathbb{R}^n, \| \cdot \|_\infty)$ are not strictly convex.

(e) Show that a strictly convex finite-dimensional Banach space is uniformly convex.

(f) Show that any $\ell^2$-direct sum (XV.9.10.15.) of strictly convex Banach spaces is strictly convex.

(g) Show that $\bigoplus_{p \in \mathbb{N}} (\mathbb{R}^2, \| \cdot \|_p)$ for $p \in \mathbb{N}, p \geq 2$, is strictly convex but not uniformly convex. Thus (f) is not true if “strictly” is replaced by “uniformly.” (But it is if the index set is finite.)

(h) Formulate and prove a precise statement to the effect that $\bigoplus_{p \in \mathbb{N}} \mathcal{X}_i$ is uniformly convex if and only if the $\mathcal{X}_i$ are “uniformly uniformly convex.” Deduce the last statement of (g).

It is known that a uniformly convex Banach space is always reflexive (Milman-Pettis Theorem). A strictly convex Banach space need not be reflexive; in fact, every separable Banach space has an equivalent strictly convex norm (cf. [https://math.stackexchange.com/questions/488790/is-there-a-non-reflexive-banach-space-whi](https://math.stackexchange.com/questions/488790/is-there-a-non-reflexive-banach-space-whi)).
XV.9.11. Sesquilinear Forms and Operators

XV.9.11.1. If $\mathcal{X}$ is a normed complex vector space, $\mathcal{H}$ a Hilbert space, and $T : \mathcal{X} \to \mathcal{H}$ a bounded operator, set

$$B(x, y) = \langle Tx, y \rangle.$$ 

Then it is easily checked that $B$ is a sesquilinear form on $\mathcal{X} \times \mathcal{H}$, which is bounded, i.e. there is a $K$ such that

$$|B(x, y)| \leq K \|x\| \|y\|$$

for all $x \in \mathcal{X}$, $y \in \mathcal{H}$. The smallest such $K$, the norm $\|B\|$ of $B$, is equal to $\|T\|$.

The following converse establishes a one-one correspondence between bounded operators and bounded sesquilinear forms. We state it for complex spaces; there is an essentially identical analogous version for real spaces, replacing “sesquilinear” with “bilinear.”

XV.9.11.2. Proposition. Let $\mathcal{X}$ be a normed vector space, $\mathcal{H}$ a Hilbert space, and $B$ a bounded sesquilinear form on $\mathcal{X} \times \mathcal{H}$. Then there is a unique bounded operator $T : \mathcal{X} \to \mathcal{H}$ such that

$$B(x, y) = \langle Tx, y \rangle$$

for all $x \in \mathcal{X}$, $y \in \mathcal{H}$. $\|T\| = \|B\|$.

Proof: Fix $x \in \mathcal{X}$. Define $\phi : \mathcal{H} \to \mathbb{C}$ by $\phi(y) = B(x, y)$. Then $\phi$ is a conjugate-linear functional on $\mathcal{H}$, and $\phi$ is bounded ($\|\phi\| \leq \|B\| \|x\|$). Thus by () there is a unique $z \in \mathcal{H}$ with

$$\phi(y) = B(x, y) = \langle z, y \rangle.$$ 

Set $Tx = z$. In this way a function $T : \mathcal{X} \to \mathcal{H}$ is defined. It is an easy consequence of the linearity of $B$ in the first variable that $T$ is linear. If $x \in \mathcal{X}$, we have

$$\|Tx\| = \sup_{\|y\|=1} |\langle Tx, y \rangle| = \sup_{\|y\|=1} |B(x, y)| \leq \|B\| \|x\|$$

and thus $T$ is bounded and $\|T\| \leq \|B\|$. By taking the supremum over all $x$ with $\|x\| = 1$, we obtain $\|T\| = \|B\|$. \(

XV.9.11.3. There is thus a one-one correspondence between bounded operators and bounded sesquilinear forms. Each point of view has its advantages. Some early authors such as HILBERT used the form approach exclusively instead of working with operators, but some parts of the theory become almost impossibly difficult and cumbersome (e.g. composition of operators) from this point of view. I. FREDHOLM and F. RIESZ emphasized the operator point of view, which is superior for most purposes.

The following special case of XV.9.11.2. is especially useful in the theory of partial differential equations:
**XV.9.11.4. Proposition.** Let $\mathcal{H}$ be a Hilbert space, and $B$ a bounded sesquilinear form on $\mathcal{H} \times \mathcal{H}$ for which there is an $\epsilon > 0$ such that

$$|B(x, x)| \geq \epsilon \|x\|^2$$

for all $x \in \mathcal{H}$. Then there is a unique $T \in \mathcal{B}(\mathcal{H})$ with

$$B(x, y) = \langle Tx, y \rangle$$

for all $x, y \in \mathcal{H}$. $T$ is invertible and $\|T\| = \|B\|$. Thus there is a unique $S \in \mathcal{B}(\mathcal{H})$, namely $S = T^{-1}$, such that

$$B(Sx, y) = \langle x, y \rangle$$

for all $x, y \in \mathcal{H}$. $S$ is invertible and $\|S\| \leq \frac{1}{\epsilon}$.

There is an analogous result for real Hilbert spaces, with “sesquilinear” replaced by “bilinear.”

**XV.9.11.5. Corollary.** Let $\mathcal{H}$ be a Hilbert space, and $B$ a bounded sesquilinear form on $\mathcal{H} \times \mathcal{H}$ for which there is an $\epsilon > 0$ such that

$$|B(x, x)| \geq \epsilon \|x\|^2$$

for all $x \in \mathcal{H}$. If $\phi$ is any bounded linear functional on $\mathcal{H}$, then there is a unique $z \in \mathcal{H}$ such that

$$\phi(x) = B(x, z)$$

for all $x \in \mathcal{H}$. Conversely, if $z$ is such a vector, then $\phi(x) = \langle x, T^* z \rangle$ for all $x$, so $T^* z = y, z = S' y$.

**Proof:** Let $T$ and $S = T^{-1}$ be as in XV.9.11.4. (so $(S^*)^{-1} = T^*$). There is a unique $y \in \mathcal{H}$ with $\phi(x) = \langle x, y \rangle$ for all $x \in \mathcal{H}$. Then $z = S' y$ is such a $z$:

$$B(x, z) = \langle Tx, z \rangle = \langle x, T^* z \rangle = \langle x, y \rangle = \phi(x)$$

for all $x$. Conversely, if $z$ is such a vector, then $\phi(x) = \langle x, T^* z \rangle$ for all $x$, so $T^* z = y, z = S' y$.

**XV.9.11.6.** For the proof of XV.9.11.4., everything follows immediately from XV.9.11.2. except invertibility of $T$, which is a consequence of the next elementary result, and uniqueness of $S$, which is immediate if $S'$ is another such operator, then for each $x \in \mathcal{H}$ we have $B(Sx, y) = B(S'x, y)$ and hence $B((S - S')x, y) = 0$ for all $y \in \mathcal{H}$, and in particular for $y = (S - S')x$, so

$$0 = |B((S - S')x, (S - S')x)| \geq \epsilon \|(S - S')x\|^2$$

and $(S - S')x = 0$.

**XV.9.11.7. Proposition.** Let $\mathcal{H}$ be a Hilbert space, and $T \in \mathcal{B}(\mathcal{H})$ with the property that there is an $\epsilon > 0$ such that $\langle Tx, x \rangle \geq \epsilon \|x\|^2$ for all $x \in \mathcal{H}$. Then $T$ is invertible. $\|T^{-1}\| \leq \frac{1}{\epsilon}$.

**Proof:** By the CBS inequality, $\|Tx\| \geq \epsilon \|x\|$ for all $x \in \mathcal{H}$, i.e. $T$ is bounded below. Thus $T$ is one-to-one with closed range ($\mathcal{R}(T)$). If $x \perp \mathcal{R}(T)$, then $\langle Tx, x \rangle = 0$, so $x = 0$, and $\mathcal{R}(T)$ is dense in $\mathcal{H}$. Thus $\mathcal{R}(T) = \mathcal{H}$. We have, for any $x \in \mathcal{H}$, $\|x\| = \|T(T^{-1}x)\| \geq \epsilon \|T^{-1}x\|$.

1809
XV.9.11.8. In many references, Proposition XV.9.11.4., or sometimes XV.9.11.5., is called the “Lax-Milgram Theorem” (or sometimes “the famous Lax-Milgram Theorem”) since it appeared in [LM54]. Although it is useful, it does not seem to merit named status, let alone fame, since

(1) It is such an easy and obvious consequence of () (although the proofs in [LM54] and in some other references such as [Yos80] are unnecessarily complicated).

(2) The more general result XV.9.11.2. was well known to Hilbert, Riesz, and other early workers in Hilbert space, long before Lax and Milgram came along.

Not everything published by prominent mathematicians deserves hagiography.
XV.10. Banach Algebras and Spectral Theory

Most of the advanced study of operators is connected with the spectrum, which is a generalization of the set of eigenvalues. While the most immediate applications of spectral theory are to operators, the theory itself is done most efficiently in the more general context of Banach algebras, and spectral theory has numerous applications beyond the case of operators. We will thus first set up the theory of Banach algebras and develop spectral theory there.

XV.10.1. Banach Algebras

A Banach algebra is a Banach space which has a multiplication with nice compatibility properties:

XV.10.1.1. Definition. Let \( F \) be \( \mathbb{R} \) or \( \mathbb{C} \). A normed algebra over \( F \) is an algebra \( \mathcal{A} \) over \( F \) with a norm satisfying
\[
\|xy\| \leq \|x\|\|y\|
\]
for all \( x, y \in \mathcal{A} \) (submultiplicative norm). If \( \mathcal{A} \) is a normed algebra which is a Banach space (i.e. is complete), \( \mathcal{A} \) is a Banach algebra.

We thus have real Banach algebras and complex Banach algebras. For technical reasons, we will usually consider complex Banach algebras, especially for spectral theory; thus we will make the convention that the term “Banach algebra” without the qualification “real” will denote a complex Banach algebra.

There are a great many important Banach algebras with varied properties. For example:

XV.10.1.2. Examples. (i) Let \( X \) be a Banach space (over \( F \)). Then \( B(X) \), with the usual operations and operator norm \( \| \cdot \| \), is a Banach algebra (over \( F \)).

(ii) Let \( X \) be a compact Hausdorff space, and let \( C(X) \) be the set of complex-valued continuous functions on \( X \). Give \( C(X) \) the usual operations of pointwise addition, pointwise multiplication, and pointwise scalar multiplication, and the supremum norm \( \| \cdot \| \). Then \( C(X) \) is a (complex) Banach algebra. Similarly, \( C_0(X) \) is a real Banach algebra. More generally, if \( X \) is locally compact, the set \( C_0(X) \) of complex-valued continuous functions vanishing at infinity \( \| \cdot \| \) is a Banach algebra with the same operations and norm.

(iii) As a special case of (i), \( M_n(F) = B(F^n) \) becomes a Banach algebra when given the operator norm from any norm on \( F^n \). Thus there are many norms on \( M_n(F) \) making it into a Banach algebra. As a special case, or as a special case of (ii) with \( X \) a one-point space, \( F \) is a Banach algebra over \( F \) with norm \( \| \alpha \| = | \alpha | \).

(iv) If \( X \) is any Banach space, define \( xy = 0 \) for all \( x, y \in X \). Then \( X \) is a Banach algebra. (This example is not very interesting, to be sure.)

These examples only scratch the surface of the possibilities, even the interesting possibilities.

Joint Continuity of Multiplication

In a Banach space (or just normed vector space), addition and scalar multiplication are jointly continuous. In a normed algebra, multiplication is also jointly continuous:
XV.10.1.3. Proposition. Let $A$ be a normed algebra. If $x_n, y_n, x, y \in A$ and $x_n \to x, y_n \to y$, then $x_n y_n \to xy$.

Proof: By the usual argument,

$$\|x_n y_n - xy\| = \|x_n y_n - x_n y + x_n y - xy\| \leq \|x_n y_n - x_n y\| + \|x_n y - xy\| \leq \|x_n\| \|y_n - y\| + \|y\| \|x_n - x\| .$$

Since $(x_n)$ converges, it is bounded.

Completion of a Normed Algebra

XV.10.1.4. Similarly, if $A$ is a normed algebra, then its completion $\overline{A}$ has a natural multiplication making it a Banach algebra. For if $(x_n)$ and $(y_n)$ are Cauchy sequences in $A$, then, for any $n$ and $m$,

$$\|x_n y_n - x_m y_m\| = \|x_n y_n - x_n y_m + x_n y_m - x_m y_m\| \leq \|x_n y_n - x_n y_m\| + \|x_n y_m - x_m y_m\| \leq \|x_n\| \|y_n - y_m\| + \|y_m\| \|x_n - x_m\| .$$

Since Cauchy sequences are bounded, it follows that $(x_n y_n)$ is a Cauchy sequence.

Unital Banach Algebras and Unitization

XV.10.1.5. Examples XV.10.1.2 (ii) and (iv) show that a Banach algebra need not have a multiplicative identity. A Banach algebra with a multiplicative identity is a unital Banach algebra. The multiplicative identity, if it exists, is generally denoted $1$. We usually assume $\|1\| = 1$; while this is not necessarily true in general, the norm can be replaced by an equivalent Banach algebra norm with this property (Exercise XV.10.6.1).

If a Banach algebra is not unital, a unit can be added in a systematic way:

XV.10.1.6. Proposition. Let $A$ be a nonunital Banach algebra over $\mathbb{F}$. Let $A^\dagger = A \oplus \mathbb{F}$. Define addition and scalar multiplication coordinatewise, and multiplication and a norm by

$$(x, \lambda) \cdot (y, \mu) = (xy + \lambda y + \mu x, \lambda \mu)$$

$$\|(x, \lambda)\| = \|x\| + |\lambda| .$$

Then $A^\dagger$ is a unital Banach algebra containing a copy of $A$ as an ideal of codimension 1, called the unitization of $A$.

The rule for multiplication can be remembered by thinking of $(x, \lambda)$ as $x + \lambda 1$. (The multiplicative identity is $(0,1)$.)

Proof: Checking the algebraic rules for an algebra is routine but tedious, and is left to the reader. It is clear that $\| \cdot \|$ is a norm on $A^\dagger$. For submultiplicativity, if $x, y \in A, \lambda, \mu \in \mathbb{F}$,

$$\|xy + \lambda y + \mu x\| + |\lambda \mu| \leq \|xy\| + \|\lambda y\| + \|\mu x\| + |\lambda \mu|$$

$$\leq \|x\| \|y\| + |\lambda| \|y\| + |\mu| \|x\| + |\lambda \mu| = (\|x\| + |\lambda|)(\|y\| + |\mu|) .$$

The map $x \mapsto (x, 0)$ identifies $A$ with a subalgebra (ideal) of $A^\dagger$. To see that $A^\dagger$ is complete, if $(a_n, \lambda_n)$ is a Cauchy sequence in $A^\dagger$, then $(a_n)$ is a Cauchy sequence in $A$ and $(\lambda_n)$ a Cauchy sequence in $\mathbb{F}$. These converge to some $a$ and $\lambda$, and $(a_n, \lambda_n) \to (a, \lambda)$.
Many aspects of Banach algebra theory are technically simpler for unital Banach algebras; allows the nonunital case to be largely reduced to the unital case. We do not want to just restrict to unital Banach algebras, however, since many naturally occurring Banach algebras are nonunital. Many, but not all, nonunital Banach algebras have an approximate unit (which can be used as a substitute).

Invertibility, Ideals, and Quotients

One of the remarkable and appealing aspects of the theory of Banach algebras is the intricate interplay between the topology and the algebraic structure. One of the most basic, and most important, examples of this is the use of power series in Banach algebras to construct inverses (and, later, other elements).

Recall that an element $x$ in a unital algebra $A$ is invertible if there is a $y \in A$ with $xy = yx = 1$. Caution: Since a Banach algebra is not necessarily commutative, for $x$ to be invertible it is not generally enough that there is a $y$ with $yx = 1$ (such an $x$ is left invertible), or that there is a $z$ with $xz = 1$ (such an $x$ is right invertible); cf. (1). However, if $x$ is both left and right invertible, the left and right inverses coincide and $x$ is invertible (and conversely): if $yx = xz = 1$, then $y = y(xz) = (yx)z = z$.

Theorem. Let $A$ be a unital Banach algebra, and $x \in A$. If the power series

$$\sum_{k=0}^{\infty} x^k$$

(where $x^0 = 1$ by convention) converges in $A$, the sum is a multiplicative inverse for $1 - x$. If $\|x\| < 1$, then the power series converges to a multiplicative inverse for $1 - x$, and

$$\|(1 - x)^{-1}\| \leq \frac{1}{1 - \|x\|}.$$ 

Proof: Suppose the series converges, and let $y$ be the sum. If

$$s_n = \sum_{k=0}^{n} x^k$$

is the partial sum to $n$, so that $s_n \to y$, we have by a simple calculation that

$$s_n(1 - x) = (1 - x)s_n = 1 - x^{n+1}.$$ 

The left side converges to $y(1 - x) = (1 - x)y$, and the right side to 1 since $x^{n+1} \to 0$. For the second statement, since $\|x^k\| \leq \|x\|^k$ for every $k$ by submultiplicativity, we have that

$$\sum_{k=1}^{\infty} \|x^k\|$$
converges by comparison to the geometric series with ratio \(|x|\), and hence \(\sum_{k=0}^{\infty} x^k\) converges. By the triangle inequality,
\[
\left\| \sum_{k=0}^{\infty} x^k \right\| \leq \sum_{k=0}^{\infty} \|x^k\| \leq \sum_{k=0}^{\infty} \|x\|^k = \frac{1}{1 - \|x\|}.
\]

\[\vspace{1cm}\]

**XV.10.2.10. Corollary.** Let \(A\) be a unital Banach algebra, and \(u \in A\). If \(\|u - 1\| < 1\), then \(u\) is invertible in \(A\), and
\[
\|u^{-1}\| \leq \frac{1}{1 - \|u - 1\|}.
\]

**Proof:** Apply the theorem with \(x = 1 - u\).

\[\vspace{1cm}\]

**XV.10.2.11. Corollary.** Let \(A\) be a unital Banach algebra, and \(u, v \in A\). If \(u\) is invertible in \(A\) and
\[
\|u - v\| < \frac{1}{\|u^{-1}\|}
\]
then \(v\) is also invertible in \(A\), and
\[
\|v^{-1}\| \leq \frac{\|u^{-1}\|}{1 - \|u^{-1}\||u - v|}.
\]
Thus the open ball around \(u\) of radius \(\frac{1}{\|u^{-1}\|}\) consists entirely of invertible elements. In particular, the set of invertible elements in \(A\) is an open set.

**Proof:** If \(\|u - v\| < \frac{1}{\|u^{-1}\|}\), then
\[
\|1 - u^{-1}v\| = \|u^{-1}(u - v)\| \leq \|u^{-1}\||u - v| < 1
\]
so \(u^{-1}v\) is invertible and \(v\) is left invertible. Similarly, \(\|1 - vu^{-1}\| < 1\) so \(v\) is right invertible. We have
\[
\|v^{-1}u\| = \|(u^{-1}v)^{-1}\| \leq \frac{1}{1 - \|u^{-1}v - 1\|}
\]
so
\[
\|v^{-1}\| = \|(v^{-1}u)^{-1}\| \leq \|v^{-1}u\||u^{-1}\| \leq \frac{\|u^{-1}\|}{1 - \|u^{-1}v - 1\|} = \frac{\|u^{-1}\|}{1 - \|u^{-1}(v - u)\|} \leq \frac{\|u^{-1}\|}{1 - \|u^{-1}\||v - u|}.
\]

\[\vspace{1cm}\]

1814
XV.10.2.12. Note that the bound
\[ \|v^{-1}\| \leq \frac{\|u^{-1}\|}{1 - \|u^{-1}v - 1\|} \]
in the proof is generally better than the bound in the statement of the result; but the bound in the statement is usually easier to compute.

Continuity of Inversion

XV.10.2.13. If \( A \) is a unital algebra, write \( A^{-1} \) for the set of invertible elements of \( A \). Note that \( A^{-1} \) is a group under multiplication, since a product of invertible elements is invertible.

XV.10.2.14. Corollary. Let \( A \) be a unital Banach algebra. Then the map \( x \mapsto x^{-1} \) is a continuous function from \( A^{-1} \) to \( A^{-1} \).

Proof: By the sequential criterion, it suffices to show that if \((u_n)\) is a sequence in \( A^{-1} \) converging to \( u \in A^{-1} \), then \( u_n^{-1} \to u^{-1} \). There is an \( N \) such that
\[ \|u_n - u\| < \frac{1}{2\|u^{-1}\|} \]
for all \( n \geq N \). Thus, for \( n \geq N \), we have
\[ \|u_n^{-1}\| \leq \frac{\|u^{-1}\|}{1 - \|u^{-1}\||u_n - u\|} < 2\|u^{-1}\| . \]
So, for \( n \geq N \),
\[ \|u_n^{-1} - u^{-1}\| = \|u_n^{-1}(u - u_n)u^{-1}\| \leq \|u_n^{-1}\||u_n - u\||u^{-1}\| < 2\|u^{-1}\|^2\|u_n - u\| \]
which goes to 0 as \( n \to \infty \).

XV.10.2.15. Corollary. If \( A \) is a unital Banach algebra, then \( A^{-1} \) (with the norm topology) is a topological group under multiplication.

XV.10.2.16. If \( I \) is an ideal in a Banach algebra \( A \), it follows from continuity of multiplication that the closure \( \bar{I} \) is also an ideal. If \( I \) is a proper ideal, it is not immediately obvious that \( \bar{I} \) is a proper ideal (i.e. \( I \) could be dense in \( A \)); in fact, this can happen if \( A \) is nonunital. But it cannot happen if \( A \) is a unital Banach algebra:

XV.10.2.17. Corollary. Let \( A \) be a unital Banach algebra, and \( I \) proper ideal of \( A \). Then \( \bar{I} \) is also a proper ideal of \( A \).

Proof: An ideal in a unital algebra is a proper ideal if and only if it contains no invertible elements. Thus if \( I \) is a proper ideal, it is contained in the set \( S \) of noninvertible elements of \( A \). But \( S \) is closed in \( A \), so \( \bar{I} \subseteq S \) and \( I \) is a proper ideal.
XV.10.3. Spectrum

We now define the crucial notion of the spectrum of an element of a Banach algebra. For reasons partially explained in XV.10.3.5., we will consider only complex Banach algebras. For simplicity, we will also only develop the theory for unital Banach algebras. Thus, in this section (except (XV.10.3.2.)), all Banach algebras will be unital and complex; subalgebras will be assumed to contain the multiplicative identity. All homomorphisms will be assumed unital.

XV.10.3.1. Definition. Let $A$ be a unital Banach algebra, $x \in A$. The spectrum of $x$ in $A$ is

$$\sigma_A(x) = \{ \lambda \in \mathbb{C} : \lambda I \text{ is not invertible} \}.$$  

The complement of $\sigma_A(x)$ in $\mathbb{C}$ is called the resolvent set of $x$ in $A$, denoted $\rho_A(x)$.

Thus $\sigma_A(x)$ is a subset of $\mathbb{C}$, which depends on $x$, and in general also on $A$ (XV.10.3.11.). In many instances the $A$ is understood (or, more importantly, the spectrum is independent of the choice of $A$, e.g. ()), and we just write $\sigma(x)$ for $\sigma_A(x)$.

XV.10.3.2. If $A$ is a nonunital Banach algebra and $x \in A$, we can define $\sigma_A(x) = \sigma_{B(X)}(x)$. We then have $0 \in \sigma_A(x)$ for every $x \in A$. Although much of the theory we develop works in the nonunital case with occasional technical complications, for simplicity we will not consider spectrum in a nonunital Banach algebra from now on.

Here are the two most important examples, which together underly and motivate spectral theory:

XV.10.3.3. Examples. (i) Let $\mathcal{X}$ be a complex Banach space, and $T \in \mathcal{B}(\mathcal{X})$. Then $\sigma(T) = \sigma_{\mathcal{B}(\mathcal{X})}(T)$ is the set of $\lambda \in \mathbb{C}$ such that $T - \lambda I$ is not invertible, i.e. is either not injective or not surjective (the Bounded Inverse Theorem implies that if $T - \lambda I$ is injective and surjective, then $(T - \lambda I)^{-1} \in \mathcal{B}(\mathcal{X})$). If $T - \lambda I$ is not injective, then $\lambda$ is by definition an eigenvalue of $T$. Thus $\sigma(T)$ can be thought of as the set of generalized eigenvalues of $T$.

If $\mathcal{X}$ is finite-dimensional, then by () $T - \lambda I$ is surjective if and only if it is injective. Thus in this case $\sigma(T)$ is exactly the set of eigenvalues of $T$, a finite nonempty subset of $\mathbb{C}$.

(ii) Let $X$ be a compact Hausdorff space, and $A = C(X)$. If $f \in A$, then $f$ is invertible in $A$ if and only if $f$ never takes the value 0. Thus $f - \lambda I$ is invertible if and only if $f$ never takes the value $\lambda$, i.e. $\sigma_A(f)$ is precisely the range of $f$, a nonempty compact subset of $\mathbb{C}$.

XV.10.3.4. Note that the spectrum of an element of a Banach algebra is a purely algebraic concept, and the norm plays no role in its definition. We may more generally define the spectrum of an element in any unital algebra over $\mathbb{C}$ in an identical way. (Thus, if $V$ is a finite-dimensional complex vector space and $T \in \mathcal{L}(V)$, then $\sigma(T)$ is the set of eigenvalues of $T$.) However, the interplay between the topological and algebraic structure in a Banach algebra has important consequences for the properties of the spectrum.

XV.10.3.5. Example XV.10.3.3.(i) shows one basic reason why we restrict to complex algebras: operators on real vector spaces can fail to have (real) eigenvalues since $\mathbb{R}$ is not algebraically closed, for example a rotation in $\mathbb{R}^2$. There are deeper reasons why we restrict to complex algebras, involving applications of Complex Analysis (e.g. XV.10.3.25.).
Topological Properties of the Spectrum and Resolvent

XV.10.3.6. Proposition. Let $A$ be a unital Banach algebra, and $x \in A$. Then $\sigma_A(x)$ is closed in $\mathbb{C}$, i.e. $\rho_A(x)$ is open in $\mathbb{C}$.

Proof: This follows immediately from the fact that $A^{-1}$ is open in $A$, since $\lambda \mapsto x - \lambda 1$ is a continuous function from $\mathbb{C}$ to $A$.

XV.10.3.7. Proposition. Let $A$ be a unital Banach algebra, and $x \in A$. If $\lambda \in A(x)$, then $|\lambda| \leq \|x\|$. Thus $\sigma_A(x)$ is bounded in $\mathbb{C}$, hence compact.

Proof: The case $x = 0$ is trivial ($A(0) = \{0\}$), so suppose $x \neq 0$. Let $\alpha \in \mathbb{C}$. If $|\alpha| < \frac{1}{\|x\|}$, then the series $\sum_{k=0}^{\infty} (\alpha x)^k$ converges to an inverse for $1 - \alpha x$ by XV.10.2.9. So if $\lambda \in \mathbb{C}$, $|\lambda| > \|x\|$, we have that $1 - \frac{1}{\lambda} x$ is invertible, and hence $x - \lambda 1 = -\lambda(1 - \frac{1}{\lambda} x)$ is also invertible and $\lambda \notin \sigma_A(x)$.

XV.10.3.8. We will see later (XV.10.3.25.) that $\sigma_A(x)$ is always nonempty. A more careful analysis (XV.10.3.30.) along the lines of the argument in the proof of XV.10.3.7. will give a more precise description of the size of the set $\sigma_A(x)$.

XV.10.3.9. Let $A$ be a unital Banach algebra, and $x \in A$. Then continuity of inversion implies that the function $R : \rho_A(x) \to A^{-1}$ given by $R(\lambda) = (\lambda 1 - x)^{-1} = -(x - \lambda 1)^{-1}$ is continuous. $R$ is called the resolvent function of $x$, with $R(\lambda)$ usually denoted $R_A(x)$; it is actually far more than just continuous in $\lambda$ (XV.10.3.23.). (The sign convention for $R_A(x)$ is not universal.)

Dependence of Spectrum on the Algebra

XV.10.3.10. The spectrum of an element can depend on which containing Banach algebra is considered: if $A$ is a (unital) Banach algebra and $B$ a (unital) closed subalgebra of $A$, hence itself a Banach algebra, and $x \in B$, then $x$ can be invertible in $A$ but not in $B$, i.e. we can have $x^{-1} \notin B$. Obviously $\sigma_A(x) \subseteq \sigma_B(x)$, but the containment can be proper:

XV.10.3.11. Example. Let $\mathbb{T}$ be the unit circle in $\mathbb{C}$, and $A = C(\mathbb{T})$. Let $f$ be the “identity function” $f(z) = z$ from $\mathbb{T}$ to $\mathbb{C}$ (note that the term “identity function” can be confusing here since $f$ is not the multiplicative identity of $A$). Then $\sigma_A(f)$ is the range of $f$ (XV.10.3.3.(ii)), i.e. $\sigma_A(f) = \mathbb{T}$.

Let $B$ be the subset of $A$ consisting of functions which extend to functions continuous on the closed unit disk $\overline{\mathbb{D}}$ and holomorphic on $\mathbb{D}$ (B is exactly the algebra $\mathcal{P}$ of Exercise XV.8.3.10.). By the Maximum Modulus Theorem (...), such an extension, if it exists, is unique. By the Maximum Modulus Theorem and X.4.1.2., $B$ is a closed unital subalgebra of $A$, and $f \in B$. However, if $|\lambda| \leq 1$, the unique extension $g_{\lambda}$ of
$f - \lambda 1$ to $\overline{D}$ is $g_\lambda(z) = z - \lambda$, which is not invertible in $B$. If $|\lambda| > 1$, then $\frac{1}{\overline{f}}$ is holomorphic on $\mathbb{C} \setminus \{\lambda\}$, hence on $\overline{D}$, so $f - \lambda 1$ is invertible in $B$. Thus $\sigma_B(f) = \overline{D}$.

However, $\sigma_B(x)$ cannot be too much larger than $\sigma_A(x)$:

**XV.10.3.12.** Proposition. Let $A$ be a unital Banach algebra and $B$ a closed unital subalgebra of $A$, and let $x \in B$. Then $\sigma_A(x) \subseteq \sigma_B(x)$ and $\partial(\sigma_B(x)) \subseteq \partial(\sigma_A(x)) \subseteq \sigma_A(x)$, where $\partial$ denotes topological boundary $()$.

**Proof:** We have already made the trivial observation that $\sigma_A(x) \subseteq \sigma_B(x)$. Suppose $\lambda \in \partial(\sigma_B(x))$. Then $\lambda \in \sigma_B(x)$ since $\sigma_B(x)$ is closed, and there is a sequence $(\lambda_n)$ in $\rho_B(x)$ with $\lambda_n \to \lambda$. Since $\rho_B(x) \subseteq \rho_A(x)$, $\lambda_n \in \rho_A(x)$ for all $n$, so either $\lambda \in \partial(\sigma_A(x))$ (if $\lambda \in \sigma_A(x)$) or $\lambda \in \rho_A(x)$. But if $\lambda \in \rho_A(x)$ (i.e. $x - \lambda 1$ is invertible in $A$), then $(x - \lambda_n 1)^{-1} \to (x - \lambda 1)^{-1}$ by XV.10.3.9., and $(x - \lambda_n 1)^{-1} \in B$ for all $n$, so $(x - \lambda 1)^{-1} \in B$ since $B$ is closed in $A$, contradicting that $\lambda \in \sigma_B(x)$. Thus $\lambda \in \partial(\sigma_A(x))$.  

**XV.10.3.13.** Thus, if $A$ is a unital Banach algebra and $B$ a closed unital subalgebra of $A$, and $x \in B$, then $\sigma_B(x)$ is the union of $\sigma_A(x)$ and possibly some bounded connected components of the complement of $\sigma_A(x)$. If $\sigma_A(x)$ does not divide $\mathbb{C}$ (i.e. if the complement is connected), then necessarily $\sigma_B(x) = \sigma_A(x)$. This is also true if $\sigma_B(x)$ has empty interior.

**Spectral Mapping Properties**

**XV.10.3.14.** If $f$ is a polynomial with complex coefficients, and $x$ is an element of a unital algebra $A$, then there is an obvious way to apply $f$ to $x$ to obtain an element $f(x) \in A$: if

$$f(X) = a_0 + a_1 X + a_2 X^2 + \cdots + a_n X^n$$

then

$$f(x) = a_0 1 + a_1 x + a_2 x^2 + \cdots + a_n x^n.$$ 

If $f$ and $g$ are polynomials with complex coefficients, and $x \in A$, then $(f + g)(x) = f(x) + g(x)$ and $(fg)(x) = f(x)g(x)$, i.e. the map $f \mapsto f(x)$ is a homomorphism $()$ from the polynomial ring $\mathbb{C}[X]$ to $A$.

**XV.10.3.15.** Proposition. [Spectral Mapping Theorem for Polynomials] Let $A$ be a unital algebra over $\mathbb{C}$, $x \in A$, and $f$ a polynomial with complex coefficients. Then

$$\sigma_A(f(x)) = \{f(\lambda) : \lambda \in \sigma_A(x)\}.$$ 

**Proof:** Let $\mu \in \mathbb{C}$. Since $\mathbb{C}$ is algebraically closed, the polynomial $f(X) - \mu$ factors into linear factors in $\mathbb{C}[X]$:

$$f(X) - \mu = (X - \lambda_1)(X - \lambda_2) \cdots (X - \lambda_n)$$

for some $\lambda_1, \ldots, \lambda_n \in \mathbb{C}$ (not necessarily distinct). We then have

$$f(x) - \mu 1 = (x - \lambda_1 1) \cdots (x - \lambda_n 1)$$

1818
in $A$. Then by the next lemma $f(x) - \mu 1$ is invertible in $A$ if and only if $x - \lambda_k 1$ is invertible in $A$ for all $k$, i.e. $\mu \in \sigma_A(f(x))$ if and only if $\lambda_k \in \sigma_A(x)$ for some $k$. Since the numbers $\lambda_1, \ldots, \lambda_n$ are precisely the complex numbers $\lambda$ such that $f(\lambda) = \mu$, the result follows.

**XV.10.3.16. Lemma.** Let $A$ be a unital ring (e.g. a unital algebra over a field $F$), and $a_1, \ldots, a_n \in A$. If the $a_k$ commute, then $a = a_1 a_2 \cdots a_n$ is invertible in $A$ if and only if each $a_k$ is invertible in $A$, i.e. $a$ is invertible if and only if each $a_k$ is invertible in $A$.

**Proof:** If the $a_k$ are invertible, then $a$ is invertible, and $a^{-1} = a_1^{-1} \cdots a_n^{-1}$ (this direction holds even if the $a_k$ do not commute). Conversely, if the $a_k$ commute and $a$ is invertible, we have for each $k$

$$a_k(a_1 a_2 \cdots a_{k-1} a_{k+1} \cdots a_n a^{-1}) = 1$$

so $a_k$ is both left and right invertible in $A$.

Note that the conclusion can be false if the $a_k$ do not commute ()

**XV.10.3.17. Proposition.** [Spectral Mapping Theorem for Inverses] Let $A$ be a unital algebra over $\mathbb{C}$, and $x \in A$. If $x$ is invertible in $A$ (i.e. $0 \notin \sigma_A(x)$), then

$$\sigma_A(x^{-1}) = \left\{ \frac{1}{\lambda} : \lambda \in \sigma_A(x) \right\}.$$

**Proof:** Since $x^{-1}$ is invertible, $0 \notin \sigma_A(x^{-1})$. If $\lambda \neq 0$, we have

$$x^{-1} - \frac{1}{\lambda} = -\frac{1}{\lambda} x^{-1}(x - \lambda 1)$$

and $x^{-1}$ and $x - \lambda 1$ commute, so $x^{-1} - \frac{1}{\lambda} 1$ is invertible if and only if $x - \lambda 1$ is invertible.

Here is a cute fact related in spirit:

**XV.10.3.18. Proposition.** Let $A$ be a unital algebra over $\mathbb{C}$, $x, y \in A$. Then

$$\sigma_A(xy) \cup \{0\} = \sigma_A(yx) \cup \{0\}.$$

**Proof:** Suppose $\lambda \neq 0$ and $xy - \lambda 1$ is invertible (i.e. $\lambda \notin \sigma_A(xy)$). Then, if $r = (xy - \lambda 1)^{-1}$, we have

$$(xy - \lambda 1)r = r(xy - \lambda 1) = 1$$

$$xyr = rxy = 1 - \lambda r$$

So we have

$$-\frac{1}{\lambda} (1 - yr)(xy - \lambda 1) = -\frac{1}{\lambda} [yx - yrxy + \lambda yrx - \lambda 1] = -\frac{1}{\lambda} [yx - y(1 - \lambda r)x + \lambda yrx - \lambda 1] = 1$$

and similarly $-\frac{1}{\lambda} (yx - \lambda 1)(1 - yr) = 1$, so $yx - \lambda 1$ is invertible and $\lambda \notin \sigma_A(yx)$. The $x$ and $y$ can be interchanged in the argument.
**XV.10.3.19.** So, while $0 \in \sigma_A(xy)$ (i.e. $xy$ not invertible) does not imply $0 \in \sigma_A(yx)$ (i.e. $yx$ not invertible), the rest of the two spectra are identical. If $xy$ is invertible but $yx$ is not invertible, then 0 is an isolated point of the spectrum of $yx$ (since $\sigma_A(xy) = \sigma_A(yx) \setminus \{0\}$ is closed in $\mathbb{C}$).

**Holomorphic Properties of the Resolvent**

Recall (XV.10.3.9.) that if $x$ is an element of a unital Banach algebra $A$, the resolvent function of $x$ is defined to be

$$R_\lambda(x) = (\lambda I - x)^{-1}$$

for $\lambda \in \rho_A(x) \subseteq \mathbb{C}$. In what follows, we keep $A$ and $x$ fixed, and just write $R_\lambda$ for $R_\lambda(x)$.

**XV.10.3.20.** **Proposition.**

$$\lim_{|\lambda| \to \infty} R_\lambda = 0 .$$

**Proof:** Note that since $\sigma_A(x)$ is bounded (XV.10.3.7.), $R_\lambda$ is defined for $|\lambda|$ sufficiently large, so the limit potentially exists. If $|\lambda|$ is large, we have

$$R_\lambda = (\lambda 1 - x)^{-1} = \alpha(1 - \alpha x)^{-1}$$

where $\alpha = \frac{1}{\lambda}$. We have

$$\lim_{\alpha \to 0}(1 - \alpha x) = 1$$

and by XV.10.2.10. and XV.10.2.14. we also have

$$\lim_{\alpha \to 0}(1 - \alpha x)^{-1} = 1 .$$

Thus

$$\lim_{\alpha \to 0} \alpha(1 - \alpha x)^{-1} = 0 .$$

\[ \checkmark \]

**XV.10.3.21.** **Proposition.** Let $\lambda, \mu \in \rho_A(x)$. Then

$$R_\mu = (1 - y)^{-1}R_\lambda$$

where $y = (\lambda - \mu)R_\lambda$.

**Proof:** We have

$$\mu 1 - x = (\lambda 1 - x) - (\lambda - \mu) = (\lambda 1 - x)(1 - y)$$

so the formula follows by taking inverses.\[ \checkmark \]

Putting this together with XV.10.2.9., we obtain:
**XV.10.3.22.** COROLLARY. Let \( \lambda_0 \in \rho_A(x) \), and \( \lambda \in \mathbb{C} \). If the series

\[
\sum_{k=0}^{\infty} (\lambda_0 - \lambda)^k R_{\lambda_0}^{k+1}
\]

converges in \( A \), then \( \lambda \in \rho_A(x) \) and the sum is \( R_\lambda \). In particular, if \( |\lambda - \lambda_0| < \frac{1}{\|R_{\lambda_0}\|} \), \( \lambda \in \rho_A(x) \) and the series converges to \( R_\lambda \).

**Proof:** Apply XV.10.3.21. with \((\lambda, \mu)\) replaced by \((\lambda_0, \lambda)\), and apply XV.10.2.9. to \( y = (\lambda_0 - \lambda)R_{\lambda_0} \). ☑️

**XV.10.3.23.** Thus \( R_\lambda \) is locally representable as a power series, and thus is an “analytic function” of \( \lambda \). There is a theory of Banach-space-valued analytic functions () which applies. However, we will need only the following weaker form which reduces consideration to complex-valued functions:

**XV.10.3.24.** COROLLARY. Let \( \phi \in A^* \), and define \( f_\phi(\lambda) = \phi(R_\lambda) \) for \( \lambda \in \rho_A(x) \). Then \( f_\phi \) is a holomorphic (analytic) complex-valued function on \( A(x) \).

**Proof:** Fix \( \lambda_0 \in \rho_A(x) \). If \( |\lambda - \lambda_0| < \frac{1}{\|R_{\lambda_0}\|} \), then the infinite series

\[
\sum_{k=0}^{\infty} \phi(R_{\lambda_0}^{k+1})(\lambda_0 - \lambda)^k = \sum_{k=0}^{\infty} (-1)^k \phi(R_{\lambda_0}^{k+1})(\lambda - \lambda_0)^k
\]

converges to \( f_\phi(\lambda) \) by XV.10.3.22. and continuity of \( \phi \). Thus \( f_\phi \) is locally representable by a convergent power series. ☑️

**The Spectrum is Nonempty!**

The first major consequence is:

**XV.10.3.25.** THEOREM. Let \( A \) be a unital Banach algebra, and \( x \in A \). Then \( \sigma_A(x) \) is nonempty.

**Proof:** Suppose \( \sigma_A(x) = \emptyset \), so \( \rho_A(x) = \mathbb{C} \). Let \( \phi \in A^* \). Then \( f_\phi \) is an entire function (). We have

\[
\lim_{|\lambda| \to \infty} f_\phi(\lambda) = 0
\]

by XV.10.3.20. and continuity of \( \phi \). Thus \( f_\phi \) is bounded, hence constant by Liouville’s Theorem (X.3.3.10.). Since the limit at infinity is 0, \( f_\phi \) is identically 0, i.e. \( \phi(R_\lambda) = 0 \) for all \( \lambda \in \mathbb{C} \) and all \( \phi \in A^* \). By () this implies that \( R_\lambda = 0 \) for all \( \lambda \), a contradiction. ☑️

A simple corollary is:
XV.10.3.26. **Corollary.** [Gelfand-Mazur Theorem] The only (complex) Banach division algebra is $\mathbb{C}$.

**Proof:** Recall that $A$ is a division algebra if every nonzero element is invertible. If $x \in A$, there is a $\lambda \in \sigma_A(x)$. For this $\lambda$, $x - \lambda 1$ is not invertible; hence $x - \lambda 1 = 0$, $x = \lambda 1$. Thus every element of $A$ is a scalar multiple of 1. ☐

### Spectral Radius

Let $x$ be an element of a unital Banach algebra $A$. Since $\sigma_A(x)$ is a nonempty compact subset of the plane, it makes sense to make the following definition:

**XV.10.3.27. Definition.** The *spectral radius* of $x$ is

$$
 r_\sigma(x) = \sup_{\lambda \in \sigma_A(x)} |\lambda| = \max_{\lambda \in \sigma_A(x)} |\lambda| .
$$

**XV.10.3.28.** The notation $r_\sigma(x)$ does not reflect the choice of the Banach algebra $A$ containing $x$, on which the spectral radius potentially depends. But it is an immediate consequence of XV.10.3.12. that if $B$ is a unital Banach subalgebra of $A$ and $x \in B$, then the same spectral radius for $x$ is obtained whether $\sigma_A(x)$ or $\sigma_B(x)$ is used in the definition, so $r_\sigma(x)$ in fact does not depend on which Banach algebra containing $x$ is used. We could indeed just use the *smallest* Banach subalgebra of $A$ containing $x$, i.e. the closed linear span of $\{x^n : n \geq 0\}$.

**XV.10.3.29.** Note also that the spectral radius of $x$ depends only on the *algebraic* structure of $A$ and not on the norm. However, we needed to know that $A$ was a Banach algebra with respect to *some* norm in order to conclude that $\sigma_A(x)$ is nonempty and bounded so that the spectral radius is well defined.

There is nonetheless a tight relationship between the spectral radius and norm:

**XV.10.3.30. Theorem.** Let $A$ be a Banach algebra and $x \in A$. Then

$$
 r_\sigma(x) = \lim_{n \to \infty} \|x^n\|^{1/n} = \inf_n \|x^n\|^{1/n} .
$$

The theorem will be proved in several steps.

**XV.10.3.31.** Part of the content of the theorem is that

$$
 \lim_{n \to \infty} \|x^n\|^{1/n}
$$

exists and equals

$$
 \inf_n \|x^n\|^{1/n} .
$$
This can be proved directly using IV.11.3., setting \( n = \| x \|^n \), since \( \| x^n + m \| = \| x^n \| \leq \| x \|^n \| x^m \| \) for any \( n, m \in \mathbb{N} \) by submultiplicativity. It will not be necessary for us to prove this since it will follow automatically from our other arguments. The sequence \( \| x^n \|^{1/n} \) is not necessarily nonincreasing.

The first observation for the proof of XV.10.3.30. is that \( \mathcal{r}(x) \leq \| x \| \) by XV.10.3.7. We can do better by noting the following consequence of the Spectral Mapping Theorem for polynomials (XV.10.3.15):

**XV.10.3.32. Proposition.** Let \( x \) be an element of a unital Banach algebra \( A \), and \( f \) a polynomial with complex coefficients. Then
\[
r_\sigma(f(x)) = \max_{\lambda \in \sigma(A)} |f(\lambda)|.
\]
In particular, \( r_\sigma(x^n) = [r_\sigma(x)]^n \) for any \( n \in \mathbb{N} \).

**XV.10.3.33. Corollary.** Let \( x \) be an element of a unital Banach algebra \( A \). Then
\[
r_\sigma(x) \leq \inf_n \| x^n \|^{1/n}.
\]

**Proof:** By XV.10.3.32. and XV.10.3.7. we have, for any \( n \),
\[
[r_\sigma(x)]^n = r_\sigma(x^n) \leq \| x^n \|.
\]

**XV.10.3.34.** So to finish the proof of Theorem XV.10.3.30., it suffices to show that
\[
r_\sigma(x) \geq \limsup_{n \to \infty} \| x^n \|^{1/n}.
\]
This will take some work using Complex Analysis. Our argument follows [Ped89]; roughly speaking, it is based on X.4.4.6.

**XV.10.3.35.** Fix \( \phi \in \mathcal{A}^* \) and let \( f_\phi(\lambda) = \phi(R_\lambda) \). Then \( f_\phi \) is analytic on \( \rho_A(x) \), and in particular on \( \Omega = \{ \lambda \in \mathbb{C} : |\lambda| > r_\sigma(x) \} \). We have that
\[
f_\phi(\lambda) = \frac{1}{\lambda} \phi \left( \left[ 1 - \frac{1}{\lambda} x \right]^{-1} \right) = \frac{1}{\lambda} \phi \left( \sum_{k=0}^{\infty} \left[ \frac{1}{\lambda} x \right]^k \right) = \frac{1}{\lambda} \sum_{k=0}^{\infty} \phi \left( \left[ \frac{1}{\lambda} x \right]^k \right) = \sum_{k=0}^{\infty} \lambda^{-k-1} \phi(x^k)
\]
for \( |\lambda| > \| x \| \); thus this is the Laurent series for \( f_\phi \) on \( \Omega \) and converges to \( f_\phi \) u.c. on \( \Omega \) (X.4.4.11.).
Now fix $s > r_\sigma(x)$. For any $n \in \mathbb{N}$, the series

$$\sum_{k=0}^{\infty} \lambda^{n-k} \phi(x^k)$$

converges uniformly to $g_n(\lambda) = \lambda^{n+1} f_\phi(\lambda)$ on the circle $\gamma$ of radius $s$ around $0$, so we can compute the integral of $g_n$ around $\gamma$ by integrating term-by-term:

$$\int_0^{2\pi} s^{n+1} e^{i(n+1)\theta} \phi(se^{i\theta}) d\theta = \sum_{k=0}^{\infty} \left[ \int_0^{2\pi} s^{-k} e^{i(n-k)\theta} \phi(x^k) d\theta \right] = \int_0^{2\pi} \phi(x^n) d\theta = 2\pi \phi(x^n)$$

since the integrals for $k \neq n$ are zero. Thus we obtain that

$$|\phi(x^n)| \leq s^{n+1} M(s) \|\phi\|$$

where $M(s) = \max_{|\lambda|=s} \|R_\lambda\|$. Since $\phi \in A^*$ is arbitrary, by the Hahn-Banach Theorem we conclude that

$$\|x^n\| \leq s^{n+1} M(s)$$

$$\|x^n\|^{1/n} \leq s^{\frac{n+1}{n}} M(s)^{1/n}$$

for every $n$. Taking lim sup as $n \to \infty$, we obtain

$$\limsup_{n \to \infty} \|x^n\|^{1/n} \leq s.$$ 

This holds for all $s > r_\sigma(x)$, so we conclude

$$\limsup_{n \to \infty} \|x^n\|^{1/n} \leq r_\sigma(x).$$

This completes the proof of Theorem XV.10.3.30.

XV.10.4. Holomorphic Functional Calculus

XV.10.4.1. If $f(t) = \alpha_1 t + \cdots + \alpha_n t^n$ is a polynomial with complex coefficients, without constant term (i.e. $f(0) = 0$), and $x$ is an element of an algebra $A$ over $\mathbb{C}$, then there is an obvious way to apply $f$ to $x$ to obtain an element $f(x) = \alpha_1 x + \cdots + \alpha_n x^n \in A$. If $A$ is a Banach algebra, there is a very important way of extending this procedure to holomorphic functions, called functional calculus.

XV.10.4.2. If $X$ is a compact subset of $\mathbb{C}$, denote by $H(X)$ the algebra of functions holomorphic in a neighborhood of $X$ and vanishing at 0 if $0 \in X$, with functions identified if they agree on a neighborhood of $X$. Functional calculus gives a homomorphism from $H(\sigma_A(x))$ to the Banach subalgebra of $A$ generated by $x$ extending the map for polynomials. The image of $f$ is denoted $f(x)$. The element $f(x)$ can be defined using the Cauchy Integral Formula, but in some cases (e.g. if $f$ is entire) it is also given by a power series. If $A$ is unital, functional calculus is also defined for holomorphic functions not vanishing at zero. Functional calculus has the following properties, which (along with the elementary definition for polynomials) determine it uniquely:
XV.10.4.3. **Proposition.** Let $A$ be a Banach algebra and $x \in A$. Then

(i) For any $f \in H(\sigma_A(x))$, $\sigma_A(f(x)) = \{f(\lambda) : \lambda \in \sigma_A(x)\}$.

(ii) If $f \in H(\sigma_A(x))$ and $g \in H(f(\sigma_A(x))) = H(\sigma_A(f(x)))$, so $g \circ f \in H(\sigma_A(x))$, then $(g \circ f)(x) = g(f(x))$.

(iii) If $f_n, f \in H(\sigma_A(x))$ and $f_n \to f$ uniformly on a neighborhood of $\sigma_A(x)$, then $f_n(x) \to f(x)$.

(iv) If $B$ is a Banach algebra and $\phi : A \to B$ a continuous (bounded) homomorphism, then $\phi(f(x)) = f(\phi(x))$ for any $f \in H(\sigma_A(x))$.

**Proof:** (i): Suppose $A$ is unital. Let $f$ be analytic on $U$ containing $\sigma_A(x)$. If $\lambda \in \sigma_A(x)$, then $f(z) - f(\lambda) = (z - \lambda)g(z)$ with $g$ analytic on $U$; then $f(x) - f(\lambda)1 = (x - \lambda 1)g(x)$, and since $x - \lambda 1$ and $g(x)$ commute and $x - \lambda 1$ is not invertible, $f(\lambda) \in \sigma_A(f(x))$. Conversely, if $\mu \notin \{f(\lambda) : \lambda \in \sigma_A(x)\}$, then $h(z) = (f(z) - \mu)^{-1}$ is analytic on $\{z \in U : f(z) \neq \mu\}$, which contains $\sigma_A(x)$, and $h(x) = (f(x) - \mu 1)^{-1}$.

(ii)-(iv) are straightforward.

XV.10.4.4. An especially important case of functional calculus uses the exponential function $f(z) = e^z$. If $x$ is any element of a unital Banach algebra $A$, then $f(x)$ is defined and denoted $e^x$. The element $e^x$ is given by the power series $\sum_{n=0}^{\infty} \frac{x^n}{n!}$. For any $x, e^x$ is invertible, with inverse $e^{-x}$; $e^{x+y} = e^x e^y$ if $x$ and $y$ commute. If $A$ is a Banach *-algebra, then $(e^x)^* = e^{(x^*)}$. Conversely, if $\sigma_A(x)$ is contained in a simply connected open set not containing 0, let $f(z)$ be a branch of the logarithm holomorphic in a neighborhood of $\sigma_A(x)$; then $y = f(x)$ satisfies $e^y = x$. In particular, if $\|1 - x\| < 1$, then there is a $y \in A$ with $\|y\| < \pi/2$ with $e^y = x$ (use the principal branch of log).

XV.10.4.5. If $A$ is a unital Banach algebra, write $A^{-1}$ (also often written $GL_1(A)$) for the (open) set of invertible elements in $A$, and $A_0^{-1}$ (or $GL_1(A)_0$) for the connected component of the identity in $A^{-1}$. Then

$$exp(A) = \{e^y : y \in A\} \subseteq A^{-1}$$

is path-connected, and by the above the subgroup of $A^{-1}$ generated algebraically by $exp(A)$ is a connected open subgroup, hence equal to $A_0^{-1}$. In particular, $A_0^{-1}$ is an open subgroup of $A^{-1}$, and every element of $A_0^{-1}$ is a finite product of exponentials.

If $A$ and $B$ are unital Banach algebras and $\phi$ is a bounded homomorphism from $A$ onto $B$, and $y \in B^{-1}$, then there is not necessarily an $x \in A^{-1}$ with $\phi(x) = y$.

XV.10.4.6. **Example.** Let $\mathbb{D}$ be the closed unit disk in $\mathbb{C}$, and $\mathbb{T}$ its boundary. There is a *-homomorphism $\phi : C(\mathbb{D}) \to C(\mathbb{T})$ given by restriction. But if $g \in C(\mathbb{T})$ with $g(z) = z$, then $g \in C(\mathbb{T})^{-1}$, but there is no $f \in C(\mathbb{D})^{-1}$ with $\phi(f) = g$.

The image in the Calkin algebra of a Fredholm operator of nonzero index is another example. However:
XV.10.4.7. PROPOSITION. If $\phi : A \to B$ is a surjective bounded homomorphism of unital Banach algebras, then $\phi(A_o^{-1}) = B_o^{-1}$.

This can be proved either by an application of the Open Mapping Theorem or by noting that if $x \in A$, then $\phi(e^x) = e^{\phi(x)}$.

Homomorphisms

We have a generalization of XV.10.3.10:

XV.10.4.8. PROPOSITION. Let $A$ and $B$ be unital Banach algebras, and $\phi : A \to B$ a unital homomorphism. If $x \in A$, then $\sigma_B(\phi(x)) \subseteq \sigma_A(x)$.

PROOF: If $y \in A$ is invertible in $A$, then $\phi(y)$ is invertible in $B \ [\phi(y)^{-1} = \phi(y^{-1})]$. ♦
XV.10.5. Spectral Theory for Bounded Operators

In this section, we examine the spectrum and its properties for bounded operators on Banach spaces, concentrating almost exclusively on the case of operators on Hilbert spaces.

We will essentially follow the first comprehensive development and exposition of this theory, given by F. Riesz [7] in 1913, abstracted to Banach spaces and Hilbert spaces (which did not exist in 1913!) and with some modern technical simplifications.

XV.10.5.1. If \( T \in B(\mathcal{X}, \mathcal{Y}) \) (\( \mathcal{X}, \mathcal{Y} \) Banach spaces) is invertible in the algebraic sense, i.e. \( T \) is one-to-one and onto, then \( T^{-1} \) is automatically bounded by the Open Mapping Theorem. So there are two ways a bounded operator \( T \) can fail to be invertible:

- \( T \) is not bounded below (recall that \( T \) is bounded below if \( \exists \epsilon > 0 \) such that \( \|Tx\| \geq \epsilon \|x\| \) for all \( x \in \mathcal{X} \)

- \( \mathcal{R}(T) \) is not dense.

These possibilities are not mutually exclusive. For example, if \( T \) is a normal operator on a Hilbert space, then \( \mathcal{N}(T) = \mathcal{R}(T)^\perp \) (\( \perp \)), so if \( \mathcal{R}(T) \) is not dense, then \( T \) is not one-to-one and hence not bounded below. Thus a normal operator on a Hilbert space is invertible if and only if it is bounded below.

XV.10.5.2. Proposition. Let \( T \) be a bounded operator on a Hilbert space \( \mathcal{H} \). Then \( T \) is invertible if and only if both \( T \) and \( T^* \) are bounded below.

Proof: If \( T \) is invertible, then for any \( x \) we have \( \|x\| = \|T^{-1}(Tx)\| \leq \|T^{-1}\|\|Tx\| \), so \( T \) is bounded below. Since \( T^* \) is also invertible, \( T^* \) is bounded below too.

Conversely, suppose \( T \) and \( T^* \) are bounded below. In particular, \( T^* \) is one-to-one, so \( \mathcal{N}(T^*) = \mathcal{R}(T)^\perp = \{0\} \), and thus \( \mathcal{R}(T) \) is dense in \( \mathcal{H} \). If \( y \in \mathcal{H} \), then there is a sequence \( (y_n) \) in \( \mathcal{R}(T) \) with \( y_n \to y \). For each \( n \) there is an \( x_n \in \mathcal{H} \) (unique, since \( T \) is one-to-one) with \( y_n = Tx_n \). Fix \( \epsilon > 0 \) such that \( \|Tx\| \geq \epsilon \|x\| \) for all \( x \in \mathcal{H} \). Then, for any \( n \) and \( m \),

\[
\|x_n - x_m\| \leq \epsilon^{-1}\|Tx_n - Tx_m\| = \epsilon^{-1}\|y_n - y_m\|
\]

and since \( (y_n) \) is a Cauchy sequence, so is \( (x_n) \). Let \( x_n \to x \). We then have \( Tx_n \to Tx \) since \( T \) is continuous (bounded), so \( y = Tx \) and \( T \) is surjective. \( T^{-1} \) is automatically bounded by the Bounded Inverse Theorem.

Recall the following definition from XV.10.3.1., rewritten in the context of operators and expanded:

XV.10.5.3. Definition. Let \( \mathcal{X} \) be a normed vector space, \( T \in B(\mathcal{X}) \). The spectrum of \( T \) is

\[
\sigma(T) = \{ \lambda \in \mathbb{C} : T - \lambda I \text{ is not invertible} \}
\]

The point spectrum of \( T \) is

\[
\sigma_p(T) = \{ \lambda \in \mathbb{C} : T - \lambda I \text{ is not one-to-one} \}
\]

(thus \( \sigma_p(T) \) is exactly the set of eigenvalues of \( T \)). The continuous spectrum \( \sigma_c(T) \) of \( T \) is the set of \( \lambda \in \mathbb{C} \) such that \( T - \lambda I \) is one-to-one with dense range, but not bounded below. The residual spectrum \( \sigma_r(T) \) is the set of \( \lambda \in \mathbb{C} \) such that \( T - \lambda I \) is one-to-one but does not have dense range.

Note that \( \sigma(T) \) is the disjoint union of \( \sigma_p(T) \), \( \sigma_c(T) \), and \( \sigma_r(T) \). One or more of these sets can be empty (XV.10.5.7.). But we have the fundamental fact from XV.10.3.6., XV.10.3.25., and XV.10.3.30.:
**XV.10.5.4. Theorem.** Let $\mathcal{X}$ be a Banach space, $T \in \mathcal{B}(\mathcal{X})$. Then

(i) $\sigma(T)$ is a nonempty compact subset of $\mathbb{C}$.

(ii) $r_\sigma(T) = \max_{\lambda \in \sigma(T)} |\lambda| = \lim_{n \to \infty} \|T^n\|^{1/n} = \inf_n \|T^n\|^{1/n}$.

if $\mathcal{X}$ is finite-dimensional, then $\sigma(T) = \sigma_p(T)$, and if $\mathcal{X}$ is a Hilbert space and $T$ is normal, then $\sigma_*(T) = \emptyset$.

The spectrum of $T$ can be thought of as the set of “generalized eigenvalues” of $T$ (note that every actual eigenvalue of $T$ is in the spectrum). The first definition (not the same as the one here – essentially the reciprocal) and name “spectrum” were given by HILBERT; the modern definition is due to F. RIESZ.

**XV.10.5.5. Proposition.** Let $\mathcal{H}$ be a Hilbert space, and $T \in \mathcal{B}(\mathcal{H})$. Then $\sigma(T^*) = \{\bar{\lambda} : \lambda \in \sigma(T)\}$.

**Proof:** This follows immediately from the fact that if $S \in \mathcal{B}(\mathcal{H})$, then $S$ is invertible if and only if $S^*$ is invertible, and $(T + \lambda I)^* = T^* + \bar{\lambda}I$.

The relation between $\sigma_p(T)$, $\sigma_c(T)$, $\sigma_r(T)$ and $\sigma_p(T^*)$, $\sigma_c(T^*)$, $\sigma_r(T^*)$ is slightly more complicated:

**XV.10.5.6. Proposition.** Let $\mathcal{H}$ be a Hilbert space, and $T \in \mathcal{B}(\mathcal{H})$. If $\lambda \in \mathbb{C}$, then

(i) If $\lambda \in \sigma_p(T)$, then $\bar{\lambda} \in \sigma_p(T^*) \cup \sigma_r(T^*)$.

(ii) If $\lambda \in \sigma_r(T)$, then $\bar{\lambda} \in \sigma_p(T^*)$.

(iii) $\lambda \in \sigma_p(T) \cup \sigma_r(T)$ if and only if $\bar{\lambda} \in \sigma_p(T^*) \cup \sigma_r(T^*)$.

(iv) $\lambda \in \sigma_c(T)$ if and only if $\bar{\lambda} \in \sigma_c(T^*)$.

**Proof:** Parts (i) and (ii) follow immediately from the relation $\mathcal{N}(S) = \mathcal{R}(S^*)^\perp$; (iii) follows trivially from (i) and (ii), and (iv) follows from (iii) and XV.10.5.5. by process of elimination.

**XV.10.5.7. Examples.** (i) If $\mathcal{X}$ is finite-dimensional, then $\sigma(T) = \sigma_p(T)$ is the set of eigenvalues of $T$.

(ii) If $T$ is a normal operator on a Hilbert space, then $N(T) = R(T)^\perp$ (i), so if $R(T)$ is not dense, then $T$ is not one-to-one and hence not bounded below. Thus a normal operator on a Hilbert space is invertible if and only if it is bounded below, and $\sigma_r(T) = \emptyset$.

(iii) Let $(\alpha_n)$ be a bounded sequence in $\mathbb{C}$. Define $T : \ell^2 \to \ell^2$ by

$$T(\xi_1, \xi_2, \ldots) = (\alpha_1 \xi_1, \alpha_2 \xi_2, \ldots).$$

Then $T \in \mathcal{B}(\ell^2)$, $\|T\| = \sup_n |\alpha_n|$. We have $\sigma_p(T) = \{\alpha_n : n \in \mathbb{N}\}$, $\sigma_r(T) = \emptyset$ since $T$ is normal, and $\sigma(T)$ is the closure of $\sigma_p(T)$, so if $\sigma_p(T)$ is not closed we have $\sigma_c(T) = \sigma(T) \setminus \sigma_p(T) \neq \emptyset$. 

1828
(iv) Let $T$ be the unilateral shift on $\ell^2$: 

$$T(\xi_1, \xi_2, \ldots) = (0, \xi_1, \xi_2, \ldots).$$

Then $T$ is an isometry, hence $\|T\| = 1$. $T$ is one-to-one, but $\mathcal{R}(T)$ is not dense in $\ell^2$; thus $0 \in \sigma_r(T)$. It is easy to see that $\sigma_p(T) = \emptyset$. By XV.10.5.5., XV.10.5.6., and (v) below, $\sigma(T)$ is the closed unit disk $\mathbb{D}$ in $\mathbb{C}$, $\sigma_r(T)$ is the open unit disk, and $\sigma_e(T)$ is the unit circle.

(v) Let $T^*$ be the adjoint of the unilateral shift of (iv). Then $T^*$ is the left shift:

$$T^*(\xi_1, \xi_2, \ldots) = (\xi_2, \xi_3, \ldots).$$

If $\lambda \in \mathbb{C}$, $|\lambda| < 1$, then the vector $x_\lambda = (1, \lambda, \lambda^2, \ldots)$ is in $\ell^2$ and $T^*(x_\lambda) = \lambda x_\lambda$; thus $\lambda \in \sigma_p(T^*)$. It is easy to see that no complex number of absolute value 1 can be an eigenvalue of $T^*$, so $\sigma_p(T^*)$ is the open unit disk $\mathbb{D}$. Thus $\sigma(T^*)$ contains $\mathbb{D}$ since it is closed. But $\|T^*\| = 1$, so $r(\sigma(T^*)) \leq 1$ and $\sigma(T^*) \subseteq \mathbb{D}$. Thus $\sigma(T^*) = \mathbb{D}$. By XV.10.5.5., XV.10.5.6., and (iv), $\sigma_e(T^*)$ is the unit circle and $\sigma_r(T^*) = \emptyset$.

### Numerical Range

**XV.10.5.8.** The numerical range of an operator $T$ on a Hilbert space $\mathcal{H}$ is 

$$W(T) = \{\langle Tx, x \rangle : \|x\| = 1\}.$$ 

Set 

$$w(T) = \sup\{\|x\| : \lambda \in W(T)\}.$$ 

It is obvious that $W(T^*) = \{\lambda : \lambda \in W(T)\}$, so $w(T^*) = w(T)$; if $T = T^*$, then $W(T) \subseteq \mathbb{R}$. (Conversely, if $W(T) \subseteq \mathbb{R}$, then $T = T^*$: for $\xi, \eta \in \mathcal{H}$, expand $\langle T(\xi + \eta), \xi + \eta \rangle \in \mathbb{R}$ and $\langle T(\xi + i\eta), \xi + i\eta \rangle \in \mathbb{R}$.)

**XV.10.5.9.** **Proposition.** If $T \in \mathcal{B}(\mathcal{H})$, then $\sigma(T) \subseteq W(T)$ and $r(\sigma(T)) \leq w(T) \leq \|T\|$.

**Proof:** To see that $\sigma(T) \subseteq W(T)$, note that if $\lambda \in \sigma(T)$, then by XV.10.5.2. either $T - \lambda I$ or $(T - \lambda I)^*$ is not bounded below, so there is a sequence $(x_n)$ of unit vectors such that either $(T - \lambda I)x_n \to 0$ or $(T - \lambda I)^*x_n \to 0$. In either case, we obtain that $(T - \lambda I)x_n, x_n) \to 0$ by the CBS inequality. The inequality $r(\sigma(T)) \leq w(T)$ follows immediately, and $w(T) \leq \|T\|$ is immediate from the CBS inequality.

**XV.10.5.10.** **Examples.** (i) Note that $r(\sigma(T)) = w(T) = \|T\|$ does not hold for general operators: for example, let $T$ be the (nilpotent) operator on $\mathbb{C}^2$ given by the matrix $\begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix}$. Then $\sigma(T) = \{0\}$, so $r(\sigma(T)) = 0$; but $\|T\| = 1$. It can be shown by an easy calculation that $W(T) = \{\lambda : |\lambda| \leq 1/2\}$, so $w(T) = 1/2$.

(ii) If $\mathcal{H}$ is finite-dimensional and $T \in \mathcal{B}(\mathcal{H})$, then $W(T)$ is closed since the unit sphere in $\mathcal{H}$ is compact, and thus $\sigma(T) \subseteq W(T)$. But if $\mathcal{H}$ is infinite-dimensional, neither statement is true in general. Let $T \in \mathcal{B}(\ell^2)$ be defined by 

$$T(\xi_1, \xi_2, \ldots) = (\xi_1, \xi_2/2, \ldots, \xi_n/n, \ldots).$$

Then $\sigma(T) = \{0\} \cup \{\frac{1}{n} : n \in \mathbb{N}\}$. But $\langle Tx, x \rangle \neq 0$ if $x \neq 0$, so $0 \notin W(T)$. It is not hard to compute that $W(T) = (0, 1]$. 

1829
**XV.10.5.11.** The expression $\langle Tx, x \rangle$ is not linear in $x$, and anyway the set of unit vectors is not convex. However, perhaps remarkably, the numerical range $W(T)$ is always convex (Hausdorff-Toeplitz Theorem). See XV.10.6.2. for a proof. It is also true that $w(T)$ is a norm on $B(H)$ for a Hilbert space $H$ (XV.10.6.3).

**Self-Adjoint and Positive Operators**

**XV.10.5.12.** Definition. A (necessarily self-adjoint; cf. XV.10.6.4.) bounded operator $T$ on a Hilbert space $H$ is positive if $\langle Tx, x \rangle \geq 0$ for all $x \in H$ (i.e. $W(T) \subseteq [0, +\infty)$). Write $T \geq 0$ if $T$ is positive, and write $B(H)_+$ for the set of positive operators on $H$.

**XV.10.5.13.** If $T \in B(H)$, then $T^*T \geq 0$ (this is also true if $T$ is conjugate-linear); if $T = T^*$, then $\lambda I - T \geq 0$ for $\lambda \geq \|T\|$. Sums and nonnegative scalar multiples of positive operators are positive.

If $S,T$ are self-adjoint operators, write $S \leq T$ if $T - S \geq 0$, i.e. if $\langle Sx, x \rangle \leq \langle Tx, x \rangle$ for all $x$. If $T = T^*$, we have $-w(T)I \leq T \leq w(T)I$, and in particular $-\|T\|I \leq T \leq \|T\|I$.

**XV.10.5.14.** Let $S$ be a positive operator, and let $m$ and $M$ be the inf and sup of $W(S)$ respectively. The form $(x, y) = \langle Sx, y \rangle$ is positive semidefinite, and thus satisfies the CBS inequality, yielding, for all $x,y$, $$|\langle Sx, y \rangle|^2 \leq \langle Sx, x \rangle \langle Sy, y \rangle \leq \langle Sx, x \rangle M \|y\|^2 \leq M^2 \|x\|^2 \|y\|^2.$$ Setting $y = Sx$ and dividing through by $\|Sx\|^2$, we obtain, for all $x$, $$\langle S^2x, x \rangle = \langle Sx, Sx \rangle = \|Sx\|^2 \leq M \langle Sx, x \rangle \leq M^2 \|x\|^2.$$ Since $0 \leq M \leq \|S\|$, we conclude:

**XV.10.5.15.** Proposition. Let $S$ be a positive operator, and let $m$ and $M$ be the inf and sup of $W(S)$ respectively. Then

(i) $\|S\| = M$ and $S^2 \leq MS$.

(ii) If $S$ is bounded below, then $m > 0$.

[For (ii), if $\|Sx\| \geq \epsilon \|x\|$ for all $x$, then $M > 0$, and for $\|x\| = 1$ we have $$\epsilon^2 = \epsilon^2 \|x\|^2 \leq \langle Sx, Sx \rangle \leq M \langle Sx, x \rangle$$ so $m \geq \frac{\epsilon^2}{M}$. In fact, $\epsilon = m$ works and this is the largest possible $\epsilon$.]

**XV.10.5.16.** Proposition. If $T$ is a self-adjoint operator on a Hilbert space $H$, and $m$ and $M$ are the inf and sup of $W(T)$ respectively, then $\sigma(T) \subseteq [m, M] \subseteq \mathbb{R}$ and $m, M \in \sigma(T)$. Thus $r_\sigma(T) = w(T)$.

Proof: $\sigma(T) \subseteq [m, M]$ by XV.10.5.9. Note that $mI \leq T \leq MI$. Applying XV.10.5.15.(ii) to $T - mI$ and $MI - T$, we obtain $m, M \in \sigma(T)$.

1830
 XV.10.5.17.  **Proposition.** Let $T$ be a self-adjoint element of $\mathcal{B}(\mathcal{H})$. Then $r_\sigma(T) = \|T\| (= w(T))$.

**Proof:** By scaling, we may assume $r_\sigma(T) = w(T) = 1$, so $-I \leq T \leq I$. Set $S = (T + I)/2$; then $0 \leq S \leq I$. By XV.10.5.15., $\|S\|^2 \leq S$, so $I - T^2 = 4(S - S^2) \geq 0$, $0 \leq T^2 \leq I$, $\|T^2\| = \|T\|^2 \leq 1$ by () and XV.10.5.15. \hfill \Box

 XV.10.5.18.  In particular, if $T \geq 0$, then $\sigma(T) \subseteq [0, \|T\|]$ and $\|T\| \in \sigma(T)$.

 XV.10.5.19.  The result of XV.10.5.17. also follows easily from the spectral radius formula, since if $T$ is self-adjoint we have $\|T^2\| = \|T\|^2$ (), so by iteration $\|T^{2n}\| = \|T\|^{2^n}$ and thus

$$r_\sigma(T) = \lim_{m \to \infty} \|T^m\|^{1/m} = \lim_{n \to \infty} \|T^{2^n}\|^{1/2^n} = \|T\|.$$  

However, the proof in XV.10.5.17. is more elementary, not requiring ()

We can by a similar argument extend XV.10.5.17.:  

 XV.10.5.20.  **Proposition.** Let $\mathcal{H}$ be a Hilbert space, and $T \in \mathcal{B}(\mathcal{H})$. If $T$ is normal, then $r_\sigma(T) = w(T) = \|T\|$.

**Proof:** We have $\|T\|^2 = \|T^*T\|$ (), and for each $n$, $\|T^n\|^2 = \|(T^n)^*T^n\| = \|(T^*T)^n\|$ since $T$ is normal. But $T^*T$ is self-adjoint, so $\|(T^*T)^{2n}\| = \|T^*T\|^{2^n} = \|T\|^{2^{n+1}}$. Thus we have

$$r_\sigma(T) = \lim_{n \to \infty} \|T^{2^n}\|^{1/2^n} = \lim_{n \to \infty} \|(T^*T)^{2^n}\|^{1/2^n} = \lim_{n \to \infty} \|T^{2^n}\|^{1/2^{n+1}} = \|T\|.$$  

 XV.10.5.21.  **Proposition.** Let $T$ be a positive operator on a Hilbert space $\mathcal{H}$, and $x, y \in \mathcal{H}$. Then

$$\langle T(x + y), x + y \rangle \leq \|\langle Tx, x \rangle + \langle Ty, y \rangle \|^{1/2}.$$  

**Proof:** We have $\langle T(x + y), x + y \rangle = \langle Tx, x \rangle + 2Re\langle Tx, y \rangle + \langle Ty, y \rangle$, and by the CBS inequality $Re\langle Tx, y \rangle \leq \|\langle Tx, x \rangle + \langle Ty, y \rangle \|^{1/2}$. \hfill \Box

 XV.10.5.22.  **Corollary.** Let $T$ be a positive operator on $\mathcal{H}$, and $\{x_i\}$ a total set of vectors in $\mathcal{H}$. If $\langle Tx_i, x_i \rangle = 0$ for all $i$, then $T = 0$.

 XV.10.5.23.  If $X$ is a compact subset of $\mathbb{C}$ not containing 0, and $k \in \mathbb{N}$, there is in general no bound on the norm of $T^{-1}$ as $T$ ranges over all operators with $\|T\| \leq k$ and $\sigma(T) \subseteq X$. For example, let $S_n \in \mathcal{B}(l^2)$ be the truncated shift:

$$S_n(\alpha_1, \alpha_2, \ldots) = (0, \alpha_1, \alpha_2, \ldots, \alpha_n, 0, 0, \ldots)$$

and let $T_n = I - S_n$, $\|S_n\| = 1$, so $\|T_n\| \leq 2$ for all $n$. Since $S_n$ is nilpotent, $\sigma(S_n) = \{0\}$, so $\sigma(T_n) = \{1\}$ for all $n$. $T_n$ is invertible, with $T_n^{-1} = I + S_n + S_n^2 + \cdots + S_n^n$, and $\|T_n^{-1}\| = \sqrt{n + 1}$, so $\|T_n^{-1}\| \geq \sqrt{n + 1}$.

If $T$ is restricted to normal operators, then there is a bound: if $T$ is an invertible normal operator, then $\|T^{-1}\| = d^{-1}$, where $d$ is the distance from 0 to $\sigma(T)$. This follows immediately from II.1.6.3 and the elementary fact that $\sigma(T^{-1}) = \{\lambda^{-1} : \lambda \in \sigma(T)\}$ (cf. II.1.5.2(i)).

1831
XV.10.6. Exercises

(a) If $A$ is a unital normed algebra, show that $\|1\| \geq 1$. [1 = 1 · 1.]

(1) Show that $\|x\| = \sup_{\|y\|=1} \langle x, y \rangle$ is a convex subset of $XV.10.6.3.$

(b) Give an example of a Banach algebra norm $\|\cdot\|$ on $M_2(\mathbb{C})$ for which $\|I\| > 1$. [Try $\|a_{ij}\| = \sum_{i,j} |a_{ij}|$.

(c) Conclude from (a) and (b) that to show that $\|\cdot\|$ is a Banach algebra norm on $A$ equivalent to $\|\cdot\|$, and that $\|1\| = 1$.

(d) [Kat04, VIII.1.4] Show, more generally, that if $A$ is a Banach space with norm $\|\cdot\|$ which is a unital algebra under a multiplication which is separately continuous, then the norm $\|\cdot\|$ defined in (c) is a Banach algebra norm on $A$ equivalent to $\|\cdot\|$, with $\|1\| = 1$. [First observe that $\|a\| \geq \|a\|_{\text{op}}$ for any $a$. Then show the map $a \mapsto L_a$ from $A$ to $B(A)$ has closed graph. Conclude that $(A, \|\cdot\|)$ is complete and (using the Closed Graph Theorem) that $\|\cdot\|$ is equivalent to $\|\cdot\|.$]

(e) What if $A$ is nonunital? See XV.14.1.2. for a nonunital version.

XV.10.6.2. This problem gives a proof of the Hausdorff-Toeplitz Theorem:

THEOREM. Let $\mathcal{V}$ be a (complex) inner product space, and $T \in \mathcal{L}(\mathcal{V})$ (not necessarily bounded). Then $W(T)$ is a convex subset of $\mathbb{C}$.

(a) Show that $W(\alpha T + \beta I) = \{\alpha \lambda + \beta : \lambda \in W(T)\}$ for $\alpha, \beta \in \mathbb{C}$, and $\langle Tx, x \rangle = \langle T(\lambda x), \lambda x \rangle$ for $|\lambda| = 1$.

(b) If $\alpha$ and $\beta$ are complex numbers, show that there is a $\lambda \in \mathbb{C}$, $|\lambda| = 1$, with $\lambda \alpha + \lambda \beta$ a nonnegative real number. [Consider $\frac{\alpha - \beta}{|\alpha - \beta|}$ if $\beta \neq \bar{\alpha}$.] Conclude that if $x, y \in \mathcal{V}$, there is a $\lambda \in \mathbb{C}$, $|\lambda| = 1$, such that $\langle T(\lambda x), y \rangle + \langle T y, \lambda x \rangle$ is a nonnegative real number.

(c) Conclude from (a) and (b) that to show that $W(T)$ is convex for all $T$, it suffices to show that if $\langle Tx, x \rangle = 0$ and $\langle Ty, y \rangle = 1$ for $x, y \in \mathcal{V}$, $\|x\| = \|y\| = 1$, $(Tx, x) + (Ty, y) \geq 0$, then for any $\lambda \in [0, 1]$ there is a $z \in \mathcal{V}$, $\|z\| = 1$, with $\langle Tx, z \rangle = \lambda$.

(d) Let $x, y \in \mathcal{V}$ be as in (c). Show that if $0 \leq \alpha \leq 1$, then $(1 - \alpha)x + \alpha y \neq 0$.

(e) For $0 \leq \alpha \leq 1$, set

$$z_{\alpha} = \frac{(1 - \alpha)x + \alpha y}{\| (1 - \alpha)x + \alpha y \|}$$

and $f(\alpha) = \langle Tz_{\alpha}, z_{\alpha} \rangle$. Show that $f$ is a real-valued continuous function on $[0, 1]$.

(f) Since $f(0) = 0$ and $f(1) = 1$, $f$ takes all values in $[0, 1]$ by the Intermediate Value Theorem.

XV.10.6.3. (a) Let $\mathcal{V}$ be a (complex) inner product space, and $T \in \mathcal{L}(\mathcal{V})$ (not assumed bounded). If $w(T) = 0$, i.e. if $\langle Tx, x \rangle = 0$ for all $x \in \mathcal{V}$, show that $T = 0$. [If $x, y \in \mathcal{V}$, expand $\langle T(x + y), x + y \rangle$ and $T(x + iy), x + iy \rangle$ and conclude that $\langle Tx, y \rangle = 0$.

(b) Show that the result in (a) is not necessarily true in a real inner product space. [Consider a 90° rotation in $\mathbb{R}^2$.]

(c) Let $\mathcal{H}$ be a Hilbert space. If $S, T \in \mathcal{B}(\mathcal{H})$, show that $w(S + T) \leq w(S) + w(T)$. Thus $w$ is a norm on $\mathcal{B}(\mathcal{H})$. Is it equivalent to the operator norm? Is $\mathcal{B}(\mathcal{H})$ complete with respect to the norm $w$?
XV.10.6.4. Let $\mathcal{V}$ be a (complex) inner product space, and $T \in \mathcal{L}(\mathcal{V})$ (not necessarily bounded). Suppose $W(T) \subseteq \mathbb{R}$, i.e. $\langle Tx, x \rangle \in \mathbb{R}$ for all $x \in \mathcal{V}$. Show that $\langle Tx, y \rangle = \langle x, Ty \rangle$ for all $x, y \in \mathcal{V}$. [As in XV.10.6.3., expand $\langle T(x+y), x+y \rangle$ and $\langle T(x+iy), x+iy \rangle$.]

XV.10.6.5. Prove the following nonlinear version of XV.10.2.9.:

Theorem. Let $X$ be a Banach space, and $f : X \to X$ a strict contraction (a Lipschitz function with Lipschitz constant $< 1$). Let $i : X \to X$ be the identity function. Then $g = i - f$ is a homeomorphism from $X$ onto $X$.

[Reduce to the case $f(0) = 0$. Set $f^0 = i$ and $f^k = f \circ f \circ \cdots \circ f$ ($k$ times) for $k > 0$, and $h_n = \sum_{k=0}^{n} f^k$.

Show that $(h_n)$ converges pointwise on $X$ to an inverse for $g$.]

XV.10.6.6. (a) Let $T \in \mathcal{B}(\mathbb{R}^2)$ have matrix

$$A = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$$

with respect to the standard basis. Show that

$$\|T\| = \|A\| = \sqrt{\frac{a^2 + b^2 + c^2 + d^2 + \sqrt{a^4 + 6a^2b^2 - 2a^2c^2 - 2a^2d^2 + 8abcd + b^4 - 2b^2c^2 - 2b^2d^2 + c^4 + 6c^2d^2 + d^4}}{2}}.$$

[Use that $\|A\|$ is the square root of the largest eigenvalue of $A^tA$.]

(b) Find a similar formula if $T \in \mathcal{B}(\mathbb{C}^2)$, i.e. $a, b, c, d \in \mathbb{C}$.

(c) (For masochists only, or for someone adept at using computer algebra programs) Find a similar formula for $3 \times 3$ and $4 \times 4$ matrices.

(d) Show that if $n \geq 5$, there is no algebraic formula for the norm of an $n \times n$ matrix $A$ in terms of the entries of $A$. Specifically, show that the norm of the matrix

$$\begin{bmatrix} 2 & 1 & 0 & 0 \\ 1 & 3 & 1 & 0 \\ 0 & 1 & 1 & 1 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

which in this case is just the largest eigenvalue, approximately 3.917, cannot be written in terms of radicals and rational numbers, i.e. its characteristic polynomial is not solvable by radicals over $\mathbb{Q}$ (D. Zare; cf. https://mathoverflow.net/questions/268453/is-there-an-algebraic-formula-for-the-eigenvalues-of-a-symmetric-n).

For larger $n$ just add rows and columns of 0’s.

The formula in (a) is not for serious use; it is only to indicate that even in the $2 \times 2$ case, the norm of a matrix or linear transformation does not have a simple algebraic formula.
**XV.11. Fredholm Operators and Fredholm Index**

Fredholm operators are a very important class of “almost invertible” operators. To each Fredholm operator there is associated an integer “index” which roughly speaking measures the extent to which the operator fails to be invertible (or, more precisely, to have a “small” invertible perturbation). Arguably the most important fact about Fredholm operators is that a compact perturbation of a Fredholm operator is also Fredholm, with the same index; in particular, any compact perturbation of an invertible operator is Fredholm, with index 0.

The name “Fredholm operator” is in honor of Swedish mathematician I. Fredholm. It is argued in [Lax02] that there is “no historical justification for this,” and that the notions of Fredholm operator and Fredholm index should be attributed to Fritz Noether (son of Max Noether and brother of Emmy Noether). However, Fredholm, who worked around the turn of the 20th century, before Banach spaces were defined, developed some of the crucial basic properties of such operators in his work on integral equations (nicely described in [Lax02]), although he did indeed only consider operators of index 0. The names “Fredholm operator” and “Fredholm index” are also well established so we will use them instead of the names “Noether operator” and “Noether index” used in [Lax02].

The theory of Fredholm operators and Fredholm index is not only important for applications, but (in retrospect) was a pioneering example of bringing algebraic topology into the theory of operator algebras. In fact, it was one of the first examples of the process called “noncommutative topology,” which underlies much of the modern theory of operator algebras. See the introduction to [Con94] for an excellent survey of noncommutative topology and geometry.

**XV.11.1. Banach Space Preliminaries**

The first elementary result uses the quotient norm: if \( \mathcal{Y} \) is a closed subspace of a normed vector space \( \mathcal{X} \), the **quotient norm** on \( \mathcal{X}/\mathcal{Y} \) is the norm \( \|x + \mathcal{Y}\| = \inf \{\|x - y\| : y \in \mathcal{Y}\} = \inf \{\|z\| : z + \mathcal{Y} = x + \mathcal{Y}\} \).

**Proposition.** Let \( \mathcal{Y} \) be a proper closed subspace of a normed vector space \( \mathcal{X} \), and \( \epsilon > 0 \). Then there is a \( x \in \mathcal{X} \) with \( \|x\| \leq 1 + \epsilon \) and \( \|x - y\| \geq 1 \) for all \( y \in \mathcal{Y} \).

**Proof:** Let \( x \) be a suitable preimage of a unit vector in \( \mathcal{X}/\mathcal{Y} \).

Next we obtain a useful fact which is a simple consequence of the Hahn-Banach Theorem:

**Proposition.** Let \( \mathcal{X} \) be a normed vector space, and \( \mathcal{Y} \) a finite-dimensional subspace (which is automatically closed.) Then \( \mathcal{Y} \) has a closed complementary subspace \( \mathcal{Z} \) (i.e. \( \mathcal{Y} + \mathcal{Z} = \mathcal{X} \) and \( \mathcal{Y} \cap \mathcal{Z} = \{0\} \).) If \( \mathcal{R} \) is a closed subspace of \( \mathcal{X} \) with \( \mathcal{Y} \cap \mathcal{R} = \{0\} \), then \( \mathcal{Z} \) may be chosen to contain \( \mathcal{R} \).

**Proof:** Let \( \{x_1, \ldots, x_n\} \) be a basis for \( \mathcal{Y} \), and define linear functionals \( \phi_i \) (1 \( \leq i \leq n \)) on \( \mathcal{Y} \) by \( \phi_i(\sum_{j=1}^n \alpha_j x_j) = \alpha_i \) (i.e. \( \phi_i(x_j) = \delta_{ij} \)). Then each \( \phi_i \) is bounded since \( \mathcal{Y} \) is finite-dimensional. If \( \mathcal{W} \) is the subspace of \( \mathcal{X} \) spanned by \( \mathcal{Y} \) and \( \mathcal{R} \), then \( \mathcal{W} \) is closed (the image of \( \mathcal{W} \) in \( \mathcal{X}/\mathcal{R} \) is the same as the image of \( \mathcal{Y} \), hence is finite-dimensional and therefore closed), so \( \mathcal{W} = \mathcal{Y} \oplus \mathcal{R} \). Extend \( \phi_i \) to \( \mathcal{W} \) by setting it equal to 0 on \( \mathcal{R} \). Then extend \( \phi_i \) to a bounded linear functional \( \psi_i \) on \( \mathcal{X} \) by the Hahn-Banach Theorem. Define \( P \in B(\mathcal{X}) \) by \( Py = \sum_{i=1}^n \psi_i(y) x_i \). Then \( \mathcal{R}(P) = \mathcal{Y} \), and \( P|_\mathcal{Y} \) is the identity (\( P \) is a projection onto \( \mathcal{Y} \).) Then \( \mathcal{Z} = N(P) \) is a closed subspace of \( \mathcal{X} \) complementary to \( \mathcal{Y} \), containing \( \mathcal{R} \).

We recall the definitions of some standard terms from operator theory which will be used in this section.
XV.11.1.3. Definition. Let $\mathcal{X}$ and $\mathcal{Y}$ be normed vector spaces, and $T \in \mathcal{B}(\mathcal{X}, \mathcal{Y})$. Then $T$ is bounded below if there is an $\epsilon > 0$ such that $\|Tx\| \geq \epsilon \|x\|$ for all $x \in \mathcal{X}$.

An operator which is bounded below is one-to-one, and its range is closed if $\mathcal{X}$ is a Banach space.

XV.11.1.4. Definition. An operator $T \in \mathcal{B}(\mathcal{X})$ has finite ascent $n$ if the chain $\mathcal{N}(T) \subseteq \mathcal{N}(T^2) \subseteq \cdots$ stabilizes at $n$, i.e. $\mathcal{N}(T^n) = \mathcal{N}(T^{n+1}) = \cdots$.

$T$ has finite descent $m$ if the chain $\mathcal{R}(T) \supseteq \mathcal{R}(T^2) \supseteq \cdots$ stabilizes at $m$.

XV.11.1.5. Note that if $\mathcal{N}(T^n) = \mathcal{N}(T^{n+1})$, then $\mathcal{N}(T^n) = \mathcal{N}(T^{n+m})$ for all $m$; if $x \in \mathcal{N}(T^{r+1}) \setminus \mathcal{N}(T^r)$ for some $r > n$, then $T^{r-n}x \in \mathcal{N}(T^{n+1}) \setminus \mathcal{N}(T^n)$. Similarly, if $\mathcal{R}(T^n) = \mathcal{R}(T^{n+1})$, then $\mathcal{R}(T^n) = \mathcal{R}(T^{n+m})$ for all $m$.

XV.11.1.6. It is fairly exceptional for an operator to have finite ascent or descent, but note that an injective operator has finite ascent 1, and a surjective operator finite descent 1. Every operator on a finite-dimensional space has finite ascent and descent. A normal operator $T$ on a Hilbert space has finite ascent 1, but not necessarily finite descent, even if it is compact (Exercise XV.11.6.1.).

XV.11.1.7. Definition. If $T : \mathcal{X} \to \mathcal{Y}$ is a bounded operator, the adjoint of $T$ is the operator $T^* : \mathcal{Y}^* \to \mathcal{X}^*$ defined by $T^*(\phi) = \phi \circ T$. ($\mathcal{X}^*$ is the usual Banach space dual of $\mathcal{X}$, the space of bounded linear functionals on $\mathcal{X}$.)

XV.11.1.8. $T^* \in \mathcal{B}(\mathcal{Y}^*, \mathcal{X}^*)$ and $\|T^*\| = \|T\|$ by the Hahn-Banach Theorem. If $\mathcal{X}$ and $\mathcal{Y}$ are Hilbert spaces, then $\mathcal{X}^*$ and $\mathcal{Y}^*$ can be identified with $\mathcal{X}$ and $\mathcal{Y}$ in the standard way, and then $T^*$ agrees with the usual adjoint operator defined by the inner product: $\langle Tx, y \rangle = \langle x, T^*y \rangle$ for $x \in \mathcal{X}$, $y \in \mathcal{Y}$.

XV.11.1.9. Proposition. If $T \in \mathcal{B}(\mathcal{X}, \mathcal{Y})$ is finite-rank, then $T^*$ is finite-rank.

Proof: $T$ factors through $\mathcal{R}(T)$, so $T^*$ factors through $\mathcal{R}(T)^*$, which is finite-dimensional. ☑

XV.11.2. Compact Operators

XV.11.2.1. Definition. Let $\mathcal{X}$ and $\mathcal{Y}$ be Banach spaces. An operator $T : \mathcal{X} \to \mathcal{Y}$ is compact if $T$ sends bounded subsets of $\mathcal{X}$ to precompact subsets of $\mathcal{Y}$.

XV.11.2.2. In other words, if $B$ is a bounded subset of $\mathcal{X}$, then $\overline{T(B)}$ is a compact subset of $\mathcal{Y}$. Equivalently, whenever $(x_n)$ is a bounded sequence of vectors in $\mathcal{X}$, then $(Tx_n)$ has a convergent subsequence. $T$ is compact if and only if $T(\mathcal{B}_X)$ is totally bounded. Since a compact metric space is separable, if $T : \mathcal{X} \to \mathcal{Y}$ is compact, $\overline{\mathcal{R}(T)}$ is a separable subspace of $\mathcal{Y}$.

XV.11.2.3. In many references, particularly older ones, compact operators are called completely continuous operators.
**XV.11.2.4.** It is obvious that a compact operator is bounded, and the composition (in either order) of a compact operator with a bounded operator is compact. It is easily seen using the total boundedness criterion that a (norm-)limit of compact operators is compact. The set of compact operators from $\mathcal{X}$ to $\mathcal{Y}$, denoted $\mathcal{K}(\mathcal{X}, \mathcal{Y})$, is a closed subspace of $\mathcal{B}(\mathcal{X}, \mathcal{Y})$: $\mathcal{K}(\mathcal{X}, \mathcal{Y}) = \mathcal{K}(\mathcal{X}, \mathcal{X})$ is a closed two-sided ideal in $\mathcal{B}(\mathcal{X})$. Every finite-rank bounded operator is compact; for many, but not all, Banach spaces, every compact operator is a limit of finite-rank operators (see the discussion below.)

**XV.11.2.5.** It is easily seen that a bounded operator is weakly continuous (cf. [?]). So if $\mathcal{X}$ is a Hilbert space (or, more generally, a reflexive Banach space), $\mathcal{B}_\mathcal{X}$ is weakly compact, so if $T \in \mathcal{B}(\mathcal{X}, \mathcal{Y})$, $T(\mathcal{B}_\mathcal{X})$ is weakly compact and thus (norm-)closed. In particular, if $T \in \mathcal{K}(\mathcal{X}, \mathcal{Y})$, then $T(\mathcal{B}_\mathcal{X})$ is already closed and therefore compact.

**XV.11.2.6.** Proposition. If $T \in \mathcal{K}(\mathcal{X}, \mathcal{Y})$, then $T^* \in \mathcal{K}(\mathcal{Y}^*, \mathcal{X}^*)$.

**Proof:** Let $\epsilon > 0$. Since $T(\mathcal{B}_\mathcal{X})$ is totally bounded, there are $x_1, \ldots, x_n \in \mathcal{B}_\mathcal{X}$ such that, for each $x \in \mathcal{B}_\mathcal{X}$, there is an $i$ with $\|Tx - Tx_i\| < \epsilon/3$. Give $\mathbb{F}^n$ the infinity norm, i.e. $\| (\alpha_1, \ldots, \alpha_n) \| = \max |\alpha_i|$, and define $S : \mathcal{Y}^* \to \mathbb{F}^n$ by $S\phi = (\phi(Tx_1), \ldots, \phi(Tx_n))$. $S$ is finite-rank and bounded and hence compact, so $S(\mathcal{B}_{\mathcal{Y}^*})$ is totally bounded; let $\phi_1, \ldots, \phi_m \in \mathcal{B}_{\mathcal{Y}^*}$ be such that, for every $\phi \in \mathcal{B}_{\mathcal{Y}^*}$, there is a $j$ such that $\| S\phi - S\phi_j \| < \epsilon/3$. If $\phi \in \mathcal{B}_{\mathcal{Y}^*}$, choose a corresponding $\phi_j$; then, for any $x \in \mathcal{B}_\mathcal{X}$, with corresponding $x_i$,

$$\| T^*\phi(x) - T^*\phi_j(x) \| = \| \phi(Tx) - \phi_j(Tx) \|$$

$$\leq \| \phi(Tx) - \phi(Tx_i) \| + \| \phi_j(Tx_i) - \phi_j(Tx) \|$$

$$\leq \| Tx - Tx_i \| = \| S\phi - S\phi_j \| + \| Tx_i - Tx \| < \epsilon/3 + \epsilon/3 + \epsilon/3 = \epsilon .$$

Thus $\| T^*\phi - T^*\phi_j \| \leq \epsilon$, so $T^*(\mathcal{B}_{\mathcal{Y}^*})$ is totally bounded. ✷

While the proof of XV.11.2.6. is not difficult, there is an alternate approach (of comparable difficulty) on a Hilbert space which is worth noting:

**XV.11.2.7.** Theorem. If $\mathcal{Y}$ is a Hilbert space, then $\mathcal{K}(\mathcal{X}, \mathcal{Y})$ is the closure of the finite-rank bounded operators from $\mathcal{X}$ to $\mathcal{Y}$.

**Proof:** We again use a total boundedness argument. Let $T \in \mathcal{K}(\mathcal{X}, \mathcal{Y})$, and $\epsilon > 0$. Choose $x_1, \ldots, x_n \in \mathcal{B}_\mathcal{X}$ such that, for any $x \in \mathcal{B}_\mathcal{X}$, there is an $i$ with $\| Tx - Tx_i \| < \epsilon/2$. Let $P \in \mathcal{B}(\mathcal{Y})$ be the orthogonal projection onto the subspace spanned by $\{Tx_1, \ldots, Tx_n\}$. Then $P$ is finite-rank, $PTx_i = Tx_i$ for all $i$, and $\|P\| = 1$. If $x \in \mathcal{B}_\mathcal{X}$, and a corresponding $x_i$ is chosen, then

$$\| PTx - Tx \| \leq \| PTx - PTx_i \| + \| Tx_i - Tx \| < \epsilon/2 + \epsilon/2 = \epsilon .$$

Thus $\| PT - T \| \leq \epsilon$, and $PT$ has finite rank. ✷

**XV.11.2.8.** If $T \in \mathcal{K}(\mathcal{X}, \mathcal{Y})$ and $\mathcal{Y}$ is a Hilbert space, an alternate proof of XV.11.2.6. is then obtained by taking $(T_n)$ of finite rank and $T_n \to T$; then $T_n^* \to T^*$, and $T_n^*$ is finite-rank by XV.11.1.9. Similarly, if $T \in \mathcal{K}(\mathcal{X}, \mathcal{Y})$ and $\mathcal{X}$ is a Hilbert space, apply XV.11.2.7. to $T^* \in \mathcal{K}(\mathcal{Y}^*, \mathcal{X})$ (using XV.11.2.6.) to conclude that $\mathcal{K}(\mathcal{X}, \mathcal{Y})$ is also the closure of the finite-rank bounded operators from $\mathcal{X}$ to $\mathcal{Y}$ (there is also a simple direct proof.)

1836
XV.11.2.9. Definition. A Banach space $\mathcal{X}$ has the approximation property if every compact operator on $\mathcal{X}$ is a (norm-)limit of finite-rank (bounded) operators on $\mathcal{X}$.

XV.11.2.10. XV.11.2.7. shows that Hilbert spaces have the approximation property. All standard Banach spaces have the approximation property. P. Enflo [Enf73] constructed the first example of a Banach space without the approximation property; see [Jam82] for a discussion of this and related matters, and [Gow95] for more recent developments.

Strictly Singular Operators
There is a slightly larger class of operators which to some extent behave like compact operators:

XV.11.2.11. Definition. Let $\mathcal{X}$ and $\mathcal{Y}$ be Banach spaces, with $\mathcal{X}$ infinite-dimensional. An operator $T \in \mathcal{B}(\mathcal{X}, \mathcal{Y})$ is strictly singular if $T$ is not bounded below on any infinite-dimensional subspace of $\mathcal{X}$.

XV.11.2.12. It follows from () that every compact operator is strictly singular. Every strictly singular operator on a Hilbert space, or many standard Banach spaces, is compact; but there are operators on some Banach spaces which are strictly singular but not compact (XV.11.6.2.).

XV.11.3. Fredholm Operators

XV.11.3.1. Definition. Let $\mathcal{X}$ and $\mathcal{Y}$ be Banach spaces and $T \in \mathcal{B}(\mathcal{X}, \mathcal{Y})$. $T$ is a Fredholm operator if $\mathcal{N}(T)$ is finite-dimensional and $\mathcal{R}(T)$ has finite codimension. The index of $T$ is $\dim \mathcal{N}(T) - \text{codim} \mathcal{R}(T)$. Denote the set of Fredholm operators from $\mathcal{X}$ to $\mathcal{Y}$ by $\mathcal{F}(\mathcal{X}, \mathcal{Y})$, and write $\mathcal{F}(\mathcal{X})$ for $\mathcal{F}(\mathcal{X}, \mathcal{X})$.

XV.11.3.2. Examples.

(i) If $\mathcal{X}$ and $\mathcal{Y}$ are finite-dimensional, then every operator from $\mathcal{X}$ to $\mathcal{Y}$ is Fredholm with index $\dim \mathcal{X} - \dim \mathcal{Y}$.

(ii) If $T$ is invertible, then $T$ is Fredholm with index 0.

(iii) Let $S$ be the unilateral shift on the Hilbert space $l^2$ of square-summable sequences, defined by $S(\alpha_1, \alpha_2, \ldots) = (0, \alpha_1, \alpha_2, \ldots)$. Then $S$ is Fredholm with index $-1$. $S^n$ is Fredholm with index $-n$, and $(S^n)^n$ is Fredholm with index $n$.

XV.11.3.3. Definition XV.11.3.1. is not the most common one, which in addition requires $\mathcal{R}(T)$ to be closed. However, the two definitions are equivalent, since a Fredholm operator in the sense of XV.11.3.1. always has closed range. Although strictly speaking we will not need this fact for our development of the theory, we give a proof for completeness (and to show that we are not redefining the notion of Fredholm operator), and also because the argument gives some important structural properties of Fredholm operators.
**XV.11.3.4. Proposition.** Let $T \in \mathcal{F}(\mathcal{X}, \mathcal{Y})$. Then $\mathcal{R}(T)$ is closed.

**Proof:** Let $W$ be a complementary subspace for $\mathcal{R}(T)$ in $\mathcal{Y}$; then $W$ is finite-dimensional and hence closed. Let $Z$ be a closed subspace of $\mathcal{X}$ complementary to $\mathcal{N}(T)$ (XV.11.1.2.). Then $\mathcal{R}(T|_Z) = \mathcal{R}(T)$. Define a bounded operator $S$ from the Banach space $W \oplus Z$ to $\mathcal{Y}$ by $S(w, z) = w + Tz$. Then $S$ is a bijection, hence a homeomorphism by the Open Mapping Theorem, and $S(\{0\} \oplus Z) = \mathcal{R}(T)$. 

A corollary of the proof gives a simple picture of a Fredholm operator:

**XV.11.3.5. Corollary.** Let $\mathcal{X}, \mathcal{Y}$ be Banach spaces, and $T \in \mathcal{F}(\mathcal{X}, \mathcal{Y})$. Then there are closed subspaces $Z, W$ of $\mathcal{X}$ and $\mathcal{Y}$ complementary to $\mathcal{N}(T)$ and $\mathcal{R}(T)$, respectively, such that $\mathcal{X} \cong \mathcal{N}(T) \oplus Z$, $\mathcal{Y} \cong W \oplus \mathcal{R}(T)$, and $T \cong 0 \oplus U$, where $U$ is a linear isomorphism from $Z$ onto $\mathcal{R}(T)$ (i.e. $U$ is bounded below.)

**XV.11.3.6. Corollary.** Let $T \in \mathcal{F}(\mathcal{X}, \mathcal{Y})$. Then there is an $S \in \mathcal{F}(\mathcal{Y}, \mathcal{X})$, with $\text{index}(S) = -\text{index}(T)$, such that $ST = I_\mathcal{X} - P$ and $TS = I_\mathcal{Y} - Q$, where $P$ and $Q$ are finite-rank bounded idempotent operators.

**Proof:** Under the above identifications, $S$ may be taken as $0 \oplus U^{-1} : W \oplus \mathcal{R}(T) \to \mathcal{N}(T) \oplus Z$. 

**XV.11.3.7.** The operator $S$ is a quasi-inverse for $T$: $T = TST$. (If $S$ is as defined in the proof, $T$ is also a quasi-inverse for $S$.)

We obtain another characterization of Fredholm operators from XV.11.3.5.:

**XV.11.3.8. Corollary.** Let $\mathcal{X}, \mathcal{Y}$ be Banach spaces, and $T \in \mathcal{B}(\mathcal{X}, \mathcal{Y})$. Then $T \in \mathcal{F}(\mathcal{X}, \mathcal{Y})$ if and only if there is a closed subspace $Z$ of $\mathcal{X}$, of finite codimension, with $T(Z)$ of finite codimension in $\mathcal{Y}$, such that $T$ is bounded below on $Z$. If there is such a $Z$, then $\text{index}(T) = \text{codim}(Z) - \text{codim}T(Z))$.

**XV.11.3.9. Corollary.** Let $\mathcal{X}, \mathcal{Y}$ be Banach spaces, and $T \in \mathcal{F}(\mathcal{X}, \mathcal{Y})$. Then there is an $\epsilon > 0$ such that $T + S \in \mathcal{F}(\mathcal{X}, \mathcal{Y})$ and $\text{index}(T + S) = \text{index}(T)$ for all $S \in \mathcal{B}(\mathcal{X}, \mathcal{Y})$, $\|S\| < \epsilon$.

**Proof:** Let $Z$ be a closed subspace of finite codimension in $\mathcal{X}$ such that $T$ is bounded below on $Z$. Then, if $\|S\|$ is sufficiently small, $T + S$ is bounded below on $Z$ and $(T + S)(Z)$ is a small enough perturbation of $T(Z)$ to have the same codimension ( ).

Another important consequence of XV.11.3.5. is:
**XV.11.3.10.** Corollary. Let \( T \in \mathcal{F}(\mathcal{X}, \mathcal{Y}) \). Then \( T^* \in \mathcal{F}(\mathcal{Y}^*, \mathcal{X}^*) \), \( \dim(\mathcal{N}(T^*)) = \text{codim}(\mathcal{R}(T)) \), \( \text{codim}(\mathcal{R}(T^*)) = \dim(\mathcal{N}(T)) \), and \( \text{index}(T^*) = -\text{index}(T) \).

**Proof:** If \( T = 0 \oplus U : \mathcal{N}(T) \oplus \mathcal{Z} \to \mathcal{W} \oplus \mathcal{R}(T) \), then \( T^* = 0 \oplus U^* : \mathcal{W}^* \oplus \mathcal{R}(T)^* \to \mathcal{N}(T)^* \oplus \mathcal{Z}^* \), and \( U^* \) is invertible; thus \( \mathcal{N}(T^*) = \mathcal{W}^* \oplus \{0\} \) and \( \mathcal{R}(T^*) = \{0\} \oplus \mathcal{Z}^* \). We have \( \mathcal{W}^* \cong \mathcal{W} \) and \( \mathcal{N}(T)^* \cong \mathcal{N}(T) \) since they are finite-dimensional. \( \blacksquare \)

**XV.11.3.11.** Actually, if \( T \in \mathcal{B}(\mathcal{X}, \mathcal{Y}) \), then \( \mathcal{N}(T^*) = \mathcal{R}(T)^\perp = \{\phi \in \mathcal{Y}^* : \phi|_{\mathcal{R}(T)} = 0\} \cong (\mathcal{Y}/\mathcal{R}(T))^* \).

Thus \( T \in \mathcal{B}(\mathcal{X}, \mathcal{Y}) \) is Fredholm if and only if \( \mathcal{R}(T) \) is closed and \( \mathcal{N}(T) \) and \( \mathcal{N}(T^*) \) are finite-dimensional, and \( \text{index}(T) = \dim \mathcal{N}(T) - \dim \mathcal{N}(T^*) \).

It is useful not to require that the range of a Fredholm operator be closed as part of the definition. The next proof is an example.

**XV.11.3.12.** Proposition. Let \( \mathcal{X} \) and \( \mathcal{Y} \) be Banach spaces, \( T \in \mathcal{B}(\mathcal{X}, \mathcal{Y}) \), \( S \in \mathcal{B}(\mathcal{Y}, \mathcal{X}) \). If \( ST \) and \( TS \) are Fredholm, then \( S \) and \( T \) are Fredholm.

**Proof:** We show \( T \) is Fredholm. \( \mathcal{N}(T) \subseteq \mathcal{N}(ST) \), which is finite-dimensional, and \( \mathcal{R}(T) \supseteq \mathcal{R}(TS) \), which has finite codimension. \( \blacksquare \)

Conversely:

**XV.11.3.13.** Theorem. Let \( \mathcal{X}, \mathcal{Y}, \mathcal{Z} \) be Banach spaces, and \( T \in \mathcal{F}(\mathcal{X}, \mathcal{Y}) \) and \( S \in \mathcal{F}(\mathcal{Y}, \mathcal{Z}) \). Then \( ST \in \mathcal{F}(\mathcal{X}, \mathcal{Z}) \) and \( \text{index}(ST) = \text{index}(S) + \text{index}(T) \).

**Proof:** Let \( \mathcal{U} \) be a closed subspace of \( \mathcal{X} \) complementary to \( \mathcal{N}(T) \) on which \( T \) is bounded below. Then \( U = T|_{\mathcal{U}} \) is an isomorphism from \( \mathcal{U} \) onto \( \mathcal{R}(T) \). Set \( \mathcal{X}_2 = \mathcal{R}(T) \cap \mathcal{N}(S) \) and \( \mathcal{X}_2 = U^{-1}(\mathcal{X}_2) \). Then \( \mathcal{X}_2 \) is a finite-dimensional subspace of \( \mathcal{U} \). Let \( \mathcal{X}_1 \) be a closed subspace of \( \mathcal{U} \) complementary to \( \mathcal{X}_2 \), and let \( \mathcal{Y}_1 = U(\mathcal{X}_1) = T(\mathcal{X}_1) \). Then \( \mathcal{Y}_1 \) is a closed subspace of \( \mathcal{Y} \) with zero intersection with \( \mathcal{N}(S) \), and \( \mathcal{Y}_1 \) and \( \mathcal{Y}_2 \) span \( \mathcal{R}(T) \), and since \( \mathcal{Y}_2 \) is finite-dimensional and \( \mathcal{R}(T) \) has finite codimension in \( \mathcal{Y} \), \( \mathcal{Y}_1 \) has finite codimension in \( \mathcal{Y} \). Let \( \mathcal{V} \) be a closed subspace of \( \mathcal{Y} \) containing \( \mathcal{Y}_1 \) which is complementary to \( \mathcal{N}(S) \) (XV.11.1.2.), and \( \mathcal{Y}_3 \) a subspace of \( \mathcal{V} \) complementary to \( \mathcal{Y}_1 \). Then \( \mathcal{Y}_3 \) is finite-dimensional, and we have

\[
\mathcal{Y} \cong \mathcal{Y}_1 \oplus \mathcal{Y}_2 \oplus \mathcal{Y}_3 \oplus \mathcal{Y}_4
\]

where \( \mathcal{Y}_4 \) is a subspace of \( \mathcal{N}(S) \) complementary to \( \mathcal{Y}_2 \). Then \( \mathcal{Y}_2, \mathcal{Y}_3, \mathcal{Y}_4 \) are finite-dimensional, \( \mathcal{Y}_2 \) and \( \mathcal{Y}_4 \) span \( \mathcal{N}(S) \), and \( \mathcal{Y}_1 \) and \( \mathcal{Y}_2 \) span \( \mathcal{R}(T) \). Then \( S \) is bounded below on \( \mathcal{Y} \) (cf. the proof of XV.11.3.4.), and \( V = S|_{\mathcal{Y}} \) maps \( \mathcal{V} \) isomorphically onto \( \mathcal{R}(S) \). Also, \( UV = ST|_{\mathcal{X}_1} \) maps \( \mathcal{X}_1 \) isomorphically onto \( \mathcal{Z}_1 = V(\mathcal{Y}_1) = S(\mathcal{Y}_1) \). Since \( \mathcal{Y}_1 \) has finite codimension in \( \mathcal{Y} \) and \( \mathcal{R}(S) \) has finite codimension in \( \mathcal{Z} \), \( \mathcal{Z}_1 \) has finite codimension in \( \mathcal{Z} \) and \( ST \) is Fredholm.

We have

\[
\mathcal{X} \cong \mathcal{X}_1 \oplus \mathcal{X}_2 \oplus \mathcal{X}_3
\]

\[
\mathcal{Z} \cong \mathcal{Z}_1 \oplus \mathcal{Z}_2 \oplus \mathcal{Z}_3
\]
where \( X_3 = N(T), Z_3 = V(Y_3) = S(Y_3), \) and \( Z_2 \) is a subspace of \( Z \) complementary to \( R(S) \). Set \( a_k = \text{dim}(X_k), b_k = \text{dim}(Y_k), \) and \( c_k = \text{dim}(Z_k) \). We then have
\[
\text{index}(T) = a_3 - (b_3 + b_4) \\
\text{index}(S) = (b_2 + b_4) - c_2 \\
\text{index}(ST) = (a_2 + a_3) - (c_2 + c_3).
\]
But \( b_2 = a_2 \) and \( c_3 = b_3 \) since \( U \) and \( V \) are isomorphisms, so we have
\[
\text{index}(ST) = b_2 + a_3 - b_3 - c_2 = \text{index}(S) + \text{index}(T).
\]

**XV.11.4. Fredholm Operators of Index 0 and the Fredholm Alternative**

We first note an immediate consequence of **XV.11.3.5.**:

**XV.11.4.1. Proposition.** Let \( T \in \mathcal{F}(X, Y) \) have index 0. Then there are \( V, F \in \mathcal{B}(X, Y) \) with \( V \) invertible and \( F \) finite-rank, with \( T = V + F \).

The converse is also true (**XV.11.5.12.**).

**Proof:** Under the identifications \( X \cong N(T) \oplus Z, Y \cong W \oplus R(T), T \cong 0 \oplus U, \) we have that \( \text{dim}(N(T)) = \text{dim}(W) < \infty, \) so there is a (necessarily bounded) linear isomorphism \( S : N(T) \to W. \) Set \( V = S \oplus U, F = -S \oplus 0. \)

The next observation is called the **Fredholm Alternative.** The last statement follows from **XV.11.3.10.**

**XV.11.4.2. Proposition.** Let \( T \in \mathcal{F}(X, Y) \) have index 0. Then \( T \) is injective if and only if \( T \) is surjective. So either the equation \( Tx = y \) has a unique solution for each \( y \in Y, \) or the homogeneous equation \( Tx = 0 \) has a nontrivial (but finite-dimensional) space of solutions.

Furthermore, the equation \( T^* \phi = \psi \) has a unique solution for each \( \psi \) if and only if \( Tx = y \) has a unique solution for each \( y, \) and the solution set of \( T^* \phi = 0 \) has the same (finite) dimension as the solution set of \( Tx = 0. \)

**XV.11.4.3.** The result is sometimes paraphrased: “If the solution to \( Tx = y \) is unique, then it exists.”

**XV.11.5. Relation between Compact and Fredholm Operators**

The next theorem is the main result of this section.

**XV.11.5.1. Theorem.** Let \( X \) be a Banach space, \( T \in \mathcal{K}(X). \) Then \( I + T \) is Fredholm, of index 0.

The proof that \( I + T \) is Fredholm consists of the next three lemmas.
**XV.11.5.2. Lemma.** Let $\mathcal{X}$ be a Banach space, $T \in \mathcal{K}(\mathcal{X})$. Then $\mathcal{N}(I+T)$ is finite-dimensional.

Proof: $T = -I$ on $\mathcal{N}(I+T)$, and thus the unit ball of $\mathcal{N}(I+T)$ is compact. 

**XV.11.5.3. Lemma.** Let $\mathcal{X}$ be a Banach space, $T \in \mathcal{K}(\mathcal{X})$. Then $\mathcal{R}(I+T)$ is closed.

Proof: Let $Z$ be a closed subspace of $\mathcal{X}$ complementary to $\mathcal{N}(I+T)$ (XV.11.1.2). It suffices to show that $I+T$ is bounded below on $Z$; then $\mathcal{R}(I+T) = \mathcal{R}((I+T)|_{Z})$ is closed. Suppose $(x_{n})$ is a sequence of unit vectors in $Z$ with $\|(I+T)x_{n}\| \to 0$. Passing to a subsequence we may assume that $Tx_{n} \to y$ for some $y$, since $T$ is compact. But $(I+T)x_{n} \to 0$, so $x_{n} \to -y$, and thus $\|y\| = 1$ and $Ty = -y$, i.e. $(I+T)y = 0$, $y \in \mathcal{N}(I+T)$. But $y \in Z$ since $-x_{n} \to y$ and $Z$ is closed; hence $y \in Z \cap \mathcal{N}(I+T) = \{0\}$, a contradiction. 

**XV.11.5.4. Lemma.** Let $\mathcal{X}$ be a Banach space, $T \in \mathcal{K}(\mathcal{X})$. Then $\mathcal{R}(I+T)$ has finite codimension.

Proof: Consider the Banach space $\mathcal{Y} = \mathcal{X}/\mathcal{R}(I+T)$. We show that $\mathcal{Y}$ is finite-dimensional by showing that the dual space $\mathcal{Y}^{*}$ is finite-dimensional. $\mathcal{Y}^{*}$ can be identified with the subspace of $\mathcal{X}^{*}$ consisting of functionals vanishing on $\mathcal{R}(I+T)$. But $\mathcal{Y}^{*}$ is precisely $\mathcal{N}((I+T)^{*}) = \mathcal{N}(I+T^{*})$. $T^{*} \in \mathcal{K}(\mathcal{X}^{*})$ by XV.11.2.6, so $\mathcal{N}(I+T^{*})$ is finite-dimensional by XV.11.5.2.

It remains to be shown that $\text{index}(I+T) = 0$. Our proof is partly based in spirit on [RSN90, §70] (repeated without attribution in the rather dreadful paper [Ram01]). We first obtain another important property of $I+T$ which is a simple (but nonobvious) consequence of the compactness of $T$.

**XV.11.5.5. Proposition.** Let $\mathcal{X}$ be a Banach space, $T \in \mathcal{K}(\mathcal{X})$. Then $I+T$ has finite ascent and finite descent.

Proof: If $I+T$ does not have finite ascent, by XV.11.1, choose for each $n$ a vector $x_{n} \in \mathcal{N}((I+T)^{n})$ with $\|x_{n}\| \leq 2$ and $\|x_{n} - y\| \geq 1$ for all $y \in \mathcal{N}((I+T)^{n-1})$. Then, for $m < n$,

$$\|Tx_{m} - Tx_{n}\| = \|x_{n} - (I+T)x_{n} + (I+T)x_{m} - x_{m}\| \geq 1$$

since $x_{m} - (I+T)x_{m} + (I+T)x_{n} \in \mathcal{N}((I+T)^{n-1})$. Thus $(Tx_{n})$ has no convergent subsequence, contradicting compactness of $T$.

The proof that $I+T$ has finite descent is virtually identical. 

1841
**XV.11.5.6.** **Lemma.** If $\mathcal{X}$ is a Banach space and $T \in \mathcal{K}(\mathcal{X})$, then $\text{index}(I + T) = 0$.

**Proof:** Let $n$ be the maximum of the ascent and descent of $I + T$, so $\mathcal{N}((I + T)^n) = \mathcal{N}((I + T)^{n+k})$ and $\mathcal{R}((I + T)^n) = \mathcal{R}((I + T)^{n+k})$ for all $k$. Note that $(I + T)^n = I + S$ for $S \in \mathcal{K}(\mathcal{X})$, so $(I + T)^n$ is Fredholm and hence $\mathcal{R} = \mathcal{R}((I + T)^n)$ is closed and $\mathcal{N} = \mathcal{N}((I + T)^n)$ is finite-dimensional. Then $\mathcal{N} \cap \mathcal{R} = \{0\}$, for if $0 \neq y = (I + T)^nx \in \mathcal{N} \cap \mathcal{R}$, then $x \in \mathcal{N}((I + T)^{2n}) \setminus \mathcal{N}((I + T)^n)$, a contradiction. Thus $(I + T)^n$ maps $\mathcal{R}$ isomorphically onto $\mathcal{R}$ (since $\mathcal{R} = \mathcal{R}((I + T)^{2n})$.) If $\mathcal{Z}$ is a closed subspace of $\mathcal{X}$ containing $\mathcal{R}$ which is complementary to $\mathcal{N}$, then $(I + T)^n$ also maps $\mathcal{Z}$ isomorphically onto $\mathcal{R}$, and it follows that $\mathcal{Z} = \mathcal{R}$, i.e. $\mathcal{N}$ and $\mathcal{R}$ are complementary subspaces of $\mathcal{X}$. Since both $\mathcal{N}$ and $\mathcal{R}$ are invariant under $I + T$ and $(I + T)|_{\mathcal{R}}$ is an isomorphism, $\text{index}(I + T) = \text{index}((I + T)|_{\mathcal{N}})$. But $\mathcal{N}$ is finite-dimensional, so $\text{index}((I + T)|_{\mathcal{N}}) = 0$. \hfill $\Box$

This completes the proof of XV.11.5.1..

The proof of XV.11.5.6. actually shows that $I + T$ has a simple form:

**XV.11.5.7.** **Corollary.** Let $\mathcal{X}$ be a Banach space, $T \in \mathcal{K}(\mathcal{X})$. Then there are complementary closed subspaces $\mathcal{N}$ and $\mathcal{R}$ of $\mathcal{X}$, each invariant under $T$ (and hence under $I + T$), with $\mathcal{N}$ finite-dimensional, such that $(I + T)|_{\mathcal{R}}$ is invertible and $(I + T)|_{\mathcal{N}}$ is nilpotent.

It is well known (and useful) that every operator on a finite-dimensional space has this property.

The next theorem [Atk53] gives a useful alternate characterization of Fredholm operators.

**XV.11.5.8.** **Theorem.** [Atkinson’s Theorem] Let $\mathcal{X}$ be an infinite-dimensional Banach space and $\pi : \mathcal{B}(\mathcal{X}) \to \mathcal{Q}(\mathcal{X})$ the quotient map onto the Calkin algebra $\mathcal{Q}(\mathcal{X}) = \mathcal{B}(\mathcal{X})/\mathcal{K}(\mathcal{X})$ of $\mathcal{X}$. Then $T \in \mathcal{B}(\mathcal{X})$ is Fredholm if and only if $\pi(T)$ is invertible in $\mathcal{Q}(\mathcal{X})$.

**Proof:** If $T$ is Fredholm, let $S$ be a quasi-inverse for $T$ as in XV.11.3.6.; then $\pi(S)$ is an inverse for $\pi(T)$.

Conversely, suppose $\pi(T)$ is invertible in $\mathcal{Q}(\mathcal{X})$, and let $S \in \mathcal{B}(\mathcal{X})$ such that $\pi(S) = \pi(T)^{-1}$. Then $ST = I + K$, $TS = I + L$ for $K, L \in \mathcal{K}(\mathcal{X})$. $I + K$ and $I + L$ are Fredholm by XV.11.5.1., so $S$ and $T$ are Fredholm by XV.11.3.12. \hfill $\Box$

**XV.11.5.9.** **Corollary.**

(i) If $\mathcal{X}$ is a Banach space, $S, T \in \mathcal{F}(\mathcal{X})$, and $K \in \mathcal{K}(\mathcal{X})$, then $ST$ and $T + K$ are Fredholm.

(ii) The set $\mathcal{F}(\mathcal{X})$ of Fredholm operators on $\mathcal{X}$ is open in $\mathcal{B}(\mathcal{X})$.

Part (ii) is an immediate consequence of XV.11.3.9., or follows directly from (i). It also follows from XV.11.3.9. that index is locally constant on $\mathcal{F}(\mathcal{X})$, hence constant on connected components. In particular, we obtain:
**XV.11.5.10.** Corollary. Let $\mathcal{X}$ be a Banach space, and $T \in \mathcal{F}(\mathcal{X})$. Then $\text{index}(T) = \text{index}(T + K)$ for any $K \in \mathcal{K}(\mathcal{X})$.

Proof: $T$ and $T + K$ are connected in $\mathcal{F}(\mathcal{X})$ by the path $T + tK$, $0 \leq t \leq 1$.

**XV.11.5.11.** The index map from the connected components of $\mathcal{F}(\mathcal{X})$ to $\mathbb{Z}$ is thus well defined, but it is not either injective or surjective in general: it can fail to be injective since the invertible elements of $\mathcal{B}(\mathcal{X})$ are not necessarily connected [?], and we can even have $\text{index}(T) = 0$ for every $T \in \mathcal{F}(\mathcal{X})$ (e.g. for the examples of [?]; cf. [?]). If $\mathcal{H}$ is a Hilbert space, the index map is a bijection from the connected components of $\mathcal{F}(\mathcal{H})$ onto $\mathbb{Z}$.

**XV.11.5.12.** Theorem. Let $T \in \mathcal{F}(\mathcal{X})$. Then the following are equivalent:

(i) $\text{index}(T) = 0$.

(ii) There are $U, K \in \mathcal{B}(\mathcal{X})$ with $U$ invertible, $K$ compact, and $T = U + K$.

(iii) There are $V, F \in \mathcal{B}(\mathcal{X})$ with $V$ invertible, $F$ finite-rank, and $T = V + F$.

Proof: (i) $\Rightarrow$ (iii) is XV.11.4.1., and (iii) $\Rightarrow$ (ii) is trivial. For (ii) $\Rightarrow$ (i), if $T = U + K$, then $U^{-1}T = I + U^{-1}K$ is Fredholm with index 0 by XV.11.5.11. It is obvious that if $S$ is Fredholm and $W$ is invertible, then $WS$ is Fredholm and $\text{index}(WS) = \text{index}(S)$; thus $T = U(U^{-1}T)$ is Fredholm and $\text{index}(T) = 0$.

The argument of [RSN90, §70] gives a direct proof of (iii) $\Rightarrow$ (i).

**XV.11.5.13.** Note that if $\mathcal{X}$ has the approximation property, then there is a simple proof of (ii) $\Rightarrow$ (iii): if $T = U + K$ with $U$ invertible and $K$ compact, approximate $K$ closely enough by a finite rank $F$ that $V = U + (K - F)$ is invertible (using the fact that the set of invertible elements of $\mathcal{B}(\mathcal{X})$ is open); then $T = V + F$.

Finally, we state the Fredholm Alternative in its usual form:

**XV.11.5.14.** Corollary. [Fredholm Alternative] If $\mathcal{X}$ is a Banach space and $T \in \mathcal{K}(\mathcal{X})$, then $I + T$ is injective if and only if it is surjective. So either the equation $(I + T)x = y$ has a unique solution for every $y$, or the homogeneous equation $(I + T)x = 0$ has a nontrivial (but finite-dimensional) space of solutions.

Furthermore, the equation $(I + T^*)\phi = \psi$ has a unique solution for each $\psi$ if and only if $(I + T)x = y$ has a unique solution for each $y$, and the solution set of $(I + T^*)\phi = 0$ has the same (finite) dimension as the solution set of $(I + T)x = 0$.

**XV.11.5.15.** Note also that if $T \in \mathcal{K}(\mathcal{X})$, then XV.11.5.1. and its consequences, notably XV.11.5.14., are valid not only for $I + T$ but also for $T - \lambda I = -\lambda(I + (-\lambda^{-1}T))$ for any $\lambda \neq 0$. This is useful in describing the eigenvalues of $T$. The results of Fredholm theory, especially XV.11.5.5., are used to prove that the spectrum of a compact operator on an infinite-dimensional Banach space consists of 0 and at most countably many isolated nonzero eigenvalues of finite multiplicity.

1843
XV.11.5.16. The results of this section can be extended: if $T$ is Fredholm and $S$ is strictly singular, then $T + S$ is Fredholm and $\text{index}(T + S) = \text{index}(T)$ (cf. ()). Thus the Fredholm Alternative holds more generally for strictly singular operators.

XV.11.6. Exercises

XV.11.6.1. (a) Use the Spectral Theorem () to show that every normal operator on a Hilbert space has finite ascent 1.

(b) Consider the multiplication operator on $\ell^2$ given by

$$T(x_1, x_2, \ldots) = \left( x_1, \frac{x_2}{2}, \ldots, \frac{x_n}{n}, \ldots \right).$$

Show that $T$ is self-adjoint, hence normal, and compact, but does not have finite descent.

The difference between ascent and descent (at least in this case) is that the null space of an operator is closed but the range is not necessarily closed. In fact, if $T$ is a normal operator on a Hilbert space, then the closure of the range of $T^n$ is the same as the closure of $\mathcal{R}(T)$ for all $n$ (it is the orthogonal complement of $\mathcal{N}(T) = \mathcal{N}(T^n)$).

XV.11.6.2. (a) Show that every strictly singular operator on a Hilbert space is compact.

(b) Show that the inclusion map from $\ell^1$ to $\ell^2$ is not compact. [Consider the standard basis.]

(c) Show that the inclusion map from $\ell^1$ to $\ell^2$ is strictly singular. [Use that the weak topology on $\ell^1$ has the same convergent sequences as as the norm topology ()].

(d) Let $X = \ell^1 \oplus \ell^2$. Define $T \in \mathcal{B}(X)$ by $T(x, y) = (0, x)$. Show that $T$ is strictly singular but not compact.

(e) Show that if $p < q$, the inclusion of $\ell^p$ into $\ell^q$ is strictly singular but not compact. So if $1 < p < q < \infty$, there is an operator on the reflexive (even uniformly convex, if the 2-norm is used on the direct sum) Banach space $\ell^p \oplus \ell^q$ which is strictly singular but not compact.

XV.11.6.3. Let $X$ be a Banach space. Show that the set of strictly singular operators on $X$ is a closed two-sided ideal in $\mathcal{B}(X)$.

XV.11.6.4. Let $X$ be a Banach space, and $S$ a strictly singular operator on $X$. Modify the proofs for compact operators to show the following:

(a) If $T \in \mathcal{F}(X)$, then $T + S \in \mathcal{F}(X)$ and $\text{index}(T + S) = \text{index}(T)$. In particular, if $T$ is invertible, then $T + S$ is a Fredholm operator of index 0.

(b) $\sigma(S)$ consists of 0 and at most countably many nonzero numbers, each an eigenvalue of finite multiplicity, with no nonzero accumulation point.
XV.12. The Spectral Theorem

The Spectral Theorem, in its various forms, gives a precise description of the structure of self-adjoint and, more generally, normal operators on a Hilbert space. It roughly says that such an operator is, up to unitary equivalence, a “multiplication operator with multiplicity” with a simple explicit description. The name “Spectral Theorem” comes from the fact that the description is expressed in terms of the spectrum of the operator.

XV.12.1. The Finite-Dimensional Spectral Theorem

We first discuss the Spectral Theorem on a finite-dimensional Hilbert space. As might be expected, this situation is pure Linear Algebra with no essential use of functional analysis.

XV.12.1.1. Theorem. [Finite-Dimensional Spectral Theorem] Let \( \mathcal{H} \) be a finite-dimensional Hilbert space, and \( T \) a normal operator on \( \mathcal{H} \). Then there is an orthonormal basis for \( \mathcal{H} \) consisting of eigenvectors of \( T \).

XV.12.1.2. Corollary. Let \( A \in M_n = M_n(\mathbb{C}) \) be a normal matrix. Then \( A \) is unitarily equivalent to a diagonal matrix.

XV.12.1.3. The converse is true too: if \( A \in M_n \) is unitarily equivalent to a diagonal matrix, then \( A \) is normal.

We now give the proof of Theorem XV.12.1.1.

Proof: The proof of XV.12.1.1. is a simple complete induction (infinite regress), based on () and the elementary facts that if \( T \) is normal, then so is \( T - \lambda I \) for any \( \lambda \in \mathbb{C} \) and that any operator on a finite-dimensional complex vector space has at least one eigenvalue ()

Suppose the result holds for Hilbert spaces of dimension \( < n \), and that \( \mathcal{H} \) is \( n \)-dimensional. Let \( \lambda \) be an eigenvalue of \( T \), and \( E_\lambda \) the corresponding eigenspace, i.e.

\[
E_\lambda = \{ x \in \mathcal{H} : Tx = \lambda x \}.
\]

Then \( E_\lambda = \mathcal{N}(T - \lambda I) \) is a nontrivial subspace of \( \mathcal{H} \), so \( E_\lambda^\perp = \mathcal{R}(T - \lambda I) \) is a subspace of \( \mathcal{H} \) of dimension \( < n \) (recall that every subspace of \( \mathcal{H} \) is closed). If \( x \in E_\lambda^\perp \), then \( x = (T - \lambda I)y \) for some \( y \), and hence

\[
Tx = T(T - \lambda I)y = (T - \lambda I)(Ty) \in \mathcal{R}(T - \lambda I) = E_\lambda^\perp.
\]

So \( T \) maps \( E_\lambda^\perp \) into itself, and so \( S = T|_{E_\lambda^\perp} \) is an operator on \( E_\lambda^\perp \). It is easily checked that the adjoint of \( S \) is \( T^*|_{E_\lambda^\perp} \), since \( E_\lambda = \mathcal{N}((T - \lambda I)^*) \) and \( E_\lambda^\perp = \mathcal{R}((T - \lambda I)^*) \) because \( T - \lambda I \) is normal, and therefore \( E_\lambda \) and \( E_\lambda^\perp \) are invariant under \( T^* \) by the same argument as for \( T \). Thus \( S \) is normal, so by the inductive assumption there is an orthonormal basis for \( E_\lambda^\perp \) consisting of eigenvectors of \( S \), and putting this basis together with any orthonormal basis of \( E_\lambda \) gives an orthonormal basis for \( \mathcal{H} \) consisting of eigenvectors of \( T \). ☑
XV.12.1.4. The orthonormal basis in XV.12.1.1. is not unique. However, the decomposition of \( \mathcal{H} \) into eigenspaces of \( T \) is unique, and is a more natural way to phrase the Spectral Theorem:

\[ \text{XV.12.1.5. Corollary.} \]
Let \( \mathcal{H} \) be a finite-dimensional Hilbert space, and \( T \) a normal operator on \( \mathcal{H} \). Let \( \lambda_1, \ldots, \lambda_m \) be the distinct eigenvalues of \( T \), and \( \mathcal{E}_{\lambda_1}, \ldots, \mathcal{E}_{\lambda_m} \) the corresponding eigenspaces. Then

(i) \( \mathcal{E}_{\lambda_j} \perp \mathcal{E}_{\lambda_k} \) for \( j \neq k \).

(ii) The subspaces \( \{\mathcal{E}_{\lambda_1}, \ldots, \mathcal{E}_{\lambda_m}\} \) span \( \mathcal{H} \).

Thus \( \mathcal{H} \cong \mathcal{E}_{\lambda_1} \oplus \cdots \oplus \mathcal{E}_{\lambda_m} \).

There is an alternate phrasing in terms of projection operators. For each \( k \), let \( E_k \) be the orthogonal projection of \( \mathcal{H} \) onto \( \mathcal{E}_{\lambda_k} \). Then:

\[ \text{XV.12.1.6. Corollary.} \]
Let \( \mathcal{H} \) be a finite-dimensional Hilbert space, and \( T \) a normal operator on \( \mathcal{H} \). Let \( \lambda_1, \ldots, \lambda_m \) be the distinct eigenvalues of \( T \). Then there are unique projections \( E_1, \ldots, E_m \in \mathcal{B}(\mathcal{H}) \) such that

(i) \( E_j \perp E_k \) for \( j \neq k \).

(ii) \( E_1 + \cdots + E_m = I \).

(iii) \( E_k T = TE_k = E_k T E_k = \lambda_k E_k \) for each \( k \).

(iv) \( \lambda_1 E_1 + \cdots + \lambda_m E_m = T \).

The expression in (iv) is called the spectral resolution of \( T \).

\[ \text{XV.12.1.7.} \]
This representation can be extended. If \( f \) is a polynomial with complex coefficients, and \( f(T) \) is defined in the standard way (), then an easy calculation shows that

\[ f(T) = f(\lambda_1)E_1 + \cdots + f(\lambda_m)E_m \]

where \( E_1, \ldots, E_m \) are as in XV.12.1.6. Since \( f(T) \) is also normal, and the eigenvalues of \( f(T) \) are \( f(\lambda_1), \ldots, f(\lambda_m) \), then this expression is almost the spectral resolution of \( f(T) \), except that the \( f(\lambda_k) \) need not be distinct and if not some terms in this sum could be combined.

\[ \text{XV.12.1.8.} \]
In particular, if \( f_k \) is a polynomial with \( f_k(\lambda_k) = 1 \) and \( f_k(\lambda_j) = 0 \) for \( j \neq k \) (cf. V.11.1.3.), then \( f_k(T) = E_k \). Thus the \( E_k \) are expressible as polynomials in \( T \).
XV.13. \textit{L}^p\textit{-Spaces}

In this section, we define and prove the basic properties of the \textit{L}^p\textit{-spaces of a measure space. These are very important examples of Banach spaces, especially \textit{L}^2\textit{-spaces, which are Hilbert spaces.}

XV.13.1. Conjugate Exponents

This subsection simply sets up some simple notation and terminology which will prove very useful.

XV.13.1.1. Definition. Let \( p \) be a real number greater than 1. The number \( q = \frac{p}{p-1} \) is called the \textit{conjugate exponent} to \( p \). The pair \((p,q)\) is a \textit{conjugate pair of exponents}.

If \( p > 1 \), then \( q > 1 \) also. This definition is symmetric in \( p \) and \( q \), as is immediate from the next proposition, which gives several equivalent versions of the defining equality. The proof is a simple exercise in high-school algebra.

XV.13.1.2. Proposition. Let \( p, q > 1 \). The following are equivalent:

(i) \( q \) is the conjugate exponent to \( p \), i.e. \( q = \frac{p}{p-1} \).

(ii) \( p \) is the conjugate exponent to \( q \), i.e. \( p = \frac{q}{q-1} \).

(iii) \( \frac{1}{p} + \frac{1}{q} = 1 \).

(iv) \( pq - q = p \).

(v) \( p - \frac{p}{q} = 1 \).

(vi) \( \frac{p}{q} = p - 1 \).

(vii) \( (p - 1)(q - 1) = 1 \).

Note that if \( 1 < p < 2 \), then \( q > 2 \), and if \( p = 2 \) then \( q = 2 \) (i.e. \( 2 \) is “self-conjugate”). As \( p \) increases, \( q \) decreases; as \( p \to 1 \), \( q \to \infty \) (and vice versa). We extend the definition of a conjugate pair to include the pairs \((1, \infty)\) and \((\infty, 1)\), i.e. the conjugate exponent to 1 is \( \infty \) and vice versa. These pairs behave somewhat differently than the pairs for \( 1 < p < \infty \), however, and some results do not apply to them.

XV.13.2. \textit{L}^p\textit{-Spaces, Norms, and Inequalities}

XV.13.2.1. Definition. Let \((X, \mathcal{A}, \mu)\) be a measure space and \( 0 < p < \infty \). If \( f \) is an \( \mathcal{A}\)-measurable function from \( X \) to \( \mathbb{C} \), set

\[
J_p(f) = \int_X |f|^p \, d\mu 
\]

\[
||f||_p = [J_p(f)]^{1/p} = \left[ \int_X |f|^p \, d\mu \right]^{1/p}
\]

(where \( \infty^{1/p} = \infty \)).
We let \( L^p_c(X,A,\mu) \) (or \( L^p(\mu) \)) if \( X \) and \( A \) are understood) be the set of measurable functions from \( X \) to \( \mathbb{C} \) such that \( J_\mu(f) < \infty \). \( L^p_c(X,A,\mu) \) is defined similarly. We let \( L^p(X,A,\mu) \) stand for either \( L^p_c(X,A,\mu) \) or \( L^p_c(X,A,\mu) \) when the base field is unimportant (it must of course always be specified and kept in mind).

The space \( L^p(\mu) \) is really only interesting if \( \mu \) is \( \sigma \)-finite or at least semifinite, since it is rather degenerate otherwise (XV.13.5.7., Exercise XV.13.7.4.–XV.13.7.5.). However, the definition and basic properties need no assumptions about the measure space.

The next proposition records some obvious properties of the \( L^p \)-spaces.

**XV.13.2.2.** Proposition. Let \( (X,A,\mu) \) be a measure space and \( 0 < p < \infty \). Then

(i) \( L^p(X,A,\mu) \subseteq L^p_c(X,A,\mu) \).

(ii) If \( f \in L^p(X,A,\mu) \), \( g \) is \( A \)-measurable, and \( |g| \leq |f| \) a.e., then \( g \in L^p(X,A,\mu) \). In particular, if \( g \) is \( A \)-measurable, then \( g \in L^p(X,A,\mu) \) if and only if \( |g| \in L^p(X,A,\mu) \).

(iii) If \( r > 0 \) and \( f \in L^p(X,A,\mu) \), then \( |f|^{p/r} \in L^r(X,A,\mu) \) and \( \| |f|^{p/r} \|_r = \| f \|_{p/r} \). In particular, if \( p > 1 \) and \( q \) is the conjugate exponent to \( p \), and \( f \in L^p(X,A,\mu) \), then \( |f|^{p^{-1}} \in L^q(X,A,\mu) \) and \( \| |f|^{p^{-1}} \|_q = \| f \|_{p^{-1}} \) (XV.13.1.2.(vi)).

(iv) If \( f : X \to \mathbb{C} \) is \( A \)-measurable, then \( f \in L^p_c(X,A,\mu) \) if and only if the real and imaginary parts of \( f \) are in \( L^p_c(X,A,\mu) \).

We will eventually show that \( \| \cdot \|_p \) is a seminorm on \( L^p(\mu) \) if \( p \geq 1 \). The triangle inequality (which only holds for \( p \geq 1 \)) will take some work. We first get a weak form of the triangle inequality which will be enough to show that \( L^p(\mu) \) is a vector space, even for \( 0 < p < 1 \):

**XV.13.2.3.** Proposition. Let \( (X,A,\mu) \) be a measure space, \( 0 < p < \infty \), and \( f \in L^p_c(X,A,\mu) \), \( \alpha \in \mathbb{C} \). Then

\[
J_p(f + g) \leq 2^p[J_p(f) + J_p(g)] \\
J_p(\alpha f) = |\alpha|^p J_p(f)
\]

In particular, \( f + g \) and \( \alpha f \) are in \( L^p_c(X,A,\mu) \), and \( L^p_c(X,A,\mu) \) is a complex vector space (hence \( L^p(X,A,\mu) \) is a real vector space).

**Proof:** The statement for \( \alpha f \) is obvious. For the first statement, we have

\[
J_p(f + g) = \int_X |f + g|^p d\mu \leq \int_X (|f| + |g|)^p d\mu \leq \int_X (2\max(|f|,|g|))^p d\mu \\
= 2^p \int_X (\max(|f|^p,|g|^p)) d\mu \leq 2^p \int_X (|f|^p + |g|^p) d\mu \\
= 2^p \left[ \int_X |f|^p d\mu + \int_X |g|^p d\mu \right] = 2^p[J_p(f) + J_p(g)].
\]

\( \blacksquare \)

In order to prove the triangle inequality for \( \| \cdot \|_p \) \((1 < p < \infty)\), we need to establish some inequalities: Young’s Inequality for products, Hölder’s Inequality, and finally Minkowski’s Inequality. We begin with Young’s Inequality for products after observing a simple preliminary lemma:
**XV.13.2.4.** **Lemma.** Let \( x, y \in (0, \infty) \) and \( 0 \leq t \leq 1 \). Then
\[
t \log x + (1-t) \log y \leq \log(tx + (1-t)y) .
\]
We have equality if and only if \( x = y \) or \( t = 0 \) or 1.

The proof is essentially just the observation that the graph of \( \log x \) is (strictly) concave downward.

**XV.13.2.5.** **Proposition.** [Young’s Inequality for Products] Let \( \alpha, \beta \in [0, \infty) \) and \( (p,q) \) a conjugate pair of exponents with \( 1 < p < \infty \). Then
\[
\alpha \beta \leq \frac{1}{p} \alpha^p + \frac{1}{q} \beta^q
\]
with equality if and only if \( \alpha^p = \beta^q \).

**Proof:** If \( \alpha \) or \( \beta \) is 0, the result is trivial. Otherwise, we have
\[
\log(\alpha \beta) = \log \alpha + \log \beta = \frac{1}{p} \log(\alpha^p) + \frac{1}{q} \log(\beta^q) \leq \log \left( \frac{1}{p} \alpha^p + \frac{1}{q} \beta^q \right)
\]
where the inequality comes from Lemma XV.13.2.4. with \( x = \alpha^p, \ y = \beta^q, \ t = \frac{1}{p} \). Since the log function is strictly increasing, the result follows.

See Exercise XV.13.7.1. for an equivalent statement and another proof of Young’s Inequality for products, and Exercise XV.13.7.2. for a more general version. There is another inequality due to Young for convolutions ()

We now obtain Hölder’s Inequality, which is a generalization of the CBS Inequality (XV.9.2.1.). This inequality will not only be used in this section, but will be important in other applications.

**XV.13.2.6.** **Proposition.** [Hölder’s Inequality] Let \( (X, \mathcal{A}, \mu) \) be a measure space, \( (p,q) \) a conjugate pair with \( 1 < p < \infty \), \( f \in L^p(\mu) \), and \( g \in L^q(\mu) \). Then \( fg \in L^1(\mu) \) and
\[
\int_X |fg| \, d\mu \leq \|f\|_p \|g\|_q .
\]
We have equality if and only if \( |g|^q = \alpha |f|^p \) a.e. for some \( \alpha > 0 \), or if \( f = 0 \) a.e. or \( g = 0 \) a.e.

**Proof:** If \( f = 0 \) a.e. or \( g = 0 \) a.e. both sides are 0, so equality holds. Otherwise, let \( F = \frac{1}{\|f\|_p} f \), \( G = \frac{1}{\|g\|_q} g \). Then \( \|F\|_p = \|G\|_q = 1 \), and we have, using Young’s Inequality for products,
\[
\frac{1}{\|f\|_p \|g\|_q} \int_X |fg| \, d\mu = \int_X |FG| \, d\mu \leq \frac{1}{p} \int_X |F|^p \, d\mu + \frac{1}{q} \int_X |G|^q \, d\mu = \frac{1}{p} + \frac{1}{q} = 1 .
\]
We have equality if and only if \( |F|^p = |G|^q \) a.e. Note that multiplying \( f \) or \( g \) by a nonzero scalar does not change \( |F| \) and \( |G| \).

We can now prove the triangle inequality for \( \| \cdot \|_p \) for \( 1 \leq p < \infty \). This inequality is usually called Minkowski’s Inequality.
**XV.13.2.7.** Theorem. [Minkowski’s Inequality] Let \((X, \mathcal{A}, \mu)\) be a measure space, and \(1 \leq p < \infty\). If \(f, g \in \mathcal{L}^p(X, \mathcal{A}, \mu)\), then \(f + g \in \mathcal{L}^p(X, \mathcal{A}, \mu)\) and
\[
\|f + g\|_p \leq \|f\|_p + \|g\|_p.
\]

Proof: The case \(p = 1\) is essentially just the usual triangle inequality for numbers, and is left to the reader. So we assume \(p > 1\).

We have already noted that \(f + g \in \mathcal{L}^p(\mu)\) (XV.13.2.3.). Let \(q\) be the conjugate exponent to \(p\). Then by XV.13.2.2.(iii), \(|f + g|^{p-1} \in \mathcal{L}^q(\mu)\) and
\[
\|\|f + g|^{p-1}\|_q = \|f + g\|_p^{p/q} = \|f + g\|_p^{p-1}.
\]

Next note that
\[
|f + g|^p = |f + g| \cdot |f + g|^{p-1} \leq (|f| + |g|) \cdot |f + g|^{p-1} = |f| |f + g|^{p-1} + |g| |f + g|^{p-1}.
\]

Thus, by Hölder’s Inequality,
\[
\|f + g\|_p^p = \int_X |f + g|^p d\mu \leq \int_X |f| |f + g|^{p-1} d\mu + \int_X |g| |f + g|^{p-1} d\mu
\leq \|f\|_p \|f + g|^{p-1}\|_q + \|g\|_p \|f + g|^{p-1}\|_q = (\|f\|_p + \|g\|_p) \|f + g\|_p^{p-1}.
\]

If \(\|f + g\|_p = 0\), the result is trivial; otherwise, divide by \(\|f + g\|_p^{p-1}\).

**XV.13.2.8.** Corollary. Let \((X, \mathcal{A}, \mu)\) be a measure space, and \(1 \leq p < \infty\). Then \(\| \cdot \|_p\) is a seminorm on \(\mathcal{L}^p(X, \mathcal{A}, \mu)\).

Proof: It is obvious that \(\|f\|_p \in [0, \infty)\) if \(f \in \mathcal{L}^p(\mu)\), and it follows from XV.13.2.3. that if \(f \in \mathcal{L}^p(\mu)\) and \(\alpha\) is a scalar, then \(\|\alpha f\|_p = |\alpha| \|f\|_p\) (these statements are also true if \(0 < p < 1\)). Minkowski’s Inequality gives the triangle inequality (for \(1 \leq p < \infty\)).

This seminorm is usually not a norm: \(\|f\|_p = 0\) if (and only if) \(f = 0\) a.e. We will remedy this in the next section.

The function \(\| \cdot \|_p\) does not satisfy the triangle inequality for \(0 < p < 1\) in general:

**XV.13.2.9.** Example. Let \(X = \{a, b\}\) be a two-point space, and \(\mu\) counting measure on \((X, \mathcal{P}(X))\). Let \(f(a) = 1\), \(f(b) = 0\), \(g(a) = 0\), \(g(b) = 1\). For any \(p\), \(0 < p < \infty\), we have \(\|f\|_p = \|g\|_p = 1\), \(\|f + g\|_p = 2^{1/p}\).

So if \(p < 1\), \(\|f + g\|_p > 2\) and \(\| \cdot \|_p\) does not satisfy the triangle inequality.
XV.13.3. \textit{L}^{p}\text{-Spaces}

Definition as a quotient, completeness, density of simple functions, density of continuous functions for Borel measures

Let \((X, \mathcal{A}, \mu)\) be a measure space. Since \(\|\cdot\|_p\) is usually only a seminorm and not a norm on \(L^p(X, \mathcal{A}, \mu)\), by the usual process () we reduce to the quotient by the subspace of vectors of seminorm 0, which in this case is the set of functions which are 0 a.e. This reduction effectively means that we identify functions which are equal a.e.

XV.13.3.1. Definition. Let \(0 < p < \infty\). \(L^p(X, \mathcal{A}, \mu)\) (denoted just \(L^p\) when \(X\) and \(\mathcal{A}\) are understood) is the quotient of \(L^p(X, \mathcal{A}, \mu)\) by the subspace

\[\{ f \in L^p(X, \mathcal{A}, \mu) : \| f \|_p = 0 \} = \{ f : f \text{ measurable, } f = 0 \text{ a.e.} \} .\]

(As with \(L^p\), \(L^p\) can stand for either \(L^p_{\mathbb{R}}\) or \(L^p_{\mathbb{C}}\); the base field should always be specified in a specific context.)

If \(f \in L^p(\mu)\), we denote by \([f]\) the image of \(f\) in \(L^p(\mu)\):

\([f] = \{ g \in L^p(\mu) : f = g \text{ a.e.} \} .\]

As in (), the seminorm \(\| \cdot \|_p\) on \(L^p(\mu)\) drops to a norm on \(L^p(\mu)\), also denoted \(\| \cdot \|_p\), by \(\|[f]\|_p = \|f\|_p\).

Many authors are rather sloppy in distinguishing between \(L^p(\mu)\) and \(L^p(\nu)\), and functional analysts tend to be rather casual about the difference; we will eventually follow this convention of thinking of elements of \(L^p(\mu)\) as functions rather than equivalence classes of functions, but in this section we will make a careful distinction in establishing the basic properties of these spaces (which can be used to carefully justify the casual convention).

The most important fact about \(L^p\)-spaces is that they are Banach spaces:

XV.13.3.2. Theorem. Let \((X, \mathcal{A}, \mu)\) be a measure space, and \(1 \leq p < \infty\). Then \(L^p(X, \mathcal{A}, \mu)\) is complete.

Proof: We will use (). Suppose \((f_k)\) is a sequence in \(L^p(X, \mathcal{A}, \mu)\) with

\[\sum_{k=1}^{\infty} \| f_k \|_p = M < \infty .\]

We will show that there is an \(f \in L^p(X, \mathcal{A}, \mu)\) with

\[\lim_{n \to \infty} \left\| f - \sum_{k=1}^{n} f_k \right\|_p = 0\]

which will imply that the series \(\sum_{k=1}^{\infty} |f_k|\) converges to \([f]\) in \(L^p(X, \mathcal{A}, \mu)\).

For each \(n\), let \(g_n = \sum_{k=1}^{n} |f_k|\). Then \((g_n)\) is an increasing sequence; let \(g = \lim g_n = \sup g_n\). Then \(g\) is an extended nonnegative real-valued measurable function on \((X, \mathcal{A})\). By Minkowski’s Inequality, for each \(n\) we have

\[\int_X g_n^p \, d\mu = \| g_n \|_p^p \leq \left[ \sum_{k=1}^{n} \| f_k \|_p \right]^p \leq M^p .\]
and so, by the Monotone Convergence Theorem,
\[
\int_X g^p \, d\mu = \sup_n \int_X g_n^p \, d\mu \leq M^p < \infty .
\]
Thus, although \( g \) may technically not be in \( L^p(X, \mathcal{A}, \mu) \) since it may take the value \(+\infty\), it is finite a.e. and equal a.e. to a function \( h \in L^p(X, \mathcal{A}, \mu) \). For any \( x \in X \) with \( g(x) < \infty \) the series \( \sum_{k=1}^\infty f_k(x) \) of scalars converges absolutely, hence converges; call the sum \( f(x) \). Extend \( f \) to be 0 on the \( x \)'s for which \( g(x) = +\infty \). Then \( f \) is an \( \mathcal{A} \)-measurable function from \( X \) to \( \mathbb{C} \), and \( |f| \leq |h| \) a.e., so \( f \in L^p(X, \mathcal{A}, \mu) \). We also have
\[
\left| f - \sum_{k=1}^n f_k \right|^p \leq |h|^p \text{ a.e.}
\]
for all \( n \), and \( |h|^p \in L^1(X, \mathcal{A}, \mu) \); since \(|f - \sum_{k=1}^n f_k|^p \to 0 \) pointwise a.e., by the Dominated Convergence Theorem we have
\[
\lim_{n \to \infty} \left\| f - \sum_{k=1}^n f_k \right\|_p^p = \lim_{n \to \infty} \left[ \int_X \left| f - \sum_{k=1}^n f_k \right|^p \right] = 0 .
\]
It is interesting to note that, although it is somewhat easier to prove that \( \| \cdot \|_p \) is a seminorm (i.e. satisfies the triangle inequality) for \( p = 2 \) than for general \( p \) (cf. ()), and considerably easier for \( p = 1 \), it is no easier to prove completeness of \( L^p \) for \( p = 1 \) or \( p = 2 \) than for general \( p \).

It is usually important to identify some dense subsets of “nice” elements in any Banach space, and this is particularly important in the \( L^p \)-spaces. For example, we will show (that in \( L^p \)-spaces arising from Borel measures on good topological spaces, the continuous functions are dense in \( L^p \) for any \( p \). One general and very useful fact is true in any \( L^p \)-space:

**Theorem.** Let \((X, \mathcal{A}, \mu)\) be a measure space, and \(1 \leq p < \infty\). Then the (classes of) simple functions in \( L^p(X, \mathcal{A}, \mu) \) are dense in \( L^p(X, \mathcal{A}, \mu) \).

**Proof:** By working with real and imaginary parts, it suffices to prove the result for \( L^p_{\mathbb{R}}(\mu) \). If \( f \in L^p_{\mathbb{R}}(\mu) \), then by (1) there is a sequence of real-valued simple functions \((s_n)\) converging pointwise to \( f \), with \( |s_n| \leq |f| \) for all \( n \). Thus each \( s_n \in L^p_{\mathbb{R}}(\mu) \). We have \( |s_n - f|^p \leq 2|f|^p \) for all \( n \), and \( 2|f|^p \in L^1(\mu) \). Since \( |s_n - f|^p \to 0 \) pointwise, by the Dominated Convergence Theorem we have
\[
\lim_{n \to \infty} \|s_n - f\|_p^p = \lim_{n \to \infty} \left[ \int_X |s_n - f|^p \, d\mu \right] = 0 .
\]
XV.13.4. $L^\infty$- and $L^\infty$-Spaces

XV.13.5. Comparison Between $L^p$-Spaces and $L^p$-Spaces

Let $(X, \mathcal{A}, \mu)$ be a measure space. There is no containment between the $L^p$-spaces or the $L^p$-spaces of $(X, \mathcal{A}, \mu)$ as $p$ varies, except in certain special cases. There are two competing constraints which can cause a (measurable) function $f$ to fail to be in $L^p(X, \mathcal{A}, \mu)$:

(i) $f$ can go to zero “too slowly” (or not at all) at “infinity.”

(ii) $f$ can go to infinity “too rapidly” on a small portion of $X$.

The first problem gets worse as $p$ decreases, and the second problem gets worse as $p$ increases. We will make these problems precise in this subsection, and give examples.

Consider the first constraint.

XV.13.5.1. Example. Suppose $(X, \mathcal{A}, \mu)$ contains measurable subsets of arbitrarily large finite measure (e.g. $\mu$ is $\sigma$-finite but not finite). Choose an increasing sequence $(B_n)$ in $\mathcal{A}$ with $\mu(B_1) \geq 1$ and $\mu(B_n) + 1 < \mu(B_{n+1}) < \infty$ for all $n > 1$. Then, by taking successive differences, there is a sequence $(A_n)$ of pairwise disjoint sets in $\mathcal{A}$ with $1 \leq \mu(A_n) < \infty$ for all $n$. Fix $p, 0 < p < 1$, and define a function $f : X \to [0, 1]$ by setting

\[ f(x) = \frac{1}{[n\mu(A_n)]^{1/p}} \text{ if } x \in A_n \]

\[ f(x) = 0 \text{ if } x \notin \cup_n A_n . \]

Then $f$ is measurable, and we have

\[ J_p(f) = \sum_{n=1}^{\infty} \frac{1}{n\mu(A_n)} \mu(A_n) = \sum_{n=1}^{\infty} \frac{1}{n} = \infty \]

so $f \notin L^p(X, \mathcal{A}, \mu)$. However, if $p < r < \infty$, we have

\[ J_r(f) = \sum_{n=1}^{\infty} \frac{1}{n^{r/p}\mu(A_n)^{r/p}} \mu(A_n) = \sum_{n=1}^{\infty} \frac{1}{n^{r/p}\mu(A_n)^{r/p}} \leq \sum_{n=1}^{\infty} \frac{1}{n^{r/p}} < \infty \]

so $f \in \cap_{r>p} L^r(X, \mathcal{A}, \mu)$. (Note that $f$ is bounded, so $f \in L^\infty(X, \mathcal{A}, \mu)$ also.) In particular, $L^r(X, \mathcal{A}, \mu)$ is not contained in $L^p(X, \mathcal{A}, \mu)$ for $p < r \leq \infty$.

In the absence of such subsets, we have a containment:

XV.13.5.2. Proposition. Let $(X, \mathcal{A}, \mu)$ be a finite measure space, and let $0 < p \leq r \leq \infty$. Then $L^r(X, \mathcal{A}, \mu)$ is contained in $L^p(X, \mathcal{A}, \mu)$.

Proof: If $r = \infty$, the result holds since any bounded measurable function on a finite measure space is integrable. So assume $r < \infty$ and let $f \in L^r(X, \mathcal{A}, \mu)$. Set

\[ A = \{ x \in X : |f(x)| \geq 1 \} \]
\[ B = \{ x \in X : |f(x)| < 1 \} . \]

Then \(|f|^p \leq |f|^r\) on \(A\), so we have
\[
J_p(f) = \int_X |f|^p d\mu = \int_A |f|^p d\mu + \int_B |f|^p d\mu \leq \int_A |f|^r d\mu + \int_B |f|^p d\mu
\]
\[
\leq J_r(f) + \mu(B) < \infty
\]
so \(f \in L^p(X, \mathcal{A}, \mu)\).  

Now we turn to the second constraint.

\textbf{XV.13.5.3. Example.} Let \((X, \mathcal{A}, \mu)\) be a measure space which contains measurable sets of arbitrarily small positive measure. Let \(B_1 \in \mathcal{A}\) with \(0 < \mu(B_1) \leq 1\), and inductively let \(B_n \in \mathcal{A}\) with \(0 < \mu(B_n) \leq \frac{1}{2} \mu(B_{n-1})\) for \(n > 1\). Set \(A_n = B_n \setminus (\bigcup_{k=n+1}^{\infty} B_k)\). Then the \(A_n\) are pairwise disjoint, and since
\[
\mu(\bigcup_{k=n+1}^{\infty} B_k) \leq \sum_{k=n+1}^{\infty} \mu(B_k) \leq \sum_{m=1}^{\infty} 3^{-m} \mu(B_n) = \frac{\mu(B_n)}{2}
\]
we have \(0 < \frac{1}{2} \mu(B_n) \leq \mu(A_n)\). Also, \(\mu(A_n) \leq \mu(B_n) \leq 3^{-n+1}\).

Fix \(p, 0 < p < \infty\). Define a function \(f : X \to [0, \infty)\) by
\[
f(x) = [\mu(A_n)]^{-1/p} \text{ if } x \in A_n
\]
\[
f(x) = 0 \text{ if } x \notin \bigcup_n A_n .
\]
Then we have
\[
J_p(f) = \sum_{n=1}^{\infty} [\mu(A_n)]^{-1} \mu(A_n) = \infty
\]
so \(f \notin L^p(X, \mathcal{A}, \mu)\). But if \(0 < r < p\), we have
\[
J_r(f) = \sum_{n=1}^{\infty} [\mu(A_n)]^{-r/p} \mu(A_n) = \sum_{n=1}^{\infty} [\mu(A_n)]^{1-r/p} \leq \sum_{n=1}^{\infty} [3^{1-r/p}]^{-n+1} < \infty
\]
so \(f \in \cap_{r<p} L^r(X, \mathcal{A}, \mu)\). In particular, \(L^r(X, \mathcal{A}, \mu)\) is not contained in \(L^p(X, \mathcal{A}, \mu)\) for any \(r < p\). Also, \(f\) is not essentially bounded, so \(f \notin L^\infty(X, \mathcal{A}, \mu)\), i.e. \(L^p(X, \mathcal{A}, \mu)\) is not contained in \(L^\infty(X, \mathcal{A}, \mu)\).

We again have a containment in the absence of this situation:
**XV.13.5.4.** Proposition. Let \((X, \mathcal{A}, \mu)\) be a measure space. Suppose there is an \(\epsilon > 0\) such that, for every \(A \in \mathcal{A}\), either \(\mu(A) = 0\) or \(\mu(A) \geq \epsilon\). Let \(0 < r \leq p \leq \infty\). Then \(L^r(X, \mathcal{A}, \mu)\) is contained in \(L^p(X, \mathcal{A}, \mu)\).

**Proof:** Let \(f \in L^r(\mu)\). We first show that \(f\) is essentially bounded. We may assume \(\|f\|_r > 0\), since otherwise \(f = 0\) a.e. Set \(M = \frac{\|f\|_r}{\epsilon}\) and let \(C = \{x \in X : |f(x)| > M\}\). Since

\[
M^r \mu(C) = \frac{\|f\|_r^r}{\epsilon} \mu(C) < \int_C |f|^r \, d\mu \leq \int_X |f|^r \, d\mu = \|f\|_r^r
\]

we have \(\mu(C) < \epsilon\), so \(\mu(C) = 0\), i.e. \(|f| \leq M\) a.e. and \(f \in L^\infty(X, \mathcal{A}, \mu)\). If \(p < \infty\), let \(A = \{x : |f(x)| \geq 1\}\) and \(B = \{x : |f(x)| < 1\}\). Then \(|f|^p < |f|^r\) on \(B\), and

\[
\mu(A) \leq \int_A |f|^r \, d\mu \leq \int_X |f|^r \, d\mu = J_r(f) < \infty
\]

and we have

\[
J_p(f) = \int_X |f|^p \, d\mu = \int_A |f|^p \, d\mu + \int_B |f|^p \, d\mu < \int_A |f|^p \, d\mu + \int_B |f|^r \, d\mu \leq M^p \mu(A) + J_r(f) < \infty
\]

so \(f \in L^p(X, \mathcal{A}, \mu)\).

**XV.13.5.5.** Examples. (a) A set with counting measure satisfies the hypotheses of XV.13.5.4. (with \(\epsilon = 1\)). Thus \(\ell^r(X) \subseteq \ell^p(X)\) for any \(X\) if \(r < p\).

(b) If \((X, \mathcal{A}, \mu)\) is a measure space containing both sets of arbitrarily large and arbitrarily small finite positive measure (e.g. \((\mathbb{R}, \mathcal{M}, \lambda))\), then there is no containment either way between \(L^p(X, \mathcal{A}, \mu)\) and \(L^r(X, \mathcal{A}, \mu)\) for \(p \neq r\).

There is, however, a large subspace which is common to \(L^p(\mu)\) for all \(p\). A measurable function \(f\) has support of finite measure if \(\{x : f(x) \neq 0\}\) has finite measure. (Some authors say that such a function has finite support, but this term, while more efficient, is ambiguous.) We can similarly define functions with support of \(\sigma\)-finite measure.

If \((X, \mathcal{A}, \mu)\) is a measure space, let \(L^{oo}(X, \mathcal{A}, \mu)\) (distinguish between oo and \(\infty\!\!)\) be the set of essentially bounded measurable functions with support of finite measure. The characteristic function of a set of finite measure is in \(L^{oo}(X, \mathcal{A}, \mu)\), hence so is any linear combination of such functions (simple functions with support of finite measure).

**XV.13.5.6.** Proposition. \(L^{oo}(X, \mathcal{A}, \mu) \subseteq L^p(X, \mathcal{A}, \mu)\) for \(0 < p \leq \infty\), and \(L^{oo}(X, \mathcal{A}, \mu)\) is dense in \(L^p(X, \mathcal{A}, \mu)\) if \(p < \infty\).

The density for \(p < \infty\) is immediate from the proof of XV.13.3.3., since a simple function which is in \(L^p\) for some \(p\) must be in \(L^{oo}\) (Exercise ())).
\( L^{\infty}(X, \mathcal{A}, \mu) \) is not dense in \( L^{\infty}(X, \mathcal{A}, \mu) \) unless \( \mu \) is finite, in which case \( L^{\infty}(X, \mathcal{A}, \mu) = L^{\infty}(X, \mathcal{A}, \mu) \).

We say a function \( f \) has support of almost finite measure if \( \{ x : |f(x)| > \epsilon \} \) has finite measure for all \( \epsilon > 0 \). This implies, but is not equivalent to, that \( f \) has support of \( \sigma \)-finite measure (consider the constant function 1 on \((\mathbb{R}, \mathcal{M}, \lambda)\)). It is easily shown (Exercise (\ref{ex})) that the closure of \( L^{\infty}(X, \mathcal{A}, \mu) \) in \( L^{\infty}(X, \mathcal{A}, \mu) \) is the set of essentially bounded functions with support of almost finite measure.

It is worth noting the next result:

\textbf{XV.13.5.7.} \textsc{Proposition.} Let \((X, \mathcal{A}, \mu)\) be a measure space and \(0 < p < \infty\). Then any function in \( L^p(X, \mathcal{A}, \mu) \) has support of almost finite measure (in particular, of \( \sigma \)-finite measure).

This proposition is false for \( L^{\infty}(X, \mathcal{A}, \mu) \) if \( \mu \) is not finite.

\textbf{XV.13.5.8.} \textsc{Remark.} For a fixed measure space \((X, \mathcal{A}, \mu)\), \( L^p(X, \mathcal{A}, \mu) \) is constructed from \( L^p(X, \mathcal{A}, \mu) \) by dividing out by the same subspace of functions for every \( p \). Thus if \( L^r(X, \mathcal{A}, \mu) \) is contained in \( L^p(X, \mathcal{A}, \mu) \) for some \( p \) and \( r \), it is technically strictly correct also that \( L^r(X, \mathcal{A}, \mu) \) is contained in \( L^p(X, \mathcal{A}, \mu) \). The converse also holds, as is easy to check. Thus, in all the above containment results of this section, \( L^p \) and \( L^r \) can be replaced by \( L^p \) and \( L^r \) to give strictly correct containment statements.

\textbf{XV.13.5.9.} Now suppose \((X, \mathcal{A}, \mu)\) is a measure space and \( \mathcal{B} \) is a sub-\( \sigma \)-algebra of \( \mathcal{A} \). Set \( \nu = \mu|_{\mathcal{B}} \). It is then obvious that \( L^p(X, \mathcal{B}, \nu) \) is a subspace of \( L^p(X, \mathcal{A}, \mu) \) for any \( p \), and the \( p \)-seminorms agree.

However, it is technically not strictly correct in most cases to say that \( L^p(X, \mathcal{B}, \nu) \) is a subspace of \( L^p(X, \mathcal{A}, \mu) \), since the elements of these spaces are different: if \( f \in L^p(X, \mathcal{B}, \nu) \), the corresponding elements are

\[
[f]_\mathcal{A} = \{ g : g \text{-measurable}, g = f \text{ a.e.} \}
\]

\[
[f]_\mathcal{B} = \{ g : g \text{-measurable}, g = f \text{ a.e.} \}
\]

which are not the same sets in general. However, the map \( [f]_\mathcal{B} \mapsto [f]_\mathcal{A} \) is a linear isometry from \( L^p(X, \mathcal{B}, \nu) \) onto a (complete, hence closed) subspace of \( L^p(X, \mathcal{A}, \mu) \), usually called the inclusion map, and by making this identification we usually, if rather casually, think of \( L^p(X, \mathcal{B}, \nu) \) as a closed subspace of \( L^p(X, \mathcal{A}, \mu) \) for any \( p \).

Normally, the inclusion map sends \( L^p(X, \mathcal{B}, \nu) \) onto a proper subspace of \( L^p(X, \mathcal{A}, \mu) \). But there is one important case where it should be noted that the inclusion map is surjective, hence an isometric isomorphism:

\textbf{XV.13.5.10.} \textsc{Proposition.} Let \((X, \mathcal{A}, \mu)\) be a measure space, and \((X, \mathcal{M}, \bar{\mu})\) its completion. Then, for any \( p \), the inclusion map from \( L^p(X, \mathcal{A}, \mu) \) to \( L^p(X, \mathcal{M}, \bar{\mu}) \) is an isomorphism.

The proof is immediate from the fact that every \( \mathcal{M} \)-measurable function is equal a.e. to an \( \mathcal{A} \)-measurable function (\ref{eq}). Note that \( L^p(X, \mathcal{M}, \bar{\mu}) \) is considerably larger than \( L^p(X, \mathcal{A}, \mu) \) in general.

In particular, \( L^p(\mathbb{R}, \mathcal{M}, \lambda) \) is naturally isomorphic to \( L^p(\mathbb{R}, \mathcal{B}, \lambda) \) for any \( p \).

\textbf{XV.13.6. \textit{L}^p\text{-spaces for Borel Measures}}

Density of continuous functions, separability, Egorov’s Theorem

1856
XV.13.7. Exercises

XV.13.7.1. Let $0 < r < 1$.
(a) Let $f(x) = x^r - rx$ for $x \geq 0$. Show that $f$ is increasing on $[0,1]$ and decreasing on $[1,\infty)$, and has a unique maximum $1 - r$ at $x = 1$.
(b) If $x \in [0,\infty)$, show that $x^r \leq rx + (1 - r)$, with equality if and only if $x = 1$.
(c) If $a, b > 0$, show that $a^r b^{1-r} \leq ra + (1 - r)b$, with equality if and only if $a = b$. [Apply (b) with $x = \frac{a}{b}$.
(d) Show that the inequality in (c) is equivalent to Young’s Inequality for products. [Let $r = \frac{1}{p}$, $\alpha = a^r$, $\beta = b^{1-r}$.

XV.13.7.2. Here is the general version of Young’s Inequality for products:

**Theorem.** [Young’s Inequality for Products, General Version] Let $\phi$ be a strictly increasing continuous function from $[0,\infty)$ onto $[0,\infty)$ (that is, $\phi(0) = 0$ and $\lim_{x \to \infty} \phi(x) = +\infty$), and let $\psi$ be the inverse function of $\phi$. For $x \geq 0$, set

$$\Phi(x) = \int_0^x \phi(t) \, dt$$
$$\Psi(x) = \int_0^x \psi(t) \, dt$$

If $\alpha, \beta \in [0,\infty)$, then

$$\alpha \beta \leq \Phi(\alpha) + \Psi(\beta)$$

with equality if and only if $\beta = \phi(\alpha)$.

See Figure XV.1 for a geometric interpretation in terms of areas. The red area is $\Phi(\alpha)$ and the blue area is $\Psi(\beta)$, and $\alpha \beta$ is the area of the rectangle bounded by the dotted lines and the axes.

(a) Use (a) to show that, for $\beta \geq 0$,

$$\Psi(\beta) = \int_0^\beta \int_0^{\psi(y)} dx \, dy = \int_0^{\psi(\beta)} \int_0^\beta dy \, dx$$

(b) If $\beta \geq \phi(\alpha)$, then

$$\alpha \beta = \int_0^\alpha \int_0^\beta dy \, dx = \int_0^\alpha \int_0^{\phi(x)} dy \, dx + \int_0^\beta \int_0^{\beta} dy \, dx = \Phi(\alpha) + \int_0^\alpha \int_{\phi(x)}^\beta dy \, dx$$

(c) Use (a) and (b) to prove the Theorem if $\beta \geq \phi(\alpha)$. Give a similar proof if $\beta \leq \phi(\alpha)$.

(d) Show that the Young’s Inequality for products of XV.13.2.5. is the special case $\phi(x) = x^{p-1}$.
XV.13.7.3. Prove the following generalized versions of Hölder’s Inequality:

**Theorem. [Hölder’s Inequality, General Version]** Let \((X, \mathcal{A}, \mu)\) be a measure space.

(i) Let \(p, q > 1, r \geq 1\), with

\[
\frac{1}{p} + \frac{1}{q} = \frac{1}{r}
\]

and let \(f \in L^p(\mu)\) and \(g \in L^q(\mu)\). Then \(fg \in L^r(\mu)\) and

\[
\|fg\|_r \leq \|f\|_p \|g\|_q.
\]

(ii) Let \(p_1, \ldots, p_n > 1, r \geq 1\), with

\[
\frac{1}{p_1} + \cdots + \frac{1}{p_n} = \frac{1}{r}
\]

and let \(f_k \in L^{p_k}(\mu)\) for \(1 \leq k \leq n\). Then \(f_1 f_2 \cdots f_n \in L^r(\mu)\) and

\[
\|f_1 f_2 \cdots f_n\|_r \leq \|f_1\|_{p_1} \|f_2\|_{p_2} \cdots \|f_n\|_{p_n}.
\]

[To prove (i), note that]

\[
\frac{1}{p/r} + \frac{1}{q/r} = 1
\]
and apply Hölder’s inequality to $|f|^r$ and $|g|^r$. Prove (ii) by induction on $n$. For the inductive step set

$$
\frac{1}{p} = \frac{1}{p_1} + \cdots + \frac{1}{p_n}
$$

and $q = p_{n+1}$ to obtain $f_1 f_2 \cdots f_n \in L^p$ and $\|f_1 \cdots f_{n+1}\|_r \leq \|f_1 \cdots f_n\|_p \|f_{n+1}\|_{p_{n+1}}$.

**XV.13.7.4.** Let $X = \{x\}$ be a one-point space, and let $\mu(\{x\}) = \infty$. Show that $L^p(X, \mathcal{P}(X), \mu) = \{0\}$ for $1 \leq p < \infty$, and that $L^\infty(X, \mathcal{P}(X), \mu)$ is one-dimensional (the set of all scalar-valued functions).

**XV.13.7.5.** Let $X$ be an uncountable set, and for $A \subseteq X$ let $\mu(A) = 0$ if $A$ is countable and $\mu(A) = \infty$ if $A$ is uncountable.

(a) If $1 \leq p < \infty$, show that $L^p(X, \mathcal{P}(X), \mu)$ is the set of functions vanishing except on a countable set, and $L^p(X, \mathcal{P}(X), \mu) = \{0\}$.

(b) Show that $L^\infty(X, \mathcal{P}(X), \mu)$ is the set of all functions which are bounded on a cocountable set, and $L^\infty(X, \mathcal{P}(X), \mu)$ is infinite-dimensional and even nonseparable.

**XV.13.7.6.** (a) Even in a finite continuous measure space the $L^p$-spaces can be small simply because of the lack of sufficiently many measurable functions. Let $X$ be an uncountable set, $\mathcal{A}$ the $\sigma$-algebra of countable-cocountable sets, and $\mu$ the measure on $(X, \mathcal{A})$ with $\mu(A) = 0$ if $A$ is countable and $\mu(A) = 1$ if $A$ is cocountable. A scalar-valued measurable function on $A$ must be constant except on a countable set (1). Show that $L^p(X, \mathcal{A}, \mu)$ is one-dimensional for all $p$, $1 \leq p \leq \infty$ (every measurable function is equal a.e. to a constant function).

(b) Show that the result of (a) holds true in any measure space in which every measurable set has measure either 0 or 1. Thus, if $X$ is a set of measurable cardinality () and $\mu$ is a full $\{0,1\}$-valued measure on $(X, \mathcal{P}(X))$, then $L^p(X, \mathcal{P}(X), \mu)$ is one-dimensional for $1 \leq p \leq \infty$ even though there are plenty of measurable functions; every scalar-valued function is still equal a.e. to a constant function.

**XV.13.7.7.** (a) Show that, in the situation of Example XV.13.5.1., for any $p$ there is an $f \in L^p(X, \mathcal{A}, \mu)$ which is not in $L^r(X, \mathcal{A}, \mu)$ for any $r < p$. [For each $n$, construct a function $f_n$ as in Example XV.13.5.1. which is in $L^p(\mu)$ but not in $L^{p-1/n}(\mu)$, and consider $\sum_{n=1}^{\infty} \frac{2^{-n}}{\|f_n\|_p} f_n$. Modify the argument slightly for $p = \infty$.]

(b) In the situation of XV.13.5.3., use a similar argument to show that if $0 < p < \infty$, there is an $f \in L^p(X, \mathcal{A}, \mu)$ which is not in $L^r(X, \mathcal{A}, \mu)$ for any $r > p$.

(c) If $(X, \mathcal{A}, \mu)$ contains sets of both arbitrarily large and arbitrarily small finite positive measure, and $0 < s \leq r \leq \infty$, show that

(i) There is an $f$ such that $f \in L^p(X, \mathcal{A}, \mu)$ if and only if $s \leq p \leq r$ (in particular, if $s = r$, there is an $f$ such that $f \in L^p(X, \mathcal{A}, \mu)$ if and only if $p = r$).

(ii) If $s < r$, there is an $f$ such that $f \in L^p(X, \mathcal{A}, \mu)$ if and only if $s < p \leq r$.

(iii) If $s < r$, there is an $f$ such that $f \in L^p(X, \mathcal{A}, \mu)$ if and only if $s \leq p < r$.

(iv) If $s < r$, there is an $f$ such that $f \in L^p(X, \mathcal{A}, \mu)$ if and only if $s < p < r$.  

1859
XV.13.7.8. Let \((X, \mathcal{A}, \mu)\) be a measure space, and \(0 < s < p < r \leq \infty\).

(a) Using the arguments of the proofs of XV.13.5.2. and XV.13.5.4., show that every \(f \in L^p(X, \mathcal{A}, \mu)\) can be written as \(f = g + h\) with \(g \in L^s(X, \mathcal{A}, \mu), h \in L^r(X, \mathcal{A}, \mu), gh = 0\), and \(J_p(f) \leq J_s(g) + J_r(h)\).

(b) Show that the function

\[
\|f\| = \inf \{\|g\|_s + \|h\|_r : g \in L^s(\mu), h \in L^r(\mu), f = g + h\}
\]

is a seminorm on the subspace \(L^s(\mu) + L^r(\mu)\) of the space of \(\mathcal{A}\)-measurable functions, that \(\|f\| = 0\) if and only if \(f \in Z\), and that the quotient, which we denote \(L^s(\mu) + L^r(\mu)\), is complete under the corresponding norm. Show that the inclusion map from \(L^p(\mu)\) into \(L^s(\mu) + L^r(\mu)\) is bounded.

(c) Show that \(L^s(\mu) \cap L^r(\mu) \subseteq L^p(\mu)\), that \(\|f\| = \|f\|_s + \|f\|_r\) is a seminorm on \(L^s(\mu) \cap L^r(\mu)\), \(\|f\| = 0\) if and only if \(f \in Z\), and that the quotient, which we denote \(L^s(\mu) \cap L^r(\mu)\), is complete under the corresponding norm. Show that the inclusion map from \(L^s(\mu) \cap L^r(\mu)\) into \(L^p(\mu)\) is bounded.

XV.13.7.9. (a) Prove directly that if \(p > 1\) and \(q\) is conjugate to \(p\), the map \(a \mapsto \phi_a\) is an isometric isomorphism from \(\ell^q\) to \((\ell^p)^*\), where

\[
\phi_a(x) = \sum_{k=1}^{\infty} \alpha_k \xi_k
\]

for \(a = (\alpha_1, \alpha_2, \ldots)\) and \(x = (\xi_1, \xi_2, \ldots)\). [Use Hölder’s inequality and the fact that \(\{e_k\}\) is a Schauder basis for \(\ell^p\).]

(b) Give a similar proof that \((c_0)^* \cong \ell^1\) and that \((\ell^1)^* \cong \ell^\infty\).

This gives an alternate proof that \(\ell^p\) is complete for \(1 \leq p \leq \infty\).
XV.14. C*-Algebras

C*-algebras are the nicest kinds of Banach algebras, and have a beautiful theory with profound applications. We will touch on only some of the basics of this extensive theory here; see [Bla06] for a much more comprehensive treatment.

XV.14.1. Banach *-Algebras and C*-Algebras

**XV.14.1.1. Definition.** An involution on a Banach algebra $A$ is a conjugate-linear isometric antiautomorphism of order two, usually denoted $x \mapsto x^*$. In other words, $(x + y)^* = x^* + y^*$, $(xy)^* = y^*x^*$, $(\lambda x)^* = \lambda x^*$, $(x^*)^* = x$, $\|x^*\| = \|x\|$ for all $x, y \in A$, $\lambda \in \mathbb{C}$. A Banach *-algebra is a Banach algebra with an involution.

An (abstract) C*-algebra is a Banach *-algebra $A$ satisfying the C*-axiom:

$$\|x^*x\| = \|x\|^2$$

for all $x \in A$.

The deceptively simple and innocuous C*-axiom turns out to be extremely powerful, forcing rigid structure on a C*-algebra. For example, it follows that the norm is completely determined by the algebraic structure and is thus unique (XV.14.2.34.), that *-homomorphisms of C*-algebras are automatically contractive (XV.14.1.11.), and that every C*-algebra can be isometrically represented as a concrete C*-algebra of operators (XV.14.4.35.). One obvious, but useful, consequence is that in a C*-algebra, $x^*x = 0$ implies that each $x_j = 0$ (XV.14.3.2. (i), XV.14.3.3.).

**XV.14.1.2.** In many older references, abstract C*-algebras were called $B^*$-algebras, with the name “C*-algebra” reserved for concrete C*-algebras. The term “C*-algebra,” first introduced in [Seg47] (for concrete C*-algebras, but viewed in a somewhat abstract manner), did not become universal until well after the publication of [Dix69] in 1964 (there were occasional references to “$B^*$-algebras” in the literature at least as late as 1980; see even [Lax02]). According to [DB86, p. 6], the “C” in “C*-algebra” originally meant “closed”, and not, as commonly believed, “continuous”, although the interpretation as standing for “continuous” is nicely in line with the modern point of view of C*-algebra theory as “noncommutative topology.”

The issue of terminology is clouded by the fact that several different (but ultimately equivalent) axiom schemes have been used for C*-algebras over the years. For example, it is easily seen that the C*-axiom, along with submultiplicativity of the norm, implies that the involution is isometric, so it is unnecessary to include isometry of the involution as an axiom. The C*-axiom has sometimes been replaced by the apparently weaker axiom that $\|x^*x\| = \|x\|\|x\|$ for all $x$. It turns out that this weaker axiom, along with the Banach algebra axioms, also implies isometry of the involution (a much harder result), so the weakened axiom is equivalent to the C*-axiom. See also XV.14.3.4.. See [DB86] for details about the C*-algebra axioms.

**XV.14.1.3. Examples.**

(i) $B(\mathcal{H})$ with the usual algebraic operations, involution, and operator norm, is a C*-algebra for any Hilbert space $\mathcal{H}$. If $\mathcal{H}$ is $n$-dimensional, we obtain that the $n \times n$ matrices $M_n = B(\mathbb{C}^n)$ form a C*-algebra with the usual involution (conjugate transpose) and operator norm. More generally, any norm-closed *-subalgebra of $B(\mathcal{H})$ is a C*-algebra; such C*-algebras are called concrete C*-algebras. For example, the algebra $K(\mathcal{H})$ of compact operators on a Hilbert space $\mathcal{H}$ is a concrete C*-algebra. If $\mathcal{H}$ is infinite-dimensional, $K(\mathcal{H})$ is nonunital; thus a C*-algebra need not be unital. We denote by $\mathbb{K}$ the C*-algebra of compact operators on a separable, infinite-dimensional Hilbert space.
(ii) Let $X$ be a locally compact Hausdorff space, and $C_0(X)$ the complex-valued continuous functions on $X$ vanishing at infinity. Give $C_0(X)$ its usual pointwise operations and supremum norm. Define an involution by $f^*(x) = \overline{f(x)}$. Then $C_0(X)$ is a commutative C*-algebra. In fact, every commutative C*-algebra is of this form (XV.14.2.5). $C_0(X)$ has a unit (identity) if and only if $X$ is compact; in this case, we usually write $C(X)$. More generally, if $B$ is a C*-algebra, then the set $C_0(X,B)$ of (norm-)continuous functions from $X$ to $B$ vanishing at infinity, with pointwise operations and supremum norm, is a C*-algebra. In particular, $C_0(X,M_n) \cong M_n(C_0(X))$ is a C*-algebra. (In fact, a matrix algebra over any C*-algebra is a C*-algebra (??); this is a special case of the tensor product for C*-algebras (??)).

(iii) Let $G$ be a locally compact topological group with (left) Haar measure $\mu$. Then $L^1(G,\mu)$ becomes a Banach *-algebra under convolution. It is not a C*-algebra unless $G$ is trivial. This example will be treated in more detail in ??.

XV.14.1.4. If $A$ is a Banach algebra and $J$ is a closed ideal ("ideal" will always mean "two-sided ideal" unless otherwise specified) in $A$, then the quotient norm makes $A/J$ into a Banach algebra. If $A$ is a Banach *-algebra and $J$ is a *-ideal (i.e. closed under *), then $A/J$ is a Banach *-algebra. It turns out that if $A$ is a C*-algebra and $J$ is a closed ideal in $A$, then $J$ is automatically a *-ideal and $A/J$ is a C*-algebra in the quotient norm (XV.14.3.14).

XV.14.1.5. A Banach algebra is separable if and only if it is countably generated as a Banach algebra (a countably generated algebra over $\mathbb{Q}(i)$ is countable). A C*-algebra is separable if and only if it is countably generated as a C*-algebra.

XV.14.1.1 Unitization

XV.14.1.1. A Banach algebra, even a C*-algebra, need not be unital (e.g. $K(H)$, $C_0(X)$ for $X$ non-compact). However, every nonunital Banach algebra $A$ can be embedded in a unital Banach algebra $A^\dagger$ (XV.10.1.6.). If $A$ is a Banach *-algebra, for $(a, \lambda) \in A^\dagger$ define $(a, \lambda)^* = (a^*, \overline{\lambda})$; this is an involution making $A^\dagger$ a (unital) Banach *-algebra. With the norm of XV.10.1.6. $A^\dagger$ is not a C*-algebra, but:

XV.14.1.2. Proposition. If $A$ is a C*-algebra, the operator norm on $A^\dagger$ as left multiplication operators on $A$, i.e.

$$\| (a, \lambda) \| = \sup \{ \| ab + \lambda b \| : \| b \| = 1 \}$$

is a C*-norm on $A^\dagger$ extending the norm of $A$.

Proof: $A^\dagger$ is a subalgebra of $B(A)$ with the operator norm; thus it is a normed algebra, and in particular the norm is submultiplicative. If $(a, \lambda) \in A^\dagger$ and $b \in A$, $\| b \| = 1$, then $(a, \lambda)^*(a, \lambda) = (a^* a + \lambda a^* + \overline{\lambda} a, \overline{\lambda})$, so

$$\| ab + \lambda b \|^2 = \| (ab + \lambda b)^*(ab + \lambda b) \| = \| (b^* a^* + \overline{\lambda} b^*)(ab + \lambda b) \|$$

$$= \| b^* (a^* a b + \lambda a b + \overline{\lambda} a b + \overline{\lambda} \lambda b) \| \leq \| a^* a b + \lambda a b + \overline{\lambda} a b + \overline{\lambda} \lambda b \| \leq \| (a, \lambda)^*(a, \lambda) \|$$

and taking the supremum over all $b$ we obtain $\| (a, \lambda) \|^2 \leq \| (a, \lambda)^*(a, \lambda) \|$, and the opposite inequality follows from submultiplicativity (first use this inequality and submultiplicativity to conclude that $\| (a, \lambda)^* = \ldots$
The algebra \( A^\dagger \) contains \( A \) as a (closed) ideal, and \( A^\dagger/A \cong \mathbb{C} \). If \( A \) is unital, \( A^\dagger \cong A \oplus \mathbb{C} \) as \( C^* \)-algebras (under the map \((a,\lambda) \mapsto (a - \lambda 1, \lambda))\).

**XV.14.1.3.** As an example, if \( X \) is a locally compact noncompact Hausdorff space, it is easy to see that \( C_0(X)^\dagger \cong C(X^\dagger) \), where \( X^\dagger \) is the one-point compactification of \( X \).

**XV.14.1.4.** A bounded homomorphism between the Banach algebras \( A \) and \( B \) extends uniquely to a bounded unital homomorphism from \( A^\dagger \) to \( B^\dagger \). A \( * \)-homomorphism between Banach \( * \)-algebras extends to a unital \( * \)-homomorphism between the unitizations.

### Special Elements in a \( C^* \)-Algebra

In a \( C^* \)-algebra, certain types of elements have standard names arising from operator theory, reflecting the types of operators they become when the \( C^* \)-algebra is represented as a concrete \( C^* \)-algebra of operators:

**XV.14.1.5.** **Definition.** Let \( A \) be a \( C^* \)-algebra and \( x \in A \). Then \( x \) is

- **self-adjoint** if \( x = x^* \).
- **normal** if \( x^*x = xx^* \).
- **a projection** if \( x = x^* = x^2 \).
- **a partial isometry** if \( x^*x \) is a projection.

If \( A \) is unital, then \( x \) is

- **an isometry** if \( x^*x = 1 \).
- **a coisometry** if \( xx^* = 1 \).
- **unitary** if \( x^*x = xx^* = 1 \).

**XV.14.1.6.** The self-adjoint elements of \( A \) form a closed real vector subspace \( A_{sa} \) of \( A \). (Note, however, that \( A_{sa} \) is not closed under multiplication unless \( A \) is commutative.) If \( A \) is unital, then the set of unitaries of \( A \) forms a group \( U(A) \). Every self-adjoint or unitary element is normal. If \( x \) is self-adjoint, then \( e^{ix} \) is unitary. 0 and 1 are projections; isometries (and, in particular, unitaries) are partial isometries. Coisometries are too; in fact, \( x \) is a partial isometry if and only if \( x = xx^*x \) [one direction is obvious; for the other, if \( x^*x \) is a projection and \( y = x - xx^*x \), then \( y^*y = 0 \), so \( y = 0 \)]. Thus if \( x \) is a partial isometry, then so is \( x^* \).

**XV.14.1.7.** If \( x \) is any element, then \( a = (x + x^*)/2 \) and \( b = (x - x^*)/2i \) are self-adjoint, and \( x = a + ib \); thus \( A_{sa} + iA_{sa} = A \). The elements \( a \) and \( b \) are called the **real** and **imaginary** parts of \( x \). It is obvious from their definitions that \( \|a\|, \|b\| \leq \|x\| \).
Norm and Spectrum

XV.14.1.8. It follows from the C*-axiom that every nonzero projection, and hence every nonzero partial isometry (in particular, every unitary), has norm 1. Thus, if \( x \) is unitary, then \( \sigma_A(x) \subseteq \{ \lambda : |\lambda| \leq 1 \} \). Since \( x^{-1} = x^* \) is also unitary and hence \( \sigma_A(x^{-1}) = \{ \lambda^{-1} : \lambda \in \sigma_A(x) \} \) is also contained in the unit disk, \( \sigma_A(x) \) is actually contained in the unit circle.

The next two results give important properties of the spectrum and norm for self-adjoint and, more generally, normal elements of a C*-algebra.

XV.14.1.9. Proposition. If \( x \) is self-adjoint, then \( \sigma_A(x) \subseteq \mathbb{R} \).

Proof: If \( x \) is self-adjoint, then \( e^{ix} \) is unitary, so
\[
\sigma_A(e^{ix}) = \{ e^{i\lambda} : \lambda \in \sigma_A(x) \}
\]
(XV.10.4.3. (i)) is contained in the unit circle.

XV.14.1.10. Proposition. If \( A \) is a C*-algebra and \( x \in A \) is normal (e.g. self-adjoint), then \( r(x) = \|x\| \), i.e. there is a \( \lambda \in \sigma_A(x) \) with \( |\lambda| = \|x\| \).

Proof: If \( x \) is self-adjoint, then from the C*-axiom \( \|x^2\| = \|x\|^2 \), and by iteration \( \|x^{2^n}\| = \|x\|^{2^n} \) for all \( n \). Thus \( r(x) = \lim_{n \to \infty} \|x^{2^n}\|^{2^{-n}} = \|x\| \). More generally, if \( y \) is normal, then
\[
r(y) = \lim_{n \to \infty} \|y^{2^n}\|^{2^{-n}} = \lim_{n \to \infty} \|(y^*)^{2^n}y^{2^n}\|^{2^{-n-1}}
\]
\[
= \lim_{n \to \infty} \|(y^*)^{2^n}y\|^{2^{-n-1}} = [r(y^*y)]^{1/2} = \|y^*y\|^{1/2} = \|y\| \).
\]

As a consequence, *-homomorphisms between C*-algebras are automatically contractive:

XV.14.1.11. Corollary. If \( A \) is a Banach *-algebra, \( B \) a C*-algebra, and \( \phi : A \to B \) a *-homomorphism, then \( \|\phi\| \leq 1 \).

Proof: If \( x \in A \), then \( \sigma_B(\phi(x)) \cup \{0\} \subseteq \sigma_A(x) \cup \{0\} \). Thus
\[
\|\phi(x)\|^2 = \|\phi(x^*x)\| = r(x^*x) \leq r(x^*x) \leq \|x^*x\| \leq \|x\|^2 .
\]

If \( A \) is a unital Banach algebra and \( B \) is a unital Banach subalgebra, and \( x \in B \), then it is not necessarily true that \( \sigma_B(x) = \sigma_A(x) \) (XV.10.3.11.). But if \( A \) is a C*-algebra, the spectra are the same:

1864
**XV.14.1.12.** Corollary. If $B$ is a unital $C^*$-subalgebra of a unital $C^*$-algebra $A$ and $x \in B$, then $\sigma_B(x) = \sigma_A(x)$. If $B$ is a general $C^*$-subalgebra of a general $C^*$-algebra $A$, and $x \in B$, then $\sigma_B(x) \cup \{0\} = \sigma_A(x) \cup \{0\}$.

Proof: This is true if $x = x^*$ by XV.10.3.12. and XV.14.1.9. For general $x$, if $x - \lambda 1$ is invertible in $A$, then so are $(x - \lambda 1)^*(x - \lambda 1)$ and $(x - \lambda 1)(x - \lambda 1)^*$. Thus they are invertible in $B$, so $x - \lambda 1$ is left and right invertible in $B$. \hfill \Diamond

**XV.14.2.** Commutative $C^*$-Algebras and Continuous Functional Calculus

The main result of this section is Gelfand’s Theorem (sometimes called the Gelfand-Naimark Theorem, although this name is more commonly used for a different theorem, cf. XV.14.4.35.):

**XV.14.2.1.** Theorem. (i) Let $A$ be a commutative unital $C^*$-algebra. Then there is a compact Hausdorff space $X$ such that $A$ is isometrically $*$-isomorphic to $C(X)$.

(ii) $X$ can be recovered from $C(X)$ either as $\text{Prim}(C(X)) = \text{Maxspec}(C(X))$ (XI.7.8.16., XV.14.4.39.) with the hull-kernel topology, or as the set $\overline{C(X)}$ of unital $*$-homomorphisms from $C(X)$ to $\mathbb{C}$ with the topology of elementwise convergence (weak-* topology). In particular, if $C(X) \cong C(Y)$, then $X$ is homeomorphic to $Y$.

(iii) If $X$ and $Y$ are compact Hausdorff spaces and $\phi : X \to Y$ is a continuous function, then $\hat{\phi} : C(Y) \to C(X)$ defined by $\hat{\phi}(f) = f \circ \phi$ is a unital $*$-homomorphism, and every unital $*$-homomorphism arises in this manner.

(iv) The correspondences $X \leftrightarrow C(X)$ and $\phi \leftrightarrow \hat{\phi}$ give a contravariant category equivalence between the category of compact Hausdorff spaces and continuous functions and the category of commutative unital $C^*$-algebras and unital $*$-homomorphisms.

**XV.14.2.2.** As a result, all the topology of compact Hausdorff spaces is encoded in the corresponding $C^*$-algebras, and in principle all of topology (of compact Hausdorff spaces) can be done on the $C^*$-algebra level. In practice, this is certainly not the way to do most topology! However, the point of view that a general $C^*$-algebra is a “noncommutative topological space” is very powerful and underlies much of the modern theory and applications of $C^*$-algebras. Interaction with topology has gone both ways: ideas and techniques from topology, particularly $K$-theory, have proved fundamentally useful in operator algebra theory, and on the other hand operator algebra methods have been of significant use in some parts of topology.

**XV.14.2.3.** There is much more fine structure associated with the category equivalence. For example, if $X$ and $Y$ are compact Hausdorff spaces and $\phi : X \to Y$ is continuous, the $*$-homomorphism $\hat{\phi} : C(Y) \to C(X)$ is surjective (i.e. a quotient map, cf. XV.14.3.15.) if and only if $\phi$ is injective, and $\hat{\phi}$ is injective if and only if $\phi$ is surjective (i.e. a quotient map, cf. XI.8.3.13.). The closed ideals of $C(X)$ are in natural one-one correspondence with the closed subsets of $X$: the ideal of $C(X)$ corresponding to a closed subset $Z$ of $X$ is the set $J_Z$ of continuous functions from $X$ to $\mathbb{C}$ vanishing on $Z$. The quotient $C^*$-algebra $C(X)/J_Z$ is naturally isomorphic to $C(Z)$ via restriction of functions (the Tietze Extension Theorem () for compact Hausdorff spaces is included in this fact, since it implies that every element of $C(Z)$ can be extended to an element of $C(X)$, cf. XV.8.3.12.).
The Nonunital Case

XV.14.2.4. There is a nonunital version of XV.14.2.1., but it cannot be stated quite so cleanly. The commutative C*-algebras are easy to describe: they are all of the form \( C_0(X) \), the complex-valued continuous functions vanishing at infinity on a locally compact Hausdorff space \( X \). But the *-homomorphisms from \( C_0(X) \) to \( C_0(Y) \) do not generally correspond to continuous functions from \( Y \) to \( X \). For example, a constant function from \( \mathbb{R} \) to \( \mathbb{R} \) does not give a *-homomorphism from \( C_0(\mathbb{R}) \) to \( C_0(\mathbb{R}) \), and conversely the zero homomorphism from \( C_0(\mathbb{R}) \) to \( C_0(\mathbb{R}) \) does not come from a continuous function from \( \mathbb{R} \) to \( \mathbb{R} \) (there are many less trivial examples too). Instead, the *-homomorphisms from \( C_0(X) \) to \( C_0(Y) \) can be described as corresponding to proper () continuous functions from open subsets of \( Y \) to \( X \).

Alternatively, it is much cleaner to consider pointed compact Hausdorff spaces \((Z, *)\), where \( Z \) is a compact Hausdorff space and \(*\) is a fixed basepoint in \( Z \). There is a natural correspondence with locally compact Hausdorff spaces: if \( X \) is locally compact, associate \( X \) with \((X^\dagger, \infty)\), where \( X^\dagger \) is the one-point compactification of \( X \). Conversely, if \((Z, *)\) is a pointed compact Hausdorff space, associate the locally compact Hausdorff space \( Z \setminus \{ * \} \). The pointed space \((Z, *)\) corresponds to a compact Hausdorff space if and only if \(*\) is an isolated point in \( Z \). Then, if \( X \) is locally compact, we have that \( C_0(X) \) is naturally isomorphic to the ideal of \( C(X^\dagger) \) consisting of functions which are zero at \( \infty \), i.e. if \((Z, *)\) is a pointed compact Hausdorff space, the associated commutative C*-algebra is the algebra of complex-valued continuous functions on \( Z \) vanishing at \(*\). It is then easy to see that the *-homomorphisms from \( C_0(X) \) to \( C_0(Y) \) exactly correspond to continuous functions from \( Y^\dagger \) to \( X^\dagger \) sending \( \infty \) to \( \infty \), i.e. basepoint-preserving continuous maps. (For example, the extreme case of the zero homomorphism corresponds to the constant function from \( Y^\dagger \) to \( X^\dagger \) sending everything to \( \infty \).) Thus, as a slight extension of XV.14.2.1., we obtain:

XV.14.2.5. **Theorem.**

(i) Let \( A \) be a commutative C*-algebra. Then there is a compact Hausdorff space \( Z \) and point \(* \in Z \) such that \( A \) is isometrically *-isomorphic to \( C^*(Z, *) := C_0(X) \), where \( X = Z \setminus \{ * \} \) is locally compact.

(ii) \( X \) can be recovered from \( C_0(X) \) as \( \text{Prim}(C_0(X)) = \text{Maxspec}(C_0(X)) \) with the hull-kernel topology. \( Z \) can be recovered from \( C^*(Z, *) \) as the set \( C^*(Z, *) \) of *-homomorphisms from \( C^*(Z, *) \) to \( \mathbb{C} \) with the topology of elementwise convergence (weak-* topology), with * corresponding to the zero homomorphism. In particular, if \( C_0(X) \cong C_0(Y) \) for locally compact Hausdorff spaces \( X \) and \( Y \), then \( X \) is homeomorphic to \( Y \).

(iii) If \((Z, *_Z)\) and \((W, *_W)\) are pointed compact Hausdorff spaces and \( \phi : Z \to W \) is a pointed continuous function (i.e. \( \phi \) is continuous and \( \phi(*_Z) = *_W \)), then \( \hat{\phi} : C^*(W, *_W) \to C^*(Z, *_Z) \) defined by \( \hat{\phi}(f) = f \circ \phi \) is a *-homomorphism, and every *-homomorphism arises in this manner.

(iv) The correspondences \((Z, *) \leftrightarrow C^*(Z, *)\) and \( \phi \leftrightarrow \hat{\phi} \) give a contravariant category equivalence between the category of pointed compact Hausdorff spaces and pointed continuous functions and the category of commutative C*-algebras and *-homomorphisms.

XV.14.2.6. The fine structure described in XV.14.2.3. persists in this setting, but care must be exercised in phrasing it. Details are left to the interested reader.

**Proof of the Theorem**

We now prove Gelfand’s Theorem. We will only prove the unital version XV.14.2.1.; the proof of the nonunital version XV.14.2.5. is a straightforward variation, but the additional technicalities detract from
an intuitive appreciation of the argument. We first prove (ii) and (iii), which are fairly elementary (given Urysohn’s Lemma), and then return to (i) which requires some nontrivial Banach algebra theory. The proof will actually give some fine structure beyond the statement of the theorem.

We begin with a characterization of the maximal ideals of a C(X).

**XV.14.2.7. Lemma.** Let X be a compact Hausdorff space. For each p ∈ X, the set Mp of all functions in C(X) which vanish at p is a maximal ideal in C(X), and every maximal ideal of C(X) is of this form. If p, q ∈ X, p ≠ q, then Mp ≠ Mq.

**Proof:** Let p ∈ X. It is obvious that C(X)/Mp is isomorphic to C via the correspondence f → f(p). Since the quotient is a field, Mp is a maximal ideal in C(X). Conversely, suppose M is a maximal ideal in C(X), and suppose that there is no point of X for which all functions in M vanish. For each p ∈ X, there is an fp ∈ M with fp(p) ≠ 0. The set Up = {x ∈ X : fp(x) ≠ 0} is an open set in X containing p, and {Up : p ∈ X} is an open cover of X. By compactness, there is a finite subcover {Up1, ..., Upn}. Set

\[ g = f_p1 f_{p1} + \cdots + f_{pn} f_{pn} ∈ M \]

and note that g(x) > 0 for every x ∈ X. Thus g is invertible in C(X), a contradiction since a proper ideal cannot contain an invertible element. Thus there is some p ∈ X at which all functions in M vanish, so M ⊆ Mp, and M = Mp by maximality. Since functions in C(X) separate points of X by Urysohn’s Lemma, and constant functions are in C(X), we have Mp ≠ Mq if p ≠ q.

**XV.14.2.8.** Thus p ↔ Mp is a one-one correspondence between X and Maxspec(C(X)). If φ is a unital *-homomorphism from C(X) to C, then the kernel of φ is a maximal ideal of C(X), hence of the form Mp for some p ∈ X, and φ must just be evaluation at p, i.e. φ(f) = ̂f(p) = f(p). Thus there is also a natural one-one correspondence between X and Maxspec(C(X)), so as sets X, Maxspec(C(X)), and C(X) can be naturally identified.

**XV.14.2.9.** We now show how the topology of X can be recovered as the hull-kernel topology on Maxspec(C(X)). If E is a subset of X ≃ Maxspec(C(X)), recall that the closure E of E in the hull-kernel topology consists of all Mp such that J := ∩q∈E Mq ⊆ Mp. The ideal J clearly consists of all f such that f(q) = 0 for all q ∈ E. If E is the closure in X of E regarded as a subset of X, and p ∈ E, then every f ∈ J vanishes at p by continuity, so Mp ∈ E. But if p ∈ E, by Urysohn’s Lemma there is an f ∈ C(X) such that f = 0 on E and f(p) = 1; this f is in J but not Mp, so Mp /∈ E. Thus E = E and the correspondence p ↔ Mp is a homeomorphism.

**XV.14.2.10.** Now consider the topology of pointwise convergence on C(X): ̂p_i → ̂p if and only if ̂p_i(f) → ̂f(f) for every f ∈ C(X), i.e. f(p_i) → f(p) for all f ∈ C(X). If p_i → p in X, this condition is clearly satisfied. If p_i ∉ p in X, there is an open neighborhood U of p such that p_i /∈ U for a cofinal set of i. By Urysohn’s Lemma there is a function f ∈ C(X) with f(p) = 1 and f = 0 on Uc, and f(p_i) /→ f(p) for this f, i.e. ̂p_i ∉ ̂p. Thus p ↔ ̂p is a homeomorphism.

1867
XV.14.2.11. Finally, we observe that every primitive ideal (XV.14.4.39.) of \( C(X) \) is of the form \( M_p \). By definition, primitive ideals are the kernels of irreducible representations. Every irreducible representation of a commutative C*-algebra is one-dimensional, hence a unital *-homomorphism to \( \mathbb{C} \), hence \( \hat{p} \) for some \( p \in X \), and its kernel is \( M_p \). Alternatively, every primitive ideal is a closed prime ideal (XV.14.4.11.), so it suffices to prove the following fact:

XV.14.2.12. Proposition. Let \( X \) be a compact Hausdorff space, and \( J \) a prime ideal of \( C(X) \). Then there is a unique \( p \in X \) such that \( O_p \subseteq J \subseteq M_p \), where

\[
O_p = \{ f \in C(X) : f = 0 \text{ in a neighborhood of } p \}.
\]

The straightforward proof is left to the reader (cf. [GJ76, 7.15]). Since \( O_p \) is dense in \( M_p \), it follows that every closed prime ideal of \( C(X) \) is maximal.

XV.14.2.13. This completes the proof of (ii). We now turn to (iii). Let \( X \) and \( Y \) be compact Hausdorff spaces. If \( \phi : X \to Y \) is continuous, it is obvious that \( \phi : C(Y) \to C(X) \), defined by \( \phi(f) = f \circ \phi \), is well defined and is a unital *-homomorphism. Conversely, let \( \alpha \) be a unital *-homomorphism from \( C(Y) \) to \( C(X) \). For any \( p \in X \), \( \hat{p} \circ \alpha \) is a unital *-homomorphism from \( C(Y) \) to \( \mathbb{C} \), hence \( \hat{p} \circ \alpha = \hat{q} \) for a unique \( q \in Y \). Set \( \phi(p) = q \). This defines a function \( \phi : X \to Y \), and \( \alpha(f) = f \circ \phi \) for all \( f \in C(X) \), and in particular \( f \circ \phi \in C(X) \) for all \( f \in C(Y) \). It remains only to show that \( \phi \) is continuous. The argument is similar to the one in XV.14.2.10.. If \( \phi \) is discontinuous at \( p \in X \), then there is a net \( (p_i) \) in \( X \) with \( p_i \to p \) in \( X \) but \( \phi(p_i) \not\to \phi(p) \) in \( Y \). There is an open neighborhood \( U \) of \( \phi(p) \) in \( Y \) with \( \phi(p_i) \notin U \) for a cofinal set of \( i \). By Urysohn’s Lemma there is an \( f \in C(Y) \) with \( f(\phi(p)) = 1 \) and \( f = 0 \) on \( U^c \). Then \( f(\phi(p_i)) \not\to f(\phi(p)) \), i.e. \( f \circ \phi \) is not continuous at \( p \), a contradiction. Thus \( \phi \) is continuous.

Now we tackle (i). We will need to bring in some Banach algebra machinery. If \( A \) is a unital commutative Banach algebra, write \( \hat{A} \) for the set of unital homomorphisms from \( A \) to \( \mathbb{C} \). Recall the definitions of spectrum and spectral radius ()

XV.14.2.14. Proposition. Let \( A \) be a unital commutative Banach algebra, and \( \phi \in \hat{A} \). If \( x \in A \), then \( \phi(x) \in \sigma_A(x) \). In particular, \( |\phi(x)| \leq r_\sigma(x) \leq ||x|| \). Thus \( \phi \) is bounded and \( ||\phi|| = 1 \).

Proof: Since \( \phi(x - \phi(x))1 = 0 \), \( x - \phi(x) \) is not invertible in \( A \). The inequality in the second statement is then obvious, so \( ||\phi|| \leq 1 \). But \( \phi(1) = 1 \), so \( ||\phi|| = 1 \).

XV.14.2.15. Corollary. Let \( A \) be a unital commutative C*-algebra, and \( \phi \in \hat{A} \). Then \( \phi \) is a *-homomorphism.

Proof: It suffices to show that if \( x = x^* \in A \), then \( \phi(x) \in \mathbb{R} \). But \( \sigma_A(x) \subseteq \mathbb{R} \) by XV.14.1.9..
**Proposition.** Let $A$ be a unital commutative Banach algebra and $x \in A$. If $\lambda \in \sigma_A(x)$, then there is a $\phi \in \hat{A}$ with $\phi(x) = \lambda$.

**Proof:** Since $x - \lambda 1$ is not invertible in $A$, it generates a proper ideal of $A$ which is contained in a maximal ideal $M$ of $A$. Then $M$ is closed (XV.10.2.17.), so $A/M$ is a Banach algebra which is a field. Thus $A/M \cong \mathbb{C}$ (XV.10.3.26.), and the quotient map $\phi : A \to A/M$ can be regarded as an element of $\hat{A}$ with $\phi(x - \lambda 1) = 0$. 

**Proposition.** Let $A$ be a unital commutative Banach algebra. By XV.14.2.14., $\hat{A}$ can be regarded as a subset of the closed unit ball $B$ of $A^*$. It is easily checked that $\hat{A}$ is closed in $B$ in the weak-* topology (topology of pointwise convergence on $A$). Since $B$ is a compact Hausdorff space in the weak-* topology (XV.8.2.3.), $\hat{A}$ is a compact Hausdorff space in the topology of pointwise convergence on $A$. If $x \in A$, define $\hat{x} : \hat{A} \to \mathbb{C}$ by $\hat{x}(\phi) = \phi(x)$ for $\phi \in \hat{A}$. Then $\hat{x} \in C(\hat{A})$.

**Definition.** The map $\gamma : A \to C(\hat{A})$ defined by $\gamma(x) = \hat{x}$ is a unital homomorphism, called the Gelfand transform of $A$.

We have that $\gamma$ is bounded and $\|\gamma\| = 1$ by XV.14.2.14.. The Gelfand transform is not injective or surjective for general unital commutative Banach algebras. However:

**Lemma.** Let $A$ be a unital commutative C*-algebra. Then the Gelfand transform $\gamma : A \to C(\hat{A})$ is an isometric *-isomorphism.

**Proof:** It follows from XV.14.2.15. that $\gamma$ is a *-homomorphism. Let $x \in A$. Then by (XV.14.2.15.) there is a $\lambda \in \sigma_A(x^*x)$ with $|\lambda| = \|x^*x\| = \|x\|^2$, and hence by XV.14.2.16. there is a $\phi \in \hat{A}$ with $|\phi(x)|^2 = |\phi(x^*x)| = \|x^*x\| = \|x\|^2$. Since $\|\gamma\| = 1$, $\gamma$ is isometric, and hence $A$ can be regarded as the *-subalgebra $\gamma(A)$ of $C(\hat{A})$, which is complete and thus closed. The subalgebra $\gamma(A)$ clearly separates points of $A$ and contains the constant functions, so $\gamma(A) = C(\hat{A})$ by the Stone-Weierstrass Theorem (XV.8.2.3.).

**Applications**

Probably the most important application of Gelfand’s Theorem is continuous functional calculus, discussed in XV.14.2.25.. But here are a couple of other applications of some interest.
XV.14.2.21. Let $X$ be a topological space. Let $BC(X)$ be the set of bounded continuous complex-valued functions on $X$. With pointwise addition and multiplication, pointwise complex conjugation as adjoint, and supremum norm, $BC(X)$ becomes a unital commutative $C^*$-algebra. Thus $BC(X) \cong C(Y)$ for a compact Hausdorff space $Y$. Each point of $X$ gives, by point evaluation, an element of $BC(X)$ and hence a point of $Y$, and it is easy to check that the induced map $\phi$ from $X$ to $Y$ is continuous. If $X$ is completely regular, a simple argument yields that $\phi$ is a homeomorphism onto its image, so $X$ can be identified with a subspace of $Y$. In this case, it is straightforward to identify $\beta X$ as $BC(X)$ or $\text{Prim}(BC(X))$ is perhaps the most elegant and efficient construction of the Stone-Čech compactification.

XV.14.2.22. Here is another interesting and modestly useful application. Give $A = L^\infty(\mathbb{R})$ pointwise addition, multiplication, and complex conjugation, and the usual essential supremum norm. Then $A$ becomes a unital commutative $C^*$-algebra, so $A \cong C(Y)$ for some compact Hausdorff space $Y$. The space $Y$ is rather horrendous as a topological space: it is extremally disconnected and not first countable. But it is occasionally useful to realize $A$ as an algebra of continuous functions on a bad space instead of as measurable functions on a nicer space. The same construction can be done for $L^\infty(X, A, \mu)$ for any measure space $(X, A, \mu)$. If done for $\mathbb{N}$ with counting measure one obtains $Y = \beta \mathbb{N}$ as in XV.14.2.21. These $L^\infty(X, A, \mu)$ are commutative von Neumann algebras (XV.3.5.1.) when realized as algebras of multiplication operators on $L^2(X, A, \mu)$.

Continuous Functional Calculus

The classification of commutative $C^*$-algebras leads to a far-reaching and powerful extension of holomorphic functional calculus (XV.10.4.).

XV.14.2.23. Let $A$ be a unital $C^*$-algebra, and $x$ a normal (e.g. self-adjoint or unitary) element of $A$, i.e. $x^*x = xx^*$. Let $B$ be the $C^*$-subalgebra of $A$ generated by $x$ and $1$: $B$ is the closure of the set of polynomials in $x$ and $x^*$. Then $B$ is a unital commutative $C^*$-algebra, and thus $B \cong C(X)$ for a compact Hausdorff space $X = \hat{B}$.

XV.14.2.24. The space $\hat{B}$ can be easily described. If $\phi \in \hat{B}$, then $\phi(x) \in \sigma_B(x) = \sigma_A(x)$ (XV.14.2.14., XV.14.1.12.). Conversely, for each $\lambda \in \sigma_A(x)$ there is a unique $\phi_\lambda \in \hat{B}$ with $\phi_\lambda(x) = \lambda$ by XV.14.2.16. [for uniqueness, if $\phi, \psi \in \hat{B}$ with $\phi(x) = \psi(x) = \lambda$, then $\phi(x^*) = \psi(x^*) = \bar{\lambda}$ by XV.14.2.15., so $\phi(p(x, x^*)) = \psi(p(x, x^*)) = p(\lambda, \bar{\lambda})$ for any polynomial $p$ of two variables with complex coefficients; such elements are dense in $B$, so $\phi = \psi$.] Thus

$$\hat{B} = \{\phi_\lambda : \lambda \in \sigma_A(x)\}. $$

More precisely, the function $\hat{x} : \hat{B} \to \mathbb{C}$ defined by $\hat{x}(\phi_\lambda) = \lambda$ is a bijection from $\hat{B}$ to $\sigma_A(x)$. Since $\hat{x}$ is continuous and $\hat{B}$ and $\sigma_A(x)$ are compact Hausdorff spaces, it is a homeomorphism. We thus have:

XV.14.2.25. Theorem. [Continuous Functional Calculus, Unital Version] Let $A$ be a unital $C^*$-algebra, $x$ a normal element of $A$, and $B$ the $C^*$-subalgebra of $A$ generated by $x$ and $1$. Then there is an isometric *-isomorphism $\theta : C(\sigma_A(x)) \to B$ with $\theta(1) = x$, where $\theta(\lambda) = \lambda$ for $\lambda \in \sigma_A(x) \subseteq \mathbb{C}$.
 XV.14.2.26. We have that \( \theta \) is just \((x)^{-}\). If \( f \in C(\sigma_A(x)) \), we normally write \( f(x) \) instead of \( \theta(f) \); thus \( \iota(x) = x \). This notation is consistent with previous notation: if \( p \) is a polynomial with complex coefficients, then \( p(x) \) is the element of \( B \) defined in XV.10.4.1. More generally, if \( f \) is holomorphic on an open disk containing \( \sigma_A(x) \), then \( f(x) \) is the element defined by a power series as in XV.10.4.3. Thus “functional calculus” can be thought of as a way to apply suitable functions to elements of a C*-algebra. Note that holomorphic functional calculus is defined for arbitrary elements of a C*-algebra (or even a general Banach algebra), but continuous functional calculus only works for normal elements of a C*-algebra.

There is a nonunital version of continuous functional calculus, which can be easily proved from the unital version by simply adding a unit (XV.14.1.2.). If \( X \) is a compact subset of \( \mathbb{C} \), write \( C_0(X) \) for the set of continuous functions \( f : X \cup \{0\} \to \mathbb{C} \) with \( f(0) = 0 \).

 XV.14.2.27. Theorem. [Continuous Functional Calculus, General Version] Let \( A \) be a C*-algebra, \( x \) a normal element of \( A \), and \( B \) the C*-subalgebra of \( A \) generated by \( x \). Then there is an isometric *-isomorphism \( \theta : C_0(\sigma_A(x)) \to B \) with \( \theta(\iota(x)) = x \), where \( \iota(\lambda) = \lambda \) for \( \lambda \in \sigma_A(x) \cup \{0\} \subseteq \mathbb{C} \).

Note that if \( 0 \notin \sigma_A(x) \), then \( A \) is automatically unital and \( 1 \) is in the C*-subalgebra of \( A \) generated by \( x \).

The following properties of functional calculus are easy consequences:

 XV.14.2.28. Proposition. Let \( A \) be a C*-algebra and \( x \in A \) a normal element. Then

(i) For any \( f \in C_0(\sigma_A(x)) \), \( \sigma_A(f(x)) = \{f(\lambda) : \lambda \in \sigma_A(x)\} \).

(ii) If \( f \in C_0(\sigma_A(x)) \) and \( g \in C_0(f(\sigma_A(x))) = C_0(\sigma_A(f(x))) \), so \( g \circ f \in C_0(\sigma_A(x)) \), then \( (g \circ f)(x) = g(f(x)) \).

(iii) If \( f_n, f \in C_0(\sigma_A(x)) \) and \( f_n \to f \) uniformly on \( \sigma_A(x) \), then \( f_n(x) \to f(x) \).

(iv) If \( B \) is a C*-algebra and \( \phi : A \to B \) a *-homomorphism, then \( \phi(f(x)) = f(\phi(x)) \) for any \( f \in C_0(\sigma_A(x)) \).

There is a useful joint continuity generalization of (iii):

 XV.14.2.29. Proposition. Let \( Y \) be a compact subset of \( \mathbb{C} \), and \( (f_n) \) a sequence of elements of \( C_0(Y) \) converging uniformly on \( Y \) to \( f \). Let \( A \) be a C*-algebra, \( (x_n) \) a sequence of normal elements of \( A \) with \( x_n \to x \in A \) and \( \sigma_A(x_n) \subseteq Y \) (so \( \sigma_A(x) \subseteq Y \) ). Then \( f_n(x_n) \to f(x) \).

Proof: Let \( \epsilon > 0 \), and approximate \( f \) uniformly on \( Y \) within \( \epsilon/4 \) by a function of the form \( g(\lambda) = p(\lambda, \bar{\lambda}) \), where \( p \) is a polynomial of two variables (XV.8.3.4.); then \( g(x) = p(x, x^*) \), so

\[
\|f_n(x_n) - f(x)\| \leq \|f_n(x_n) - f(x_n)\| + \|f(x_n) - g(x_n)\| + \|p(x_n, x_n^*) - p(x, x^*)\| + \|g(x) - f(x)\|.
\]

If \( n \) is large enough that \( |f_n - f| \) is uniformly less than \( \epsilon/4 \) on \( Y \), the first term is less than \( \epsilon/4 \); the second and fourth terms are \( < \epsilon/4 \) by choice of \( g \), and the third term goes to 0 as \( n \to \infty \) by continuity of addition, multiplication, and involution. Thus \( \|f_n(x_n) - f(x)\| < \epsilon \) for all sufficiently large \( n \).

This result is often used when \( (f_n) \) is a constant sequence.

Another simple consequence of functional calculus is:
**XV.14.2.30. Corollary.** Let $A$ be a C*-algebra, and $x$ a normal element of $A$. Then

- $x$ is self-adjoint if and only if $\sigma_A(x) \subseteq \mathbb{R}$.
- $x$ is unitary if and only if $\sigma_A(x) \subseteq \{\lambda : |\lambda| = 1\}$.
- $x$ is a projection if and only if $\sigma_A(x) \subseteq \{0, 1\}$.

**Proof:** (i): Let $f(\lambda) = \text{Re}(\lambda) = \frac{1}{2}(\lambda + \bar{\lambda})$. Then $f(x) = \frac{1}{2}(x + x^*)$ is the real part of $x$. We have $f(x) = x$ if and only if $f = \iota$ on $\sigma_A(x)$, i.e. if and only if $\sigma_A(x) \subseteq \mathbb{R}$. The other parts are similar.

**Uniqueness of Norm on a C*-Algebra**

Another important consequence of Gelfand’s Theorem is that the norm on a C*-algebra is unique in a strong sense. Thus C*-algebras are quite rigid.

We first prove one of the fine structure properties of commutative C*-algebras (XV.14.2.3.).

**XV.14.2.31. Lemma.** Let $A$ and $B$ be commutative C*-algebras, and let $\alpha : A \rightarrow B$ be a *-homomorphism. If $\alpha$ is injective, it is isometric.

**Proof:** Write $A = C^*(Z, \ast)$ and $B = C^*(W, \ast)$. We have $\alpha = \hat{\phi}$ for a pointed continuous function $\phi : (W, \ast) \rightarrow (Z, \ast)$. If $\alpha$ is injective, then $\phi$ is surjective: set $Y = \phi(W)$ and suppose there is a $p \in Z \setminus Y$. By Urysohn’s Lemma there is an $f \in C(Z)$ with $f = 0$ on $Y$ and $f(p) = 1$. Then $f \in C^*(Z, \ast)$ since $\ast \in Y$, and $\alpha(f) = 0$, contradicting that $\alpha$ is injective.

Thus, if $f \in C^*(Z, \ast)$, we have

$$\|f\| = \sup_{p \in Z} |f(p)| = \sup_{q \in W} |f(\phi(q))| = \|\alpha(f)\|.$$  

**XV.14.2.32. Corollary.** Let $A$ and $B$ be C*-algebras, $\alpha : A \rightarrow B$ an injective *-homomorphism. Then $\alpha$ is isometric.

**Proof:** If $x \in A$, then $\|x\|^2 = \|x^*x\|$ and $\|\alpha(x)\|^2 = \|\alpha(x^*x)\|$, so replacing $A$ and $B$ by $C^*(x^*x)$ and $C^*(\alpha(x^*x))$ respectively, it suffices to assume $A$ and $B$ are commutative, where the result follows from the lemma.

**XV.14.2.33. Corollary.** If $A$ is a C*-algebra with respect to a norm $\| \cdot \|$, then there is no other C*-norm $\| \cdot \|'$ on $A$ (with the same algebraic structure and involution), even incomplete.

**Proof:** Let $B$ be the completion of $A$ with respect to $\| \cdot \|'$. Then $B$ is a C*-algebra, and the natural injective *-homomorphism from $(A, \| \cdot \|)$ to $B$ is isometric.
XV.14.2.34. A \(\ast\)-algebra thus has at most one norm making it a (complete) \(C^*\)-algebra; if it has one, it has no other (even incomplete) norm satisfying the \(C^*\)-axiom (XV.14.2.33). [A \(C^*\)-algebra can have other \(C^*\)-seminorms; and a \(\ast\)-algebra (e.g. a polynomial ring) can have many different (incomplete) norms satisfying the \(C^*\)-axiom.] Note that by XV.14.1.10, the norm in a \(C^*\)-algebra is completely determined by the algebraic structure: if \(x \in A\), then
\[
\|x\| = \|x^*x\|^{1/2} = [r_\sigma(x^*x)]^{1/2}
\]
and \(r_\sigma(x^*x)\) is a purely algebraic quantity.

XV.14.3. Algebraic and Order Theory of \(C^*\)-Algebras

Positive Elements in a \(C^*\)-Algebra

XV.14.3.1. Definition. Let \(A\) be a \(C^*\)-algebra. An element \(x \in A\) is positive if \(x = x^*\) and \(\sigma_A(x) \subseteq [0, \infty)\). The set of positive elements in \(A\) is denoted \(A_+\). If \(x \in A_+\), we write \(x \geq 0\).

Note that by XV.14.1.12, the property of being positive is independent of the containing \(C^*\)-algebra, i.e. if \(B\) is a \(C^*\)-subalgebra of \(A\), then \(B_+ = B \cap A_+\). A positive element of \(C_0(X)\) is just a function taking only nonnegative real values.

The following facts are obvious from functional calculus:

XV.14.3.2. Proposition. Let \(A\) be a \(C^*\)-algebra and \(x, y \in A\). Then

(i) If \(x \geq 0\) and \(-x \geq 0\), then \(x = 0\).

(ii) If \(x\) is normal, then \(x^*x \geq 0\). In particular, if \(x = x^*\), then \(x^2 \geq 0\).

(iii) If \(x \geq 0\), then \(\|x\| = \max\{\lambda : \lambda \in \sigma(x)\}\).

(iv) If \(x = x^*\) and \(\|x\| \leq 2\), then \(x \geq 0\) if and only if \(\|1 - x\| \leq 1\) (in \(A\)).

(v) If \(x, y \geq 0\) and \(xy = yx\), then \(x + y \) and \(xy\) are positive.

(vi) If \(x = x^*\), then there is a unique decomposition \(x = x_+ - x_-\), where \(x_+, x_- \geq 0\), and \(x_+x_- = 0\). We have \(x_+, x_- \in C^*(x)\). \([x_+ = f(x)\) and \(x_- = g(x)\), where \(f(t) = \max(t, 0)\) and \(g(t) = -\min(t, 0)\).] Thus every element of \(A\) is a linear combination of four positive elements.

(vii) Every positive element of a \(C^*\)-algebra has a unique positive square root. More generally, if \(x \geq 0\) and \(\alpha\) is a positive real number, there is a positive element \(x^\alpha \in C^*(x)_+\); these elements satisfy \(x^\alpha x^\beta = x^{\alpha+\beta}\), \(x^1 = x\), and \(\alpha \mapsto x^\alpha\) is continuous. If \(x\) is invertible \(x^\alpha\) is also defined for \(\alpha \leq 0\).

(viii) \((x, \lambda) \geq 0\) in \(A^1\) if and only if \(x = x^*\) and \(\lambda \geq \|x_\|\).

For (vii), set \(x^\alpha = g_\alpha(t)\), where \(g_\alpha(t) = t^\alpha\). Then \(g_{\alpha-1}(x^\alpha) = x\). If \(b \in A_+\) with \(g_{\alpha-1}(b) = x\), then \(x\) commutes with \(b\), hence \(x^\alpha\) commutes with \(b\) since it is a limit of polynomials in \(x\); thus \(b = x^\alpha\) in \(C^*(x^\alpha, b) \subseteq A\) (we clearly have uniqueness in a commutative \(C^*\)-algebra).

Two crucial facts about positive elements are significant generalizations of (ii) and (v):
**Proposition.** Let $A$ be a C*-algebra. Then

(i) $A_+$ is a closed cone (.) in $A$; in particular, if $x, y \geq 0$ then $x + y \geq 0$.

(ii) If $x \in A$, then $x^*x \geq 0$.

**Proof:** To prove (i), since $\mathbb{R}_+A_+ \subseteq A_+$ it suffices to show that $A_+ \cap B$ is a closed convex set, where $B = B_1(A)$ is the closed unit ball in $A$. But $A_+ \cap B$ is the intersection of the closed convex sets $A_{sa}, B$, and \( \{ x : \|1 - x\| \leq 1 \} \) (XV.14.3.2 (iv)).

The proof of property (ii) uses the fact that if $x = a + ib \in A$ with $a, b \in A_{sa}$, then $x^*x \geq 0$ if and only if $xx^* \geq 0$ by XV.10.3.18., and

\[ x^*x + xx^* = 2a^2 + 2b^2 \geq 0 \]

by (i) and XV.14.3.2.(ii). If $x^*x = c = c_+ - c_-$ as in XV.14.3.2.(vi) and $y = xc_-$, then $-y^*y = c_-^2 \geq 0$, so

\[ yy^* = (y^*y + yy^*) + (-y^*y) \geq 0 \]

and thus $y^*y \geq 0$. So $y^*y = 0$ by XV.14.3.2.(i), $c_- = 0$, $x^*x \geq 0$. \( \square \)

**Corollary.** If $A$ is a C*-algebra and $a \in A_+$, then $x^*ax = (a^{1/2}x)^*(a^{1/2}x) \geq 0$ for any $x \in A$.

By XV.14.3.2.(vi), there are “many” positive elements of a C*-algebra. Unital C*-algebras also have “many” unitaries:

**Proposition.** Every element of a unital C*-algebra $A$ is a linear combination of four unitaries. In fact, if $x = x^* \in A$ and $\|x\| \leq 2$, then $x$ is a sum of two unitaries in $U(A)$ (where $U(A)$ is the connected component of 1 in $U(A)$).

**Proof:** Set $a = x/2$. Then $1 - a^2 \geq 0$ and $a \pm i(1 - a^2)^{1/2}$ are unitaries. If $0 \leq t \leq 1$, then $(ta \pm i(1 - t^2a^2)^{1/2})$ gives a path of unitaries from $\pm i$ to $a \pm i(1 - a^2)^{1/2}$, so $a \pm i(1 - a^2)^{1/2} \in U(A)$.

\( \square \)

Invertible elements have a polar decomposition analogous to ():
\textbf{XV.14.3.7. Proposition.} Let \( A \) be a unital C*-algebra, and \( x \in A \) an invertible element. Then there are a unique unitary \( u \in A \) and \( a \in A_+ \) with \( x = ua \). In fact, \( a = (x^*x)^{1/2} \) and \( u = x(x^*x)^{-1/2} \).

\textbf{Proof:} If \( u = x(x^*x)^{-1/2} \) (note that \( x^*x \) is invertible), then \( u^*u = 1 \), and in particular \( u \) is left invertible. We have \( uu^* = x(x^*x)^{-1}x^* \) is invertible, hence \( u \) is also right invertible, i.e. \( u \) is invertible and \( u^{-1} = u^* \), so \( u \) is unitary. Obviously \( u \) and \( a = (x^*x)^{1/2} \geq 0 \) give such a decomposition. For uniqueness, if \( x = ua = vb \), then \( x^*x = a^2 = b^2 \), so \( a = b \) (XV.14.3.9), and then \( u = v = xa^{-1} \).

Noninvertible elements of a C*-algebra do not have an analogous polar decomposition in general; but if \( x \) is any element of a C*-algebra \( A \) and \( 0 < \alpha < 1/2 \), then there is a \( u \in A \) (not unique in general) such that \( x = u(x^*x)\alpha \), so \( x \) has an approximate polar decomposition.

\textbf{XV.14.3.8.} Because of XV.14.3.3(i), it makes sense in a C*-algebra \( A \) to write \( x \leq y \) if \( y - x \geq 0 \). This defines a translation-invariant partial order on \( A \) (it is usually only used on \( A_{sa} \)). Note that \( x \leq y \) is well defined independent of the containing C*-algebra. If \( x = x^* \) and \( \sigma_A(x) \subseteq [\alpha, \beta] \), then \( \alpha 1 \leq x \leq \beta 1 \) (in \( A^1 \)). If \( a \leq b \), then \( x^*ax \leq x^*bx \) for any \( x \). If \( x \in A \), \( a \in A_+ \), then \( x^*ax \leq x^*(\|a\|1)x = \|a\|x^*x \). In \( C_0(X) \), if \( f \) and \( g \) are self-adjoint (i.e. real-valued), then \( f \leq g \) in \( C_0(X) \) if and only if \( f(x) \leq g(x) \) for all \( x \in X \).

\textbf{XV.14.3.9. Proposition.} Let \( A \) be a unital C*-algebra, \( x, y \in A \). If \( 0 \leq x \leq y \) and \( x \) is invertible, then \( y \) is invertible and \( 0 \leq y^{-1} \leq x^{-1} \).

\textbf{Proof:} If \( x \) is invertible, then \( \epsilon 1 \leq x \) for some \( \epsilon > 0 \), so \( \epsilon 1 \leq y \) and \( y \) is invertible by XV.14.2.1., and \( x^{-1}, y^{-1} \geq 0 \). The inequality \( y^{-1} \leq x^{-1} \) is obvious from XV.14.2.1. if \( x \) and \( y \) commute, and in particular if \( y = 1 \). For the general case, if \( x \leq y \), then
\[
y^{-1/2}xy^{-1/2} \leq y^{-1/2}yy^{-1/2} = 1 \]
\[
1 \leq (y^{-1/2}xy^{-1/2})^{-1} = y^{1/2}x^{-1}y^{1/2} \]
\[
y^{-1} = y^{-1/2}1y^{-1/2} \leq y^{-1/2}(y^{1/2}x^{-1}y^{1/2})y^{-1/2} = x^{-1}.
\]

\textbf{Approximate Units}

While a C*-algebra need not be unital, it always contains an approximate unit (sometimes called an approximate identity) which can often be used as a substitute. Some, but not all, other Banach algebras have approximate units in an analogous sense.

\textbf{XV.14.3.10. Definition.} Let \( A \) be a C*-algebra. An \textit{approximate unit} for \( A \) is a net \((h_\lambda)\) of positive elements of \( A \) of norm \( \leq 1 \), indexed by a directed set \( \Lambda \), such that \( h_\lambda x \to x \) for all \( x \in A \). If \( h_\lambda \leq h_\mu \) for \( \lambda \leq \mu \), the approximate unit \((h_\lambda)\) is \textit{increasing}.

An approximate unit \((h_\lambda)\) is \textit{idempotent} if each \( h_\lambda \) is a projection; it is \textit{almost idempotent} if \( h_\lambda \ll h_\mu \) for \( \lambda < \mu \).

An approximate unit \((h_\lambda)\) is \textit{sequential} if \( \Lambda = \mathbb{N} \); it is \textit{continuous} if \( \Lambda = (0, \infty) \) (or a cofinal subinterval) and \( \lambda \mapsto h_\lambda \) is continuous.
In many references, approximate units are assumed to be increasing, but we will not do so since there are situations where this assumption is not natural. At the other extreme, the assumption that \( \|h\| \leq 1 \) for all \( \lambda \), or even that \( \|h\| \) is bounded, is not universal.

An approximate unit in a unital C*-algebra is just a net of (eventually) invertible positive elements in the unit ball converging to 1.

If \( A \) is a C*-algebra and \( I \) is a dense (two-sided) ideal in \( A \) (the case \( I = A \) is the most important one!), let \( A_I \) be the set of all positive elements of \( I \) of norm strictly less than 1. Give \( A_I \) its ordering as a subset of \( A^+ \).

XV.14.3.11. **Proposition.**

(i) \( A_I \) is a directed set.

(ii) \( A_I \) is an increasing approximate unit for \( A \).

**Proof:** (i): By XV.14.3.9,(iii), \( h \mapsto (1 - h)^{-1} - 1 \) is an order-isomorphism of \( A_I \) onto \( I_+ \), which is a directed set. (The computation is done in \( A \), but it is easy to check that the map and its inverse \( h \mapsto 1 - (1 + h)^{-1} \) map \( I \) into \( I \) by considering the quotient map \( A \rightarrow A/I \).)

(ii): It suffices to show that for any \( x \in A \), the decreasing net

\[
\{x^*(1 - h)x : h \in A_I \}
\]

converges to 0, for then

\[
\|(1 - h)x\|^2 = \|x^*(1 - h)^2x\| \leq \|x^*(1 - h)x\| \rightarrow 0.
\]

Since \( A_I \) is dense in \( A \) [if \( x \in A_+ \), choose \( y \in I \) close to \( x^{1/2} \); then \( y^*y \in I_+ \) is close to \( x \)], we need only find for each \( x \) and \( \epsilon \) an \( h \in A \) with \( \|x^*(1 - h)x\| \leq \epsilon \). By XV.14.3.2,(vi), we may assume \( x \geq 0 \) and \( \|x\| < 1 \). But then \( \|x(1 - x^{1/n})x\| < \epsilon \) for sufficiently large \( n \).

XV.14.3.12. **Corollary.** If \( A \) is a C*-algebra and \( I \) is a dense (two-sided) ideal in \( A \), then there is an increasing approximate unit for \( A \) contained in \( I \). If \( A \) is separable, then the increasing approximate unit may be chosen to be sequential or continuous.

To construct an increasing sequential approximate unit for a separable \( A \), let \( \{x_n\} \) be a dense set in \( A \), and inductively find \( h_n \) in \( A_I \) with \( h_n \geq h_{n-1} \) and \( \|h_n x_k - x_k\| < 1/n \) for \( 1 \leq k \leq n \). For a continuous approximate unit, set \( h_t = (n + 1 - t)h_n + (t - n)h_{n+1} \) for \( n \leq t \leq n + 1 \).

**Closed Ideals and Quotients**

In this section, “ideal” means “two-sided ideal” unless otherwise specified.

XV.14.3.13. **Proposition.** Let \( A \) be a C*-algebra, and \( J \) a closed ring-theoretic ideal in \( A \). Then \( J \) is closed under scalar multiplication.

**Proof:** This is obvious if \( A \) is unital. For general \( A \), let \( \{h_\lambda\} \) be an approximate unit for \( A \). If \( x \in J \) and \( \alpha \in \mathbb{C} \), then \( (\alpha h_\lambda)x \in J \) for all \( \lambda \) and \( (\alpha h_\lambda)x = \alpha(h_\lambda x) \rightarrow \alpha x \). Since \( J \) is closed, \( \alpha x \in J \).
XV.14.3.14. **Proposition.** Let $J$ be a closed ideal in a C*-algebra $A$, and $\pi$ the quotient map from $A$ to the Banach algebra $A/J$. Then

(i) $J$ is self-adjoint (so $J$ is a C*-algebra and there is an induced involution on $A/J$).

(ii) If $(h_\lambda)$ is an approximate unit for $J$, then for all $x \in A$,

$$\|\pi(x)\| = \lim_\lambda \|x(1 - h_\lambda)\| = \inf \|x(1 - h_\lambda)\|.$$

(iii) $A/J$ is a C*-algebra in the quotient norm.

**Proof:** (i): If $x \in J$, then $(x^* x)^{1/n} \in J$ for all $n$.

$$\|x^* - (x^* x)^{1/n} x^*\|^2 = \|x - x^* x\|^2$$

$$= \|(1 - (x^* x)^{1/n}) x^* x (1 - (x^* x)^{1/n})\| \to 0.$$  

(ii): $\|\pi(x)\| = \inf \{\|x + y\| : y \in I\} \leq \inf \|x - x h_\lambda\|$. But if $y \in J$, then

$$\|x - x h_\lambda\| \leq \|(x + y)(1 - h_\lambda)\| + \|y - y h_\lambda\| \leq \|x + y\| + \|y - y h_\lambda\|,$$

so $\limsup \|x - x h_\lambda\| \leq \|\pi(x)\|$.

(iii): For any $x \in A$,

$$\|\pi(x)\|^2 = \inf \|x(1 - h_\lambda)\|^2 = \inf \|(1 - h_\lambda)x^* x (1 - h_\lambda)\|$$

$$\leq \inf \|x^* x (1 - h_\lambda)\| = \|\pi(x^* x)\| = \|\pi(x)\|^2.$$

XV.14.3.15. **Corollary.** Let $A$ and $B$ be C*-algebras, $\phi : A \to B$ a *-homomorphism. Then $\phi(A)$ is closed in $B$, and therefore a C*-subalgebra which is isometrically isomorphic to $A/J$, where $J = \text{Ker}(\phi)$.

**Proof:** $J$ is closed since $\phi$ is continuous (XV.14.1.11.), and $\phi$ induces an injective *-homomorphism from the C*-algebra $A/J$ to $B$, which is an isometry by XV.14.2.32.

XV.14.3.16. **Proposition.** Let $A$ be a C*-algebra.

(i) If $I$ and $J$ are closed ideals in $A$, then $I \cap J = IJ$, where $IJ$ is the set of finite sums of elements of the form $xy$ with $x \in I$, $y \in J$.

(ii) If $I$ is a closed ideal in $A$ and $J$ is a closed ideal of $I$, then $J$ is an ideal of $A$.

(iii) If $I$, $J$, $K$ are closed ideals of $A$, then $(I + K) \cap (J + K) = (I \cap J) + K$. 

1877
Proof: (i) Clearly $IJ \subseteq I \cap J$, and any product of two elements of $I \cap J$ is in $IJ$. But it is an easy consequence of functional calculus that any self-adjoint element of a C*-algebra is a product of two elements (in fact, any element of a C*-algebra is the product of two elements, so it is even unnecessary to allow finite sums in the definition of $IJ$).

(ii): $I$ is itself a C*-algebra, hence has an approximate unit $(h_\lambda)$. If $x \in A$ and $y \in J$, then $y \in I$, so $h_\lambda y \to y$, and thus $x h_\lambda y \to xy$. We have $x h_\lambda \in I$ and thus $(x h_\lambda) y \in J$ for all $\lambda$ since $J$ is an ideal of $I$, and so $xy \in J$ since $J$ is closed. A similar argument shows that $yx \in J$.

(iii) follows immediately from (i) and the fact that $(I + K)(J + K) \subseteq IJ + K \subseteq (I \cap J) + K \subseteq (I + K) \cap (J + K)$ (true in any ring).

 XV.14.3.17. A C*-algebra can have many nonclosed ideals, and their structure can be enormously complicated. (See, for example, [GJ76] for a description of the ideal structure of $C(X)$.) Several of the properties of closed ideals can fail for nonclosed ideals: they need not be self-adjoint, a self-adjoint ideal need not be hereditary or even positively generated, and an ideal of an ideal of $A$ need not be an ideal of $A$. See [Bla06] for examples.

 XV.14.4. Representations of Banach *-Algebras and C*-Algebras

Before about 1980, representation theory was the core of the theory of C*-algebras. It has since become less central, but it is still an extremely important part of the theory. Many applications of the theory involve representations. And there are even basic structural facts about C*-algebras which can only be reasonably obtained via representation theory.

 XV.14.4.1. Definition. A representation of a Banach *-algebra $A$ is a *-homomorphism from $A$ to $B(H)$ for some Hilbert space $H$. (Technically this should be called a *-representation; we will not consider representations which are not *-representations.) We will mostly only consider representations of C*-algebras.

Two representations $\pi$ and $\rho$ of $A$ on $\mathcal{X}$ and $\mathcal{Y}$ respectively are (unitarily) equivalent if there is a unitary operator $U \in B(\mathcal{X}, \mathcal{Y})$ with $U \pi(x) U^* = \rho(x)$ for all $x \in A$.

A subrepresentation of a representation $\pi$ on $\mathcal{H}$ is the restriction of $\pi$ to a closed invariant subspace of $\mathcal{H}$ (a subspace $\mathcal{Y}$ of $\mathcal{H}$ is invariant if $\pi(x) \xi \in \mathcal{Y}$ for all $x \in A$, $\xi \in \mathcal{Y}$).

A representation is irreducible if it has no nontrivial closed invariant subspaces.

If $\pi_i$ ($i \in \Lambda$) is a representation of $A$ on $\mathcal{H}_i$, then the sum $\oplus_i \pi_i$ of the $\pi_i$ is the diagonal sum acting on $\oplus_i \mathcal{H}_i$.

If each $\pi_i$ is equivalent to a fixed representation $\rho$, then $\oplus_i \pi_i$ is a multiple or amplification of $\rho$ by $\text{card}(\Lambda)$.

 XV.14.4.2. A representation is always norm-decreasing (XV.14.1.11.) and hence continuous. Thus the kernel of a representation is a closed ideal. A representation with kernel 0 is called faithful. By XV.14.2.32., a faithful representation of a C*-algebra is isometric.

 XV.14.4.3. If $J$ is a closed ideal of $A$, then any representation of $A/J$ gives a representation of $A$ by composition with the quotient map, whose kernel contains $J$. Conversely, if $\pi$ is a representation of $A$ whose kernel contains $J$, then $\pi$ drops to a representation of $A/J$.

1878
**XV.14.4.4.** PROPOSITION. If $\pi$ is a representation of $A$ on $\mathcal{H}$ and $\mathcal{X}$ is a closed subspace of $\mathcal{H}$, then the following are equivalent:

(i) $\mathcal{X}$ is invariant under $\pi(A)$.

(ii) $\mathcal{X}^\perp$ is invariant under $\pi(A)$.

(iii) $P_\mathcal{X} \in \pi(A)'$.

**XV.14.4.5.** If $\mathcal{N}$ is the largest subspace of $\mathcal{H}$ on which $\pi(x) = 0$ for all $x \in A$, then $\mathcal{N}$ is closed, and $\mathcal{X} = \mathcal{N}^\perp$ is an invariant subspace, called the essential subspace of $\pi$. $\mathcal{X}$ is the closed span of $\{\pi(x)\xi : x \in A, \xi \in \mathcal{H}\}$. If $A$ is unital, then $P_\mathcal{X} = \pi(1_A)$. The representation $\pi$ is nondegenerate (or essential) if $\mathcal{X} = \mathcal{H}$. An irreducible representation is always nondegenerate.

**XV.14.4.6.** PROPOSITION. Let $\pi$ be a representation of a C*-algebra $A$ on $\mathcal{H}$, and $\mathcal{X}$ the essential subspace of $\pi$. If $(h_\lambda)$ is an approximate unit for $A$, then $\pi(h_\lambda) \to P_\mathcal{X}$ strongly.

**Proof:** Fix $x \in A$ and $\zeta \in \mathcal{X}$. Since $h_\lambda x \to x$ in norm, $\pi(h_\lambda x) \to \pi(x)$ in norm, so $\pi(h_\lambda x)\zeta \to \pi(x)\zeta$. We have

$$\pi(h_\lambda)[\pi(x)\zeta] = \pi(h_\lambda x)\zeta \to \pi(x)\zeta.$$ 

Since vectors of the form $\pi(x)\zeta$ ($x \in A$, $\zeta \in \mathcal{X}$) are dense in $\mathcal{X}$, and $(h_\lambda)$ is uniformly bounded, for any $\zeta \in \mathcal{X}$ we have $\pi(h_\lambda)\zeta \to \zeta$. Since $\pi(h_\lambda)\eta = 0$ for $\eta \in \mathcal{X}^\perp$, for any $\xi \in \mathcal{H}$ write $\xi = \zeta + \eta$ with $\zeta \in \mathcal{X}$, $\eta \in \mathcal{X}^\perp$; then

$$\pi(h_\lambda)\xi = \pi(h_\lambda)\zeta + \pi(h_\lambda)\eta = \pi(h_\lambda)\zeta \to \zeta = P_\mathcal{X}\xi.$$ 

**XV.14.4.7.** PROPOSITION. If $J$ is a closed ideal in $A$, let $\mathcal{E}$ be the essential subspace of $\pi|_J$. Then $\mathcal{E}$ is invariant under $\pi(A)$, so $P_\mathcal{E} \in \pi(A)'$.

**Proof:** Fix an approximate unit $(h_\lambda)$ for $J$. If $\xi \in \mathcal{E}$, then $\pi(h_\lambda)\xi \to \xi$ (XV.14.4.6.). If $x \in A$, then $\pi(xh_\lambda)\xi \in \mathcal{E}$ since $xh_\lambda \in J$, and $\pi(xh_\lambda)\xi = \pi(x)[\pi(h_\lambda)\xi] \to \pi(x)\xi$ since $\pi(x)$ is continuous; thus $\pi(x)\xi \in \mathcal{E}$ since $\mathcal{E}$ is closed.

**XV.14.4.8.** If $J$ is a closed ideal in $A$, let $\mathcal{E}$ be the essential subspace of $\pi|_J$. Then $\mathcal{E}$ is invariant under $\pi(A)$, so $\pi$ decomposes into a sum of a representation essential on $J$ and a representation which is zero on $J$ (a representation of $A/J$). Conversely, if $\rho$ is a nondegenerate representation of $J$ on an $\mathcal{H}$, and $(h_\lambda)$ is an approximate unit for $J$, then for any $a \in A$ the net $(\rho(ah_\lambda))$ converges strongly in $B(\mathcal{H})$ to an operator we call $\rho_A(a)$ (cf. ??), defining a representation of $A$ extending $\rho$, and we have $\rho_A(A)'' = \rho(J)''$. (This $\rho_A$ is the unique extension of $\rho$ to a representation of $A$ on $\mathcal{H}$.)
XV.14.4.9. Note that for a nondegenerate representation $\pi$, the strong (or weak) closure of $\pi(A)$ is $\pi(A)''$ by the Bicommutant Theorem (XV.3.5.2); for a general $\pi$, the strong closure of $\pi(A)$ is $P_\mathcal{X}\pi(A)''$, where $\mathcal{X}$ is the essential subspace of $\pi$. (Note that $P_\mathcal{X}$ is a central projection in $\pi(A)''$.)

We get the following fact from an application of the Bicommutant Theorem:

XV.14.4.10. **Proposition.** Let $\pi$ be a representation of a C*-algebra $A$ on a Hilbert space $\mathcal{H}$. Then the following are equivalent:

(i) $\pi$ is irreducible.

(ii) $\pi(A)' = \mathbb{C}I$.

(iii) $\pi(A)'' = \mathcal{B}(\mathcal{H})$.

(iv) $\pi(A)$ is strongly dense in $\mathcal{B}(\mathcal{H})$.

It follows from XV.14.4.8. that if $\pi$ is an irreducible representation of $A$, and $J$ is a closed ideal of $A$, then $\pi|_J$ is either zero or irreducible.

XV.14.4.11. **Proposition.** The kernel of an irreducible representation of a C*-algebra is a (closed) prime ideal.

**Proof:** The kernel of any representation is closed. Let $\pi$ be an irreducible representation of a C*-algebra $A$ on $\mathcal{H}$. Replacing $A$ by $A/\ker(\pi)$ we may assume $\pi$ is faithful. Suppose there are nonzero ideals $J$ and $K$ of $A$ with $J \cap K = \{0\}$. If $(h_\lambda)$ and $(k_\mu)$ are increasing approximate units for $J$ and $K$ respectively, then $(\pi(h_\lambda))$ and $(\pi(k_\mu))$ converge strongly to the projections $P$ and $Q$ onto the closures of $\pi(J)\mathcal{H}$ and $\pi(K)\mathcal{H}$. Then $P$ and $Q$ are nonzero projections in $\mathcal{B}(\mathcal{H})$, and $P \perp Q$. Since $\pi(J)\mathcal{H}$ and $\pi(K)\mathcal{H}$ are invariant under $\pi(A)$, we have $P, Q \in \pi(A)'$, a contradiction. \hfill \$\checkmark$

XV.14.4.12. If $\pi$ is a representation of a C*-algebra $A$ on a Hilbert space $\mathcal{H}$, and $0 \neq \xi \in \mathcal{H}$, then the set $\{\pi(x)\xi : x \in A\}$ is an invariant subspace of $\mathcal{H}$, and thus its closure is also invariant. If the closure is all of $\mathcal{H}$, $\xi$ is called a cyclic vector for $\pi$. A representation of $A$ with a cyclic vector is called a cyclic representation of $A$. A cyclic representation is nondegenerate. A simple Zorn’s Lemma argument shows that every nondegenerate representation is a direct sum of cyclic representations (in a highly nonunique way in general). If $\pi$ is an irreducible representation of $A$ on $\mathcal{H}$, then every nonzero vector in $\mathcal{H}$ is a cyclic vector for $\pi$.

**Positive Linear Functionals and States**

The connection between C*-algebras and Hilbert spaces is made via the notion of a state:

XV.14.4.13. **Definition.** Let $A$ be a C*-algebra. A linear functional $\phi$ on $A$ is positive, written $\phi \geq 0$, if $\phi(x) \geq 0$ whenever $x \geq 0$. A state on $A$ is a positive linear functional of norm 1. Denote by $\mathcal{S}(A)$ the set of all states on $A$, called the state space of $A$. 1880
**XV.14.4.14.** PROPOSITION. A positive linear functional is bounded.

**Proof:** Let $\phi$ be a positive linear functional on a C*-algebra $A$. It suffices to show $\phi$ is bounded on $A_+$ by XV.14.3.2.(vi): if it is not, for each $n$ choose $x_n \geq 0$ with $\|x_n\| = 1$ and $\phi(x_n) \geq 4^n$, and then $x = \sum_{n=1}^{\infty} 2^{-n}x_n$ satisfies $\phi(x) \geq 2^{-n}\phi(x_n) \geq 2^n$ for all $n$, a contradiction. $\blacksquare$

**XV.14.4.15.** EXAMPLES.

(i) If $A$ is a concrete C*-algebra of operators acting nondegenerately on $\mathcal{H}$ and $\xi \in \mathcal{H}$, and $\phi_\xi(x) = \langle x\xi, \xi \rangle$ for $x \in A$, then $\phi_\xi$ is a positive linear functional on $A$ of norm $\|\xi\|^2$, so $\phi_\xi$ is a state if $\|\xi\| = 1$. Such a state is called a vector state of $A$. This example is the origin of the term “state”: in the mathematical formulation of quantum mechanics, the states of a physical system are given by probability distributions (unit vectors in an $L^2$-space), and observables are self-adjoint operators; the value of the observable $T$ on the state $\xi$ is $\langle T\xi, \xi \rangle$ (cf. [BR87]).

(ii) By the Riesz Representation Theorem, there is a one-one correspondence between bounded linear functionals on $C_0(X)$ and finite regular complex Baire measures (complex Radon measures) on $X$. A bounded linear functional is positive if and only if the corresponding complex measure takes only nonnegative real values (i.e. is an ordinary measure). Thus the states on $C_0(X)$ are precisely given by the regular Baire probability measures on $X$. Any nonzero homomorphism from $C_0(X)$ to $\mathbb{C}$ is a state by XV.14.2.14., XV.14.2.15., and XV.14.3.2.(ii) and (vii).

A positive linear functional takes real values on self-adjoint elements, and thus $\phi(x^*) = \overline{\phi(x)}$ for any $x$ if $\phi \geq 0$. So if $\phi$ is a positive linear functional on $A$, then $\phi$ defines a pre-inner product on $A$ by $\langle x, y \rangle_\phi = \phi(y^*x)$. Thus we get the CBS inequality:

**XV.14.4.16.** PROPOSITION. Let $A$ be a C*-algebra, $\phi$ a positive linear functional on $A$, $x, y \in A$. Then $|\phi(y^*x)|^2 \leq \phi(x^*x)\phi(y^*y)$. More symmetrically, $|\phi(xy)|^2 \leq \phi(xx^*)\phi(y^*y)$.

**XV.14.4.17.** PROPOSITION. Let $A$ be a C*-algebra and $\phi$ a bounded linear functional on $A$. Then

(i) If $\phi \geq 0$, then $\|\phi\| = \sup\{\phi(x) : x \geq 0, \|x\| = 1\} = \lim \phi(h_\lambda)$ for any approximate unit $(h_\lambda)$ for $A$ (in particular, $\|\phi\| = \phi(1_A)$ if $A$ is unital), and $\phi$ extends to a positive linear functional on $A^1$ by setting $\phi(1) = \|\phi\|$ (or $\phi(1) = t$ for any $t \geq \|\phi\|$). In particular, any state on $A$ extends uniquely to a state on $A^1$.

(ii) If $A$ is unital and $\phi(1_A) = \|\phi\|$, then $\phi \geq 0$.

**Proof:** For the first part of (i), if $(h_\lambda)$ is an approximate unit for $A$, we have

$$\|\phi\| \geq \sup\{\phi(x) : x \geq 0, \|x\| = 1\} \geq \sup \phi(h_\lambda);$$
but if \( y \in A \), \( \|y\| = 1 \), \( |\phi(y)|^2 > \|\phi\|^2 - \epsilon \), then, using XV.14.4.16.,

\[
\|\phi\|^2 - \epsilon < |\phi(y)|^2 = \text{lim} |\phi(h_{1/2}^x y)|^2 \leq \text{lim inf} \phi(h_{1/2}^x) \phi(y^* y) \leq \|\phi\| \text{lim inf} \phi(h_{1/2}^x).
\]

The second statement of (i) follows from the first and XV.14.3.2.(viii).

To prove (ii), if \( x \geq 0 \), restrict \( \phi \) to \( C^*(x,1) \cong C(X) \); then \( \phi \) corresponds to a complex measure \( \mu \) on \( X \), and \( \mu(X) = |\mu|(X) \), so \( \mu \geq 0 \). A more elementary alternate argument can be based on XV.14.1.10.: if \( \phi(1_A) = \|\phi\| = 1 \), and \( x \geq 0 \), suppose \( \phi(\sigma) \notin [0,\infty) \). Then there is a \( \lambda \in \mathbb{C} \) and \( \rho \geq 0 \) with \( \phi(\sigma) \subseteq D = \{ z \in \mathbb{C} : |z - \lambda| \leq \rho \} \), but \( \phi(\sigma) \notin D \). If \( y = x - \lambda 1_A \), then \( \phi \) is normal and \( \|y\| = r_{\sigma}(y) \leq \rho \), so \( |\phi(x) - \lambda| = |\phi(y)| \leq \|y\| \leq \rho \), a contradiction.

XV.14.4.18. Any sum or nonnegative scalar multiple of positive linear functionals on a C*-algebra \( A \) is positive. A weak-* limit of a net of positive linear functionals on \( A \) is positive. XV.14.4.17.(i) shows that if \( \phi \) and \( \psi \) are positive linear functionals on \( A \), then \( \|\phi + \psi\| = \|\phi\| + \|\psi\| \). In particular, a convex combination of states is a state, so if \( A \) is unital, \( S(A) \) is a compact convex subset of the dual of \( A \). If \( A \) is nonunital, then \( S(A) \), though convex, is not compact or even locally compact, but the set of positive linear functionals on \( A \) of norm \( \leq 1 \) is in natural one-one correspondence with \( S(A^1) \), which is a compact convex set.

XV.14.4.19. Definition. A state of a C*-algebra \( A \) is pure if it is an extreme point of \( S(A) \). Denote the set of pure states of \( A \) by \( P(A) \).

XV.14.4.20. If \( A \) is unital, then \( S(A) \) is the closed convex hull of the pure states; in general, the set of positive linear functionals of norm \( \leq 1 \) is the closed convex hull of the pure states and the zero functional. The pure states of \( C_0(X) \) are precisely the homomorphisms to \( \mathbb{C} \), i.e. the states corresponding to point masses (XV.14.4.15.(ii)).

Extension and Existence of States

XV.14.4.21. Proposition. If \( A \) is a C*-algebra and \( B \) a C*-subalgebra, then every state on \( B \) extends to a state on \( A \).

Proof: If \( A \) is a C*-algebra and \( \phi \) is a state on \( A \), then by XV.14.4.17.(i) \( \phi \) extends to a state on \( A^1 \). If \( A \) is a unital C*-algebra and \( B \) a unital C*-subalgebra, and \( \phi \) is a state on \( B \), by the Hahn-Banach Theorem () \( \phi \) extends to a linear functional \( \psi \) on \( A \) of norm \( 1 \). Since \( \psi(1) = \phi(1) = 1 \), \( \psi \) is a state on \( A \). If \( B \) is a (not necessarily unital) C*-subalgebra of a (not necessarily unital) C*-algebra \( A \), and \( \phi \) is a state on \( B \), first extend \( \phi \) to \( B^1 \), regard \( B^1 \) as a unital C*-subalgebra of \( A^1 \) and extend to \( A^1 \), and then restrict to \( A \) to get an extension of \( \phi \) to a state on \( A \).

XV.14.4.22. If \( \phi \) is a pure state on a C*-subalgebra of a (not necessarily unital) C*-algebra \( A \), then the set of extensions of \( \phi \) to \( A \) is a weak-* compact convex subset of \( S(A) \), and any extreme point of this set (extreme points exist by the Krein-Milman Theorem ()) is a pure state of \( A \). Thus we get:
Proposition. Let $A$ be a C*-algebra, $x \in A_{sa}$. Then there is a pure state $\phi$ on $A$ with $|\phi(x)| = \|x\|$.

Proof: Note that there is a pure state (homomorphism) $\phi$ on $C^*(x) \cong C_0(\sigma_A(x))$ with $|\phi(x)| = r_\sigma(x) = \|x\|$, and extend $\phi$ to a pure state on $A$.

There is also a noncommutative version of the Jordan Decomposition Theorem for signed measures:

Theorem. Let $A$ be a C*-algebra, and $\phi$ a bounded self-adjoint linear functional on $A$. Then there are unique positive linear functionals $\phi_+$ and $\phi_-$ on $A$ with $\phi = \phi_+ - \phi_-$ and $\|\phi\| = \|\phi_+\| + \|\phi_-\|$.

Since every linear functional $\phi$ can be canonically written as $\phi_{re} + i\phi_{im}$ with $\phi_{re}, \phi_{im}$ self-adjoint [define $\phi^* = \overline{\phi(x)}$, and let $\phi_{re} = (\phi + \phi^*)/2, \phi_{im} = (\phi - \phi^*)/2i$], every bounded linear functional can be written canonically as a linear combination of four states. A simple consequence of this and the Hahn-Banach Theorem is:

Corollary. Let $A$ be a C*-algebra, $x \in A$.

(i) If $\phi(x) = 0$ for all $\phi \in S(A)$, then $x = 0$.

(ii) $x = x^*$ if and only if $\phi(x) \in \mathbb{R}$ for all $\phi \in S(A)$.

(iii) $x \geq 0$ if and only if $\phi(x) \geq 0$ for all $\phi \in S(A)$.

In fact, $S(A)$ can be replaced by $\mathcal{P}(A)$ in this result.

The GNS Construction

The GNS construction, discovered independently by Gelfand and Naimark [GN43] and I. Segal [Seg47] (the essential idea appeared earlier in [Ge41]), while quite simple, is an “ingenious construction” (E. Hille [Hil43]) and one of the most fundamental ideas of the theory of operator algebras. It provides a method for manufacturing representations of C*-algebras.

Let $A$ be a C*-algebra, $\phi$ a positive linear functional on $A$. Put a pre-inner product on $A$ by $\langle x, y \rangle_\phi = \phi(y^*x)$. If

$$N_\phi = \{x \in A : \phi(x^*x) = 0\},$$

then $N_\phi$ is a closed left ideal of $A$, and $\langle \cdot, \cdot \rangle_\phi$ drops to an inner product on $A/N_\phi$. If $a \in A$, let $\pi_\phi(a)$ be the left multiplication operator by $a$ on $A/N_\phi$, i.e. $\pi_\phi(a)(x + N_\phi) = ax + N_\phi$. Since

$$x^*a^*ax \leq \|a\|^2x^*x$$

(XV.14.3.8.), $\pi_\phi(a)$ is a bounded operator and $\|\pi_\phi(a)\| \leq \|a\|$; so $\pi_\phi(a)$ extends to a bounded operator, also denoted $\pi_\phi(a)$, on the completion (Hilbert space) $\mathcal{H}_\phi = L^2(A, \phi)$ of $A/N_\phi$. The representation $\pi_\phi$ is called the GNS representation of $A$ associated with $\phi$. 1883
XV.14.4.27. There is also a (unique) distinguished vector $\xi_\phi \in \mathcal{H}_\phi$ such that $\phi(a) = \langle \pi_\phi(a)\xi_\phi, \xi_\phi \rangle_\phi$ (and $\|\xi_\phi\|^2 = \|\phi\|$). If $A$ is unital, then $\xi_\phi$ is just the image of $1_A$ in $\mathcal{H}_\phi$. In general, let $\tilde{\phi}$ be the unique extension of $\phi$ to $A^\dagger$ with $\|\tilde{\phi}\| = \|\phi\|$; then from $\tilde{\phi}(1) = \lim \phi(h_\lambda) = \lim \phi(h_\lambda^2)$, where $(h_\lambda)$ is an approximate unit for $A$, it follows that $\phi((1 - h_\lambda)^2) \to 0$, so $A/N_{\phi}$ is dense in $A^\dagger/N_{\tilde{\phi}}$, and thus $\mathcal{H}_\phi$ can be identified with $\mathcal{H}_{\tilde{\phi}}$, and $\xi_\phi$ may be taken to be $\xi_{\tilde{\phi}}$. This $\xi_\phi$ is a cyclic vector for $\pi_\phi$, i.e. $\pi_\phi(A)\xi_\phi$ is dense in $\mathcal{H}_{\tilde{\phi}}$.

XV.14.4.28. This construction is the inverse of XV.14.4.15(i): if $\pi$ is a representation of $A$ on a Hilbert space $\mathcal{H}$ and $\xi$ is a cyclic vector for $\pi$, and $\phi(a) = \langle \pi(a)\xi, \xi \rangle$, then $(\mathcal{H}_\phi, \pi_\phi, \xi_\phi)$ is unitarily equivalent to $(\mathcal{H}, \pi, \xi)$. Thus there is a precise one-one correspondence between positive linear functionals on $A$ and (cyclic) representations of $A$ with a specified cyclic vector.

XV.14.4.29. Example. Let $A = n$, with Tr the (ordinary) trace on $A$. Then $\mathcal{H}_{\text{Tr}}$ can be identified with $\mathbb{M}_n$ with the Hilbert-Schmidt norm, with $\xi_{\text{Tr}} = I$. The action $\pi_{\text{Tr}}$ is the ordinary one by left multiplication. $\mathbb{M}_n$ acting on itself in this way is called the standard form representation of $\mathbb{M}_n$. Its commutant is also isomorphic (or, more naturally, anti-isomorphic) to $\mathbb{M}_n$, acting by right multiplication.

XV.14.4.30. If $\phi$ is a positive linear functional on $A$, then $\phi$ has a canonical extension to a positive linear functional on $\mathcal{B}(\mathcal{H}_\phi)$ of the same norm, also denoted $\phi$, by $\phi(T) = \langle T\xi_\phi, \xi_\phi \rangle_\phi$.

The next simple result is a version of the Radon-Nikodym Theorem (the classical Radon-Nikodym theorem is essentially the special case where $A = L^\infty(X, \mu)$ for a finite measure space $(X, \mu)$, and $\phi(f) = \int f \, d\mu$).

XV.14.4.31. Proposition. Let $\phi$ and $\psi$ be positive linear functionals on $A$, with $\psi \leq \phi$ (i.e. $\psi(x) \leq \phi(x)$ for all $x \in A_+$). Then there is a unique operator $T \in \pi_\phi(A)' \subseteq \mathcal{B}(\mathcal{H}_\phi)$, with $0 \leq T \leq I$, such that $\psi(x) = \phi(T\pi_\phi(x)) = \langle T\pi_\phi(x)\xi_\phi, \xi_\phi \rangle_\phi$ for all $x \in A$.

Proof: For $x, y \in A$, define $(\pi_\phi(x)\xi_\phi, \pi_\phi(y)\xi_\phi) = \psi(y^*x)$. Then $(\cdot, \cdot)$ extends to a bounded sesquilinear form (pre-inner product) on $\mathcal{H}_\phi$, and thus there is a $T \in (\mathcal{H}_\phi)^\prime$, $0 \leq T \leq I$, such that $(\eta, \zeta) = \langle T\eta, \zeta \rangle_\phi$ for all $\eta, \zeta \in \mathcal{H}_\phi$ (??). If $x, y, z \in A$, then

\[
\langle T\pi_\phi(x)\xi_\phi, \pi_\phi(y)\xi_\phi \rangle_\phi = \psi(y^*(xz)) = \psi((x^*y)^*z)
\]

so, fixing $x$ and letting $y, z$ range over $A$, we conclude that $T\pi_\phi(x) = \pi_\phi(x)T$.

XV.14.4.32. In fact, if $\psi \leq \phi$ and $\omega = \phi - \psi$, so that $\phi = \psi + \omega$, then $\pi_\phi$ is unitarily equivalent to the subrepresentation of $\pi_\psi \oplus \pi_\omega$ with cyclic vector $\xi_\psi \oplus \xi_\omega$, and $T$ is projection onto the first coordinate, compressed to this subspace.

Because of the abundance of states on a C*-algebra described in (XV.14.4.23.), every C*-algebra has many representations. We can say even more:
XV.14.4.33. Proposition. If \( \phi \) is a state of \( A \), then \( \pi_\phi \) is irreducible if and only if \( \phi \) is a pure state.

Proof: It follows immediately from XV.14.4.31. and XV.14.4.10. that if \( \pi_\phi \) is irreducible, then any positive linear functional \( \psi \leq \phi \) is a multiple of \( \phi \), and hence \( \phi \) is pure. Conversely, if \( \phi \) is pure, suppose there is a projection \( P \) in \( \pi_\phi(A)' \), \( P \neq 0 \), \( I \). Then \( P\xi_\phi \neq 0 \), for otherwise

\[
0 = \pi_\phi(x) P\xi_\phi = P[\pi_\phi(x)\xi_\phi]
\]

for all \( x \in A \), so \( P = 0 \). Similarly, \( (I - P)\xi_\phi \neq 0 \). For \( x \in A \), write

\[
\phi_1(x) = \langle \pi_\phi(x) P\xi_\phi, P\xi_\phi \rangle = \phi(P\pi_\phi(x))
\]

\[
\phi_2(x) = \langle \pi_\phi(x)(I - P)\xi_\phi, (I - P)\xi_\phi \rangle = \phi((I - P)\pi_\phi(x)).
\]

Then \( \phi_1, \phi_2 \) are positive linear functionals on \( A \), \( \phi = \phi_1 + \phi_2 \), and \( \phi_1 = \lambda \phi \), \( \phi_2 = (1 - \lambda)\phi \) for some \( \lambda, 0 < \lambda < 1 \), because \( \phi \) is pure. For any \( \epsilon > 0 \), there is an \( x \in A \) with \( \|\pi_\phi(x)\xi_\phi - P\xi_\phi\|_\phi < \epsilon \) and \( \|\pi_\phi(x)\xi_\phi\|^2_\phi = \phi(x^*x) = \|P\xi_\phi\|^2_\phi \). Then \( \|(I - P)\pi_\phi(x)\xi_\phi\| = \|(I - P)(\pi_\phi(x)\xi_\phi - P\xi_\phi)\| < \epsilon \), and

\[
(1 - \lambda)\|P\xi_\phi\|^2_\phi = (1 - \lambda)\phi(x^*x) = \phi_2(x^*x) = \|(I - P)\pi_\phi(x)\xi_\phi\|^2_\phi < \epsilon^2
\]

contradicting \( \lambda \neq 1 \) and therefore the existence of \( P \). Thus \( \pi_\phi(A)' = CI \).

XV.14.4.34. Corollary. If \( A \) is a C*-algebra and \( x \in A \), then there is an irreducible representation \( \pi \) of \( A \) with \( \|\pi(x)\| = \|x\| \).

Proof: Let \( \pi = \pi_\phi \), where \( \phi \) is a pure state of \( A \) with \( \phi((xx^*)^2) = \|(xx^*)^2\| = \|x\|^4 \) (XV.14.4.23.). Then

\[
\|x\|^2 = \langle xx^*, xx^* \rangle^{1/2}_\phi = \|xx^*\|_\phi = \|\pi(x)x^*\|_\phi \leq \|\pi(x)\|\|x^*\|_\phi \leq \|\pi(x)\|\|x\|.
\]

By considering sums of irreducible representations, we obtain

XV.14.4.35. Corollary. [Gelfand-Naimark Theorem] If \( A \) is a C*-algebra, then \( A \) has a faithful representation, i.e. \( A \) is isometrically isomorphic to a concrete C*-algebra of operators on a Hilbert space \( H \). If \( A \) is separable, then \( H \) may be chosen to be separable.

XV.14.4.36. Proposition. Let \( A \) be a C*-algebra, \( B \) a C*-subalgebra of \( A \), and \( \rho \) a representation of \( B \) on a Hilbert space \( H_0 \). Then \( \rho \) can be extended to a representation \( \pi \) of \( A \) on a (possibly) larger Hilbert space \( H \), i.e. there is a Hilbert space \( H \) containing \( H_0 \) and a representation \( \pi \) of \( A \) on \( H \) such that \( \pi_\rho \) is invariant under \( \pi|_B \) and \( \pi|_B \) agrees with \( \rho \) on \( H_0 \). If \( \rho \) is irreducible, then \( \pi \) may be chosen irreducible.

Proof: Since every representation is a direct sum of cyclic representations, it suffices to show the result for \( \rho \) cyclic, i.e. \( \rho \) is the GNS representation corresponding to a state \( \psi \) of \( B \). Extend \( \psi \) to a state \( \phi \) of \( A \) (with \( \phi \) pure if \( \psi \) is pure; see XV.14.4.22.), and let \( \pi \) be its GNS representation.

1885
**XV.14.4.37.** Thus every C*-algebra can be faithfully represented on a Hilbert space, but the representation is highly nonunique in general. The major part of representation theory is concerned with how to describe the possibilities. There is a relatively small class of C*-algebras (V) for which a concrete description of the representations is even possible.

Using the GNS construction, we can obtain an extension of XV.14.4.17. (i) and a sharpening of XV.14.4.21. in the case that the subalgebra is an ideal. This result is also closely related to XV.14.4.8.

**XV.14.4.38.** **PROPOSITION.** Let $J$ be a closed ideal in a C*-algebra $A$, and $\psi$ a positive linear functional on $J$. Then there is a unique extension of $\psi$ to a positive linear functional $\phi$ on $A$ with $\|\phi\| = \|\psi\|$. If $(h_\lambda)$ is an increasing approximate unit for $J$, then $\phi(x) = \lim \psi(h_\lambda x) = \lim \psi(x h_\lambda)$ for all $x \in A$; if $x \in A_+$, then

$$\phi(x) = \lim \psi(x^{1/2}h_\lambda x^{1/2}) = \sup \psi(x^{1/2}h_\lambda x^{1/2}).$$

Any other positive linear functional $\phi'$ on $A$ extending $\psi$ satisfies $\phi' \geq \phi$.

**PROOF:** By XV.14.4.21. there is a $\phi$ extending $\psi$ with $\|\phi\| = \|\psi\|$, but we will not use this result. Instead we define $\phi$ directly as follows.

Let $\pi_\psi$ be the GNS representation of $J$ on $H_\psi$ with cyclic vector $\xi_\psi$. Extend $\pi_\psi$ to a representation $\pi$ of $A$ on $H_\psi$ as in XV.14.4.8. Then $\xi_\psi$ defines a positive linear functional $\phi$ on $A$ by $\phi(x) = \langle \pi(x)\xi_\psi, \xi_\psi \rangle$. We have $\|\phi\| = \|\xi_\psi\|^2 = \|\psi\|$, and $(H_\psi, \pi_\phi, \xi_\phi)$ can be naturally identified with $(H_\psi, \pi, \xi_\psi)$. Since $\pi(h_\lambda) \to I$ strongly, we have, for any $x \in A$,

$$\psi(h_\lambda x) = \langle \pi(h_\lambda)\pi(x)\xi_\psi, \xi_\psi \rangle \to \langle \pi(x)\xi_\psi, \xi_\psi \rangle = \phi(x)$$

and similarly $\psi(x h_\lambda) \to \phi(x)$ and, if $x \geq 0$, $\psi(x^{1/2}h_\lambda x^{1/2}) \to \phi(x)$.

If $\phi'$ is any extension of $\psi$ to a positive linear functional on $A$, and $x \in A_+$, then $\phi'(x) \geq \phi'(x^{1/2}h_\lambda x^{1/2}) = \psi(x^{1/2}h_\lambda x^{1/2})$ for all $\lambda$, so $\phi'(x) \geq \phi(x)$. Thus $\omega = \phi' - \phi$ is a positive linear functional, and we have $\|\omega\| = \|\phi\| + \|\omega\| = \|\psi\|$, so if $\|\phi'\| = \|\psi\|$, then $\omega = 0$, $\phi' = \phi$.

**Primitive Ideal Space and Spectrum**

It is common in mathematics (e.g. in algebraic geometry) to associate to a ring $A$ a topological space of ideals of $A$, generally either the set of prime ideals (denoted Spec($A$)) or the set of maximal ideals (denoted Maxspec($A$)), with the hull-kernel topology (XI.7.8.16.). For C*-algebras, the most useful variant is to consider the primitive ideal space:

**XV.14.4.39.** **DEFINITION.** Let $A$ be a C*-algebra. A **primitive ideal of $A$** is an ideal which is the kernel of an irreducible representation of $A$. Denote by Prim($A$) the set of primitive ideals of $A$. The topology on Prim($A$) is the hull-kernel topology, i.e. $\{J_i\}^{-} = \{J : J \supseteq \cap J_i\}$.

**XV.14.4.40.** A primitive ideal is closed by XV.14.4.2. and prime by XV.14.4.11.. By XV.14.4.34., the intersection of the primitive ideals of a C*-algebra $A$ is $\{0\}$. By considering irreducible representations of $A/J$, it follows that every closed ideal $J$ of $A$ is an intersection of primitive ideals. In particular, every maximal ideal is primitive. There is thus a natural one-one correspondence between the closed sets in Prim($A$) and the closed ideals of $A$. If $A$ is commutative, then every closed prime ideal is maximal and hence primitive, and Prim($A$) agrees with the set Maxspec($A$) and may be identified with $A$ as in XV.14.2.1..
If $J$ is a closed ideal in $A$, then we can identify $\text{Prim}(A/J)$ with

\[
\text{Prim}_J(A) = \{ K \in \text{Prim}(A) : J \subseteq K \},
\]

the corresponding closed set in $\text{Prim}(A)$. If $K \in \text{Prim}(A)$, $J \not\subseteq K$, and $\pi$ is an irreducible representation of $A$ with kernel $K$, then $\pi|J$ is an irreducible representation of $J$ (XV.14.4.8.) with kernel $K \cap J$. So there is a map $\rho_J$ from

\[
\text{Prim}'(A) = \{ K \in \text{Prim}(A) : J \not\subseteq K \}
\]
to $\text{Prim}(J)$, defined by $\rho_J(K) = K \cap J$, which is surjective by XV.14.4.8. Also, $\rho_J$ is injective: if $K_1, K_2 \in \text{Prim}(A)$ and $K_1 \cap J = K_2 \cap J \neq J$, then by XV.14.3.16 (iii) we have

\[
(K_1 + K_2) \cap (J + K_2) = (K_1 \cap J) + K_2 = (K_2 \cap J) + K_2 = K_2
\]
and, since $K_2$ is prime and $J + K_2 \neq K_2$, we have $K_1 + K_2 = K_2, K_1 \subseteq K_2$. Symmetrically, $K_2 \subseteq K_1$, so $K_1 = K_2$. Thus $\text{Prim}(J)$ may be identified with $\text{Prim}'(A) = \text{Prim}(A) \setminus \text{Prim}_J(A)$, an open set in $\text{Prim}(A)$.

If $J$ is a closed ideal in a C*-algebra $A$ and $x \in A$, write $\|x\|_J$ for the norm of $x$ mod $J$. If \{\text{J}_i\} is any collection of closed ideals in $A$ and $J = \cap \text{J}_i$, then $\| : \|_J = \sup_i \| : \|_{\text{J}_i}$ (by XV.14.2.33. it suffices to note that this formula defines a C*-norm on $A/J$); and if \{\text{J}_i\} is an increasing net of closed ideals with $J = [\cup \text{J}_i]^{-}$, then $\| : \|_J = \inf_i \| : \|_{\text{J}_i}$ (this follows immediately from the definition of the quotient norm). A simple consequence is:

**XV.14.4.43.** PROPOSITION. Let $A$ be a C*-algebra.

(i) If $x \in A$, define $\hat{x} : \text{Prim}(A) \rightarrow \mathbb{R}_+$ by $\hat{x}(J) = \|x\|_J$. Then $\hat{x}$ is lower semicontinuous.

(ii) If $\{x_i\}$ is a dense set in the unit ball of $A$, and $U_i = \{J \in \text{Prim}(A) : \hat{x}_i(J) > 1/2\}$, then $\{U_i\}$ forms a base for the topology of $\text{Prim}(A)$.

(iii) If $x \in A$ and $\lambda > 0$, then $\{J \in \text{Prim}(A) : \hat{x}(J) \geq \lambda\}$ is compact (but not necessarily closed) in $\text{Prim}(A)$.

**PROOF:** Part (i) is obvious. For (ii), let $J \in \text{Prim}(A)$. A neighborhood of $J$ is a set of the form $V = \{ I \in \text{Prim}(A) : K \not\subseteq I \}$ for a closed ideal $K$ not contained in $J$. Choose $y \in K \setminus J$, and $0 < \epsilon \leq \frac{1}{2}\|y\|^2_2$, and let $x = f_\epsilon(y^*y)$. Then $x \in K$, and $\|x\| = \|x\|_J = 1$. Choose $x_i$ with $\|x_i - x\| < 1/2$; then $J \subseteq U_i$ and $U_i \subseteq V$. To show (iii), let $\{K_i : i \in \Omega\}$ be a set of closed ideals in $A$, $K$ the closed ideal generated by $\cup K_i$ (so $K = [\bigcup K_i]^{-}$), and

\[
U_i = \{J \in \text{Prim}(A) : K_i \not\subseteq J\}.
\]

Then $\{U_i\}$ is an open cover of $F = \{J \in \text{Prim}(A) : \hat{x}(J) \geq \lambda\}$ if and only if $\|x\|_K < \lambda$. In this case, there are $i_1, \ldots, i_n$ such that if $K_0 = K_{i_1} + \cdots + K_{i_n}$, then $\|x\|_{K_0} < \lambda$, so $\{U_{i_1}, \ldots, U_{i_n}\}$ is a cover of $F$. \(\square\)

**XV.14.4.44.** COROLLARY. $\text{Prim}(A)$ is a locally compact space $T_0$-space which is compact if $A$ is unital. If $A$ is separable, then $\text{Prim}(A)$ is second countable.

Actually, there are several inequivalent definitions of local compactness used for non-Hausdorff spaces (XI.11.8.20.), so the statement that $\text{Prim}(A)$ is “locally compact” is ambiguous in the non-Hausdorff case. To be precise, if $A$ is a C*-algebra, then XV.14.4.43. shows that every point of $\text{Prim}(A)$ has a neighborhood base of compact sets, i.e. $\text{Prim}(A)$ satisfies XI.11.8.20.(ii). But a point need not have any closed compact neighborhood, i.e. $\text{Prim}(A)$ does not necessarily satisfy XI.11.8.20.(iii).

1887
The function $\hat{x}$ of XV.14.4.43. is not continuous in general; in fact, if Prim($A$) is not Hausdorff, then the $\hat{x}$ cannot all be continuous since $\{\hat{x} : x \in A\}$ separates the points of Prim($A$). But if Prim($A$) is Hausdorff, XV.14.4.43.(iii) shows that $\hat{x}$ is continuous for all $x \in A$. If $A$ is commutative, or more generally if $x$ is in the center of $A$, then $\hat{x}$ is continuous.

XV.14.4.46. Examples.

(i) Let $A = \mathbb{K}^\dagger$. Then Prim($A$) = $\{0, \mathbb{K}\}$; $\{\mathbb{K}\}$ is a closed point, and $\{0\}$ is a dense open point. Thus Prim($A$) homeomorphic to the Sierpiński space and is not $T_1$.

(ii) Let $A$ be the C*-algebra of all sequences of elements of $\mathbb{M}_2$ which converge to a diagonal matrix. Then Prim($A$) consists of a sequence of points simultaneously converging to two closed points at infinity. Thus Prim($A$) is $T_1$ but not Hausdorff.

(iii) Let $A$ be the C*-algebra of all sequences in $\mathbb{K}^\dagger$ converging to a scalar multiple of 1. Then Prim($A$) is the one-point compactification of a disjoint union of two-point spaces as in (i).

If $A$ is commutative, then Gelfand’s Theorem (XV.14.2.1.) identifies elements of $A$ with continuous functions on $\hat{A} \cong$ Prim($A$).

XV.14.4.47. For a general C*-algebra $A$ we define $\hat{A}$ to be the set of unitary equivalence classes of irreducible representations of $A$. There is a natural map from $\hat{A}$ onto Prim($A$) sending $\pi$ to $\text{ker}(\pi)$. This map is not injective in general, i.e. there can be inequivalent representations with the same kernel. There is also an obvious map from $\mathcal{P}(A)$ onto $\hat{A}$, sending a pure state to its GNS representation; the composite map from $\mathcal{P}(A)$ to Prim($A$) is continuous and open when $\mathcal{P}(A)$ is given the relative weak-* topology. The quotient topology (XI.8.1.1.) on $\hat{A}$ from $\mathcal{P}(A)$, which coincides with the weak topology (XI.5.1.8.) for the map of $\hat{A}$ onto Prim($A$), is the unique topology on $\hat{A}$ making the maps $\mathcal{P}(A) \to \hat{A}$ and $\hat{A} \to$ Prim($A$) continuous and open (XI.8.5.1.), but $\hat{A}$ is not $T_0$ unless the map to Prim($A$) is injective (and hence a homeomorphism).

By XV.14.4.8., if $J$ is a closed ideal in $A$, we may identify $J$ and Prim($J$) with open subsets of $\hat{A}$ and Prim($A$) respectively; the complements are naturally identified with $\hat{A}/J$ and Prim($A/J$). We may do the same with $\mathcal{P}(J)$ since if $\phi \in \mathcal{P}(A)$, then either $|\phi|_J = 0$ or $|\phi|_J$ is a pure state of $J$.

XV.14.4.48. Another way of describing the topology on $\hat{A}$ is to fix a Hilbert space $\mathcal{H}$ and let Irr$_\mathcal{H}(A)$ be the set of irreducible representations of $A$ on $\mathcal{H}$. Irr$_{\mathcal{H}}(A)$ has a natural topology, the topology of elementwise convergence, and the map from Irr$_{\mathcal{H}}(A)$ to $\hat{A}$ is continuous and open, i.e. $\hat{A}$ has the quotient topology from Irr$_{\mathcal{H}}(A)$ (more care must be taken in describing the topology if $A$ has irreducible representations of different dimensions. The difficulty can be avoided by stabilization (XV.14.4.55.) if $A$ is separable, since there are natural homeomorphisms $[A \otimes \mathbb{K}]^\sim \cong \hat{A}$ and Prim($A \otimes \mathbb{K}$) $\cong$ Prim($A$).) This procedure also yields a Borel structure (the Mackey Borel structure) on $\hat{A}$, the quotient of the natural Borel structure on Irr$_{\mathcal{H}}(A)$ induced by its topology, which is finer than the Borel structure on $\hat{A}$ induced by its topology, and which is more useful than the topology if $\hat{A}$ is not $T_0$ (e.g. the Mackey Borel structure separates points of $\hat{A}$).

Matrix Algebras and Stable Algebras

As an example of a basic fact which can be proved easily by representation theory but for which there seems to be no decent space-free proof, we observe that a matrix algebra over a C*-algebra is also a C*-algebra.
**XV.14.4.49.** If $\mathcal{H}$ is a Hilbert space, then $\mathcal{B}(\mathcal{H}^n)$ is naturally isomorphic to the matrix algebra $M_n(\mathcal{B}(\mathcal{H}))$. (More generally, $\mathcal{B}(\mathcal{H}^n, \mathcal{H}^m)$ can be identified with the $m \times n$ matrices over $\mathcal{B}(\mathcal{H})$.) So if $A$ is a concrete C*-algebra of operators on $\mathcal{H}$, then the matrix algebra $M_n(A)$ acts naturally as a concrete C*-algebra of operators on $\mathcal{H}^n$ (it is easily seen to be complete). The adjoint of a matrix $(a_{ij})$ is the matrix $(b_{ij})$, where $b_{ij} = a^*_{ji}$.

**XV.14.4.50.** Thus, if $A$ is a C*-algebra, we need only to take a faithful representation $\pi$ of $A$ on a Hilbert space $\mathcal{H}$; then $\pi$ defines entrywise a faithful representation $\pi^{(n)}$ of $M_n(A)$ (with involution defined as above) on $\mathcal{H}^n$, and thus $M_n(A)$ is a C*-algebra with the induced operator norm.

**XV.14.4.51.** By XV.14.2.34., this operator norm is the unique C*-norm on $M_n(A)$ with this involution. When we use matrix algebras over C*-algebras, we will always implicitly use this involution and norm. Note that there is no explicit formula for the norm of a matrix in terms of the entries in general (e.g. if $A = \mathbb{M}_3$ and $n = 2$, cf. XV.10.6.6.). There is, however, a simple estimate: if $a = (a_{ij})$ is a matrix, then

$$\max_{i,j} \|a_{ij}\| \leq \|a\| \leq \sum_{i,j} \|a_{ij}\|$$

since it is easily seen that if $b$ is a matrix with exactly one nonzero entry $x$, then $\|b\| = \|x\|$.

**XV.14.4.52.** $M_n(A)$ is isomorphic to $A \otimes \mathbb{M}_n = A \otimes_{\mathbb{C}} \mathbb{M}_n$ (it), and it is convenient to use tensor product notation in matrix algebras. In $\mathbb{M}_n$, let $e_{ij}$ be the matrix with 1 in the $(i,j)$'th entry and zeroes elsewhere, and write $a \otimes e_{ij}$ for the element of $M_n(A)$ with $a$ in the $(i,j)$'th entry and zeroes elsewhere. The $e_{ij}$ are called the standard matrix units in $\mathbb{M}_n$. (There is a similar set of standard matrix units in $\mathbb{K}$.)

**XV.14.4.53.** As in XV.14.4.49., $\mathcal{B}(\mathcal{H}^\infty)$ can be identified with an algebra of infinite matrices over $\mathcal{B}(\mathcal{H})$ (although it is impossible to give an explicit description of which matrices give bounded operators). If $A$ is a concrete C*-algebra of operators on $\mathcal{H}$, let $M_\infty(A)$ denote the infinite matrices over $A$ with only finitely many nonzero entries. Then $M_\infty(A)$ acts naturally as a *-algebra of bounded operators on $\mathcal{H}^\infty$, and its closure in $\mathcal{B}(\mathcal{H}^\infty)$ is denoted $A \otimes \mathbb{K}$.

**XV.14.4.54.** If $A$ is an (abstract) C*-algebra, we can form $M_\infty(A)$ in the same manner, and by choosing a faithful representation $\pi$ of $A$, $M_\infty(A)$ may be identified with $M_\infty(\pi(A))$ and thus given a norm. Using the uniqueness of norm on $M_n(A)$ for each $n$, it is easily seen that the norm on $M_\infty(A)$ does not depend on the choice of $\pi$.

**XV.14.4.55.** Definition. The completion of $M_\infty(A)$ is called the stable algebra of $A$, denoted $A \otimes \mathbb{K}$.

This is also a special case of a tensor product of C*-algebras, hence the notation.

**XV.14.4.56.** Definition. A C*-algebra $A$ is stable if $A \cong A \otimes \mathbb{K}$. Two C*-algebras $A$ and $B$ are stably isomorphic if $A \otimes \mathbb{K} \cong B \otimes \mathbb{K}$.

Note that a stable C*-algebra is always nonunital.
**XV.14.4.57.** Proposition. $\mathcal{K}(\mathcal{H}) \otimes M_n = \mathcal{K}(\mathcal{H}^n)$ and $\mathcal{K}(\mathcal{H}) \otimes K = \mathcal{K}(\mathcal{H}^\infty)$. In particular,

$$K \cong M_n(K) \cong M_n \otimes K \cong K \otimes M_n$$

for all $n$, and $K$ is isomorphic to $K \otimes K$.

**XV.14.4.58.** Similarly, it is easily verified that $(A \otimes K) \otimes K \cong A \otimes K$ for any $A$, so the stable algebra $A \otimes K$ of a C*-algebra $A$ is a stable C*-algebra, and $A$ is stably isomorphic to $A \otimes K$. Two stable C*-algebras are stably isomorphic if and only if they are isomorphic. In the same way, $A$ and $M_n(A)$ are stably isomorphic for any $A$ and $n$. Stably isomorphic C*-algebras are “the same up to ‘size’;” a stable C*-algebra has uniformly infinite “size.” (This must be taken with a grain of salt in the non-$\sigma$-unital case, but can be made precise in a nice way for $\sigma$-unital C*-algebras). If $X$ is a locally compact Hausdorff space, then $C_0(X) \otimes K \cong C_0(X,K)$ (XV.14.1.3).

**XV.14.5. Universal and Enveloping C*-Algebras**

**XV.14.6. Exercises**

**XV.14.6.1.** Use XV.14.2.14. and XV.14.2.16. to give an alternate proof of XV.14.1.9., as follows. Let $B$ be a commutative C*-algebra, which may be assumed unital by XV.14.1.2., and $x = x^* \in B$.

(a) Suppose $\lambda = \alpha + i\beta \in \sigma_B(x)$ with $\alpha, \beta \in \mathbb{R}$. By XV.14.2.16. there is a $\phi \in \hat{B}$ with $\phi(x) = \lambda$.

(b) For $t \in \mathbb{R}$, set $x_t = x + i\lambda$. Then $\|x_t\|^2 = \|x^*_tx_t\| = \|x^2 + t^2\| \leq \|x^2\| + t^2 = \|x\|^2 + t^2$.

(c) Since $|\phi(x_t)| \leq \|x_t\|$ by XV.14.2.14., we have

$$\alpha^2 + (\beta + t)^2 \leq \|x\|^2 + t^2$$

for all $t \in \mathbb{R}$. Show that this implies that $\beta = 0$.

(e) If $A$ is a general not necessarily commutative C*-algebra (which may be assumed unital) and $x = x^* \in A$, the above argument can be applied to the C*-subalgebra $B$ of $A$ generated by $x$ and 1. Why does this give an alternate proof of the full result XV.14.1.9. (what is the relation between $\sigma_B(x)$ and $\sigma_A(x)$)?

**XV.14.6.2.** (a) Let $I$ be a closed bounded interval in $\mathbb{R}$, and $A$ the set of bounded functions from $I$ to $\mathbb{C}$ whose real and imaginary parts are in $2\mathcal{C}_c(I)$ (XII.2.3.2.). Give $A$ pointwise operations and supremum norm. Show that $A$ is a (unital) commutative C*-algebra. [Use XII.2.6.7.]

(b) Let $B$ be the set of regulated functions on $I$ (V.8.6.7.). Show that $B$ is a (unital) C*-subalgebra of $A$ containing $C(I)$.

(c) Show that $B$ is homeomorphic to $I \times \{0,1\}$ with the order topology from the lexicographic ordering (). The quotient map to $I \cong C(I)$ is projection onto the first coordinate. Note that $B$ is not metrizable, so $B$ is not separable (this has an easy direct proof too).

(d) Try to describe $A$. (Note that $\hat{B}$ is a quotient of $\hat{A}$.)

**XV.14.6.3.** Let $A$ be the set of bounded uniformly continuous functions from $\mathbb{R}$ to $\mathbb{C}$. Show that $A$ is a proper unital C*-subalgebra of $BC(\mathbb{R})$. Thus $A$ is a quotient of $BC(\mathbb{R}) \cong \beta \mathbb{R}$. Describe the quotient map.
Chapter XVI

Topological Groups and Abstract Harmonic Analysis

XVI.1. Topological Groups

XVI.1.1. Groups and Homomorphisms

XVI.1.2. Topological Groups

XVI.1.2.1. Definition. A topological group is a group $G$ with a topology such that the group operation $(x, y) \mapsto xy$ is a continuous function from $G \times G$ to $G$ (i.e. multiplication is jointly continuous on $G$), and inversion $x \mapsto x^{-1}$ is a continuous function from $G$ to $G$.

XVI.1.2.2. Note that both the group operation and the topology are parts of the definition of a topological group; thus it is technically incorrect to say “Let $G$ be a topological group” (although we do it all the time). In fact, a group can have many different topologies making it into a topological group.

XVI.1.2.3. Examples. (i) Let $G$ be any group. Then $G$ is a topological group with the discrete topology or the indiscrete topology.

A topological group with the indiscrete topology is not very interesting. However, a group with the discrete topology is much more interesting than might be at first anticipated. In fact, we can regard the theory of groups (with no topology) as a special case of the theory of topological groups by using the discrete topology (although this is logically circular if not done properly).

(ii) The additive group $\mathbb{R}$ (or $\mathbb{R}^n$) with its ordinary topology is a topological group. More generally, the additive group of any normed vector space is a topological group with the topology induced by the norm.

(iii) Let $GL_n(\mathbb{R})$ be the multiplicative group of invertible $n \times n$ matrices with real entries, with the relative topology as a subset of $M_n(\mathbb{R}) \cong \mathbb{R}^{n^2}$. Then $GL_n(\mathbb{R})$ is a topological group.

(iv) Any subgroup of a topological group is a topological group with the relative topology.

(v) Groups of homeomorphisms of topological spaces can often be given natural topologies making them into topological groups, although the details can be subtle (cf. XVI.1.7.8–XVI.1.7.14.).
These examples barely scratch the surface of the possibilities.

The condition defining a topological group can be streamlined:

**XVI.1.2.4. Proposition.** Let $G$ be a group with a topology. Then $G$ is a topological group under the given topology if and only if the map $\phi : G \times G \to G$ given by $\phi(x, y) = x^{-1}y$ is continuous.

**Proof:** If $G$ is a topological group, then $\phi$ is a composition of multiplication and inversion, hence continuous. Conversely, if $\phi$ is continuous, then

$$x \mapsto (x, e) \mapsto x^{-1}e = x^{-1}$$

is continuous, and hence

$$(x, y) \mapsto (x^{-1}, y) \mapsto (x^{-1})^{-1}y = xy$$

is continuous, so $G$ is a topological group in the given topology.

**XVI.1.2.5.** Joint continuity of multiplication in a topological group implies separate continuity (). But separate continuity of multiplication does not imply joint continuity (Exercise XVI.1.7.6.). There are situations where separate continuity does imply joint continuity ()

**Translations and Homogeneity**

**XVI.1.2.6.** **Definition.** Let $G$ be a topological group, and $g \in G$. The functions $\lambda_g, \rho_g$ from $G$ to $G$ defined by

$$\lambda_g(x) = gx$$

$$\rho_g(x) = xg$$

are called *left translation* and *right translation* by $g$ respectively.

**XVI.1.2.7.** **Proposition.** Let $G$ be a topological group, and $g \in G$. Then the left and right translations $\lambda_g$ and $\rho_g$ are homeomorphisms from $G$ to $G$. If $g \neq e$, these homeomorphisms have no fixed points.

**Proof:** Translations are continuous by (separate) continuity of the group operation. Left translation $\lambda_g$ has inverse $\lambda_{g^{-1}}$, hence is a bijection and a homeomorphism; similarly $\rho_g$ has inverse $\rho_{g^{-1}}$. If $\lambda_g(x) = x$ for some $x \in G$, i.e. $gx = x$, then $g = (gx)x^{-1} = xx^{-1} = e$, and similarly for $\rho_g$.

**XVI.1.2.8.** **Corollary.** If $G$ is a topological group, then the topology of $G$ is *homogeneous*, i.e. if $x, y \in G$, then there is a homeomorphism from $G$ to $G$ sending $x$ to $y$.

**Proof:** $\lambda_{yx^{-1}}$ is such a homeomorphism.

Thus a topological group “looks the same” around every point.
XVI.1.2.9. Similarly, inversion \( \iota \), where \( \iota(x) = x^{-1} \), is a continuous map from \( G \) to \( G \) which is its own inverse, i.e. \( \iota \) is a homeomorphism.

The next result, although simple, appears quite bizarre and surprising at first glance, and is a dramatic illustration of the maxim that being open is not the opposite of being closed for subsets of a topological space. See Exercise XVI.1.7.2. for a generalization.

XVI.1.2.10. **Proposition.** Let \( G \) be a topological group. Any open subgroup of \( G \) is closed.

**Proof:** Let \( H \) be an open subgroup of \( G \). Then, for any \( g \in G \), the left coset \( gH \) is the image of \( H \) under the homeomorphism \( \lambda_g \), and hence \( gH \) is also open. The complement of \( H \) in \( G \) is the union of the nonidentity left cosets of \( H \) in \( G \), hence open. \( \Box \)

See Exercise XVI.1.7.2. for an alternate proof.

**Fundamental Systems of Neighborhoods**

XVI.1.2.11. If \( G \) is a topological group and \( U \) is a neighborhood of \( e \), then for any \( g \in G \), \( gU = \lambda_g(U) \) and \( Ug = \rho_g(U) \) are neighborhoods of \( g \), and conversely if \( V \) is a neighborhood of \( g \) then \( g^{-1}V \) and \( Vg^{-1} \) are neighborhoods of \( e \). Thus to describe a topological group topology on a group \( G \), it suffices to specify the neighborhoods of \( e \).

XVI.1.2.12. If \( A \) and \( B \) are subsets of \( G \), write \( AB = \{ xy : x \in A, y \in B \} \), and \( A^2 = AA \). If \( A, B, C \) are subsets of \( G \), then \( (AB)C = A(BC) \) by associativity; call this subset \( ABC \). Products of more than three subsets can be defined similarly. \( A^n \) has an unambiguous meaning for any \( n \in \mathbb{N} \), and \( A^nA^m = A^{n+m} \).

If \( A \subseteq G \), write \( A^{-1} = \iota(A) = \{ x^{-1} : x \in A \} \).

XVI.1.2.13. **Proposition.** If \( G \) is a topological group, \( A, B \subseteq G \), and one of \( A, B \) is open, then \( AB \) is open. If \( A \) is open, then \( A^{-1} \) is also open.

**Proof:** If \( B \) is open, then \( AB = \lambda_a(B) \) is open for each \( a \in A \), so \( AB = \bigcup_{a \in A} aB \) is open. The proof if \( A \) is open is similar. \( A^{-1} = \iota(A) \) is open if \( A \) is. \( \Box \)

XVI.1.2.14. **Proposition.** Let \( G \) be a topological group. The collection \( \mathcal{N}_e \) of neighborhoods of \( e \) has the following properties:

(i) If \( U \in \mathcal{N}_e \), then there is a \( V \in \mathcal{N}_e \) with \( V^2 \subseteq U^o \).

(ii) There is a \( W \in \mathcal{N}_e \) with \( W = W^{-1} \) and \( W \subseteq U^o \).

(iii) For every \( g \in G \), there is a \( V \in \mathcal{N}_e \) with \( gVg^{-1} \subseteq U^o \).

**Proof:** (i): Let \( \mu : G \times G \to G \) be multiplication, i.e. \( \mu(x, y) = xy \). Then \( \mu^{-1}(U^o) \) is an open neighborhood of \( (e, e) \) in \( G \times G \), hence contains a neighborhood of the form \( V_1 \times V_2 \) where each \( V_j \) is in \( \mathcal{N}_e \). Set \( V = V_1 \cap V_2 \).

(ii): Set \( W = U^o \cap (U^o)^{-1} \).

(iii): Set \( V = g^{-1}U^o g = \rho_g(\lambda_g^{-1}(U^o)) = \lambda_g^{-1}(\rho_g(U^o)) \), which is in \( \mathcal{N}_e \). \( \Box \)
XVI.1.2.15. Corollary. If $G$ is a topological group, and $\mathcal{F}$ is a local base at $e$ for the topology (not necessarily consisting of open sets), then $\mathcal{F}$ has the following properties:

(i) If $U, V \in \mathcal{F}$, then there is a $W \in \mathcal{F}$ with $W \subseteq U \cap V$.
(ii) If $U \in \mathcal{F}$ and $g \in U$, then there is a $V \in \mathcal{F}$ with $Vg \subseteq U$.
(iii) If $U \in \mathcal{F}$, then there is a $V \in \mathcal{F}$ with $V^{-1}V \subseteq U$.
(iv) If $U \in \mathcal{F}$ and $g \in G$, then there is a $V \in \mathcal{F}$ with $gV^{-1} \subseteq U$.

Such an $\mathcal{F}$ has additional properties such as:

(iiiia) If $U \in \mathcal{F}$, there is a $V \in \mathcal{F}$ with $V^2 \subseteq U$.
(iiib) If $U \in \mathcal{F}$, there is a $V \in \mathcal{F}$ with $V^{-1} \subseteq U$.

In fact, (iiiia) and (iiib) together are equivalent to (iii).

XVI.1.2.16. Definition. Let $G$ be a group. A fundamental system of neighborhoods of $e$ is a nonempty collection $\mathcal{F}$ of subsets of $G$, each containing $e$, satisfying (i)–(iv) of XVI.1.2.15. (or equivalently (i), (ii), (iiiia), (iiib), (iv)).

Note that in this definition, there is no specified topology on $G$, so the sets in $\mathcal{F}$ are not “neighborhoods” of $e$ in $G$ in the usual sense of the term. But the terminology is justified by:

XVI.1.2.17. Theorem. Let $G$ be a group. If $\mathcal{F}$ is a fundamental system of neighborhoods of $e$ in $G$, then there is a unique topology $T$ on $G$ making $G$ a topological group, for which $\mathcal{F}$ is a local base at $e$.

XVI.1.2.18. So a topological group topology on a group $G$ can be specified by giving a fundamental system of neighborhoods of $e$, and every topological group topology on $G$ arises in this manner. Specifying a topology via a fundamental system of neighborhoods of $e$ is one of the most convenient ways of defining topologies on groups.

Homogeneous Spaces and Quotients

XVI.1.2.19. If $G$ is a topological group and $H$ a subgroup of $G$, not necessarily normal, we can form the left coset space $G/H$. Since $G/H$ is a set-theoretic quotient of $G$, i.e. there is a natural quotient map $\pi : G \to G/H$, we may give $G/H$ the quotient topology. $G/H$ with this topology is called the homogeneous space of $G$ by $H$ (the terminology is justified by XVI.1.2.20.(ii)).
**XVI.1.2.20.** **Proposition.** Let $G$ be a topological group and $H$ a subgroup of $G$. Let $G/H$ be the homogeneous space. Then

(i) The quotient map $\pi : G \to G/H$ is continuous and open.

(ii) If $g \in G$, the map $\tilde{\lambda}_g : G/H \to G/H$ defined by $\tilde{\lambda}_g(xH) = gxH$ is a well-defined homeomorphism, and in particular the topology of $G/H$ is homogeneous in the sense of XVI.1.2.8. The map $(g, xH) \mapsto \lambda_g(xH) = gxH$ is continuous from $G \times G/H$ to $G/H$.

**Proof:** (i) The quotient map $\pi$ is continuous by definition of the quotient topology. If $U$ is open in $G$, then $\pi^{-1}(\pi(U)) = UH$, which is open in $G$ by XVI.1.2.13.; hence $\pi(U)$ is open in $G/H$ by definition of the quotient topology.

(ii): If $xH = yH$, i.e. $y = xz$ for some $z \in H$, then $gy = gxz$, so $gy \in gxH$, i.e. $gyH = gxH$ and $\tilde{\lambda}_g$ is well defined, and is a bijection since $\lambda_g^{-1} = \tilde{\lambda}_g^{-1}$. If $V \subseteq G/H$ is open, then $\pi^{-1}(V)$ is open in $G$, so $\lambda_g^{-1}(\pi^{-1}(V))$ is open in $G$ since $\lambda_g^{-1}$ is a homeomorphism on $G$; thus $\lambda_g^{-1}(V) = \pi(\lambda_g^{-1}(\pi^{-1}(V)))$ is open by (i). So $\lambda_g$ is continuous. Since $\lambda_g^{-1} = \tilde{\lambda}_g^{-1}$ is also continuous, $\tilde{\lambda}_g$ is a homeomorphism. For the last statement, if $x, y \in G$, then $\tilde{\lambda}_{xy^{-1}}$ sends $xH$ to $yH$, so $G/H$ is homogeneous.

**XVI.1.2.21.** **Proposition.** Let $G$ be a topological group, and $H$ a closed normal subgroup. Then

(i) $G/H$ is a topological group in the quotient topology.

(ii) If $G'$ is another topological group, and $\phi : G \to G'$ a continuous homomorphism whose kernel contains $H$, then the induced homomorphism $\psi : G/H \to G'$ () is continuous.

**Proof:** (i): Let $\tilde{V}$ be an open set in $G/H$, and let $V = \pi^{-1}(\tilde{V})$. Then $V$ is open in $G$. Since $\mu$ is continuous, $U = \mu^{-1}(V)$ is open in $G \times G$. The quotient map $\pi \times \pi$ from $G \times G$ to $(G/H) \times (G/H)$ is open, so $U = (\pi \times \pi)(U)$ is open in $(G/H) \times (G/H)$, and $U = \tilde{\mu}^{-1}(\tilde{V})$. Thus $\tilde{\mu}$ is continuous. A similar argument shows that $\tilde{\psi}$ is continuous on $G/H$.

The homeomorphisms $\tilde{\lambda}_g$ are an example of a group action:

**XVI.1.2.22.** **Definition.** Let $G$ be a topological group and $X$ a topological space. A group action of $G$ on $X$ is a continuous function $(g, x) \mapsto \alpha_g(x)$ from $G \times X$ to $X$ such that $\alpha_e(x) = x$ and $\alpha_{gh}(x) = \alpha_g(\alpha_h(x))$ for all $x \in X$, $g, h \in G$.

**XVI.1.2.23.** The point $\alpha_g(x)$ is often written $g \cdot x$. For fixed $g$, $\alpha_g$ is a continuous function from $X$ to $X$ with inverse $\alpha_{g^{-1}}$, i.e. $\alpha_g$ is a homeomorphism from $X$ to $X$. The map $\alpha : G \to \text{Homeo}(X)$ is a group-homomorphism, which is continuous if $\text{Homeo}(X)$ is given the topology of pointwise convergence.

**Separation Axioms**
Topological groups automatically have nice separation properties:

1895
XVI.1.2.24. **Proposition.** Let $G$ be a topological group. The following are equivalent:

(i) $G$ is $T_0$.

(ii) $G$ is Hausdorff.

(iii) $G$ is completely regular.

**Proof:** (iii) $\Rightarrow$ (ii) $\Rightarrow$ (i) is trivial. Since the topology on $G$ comes from a uniform structure (XVI.1.3.4.), if $G$ is $T_0$, it is completely regular, so (i) $\Rightarrow$ (iii).

XVI.1.2.25. There is a simple direct proof that a topological group is $T_3$, and hence that a $T_0$ topological group is Hausdorff; cf. Exercise XVI.1.7.3.

XVI.1.2.26. **Corollary.** A second countable $T_0$ topological group is metrizable.

One can do much better (XVI.1.3.7.).

**Closed Subgroups**

XVI.1.2.27. **Proposition.** Let $G$ be a topological group, and $H$ a subgroup. Then $G/H$ is Hausdorff (completely regular) if and only if $H$ is closed in $G$.

XVI.1.2.28. **Proposition.** Let $G$ be a topological group, and $H$ a subgroup of $G$. Then $\bar{H}$ is also a subgroup of $G$. If $H$ is a normal subgroup, so is $\bar{H}$.

XVI.1.2.29. Thus $\langle e \rangle$ is the smallest closed subgroup of $G$. It is normal, and $G/\langle e \rangle$ is the largest Hausdorff quotient group of $G$. Any continuous homomorphism from $G$ into a Hausdorff topological group factors through $G/\langle e \rangle$. The space $G/\langle e \rangle$ is the maximal $T_0$ quotient of $G$ in the sense of ()

**Products of Topological Groups**

XVI.1.2.30. **Proposition.** Any product of topological groups is a topological group with the product topology.

**Inverse Limits**

**Connectedness**

XVI.1.2.31. **Proposition.** Let $G$ be a topological group. If $U$ is any open neighborhood of $e$ in $G$, then the subgroup of $G$ generated by $U$ is open, and coincides with the subgroup of $G$ generated by $\bar{U}$.

**Proof:** The subset $[U \cup (U^{-1})]^n$ of $G$ is open for each $n$ by XVI.1.2.13. The subgroup of $G$ generated by $U$ is $\bigcup_{n=1}^{\infty}[U \cup (U^{-1})]^n$. Since an open subgroup is closed (XVI.1.2.10.), this subgroup contains $\bar{U}$.

1896
XVI.1.2.32.  COROLLARY. Let $G$ be a connected topological group. Then every neighborhood of $e$ generates $G$ as a group.

Proof: Every open subgroup of a topological group is clopen, so a connected topological group cannot contain any proper open subgroups. Every neighborhood of $e$ in $G$ contains an open neighborhood of $e$.  

XVI.1.2.33.  PROPOSITION. Let $G$ be a topological group and $H$ a subgroup. If $H$ and $G/H$ are connected, then $G$ is connected.

Proof: Suppose $H$ is connected and $G$ is not connected. Let $U$ and $V$ be nonempty disjoint clopen sets in $G$ with $U \cup V = G$. Since each left coset of $H$ is connected, it is entirely contained in either $U$ or $V$, i.e. $U$ and $V$ are each unions of left cosets of $H$. But then $\pi(U)$ and $\pi(V)$ are disjoint clopen subsets of $G/H$, so $G/H$ is not connected.

XVI.1.2.34.  PROPOSITION. Let $G$ be a topological group. Then the connected component of the identity $e$ is a closed normal subgroup $H$ of $G$, and $G/H$ is totally disconnected.

Proof: Let $H$ be the connected component of $e$ in $G$. Then $H$ is a closed subset of $G$. $H \times H$ is a connected subset of $G \times G$, and hence its image $H^2$ in $G$ under multiplication is connected, and contains $e$; thus $H^2 \subseteq H$, i.e. $H$ is closed under multiplication. Similarly, $H^{-1}$ is connected and contains $e$, thus $H^{-1} \subseteq H$ and $H$ is closed under inversion. So $H$ is a subgroup of $G$. If $g \in G$, then $gHg^{-1}$ is a connected subset of $G$, hence $gHg^{-1} \subseteq H$. Then $H = g^{-1}(gHg^{-1})g \subseteq g^{-1}Hg \subseteq H$, so $g^{-1}Hg = H$ and $H$ is normal.

To see that $G/H$ is totally disconnected, it suffices to show that the connected component of $\bar{e}$ in $G/H$ is $\{\bar{e}\}$. Let $K$ be the connected component of $\bar{e}$ in $G/H$, and $G' = \pi^{-1}(K)$. Then $G'$ is a subgroup of $G$ and $G'/H \cong K$ is connected, and since $H$ is connected, $G'$ is connected by XVI.1.2.33. Since $H \subseteq G'$, we have $G' = H$ so $K = \{\bar{e}\}$.

XVI.1.3. Uniformities on Topological Groups

Every topological group has a natural uniform structure (actually three natural uniform structures which may or may not coincide). In fact, these uniform structures are one of the models for general uniform structures ()

XVI.1.3.1.  DEFINITION. Let $(G, T)$ be a topological group.

(i) The left uniform structure $\mathcal{L}$ on $G$ is the uniform structure generated by the sets

$$L_U = \{(x, y) \in G \times G : x^{-1}y \in U\}$$

as $U$ ranges over all open neighborhoods of $e$ in $G$.

(ii) The right uniform structure $\mathcal{R}$ on $G$ is the uniform structure generated by the sets

$$R_U = \{(x, y) \in G \times G : xy^{-1} \in U\}$$

as $U$ ranges over all open neighborhoods of $e$ in $G$.

(iii) The two-sided uniform structure $\mathcal{U}$ on $G$ is the uniform structure generated by the sets $L_U$ and $R_U$ as $U$ ranges over all open neighborhoods of $e$ in $G$.  

1897
XVI.1.3.2. The uniform structures $\mathcal{L}$ and $\mathcal{R}$ coincide in many cases, e.g. if $G$ is compact () or abelian, but not in general (). The uniform structure $\mathcal{U}$ coincides with $\mathcal{L}$ or $\mathcal{R}$ if and only if $\mathcal{L} = \mathcal{R}$.

XVI.1.3.3. **Proposition.** Let $G$ be a topological group. The following are equivalent:

(i) $\mathcal{L} = \mathcal{R}$.

(ii) $\mathcal{L} = \mathcal{U}$.

(iii) $\mathcal{R} = \mathcal{U}$.

(iv) $G$ has a fundamental system of neighborhoods of $e$ invariant under all inner automorphisms, i.e. neighborhoods $U$ such that $gUg^{-1} = U$ for all $g \in G$.

However, even though the uniform structures do not coincide in general, they all define the given topology on $G$:

XVI.1.3.4. **Proposition.** Let $(G, T)$ be a topological group. Then the topology on $G$ defined by any of the three uniform structures $\mathcal{L}, \mathcal{R}, \mathcal{U}$ is $T$.

XVI.1.3.5. **Proposition.** Let $G$ be a topological group. Then

(i) The translations $\lambda_g$ are uniformly continuous for $\mathcal{L}$ and $\mathcal{U}$, for every $g \in G$.

(ii) The translations $\rho_g$ are uniformly continuous for $\mathcal{R}$ and $\mathcal{U}$, for every $g \in G$.

(iii) Inversion $\iota$ is uniformly continuous for $\mathcal{U}$.

Inversion is not uniformly continuous for $\mathcal{L}$ or $\mathcal{R}$ in general: inversion interchanges $\mathcal{L}$ and $\mathcal{R}$. In fact:

XVI.1.3.6. **Proposition.** Let $G$ be a topological group. The following are equivalent:

(i) The translations $\lambda_g$ are uniformly continuous for $\mathcal{R}$, for every $g \in G$.

(ii) The translations $\rho_g$ are uniformly continuous for $\mathcal{L}$, for every $g \in G$.

(iii) Inversion $\iota$ is uniformly continuous for $\mathcal{L}$.

(iv) Inversion $\iota$ is uniformly continuous for $\mathcal{R}$.

(v) $\mathcal{L} = \mathcal{R}(= \mathcal{U})$. 

1898
Metrization

It is an immediate corollary of XVI.1.3.4. and () that a first countable topological group is metrizable, since \( \mathcal{L} \), \( \mathcal{R} \), and \( \mathcal{U} \) are all countably generated if \( G \) is first countable. There is a more precise result:

XVI.1.3.7. **Corollary.** Every first countable Hausdorff topological group is metrizable under a left-invariant metric which generates the uniformity \( \mathcal{L} \).

XVI.1.3.8. If \( d \) is a left-invariant metric for \( G \), then the metric \( d'(g,h) = d(g^{-1}, h^{-1}) \) is right-invariant and defines the topology of \( G \) (and the uniformity \( \mathcal{R} \)), so “left-invariant” can be replaced by “right-invariant” in XVI.1.3.7.

However, \( G \) does not have a two-sided invariant metric in general; in fact, it has a two-sided invariant metric if and only if it satisfies the conditions of XVI.1.3.6. There is a metric giving the uniformity \( \mathcal{U} \) if \( G \) is first countable, for example

\[
d'(g,h) = d(g,h) + d(g^{-1}, h^{-1})
\]

if \( d \) is left-invariant; but \( d' \) is neither left- or right-invariant unless \( \mathcal{L} = \mathcal{R} = \mathcal{U} \).

Completion

XVI.1.3.9. **Definition.** A topological group \( G \) is complete if it is complete with respect to the uniformity \( \mathcal{U} \).

A group which is complete in this sense is often called *Raikov-complete*.

XVI.1.3.10. **Proposition.** Let \( G \) be a complete topological group, and \( H \) a subgroup. Then

(i) \( H \) is complete if and only if it is closed in \( G \).

(ii) If \( H \) is normal, then \( G/H \) is complete.

XVI.1.3.11. **Theorem.** Let \( G \) be a topological group. Then there is a complete topological group \( \hat{G} \) containing \( G \) as a dense subgroup. \( \hat{G} \) is unique up to topological isomorphism which is the identity on \( G \). \( \hat{G} \) is called the completion, or Raikov completion, of \( G \).

XVI.1.3.12. A topological group \( G \) does not generally have a completion with respect to \( \mathcal{L} \) or \( \mathcal{R} \) (more precisely, the completion of \( G \) with respect to \( \mathcal{L} \) or \( \mathcal{R} \) as a uniform space, called the Weil completion of \( G \), does not have a compatible structure as a topological group in general); in fact, it has such a completion (as a topological group) if and only if \( \mathcal{L} = \mathcal{R} \).

XVI.1.4. **Locally Compact Topological Groups**

Topological groups which are locally compact and Hausdorff are especially important, and have a lot of nice associated structure which allows analysis to be done on them.
**XVI.1.4.1. Definition.** A *locally compact group* is a locally compact Hausdorff topological group, i.e. a topological group whose topology is locally compact and Hausdorff. A *compact group* is a compact Hausdorff topological group.

Thus the words “Hausdorff” and “topological” will be understood in the names “locally compact group” and “compact group.”

**XVI.1.4.2. Examples.**

(i) The additive group $\mathbb{R}$, or $\mathbb{R}^n$, with its usual topology, is a locally compact group.

(ii) The group $GL_n(\mathbb{R})$ (XVI.1.2.3. (iii)) is locally compact (in its usual topology).

(iii) $\mathbb{T}$ is a compact group (in its usual topology). Any product of copies of $\mathbb{T}$ is a compact group.

(iv) Any group with the discrete topology is a locally compact group.

(v) Any closed subgroup of a locally compact group is locally compact.

(vi) The additive group of an infinite-dimensional normed vector space is not a locally compact group in the norm topology.

(vii) The additive group $\mathbb{Q}$ is not a locally compact group in its usual topology (the relative topology from $\mathbb{R}$). But it is in the discrete topology.

By homogeneity, we obtain:

**XVI.1.4.3. Proposition.** A Hausdorff topological group $G$ is locally compact if and only if there is a compact neighborhood of $e$ in $G$.

**XVI.1.4.4. Proposition.** Let $G$ be a locally compact group. Then $G$ has an open subgroup which is $\sigma$-compact. If $G$ is connected, it is $\sigma$-compact.

**Proof:** Let $U$ be a neighborhood of $e$ in $G$ with $\bar{U}$ compact. Let $H$ be the subgroup of $G$ generated by $U$. Then $H$ is open and is the subgroup of $G$ generated by $\bar{U}$ (XVI.1.2.31.). If $V = U \cup U^{-1}$, then $\bar{V}$ is compact and generates $H$. We have that $\bar{V}^n$ is compact since it is the image of $\bar{V} \times \bar{V}$ under multiplication; by induction, $\bar{V}^n$ is compact for all $n$. Thus $H = \cup_{n=1}^{\infty} \bar{V}^n$ is $\sigma$-compact.

**XVI.1.4.5. Corollary.** Let $G$ be a locally compact group. Then $G$ partitions into clopen subsets, each of which is $\sigma$-compact and thus Lindelöf. So $G$ is paracompact and hence normal.

**Proof:** The cosets of a $\sigma$-compact open subgroup give such a partition.
**Corollary.** Let $G$ be a locally compact group. The following are equivalent:

(i) $G$ is second countable.

(ii) $G$ is first countable and $\sigma$-compact.

(iii) $G$ is first countable and compactly generated.

**Proposition.** Let $G$ be a topological group, $K$ a compact subset of $G$, and $U$ an open neighborhood of $K$. Then there is an open neighborhood $V$ of $e$ in $G$ such that $KV \subseteq U$.

**Proof:** For each $g \in K$, $ge \in U$, so by joint continuity there are neighborhoods $W_g$ of $g$ and $V_g$ of $e$ with $W_gV_g \subseteq U$. The $W_g$ cover $K$, so there is a finite subcover $\{W_{g_1}, \ldots, W_{g_n}\}$. Set $V = V_{g_1} \cap \cdots \cap V_{g_n}$. If $g \in K$, then $g \in W_{g_k}$ for some $k$, so $gV \subseteq W_{g_k}V \subseteq W_{g_k}V_{g_k} \subseteq U$. Thus $KV \subseteq U$.

Similarly, we have:

**Proposition.** Let $G$ be a topological group, $K$ a compact subset of $G$, and $U$ an open neighborhood of $e$ in $G$ such that $g^{-1}Vg \subseteq U$ for all $g \in K$.

**Proof:** For each $g \in K$, $g^{-1}eg = e$, so by joint continuity there are neighborhoods $W_g$ of $g$ and $V_g$ of $e$ with $h^{-1}Vgh \subseteq U$ for all $h \in W_g$. The $W_g$ cover $K$, so there is a finite subcover $\{W_{g_1}, \ldots, W_{g_n}\}$. Set $V = V_{g_1} \cap \cdots \cap V_{g_n}$. If $g \in K$, then $g \in W_{a_k}$ for some $k$, so $g^{-1}Vg \subseteq g^{-1}V_{g_k}g \subseteq U$.

**Proposition.** Let $G$ be a (necessarily locally compact) group. If $U$ is a compact open neighborhood of $e$ in $G$, then $U$ contains a compact open subgroup of $G$.

**Proof:** There is a neighborhood $V$ of $G$ with $V = V^{-1}$ and $UV \subseteq U$ (XVI.1.4.7 with $K = U$). Then $V^2 \subseteq U$, and by induction $V^n \subseteq U$. Thus the subgroup of $G$ generated by $V$, which is open, is contained in $U$.

**Theorem.** Let $G$ be a locally compact group. Then every neighborhood of $e$ in $G$ contains a compact subgroup $H$ such that $G/H$ is metrizable. If $G$ is compactly generated, the subgroup $H$ may be chosen normal.

**Proof:** First let $U$ be a compact neighborhood of $e$ in $G$, and let $G_0$ be the subgroup of $G$ generated by $U$. Then $G_0$ is an open subgroup. If $H$ is a subgroup of $G_0$, then $G/H$ is a separated union of cosets of $G_0/H$; hence $G/H$ is metrizable if $G_0/H$ is metrizable. Thus it suffices to show the last statement, i.e. that if $G$ is generated by a compact symmetric neighborhood $U$ of $e$, then for any neighborhood $V$ of $e$, $G$ has a compact normal subgroup $H$ contained in $V$ with $G/H$ metrizable (first countable).

Fix a neighborhood $V$, which we may take to be compact and symmetric. Set $V_1 = V$. Generate a decreasing sequence $(V_n)$ of symmetric compact neighborhoods of $e$ such that $g^{-1}V_{n+1}g \subseteq V_n$ for all $g \in U$.
(XVI.1.4.8.) and such that $V_{n+1}^2 \subseteq V_n$. Set $H = \cap_n V_n$. Then $H$ is a compact subgroup of $G$, and $g^{-1}Hg \subseteq H$ for all $g \in U$; since $U$ generates $G$, $H$ is normal in $G$. If $\pi : G \to G/H$ is the quotient map, the sets $(\pi(V_n))$ are compact neighborhoods of the identity which form a local neighborhood base by XI.11.1.13. Thus $G/H$ is first countable.

**XVI.1.4.11.** PROPOSITION. Every locally compact group is complete.

**XVI.1.4.12.** PROPOSITION. Let $G$ be a locally compact group and $H$ a closed subgroup. Then $G/H$ is locally compact in the quotient topology. So if $H$ is normal, $G/H$ is a locally compact group.

The next result is closely related to the Open Mapping Theorem for Banach spaces (), with a similar proof based on the Baire Category Theorem. This result is a special case of XVI.1.6.2.

**XVI.1.4.13.** THEOREM. [Open Mapping Theorem for Locally Compact Groups] Let $G$ and $G'$ be locally compact groups, and $\phi$ a continuous group homomorphism from $G$ onto $G'$. If $G$ is $\sigma$-compact (so $G'$ is also $\sigma$-compact), then $\phi$ is an open mapping, and thus $G'$ is topologically isomorphic to $G/\ker(\phi)$.

As in the Banach space case (), we also get a Closed Graph Theorem for locally compact groups:

**XVI.1.4.14.** THEOREM. [Closed Graph Theorem for Locally Compact Groups] Let $G$ and $G'$ be $\sigma$-compact locally compact groups, and $\phi : G \to G'$ a homomorphism. If the graph $\Gamma(\phi)$ is a closed subset of $G \times G'$, then $\phi$ is continuous.

**Proof:** $G \times G'$ is locally compact and $\sigma$-compact, and $\Gamma(\phi)$ is a closed subgroup, hence also locally compact and $\sigma$-compact. The map $\pi_G : (x, \phi(x)) \mapsto x$ is a continuous bijective homomorphism from $\Gamma(\phi)$ onto $G$, hence a topological isomorphism by XVI.1.4.13.; thus the inverse map $\psi$ is continuous, and hence $\phi = \pi_{G'} \circ \psi$ is continuous.

**XVI.1.4.15.** COROLLARY. Let $G$ be a group, and let $\mathcal{T}$ be a Hausdorff topology on $G$, not necessarily a topological group topology. Then there is at most one topology on $G$ stronger than $\mathcal{T}$ making it into a $\sigma$-compact locally compact group.

**Proof:** Let $\mathcal{T}_1$ and $\mathcal{T}_2$ be topologies stronger than $\mathcal{T}$ making $G$ into a locally compact $\sigma$-compact group, and let $\phi$ be the identity map from $(G, \mathcal{T}_1)$ to $(G, \mathcal{T}_2)$. The graph of $\phi$ is the diagonal in $G \times G$. The product topology $\mathcal{T}_1 \times \mathcal{T}_2$ on $G \times G$ is stronger than the topology $\mathcal{T} \times \mathcal{T}$. Since $\mathcal{T}$ is Hausdorff, the diagonal is closed in $G \times G$ for the topology $\mathcal{T} \times \mathcal{T}$, and hence also closed in the topology $\mathcal{T}_1 \times \mathcal{T}_2$. Thus $\phi$ has closed graph and is therefore continuous, i.e. $\mathcal{T}_1$ is stronger than $\mathcal{T}_2$. The same argument with $\mathcal{T}_1$ and $\mathcal{T}_2$ interchanged shows that $\mathcal{T}_2$ is stronger than $\mathcal{T}_1$. □

1902
XVI.1.4.16. XVI.1.4.13–XVI.1.4.15. are false in general without “σ-compact”: the additive group \( \mathbb{R} \) is a locally compact group in either the ordinary topology or the discrete topology. The \( T \) in XVI.1.4.15. is also necessary in general if \( G \) is uncountable: \( \mathbb{R} \) has discontinuous group-automorphisms (using AC).

XVI.1.4.17. XVI.1.4.15. does not say that a group has at most one σ-compact Hausdorff topology making it into a topological group. In fact, there is an abelian group \( G \) which has \( 2^{\aleph_0} \) mutually nonequivalent topological group topologies, each of which is compact and metrizable [Fuc59] (where two topological group topologies \( T_1 \) and \( T_2 \) on a group \( G \) are equivalent if \( (G, T_1) \) and \( (G, T_2) \) are isomorphic as topological groups). However, we do have:

XVI.1.4.18. Corollary. The only locally compact group topology on a countable group is the discrete topology.

Any closed subgroup of a locally compact group is locally compact (). Conversely:

XVI.1.4.19. Theorem. Let \( G \) be a Hausdorff topological group, and \( H \) a subgroup which is locally compact in the relative topology. Then \( H \) is a closed subgroup of \( G \).

XVI.1.5. Polish Groups and Baire Groups

XVI.1.5.1. Definition. A Polish group is a topological group which is a Polish space (), i.e. homeomorphic to a separable complete metric space.

XVI.1.5.2. There is a large overlap between the class of locally compact groups and the class of Polish groups: the overlap consists precisely of the second countable locally compact groups (XVI.1.4.6.). The theory of Polish groups is to a large extent similar and parallel to the theory of locally compact groups. Except for one little thing: Polish groups which are not locally compact do not have Haar measure, so the most crucial tool for analysis is lacking. Thus the theory of Polish groups is not as satisfactory overall as that of locally compact groups.

There are many important topological groups which are Polish but not locally compact, for example:

XVI.1.5.3. Examples. (i) The additive group of any separable Banach space is a Polish group.
(ii) The multiplicative group of invertible elements in any separable Banach algebra is a Polish group in the relative norm topology (),().
(iii) The group of unitary operators on a separable Hilbert space is a Polish group under the strong or weak operator topologies (which coincide on this group; cf. ()).
(iv) The group of homeomorphisms of a compact metric space is a Polish group in the topology of uniform convergence ()
(v) The group of isometries of a separable complete metric space is a Polish group in the topology of pointwise convergence (which coincides with the topology of u.c. convergence; cf. ()).
(vi) Any closed subgroup of a Polish group is a Polish group.
(vii) A countable product of Polish groups is a Polish group.

XVI.1.5.4. There is one sense in which Polish groups are nicer than locally compact groups: there is a universal Polish group $\tilde{G}$, a Polish group with the property that every Polish group is topologically isomorphic to a closed subgroup of $\tilde{G}$. In fact, the group of homeomorphisms of the Hilbert cube with the topology of uniform convergence is such a universal group ([Usp86]; cf. [Kec95, 9.18]).

XVI.1.6. Open Mappings and Automatic Continuity

In this section, we collect together some miscellaneous results about when surjective homomorphisms of topological groups are automatically open mappings, and when group operations and group actions are automatically continuous.

We first give simple criteria for when homomorphisms are continuous or open:

XVI.1.6.1. Proposition. Let $G$ and $G'$ be topological groups, and $\phi : G \to G'$ a group-homomorphism. Then:

(i) If $\phi$ is continuous at one point, then it is continuous everywhere.
(ii) $\phi$ is an open mapping if and only if, for every open neighborhood $U$ of $e$, $\phi(U)$ has nonempty interior (i.e. contains a nonempty open set).

Proof: (i): Suppose $\phi$ is continuous at $g$, i.e. if $g_i \to g$, then $\phi(g_i) \to \phi(g)$. If $x_i, x \in G$ and $x_i \to x$, then $gx^{-1}x_i \to g$, so

$$\phi(g)\phi(x)^{-1}\phi(x_i) = \phi(gx^{-1}x_i) \to \phi(g)$$

and thus

$$\phi(x_i) = \phi(x)\phi(g)^{-1}\phi(g)\phi(x)^{-1}\phi(x_i) \to \phi(x)\phi(g)^{-1}\phi(g) = \phi(x).$$

The first main result is a general version of XVI.1.4.13.: 

XVI.1.6.2. Theorem. [Open Mapping Theorem for $\sigma$-Compact Groups] Let $G$ and $G'$ be topological groups, with $G'$ a Baire group, and $\phi$ a continuous group homomorphism from $G$ onto $G'$. If $G$ is $\sigma$-compact (so $G'$ is also $\sigma$-compact), then $\phi$ is an open mapping, and thus $G'$ is topologically isomorphic to $G/\ker(\phi)$.

Proof: The homomorphism $\phi$ factors topologically through $G/\ker(\phi)$, so we may assume without loss of generality that $\phi$ is a bijection. Let $G = \bigcup_{n=1}^{\infty} K_n$, with $K_n$ compact. Then $G' = \bigcup_{n=1}^{\infty} \phi(K_n)$, and $\phi(K_n)$ is compact and hence closed in $G'$ since $G'$ is Hausdorff. By the Baire Category Theorem, some $\phi(K_n)$ has nonempty interior $V$. The restriction of $\phi$ to $K_n$ is a homeomorphism, so $\phi^{-1}$ is continuous on $V$ since $V$ is open. Since $V$ is nonempty, $\phi^{-1}$ is continuous (XVI.1.6.1.(ii)), i.e. $\phi$ is an open map.
XVI.1.6.3. Note that no hypothesis on \( G \) beyond \( \sigma \)-compactness is needed, not even an assumption that \( G \) is Hausdorff. This proof is attributed to H. GLÖCKNER, who observed that the local compactness hypothesis on \( G \) in many references is not necessary.

XVI.1.6.4. Corollary. Let \( G \) be a countable group. Then the only Polish topological group topology on \( G \) is the discrete topology.

XVI.1.7. Exercises

XVI.1.7.1. Let \( G \) be the additive group of real numbers. Give \( G \) the Sorgenfrey topology (XI.7.8.10.). Show that the group operation (addition) is jointly continuous (i.e. continuous from \( G \times G \) to \( G \)), but that inversion (negation) is not continuous. Thus \((\mathbb{R},+)\) with this topology is not a topological group.

XVI.1.7.2. Let \( G \) be a topological group, and \( A \) a subset of \( G \). Show that the closure of \( A \) is contained in \( AV \) for any neighborhood \( V \) of \( e \), and in particular \( U^2 \) if \( U \) is a neighborhood of \( e \) in \( G \). [If \( g \in A \), then \( gV^{-1} \cap A \neq \emptyset \).]

XVI.1.7.3. (a) Use XVI.1.7.2. and XVI.1.2.14.(i) to give a direct proof that a topological group is \( T_3 \) (cf. XI.7.5.1.).
(b) Give a direct proof that a \( T_0 \) topological group is Hausdorff.

XVI.1.7.4. (a) Let \( G \) be a topological group and \( H \) a subgroup. If \( H \) contains a neighborhood of \( e \), show that \( H \) is open. Thus the hypothesis in XVI.1.2.31. that \( U \) be an open neighborhood can be relaxed to just requiring that \( U \) be a neighborhood.
(b) Show that a closed subgroup of a topological group is either open or nowhere dense.

XVI.1.7.5. Let \( G \) be a topological group, and \( U \) an open neighborhood of \( e \) in \( G \). Set \( W = \cup_{n=1}^{\infty} U^n \).
(a) Show that \( W \) is a clopen subset of \( G \).
(b) \( W \) need not be a subgroup of \( G \). [Consider \( \{0,1\} \subseteq \mathbb{Z} \) with the discrete topology.]
(c) If \( G \) is connected, then \( W = G \).

XVI.1.7.6. How much of the theory of topological groups requires joint continuity of multiplication? That is, if we change the definition of a topological group \( G \) to only require continuity of inversion and separate continuity of multiplication (i.e. that \( \iota \) and \( \lambda_g \), \( \rho_g \) are continuous for all \( g \in G \)), how much of the theory persists? [Consider the case where \( G \) is an infinite group with the finite complement topology.]

XVI.1.7.7. For a topological space \( X \) to have a group structure making it a topological group, i.e. for \( X \) to be homeomorphic to a topological group, it is necessary that \( X \) be homogeneous. But this is far from sufficient, even if \( X \) is compact and metrizable.
(a) The Hilbert cube \( \mathbb{H} \) is homogeneous (.), but not homeomorphic to a topological group. [Every continuous function from \( \mathbb{H} \) to \( \mathbb{H} \) has a fixed point (.)].
(b) \( S^n \) for even \( n > 0 \) is not homeomorphic to a topological group. [Use (.)]. In fact, \( S^n \) is homeomorphic to a topological group if and only if \( n \) is 0, 1, or 3 (.), (.)

1905
Groups of Homeomorphisms

If $X$ is a topological space, the group $\text{Homeo}(X)$ of homeomorphisms of $X$ can be given various topologies, e.g. the topology of pointwise convergence or the compact-open topology (which is the topology of u.c. convergence if $X$ is metrizable ())). $\text{Homeo}(X)$ is sometimes, but not always, a topological group under these topologies. The next several problems explore when $\text{Homeo}(X)$, or various natural subgroups, is or is not a topological group.

XVI.1.7.8. Let $X$ be a Hausdorff space. Give $\text{Homeo}(X)$ the compact-open topology. Show that multiplication is jointly continuous.

XVI.1.7.9. Let $X$ be a compact Hausdorff space. Show that $\text{Homeo}(X)$ is a topological group under the compact-open topology (which is the topology of uniform convergence).

XVI.1.7.10. [Are46] Let $X$ be the space $\mathbb{N}_0 \cup \{ \frac{1}{n} : n \in \mathbb{N} \}$, with its relative topology from $\mathbb{R}$. Then $X$ is a locally compact metrizable space. Show that inversion is not continuous in $\text{Homeo}(X)$. [Consider $\phi_n$, where $\phi_n(n) = \frac{1}{n}$, $\phi_n(m) = m - 1$ if $m > n$, $\phi_n(\frac{1}{m}) = \frac{1}{m+1}$ if $m \geq n$, and $\phi_n(x) = x$ otherwise.]

It is shown in [Are46] that if $X$ is locally compact and locally connected, then inversion in $\text{Homeo}(X)$ is continuous in the compact-open topology, and hence $\text{Homeo}(X)$ is a topological group in this topology.

XVI.1.7.11. Let $X$ be a topological space. Give $\text{Homeo}(X)$ the topology of pointwise convergence. Then multiplication is separately continuous.

XVI.1.7.12. Give $\text{Homeo}(\mathbb{R}^2)$ the topology of pointwise convergence. Show that multiplication is not jointly continuous, and that inversion is not continuous.

XVI.1.7.13. Let $X = \mathbb{R}$ or $[0,1]$. Show that the topology of pointwise convergence on $\text{Homeo}(X)$ coincides with the compact-open topology (topology of u.c. convergence), and that $\text{Homeo}(X)$ is a topological group under this topology.

XVI.1.7.14. Let $X$ be a metric space. Show that the group $\text{Isom}(X)$ of isometries (isometric bijections) of $X$ is a topological group in the topology of pointwise convergence.

XVI.1.7.15. Group Topologies on $\mathbb{Z}$, $\mathbb{Q}$, and $\mathbb{R}$. If $G$ is a group and $H$ a (Hausdorff) topological group, and $\phi : G \to H$ is an injective homomorphism, $G$ can be identified with $\phi(G)$ and given the relative topology, which makes $G$ into a (Hausdorff) topological group. In particular, if $H$ is a (Hausdorff) topological group and $x$ is an element of $H$ of infinite order, the map $n \mapsto x^n$ from $\mathbb{Z}$ to $H$ can be used to give a (Hausdorff) topological group topology on $\mathbb{Z}$. This gives an enormous variety of nonequivalent (XVI.1.4.17.) group topologies.

(a) Let $S$ be a nonempty subset of $\mathbb{R}$. If $G = \mathbb{Z}, \mathbb{Q}$, or $\mathbb{R}$, map $G$ into $\prod_{s \in S} T$ by sending $x \in G$ to the point $\phi_S(x)$ with $s$-coordinate $e^{2\pi i sx}$. Show that if $G = \mathbb{Z}$ or $\mathbb{Q}$, then $\phi_S$ is injective unless $S$ is contained in a cyclic subgroup of $(\mathbb{Q}, +)$, and if $G = \mathbb{R}$, then $\phi_S$ is injective unless $S$ is contained in a cyclic subgroup of $(\mathbb{R}, +)$. In these cases, give $G$ the relative topology $\mathcal{T}_S$. The topology $\mathcal{T}_S$ is metrizable (first countable) if and only if $S$ is countable.
(b) Let $B$ be a Hamel basis for $\mathbb{R}$ over $\mathbb{Q}$ consisting of irrational numbers. If $S_1, S_2$ are distinct nonempty subsets of $B$ (not singletons if $G = \mathbb{R}$), show that the topologies $T_{S_1}$ and $T_{S_2}$ are nonequivalent. Conclude that there are $2^{\aleph_0}$ mutually nonequivalent Hausdorff topologies on $G$ making $(G, +)$ a topological group. These topologies are all totally bounded, i.e. the completion is compact. These topologies are all weaker than the ordinary topology on $G$.

(c) The topologies $T_S$ are by no means all the Hausdorff topological group topologies on $(\mathbb{Q}, +)$: for example, the discrete topology, the relative topology from $\mathbb{R}$, and the $n$-adic topologies (III.5.3.9.) are not among them. (The completions with respect to these topologies are locally compact but noncompact.) But there are exactly $2^{\aleph_0}$ distinct topologies on $\mathbb{Q}$. The only locally compact or Polish topological group topology on $(\mathbb{Q}, +)$ is the discrete topology. Similar statements are true for $(\mathbb{Z}, +)$.

(d) If $G$ is any infinite abelian group of cardinality $\kappa$, then $G$ has $2^{2^\kappa}$ mutually nonequivalent Hausdorff topological group topologies [Pod77]. In particular, $(\mathbb{R}, +)$ has $2^{2^{\aleph_0}}$ mutually nonequivalent Hausdorff topological group topologies. Using that $(\mathbb{R}, +)$ is isomorphic to the direct sum of $2^{\aleph_0}$ copies of $(\mathbb{Q}, +)$, construct from (b) for $\mathbb{Q}$ a family of $2^{2^{\aleph_0}}$ mutually nonequivalent totally bounded Hausdorff topological group topologies on $(\mathbb{R}, +)$. The additive group of any separable Banach space is also isomorphic to $\mathbb{R}$.

XVI.2. Haar Measure

The most important tool for analysis on locally compact groups is Haar measure. Every locally compact group has an essentially unique translation-invariant measure called Haar measure. Haar measure generalizes Lebesgue measure on $\mathbb{R}$ or $\mathbb{R}^n$ and is of similar use and importance. And the fact that topological groups which are not locally compact do not have a similar translation-invariant measure is a serious obstacle to their study.

XVI.2.1. Definition and Existence

XVI.2.1.1. DEFINITION. Let $G$ be a Hausdorff topological group. A left Haar measure on $G$ is a measure $\mu$ defined on the Baire sets in $G$, with the following properties:

(i) $\mu(U) > 0$ for every nonempty open Baire set $U$ in $G$.

(ii) $\mu(K) < \infty$ for every compact $G$ in $G$.

(iii) $\mu$ is left invariant: $\mu(\lambda_g(A)) = \mu(A)$ for every $g \in G$ and every Baire set $A$ in $G$.

A right Haar measure on $G$ is a measure $\mu$ on the Baire sets in $G$ satisfying (i), (ii), and

(iii′) $\mu$ is right invariant: $\mu(\rho_g(A)) = \mu(A)$ for every $g \in G$ and every Baire set $A$ in $G$.

If $G$ is abelian, there is no difference between a left Haar measure and a right Haar measure on $G$. However, if $G$ is not abelian a left Haar measure need not be a right Haar measure, and conversely (XVI.2.2.6.(c)). If $G$ is second countable, the Baire sets are the same as the Borel sets in $G$, so (i) holds for all open sets and (ii) holds for all compact sets in $G$.

Conditions (i) and (ii) are nondegeneracy conditions: without (i) the zero measure would be a left and right Haar measure, and without (ii) the measure in which every nonempty set has infinite measure would be a left and right Haar measure.
XVI.2.1.2. Examples. (i) Lebesgue measure is a (left and right) Haar measure on \( \mathbb{R} \) or \( \mathbb{R}^n \) with addition.
(ii) A (left or right) Haar measure on \( \mathbb{T} \) can be described in several equivalent ways. One simple way is to identify it with \([0,1]\) by \( t \leftrightarrow e^{2\pi it} \) and transfer Lebesgue measure on \([0,1]\) to \( \mathbb{T} \). One could also take arc length measure on \( \mathbb{T} \) (or 1-dimensional Hausdorff measure) to obtain the same measure up to a factor of \( 2\pi \).
(iii) Counting measure is a (left or right) Haar measure on any discrete group.
(iv) Any positive scalar multiple of a left Haar measure on \( G \) is a left Haar measure, and similarly for right Haar measures.

The main theorem is:

XVI.2.1.3. Theorem. Let \( G \) be a locally compact group. Then there is a left Haar measure on \( G \), which is unique up to positive scalar multiple. There is also a right Haar measure on \( G \), unique up to a positive scalar multiple.

XVI.2.2. Haar Integrals

By the results of (), there is an entirely equivalent formulation of Haar measure as an integral or as a positive linear functional.

XVI.2.2.1. Definition. Let \( G \) be a locally compact group. A left Haar integral on \( G \) is a nonzero positive linear functional \( I \) on \( C_c(G) \) which is left invariant: \( I(g \cdot \phi) = I(\phi) \) for all \( g \in G, \phi \in C_c(G) \), where \((g \cdot \phi)(x) = \phi(gx)\), i.e. \( g \cdot \phi = \phi \circ \lambda_g \). A right Haar integral is a nonzero positive linear functional \( I \) on \( C_c(G) \) which is right invariant: \( I(\cdot g) = I(\cdot) \) for all \( g \in G, \phi \in C_c(G) \), where \((\phi \cdot g)(x) = \phi(xg)\), i.e. \( \phi \cdot g = \phi \circ \rho_g \).

XVI.2.2.2. By the Riesz Representation Theorem (), a positive linear functional on \( C_c(G) \) is given by integration with respect to a Baire measure. So if \( I \) is a left Haar integral on \( G \), then
\[
I(\phi) = \int_G \phi \, d\mu
\]
for a Baire measure \( \mu \).

XVI.2.2.3. Proposition. If \( I \) is a left Haar integral on \( G \), then \( \mu \) is a left Haar measure on \( G \), and similarly for a right Haar integral.

Conversely:

XVI.2.2.4. Proposition. If \( \mu \) is a left Haar measure on \( G \), then \( I \) defined by \( I(\phi) = \int_G \phi \, d\mu \) is a left Haar integral on \( G \), and similarly for a right Haar measure.

Thus Theorem XVI.2.1.3. is equivalent to:
XVI.2.2.5. Theorem. Let $G$ be a locally compact group. Then there is a left Haar integral on $G$, which is unique up to positive scalar multiple. There is also a right Haar integral on $G$, unique up to a positive scalar multiple.

The Haar integral is easier and more elementary to describe and find than the Haar measure in many cases:

XVI.2.2.6. Examples. (a) For $\mathbb{R}$ with addition, the Haar integral (left and right) is simply given by Riemann integration: if $\phi \in C_c(\mathbb{R})$, 
\[
I(\phi) = \int_{-\infty}^{+\infty} \phi(t) \, dt .
\]
This is not really an improper Riemann integral since $\phi$ has compact support: it is an ordinary Riemann (or even Cauchy) integral over a finite interval, which varies from function to function.  

(b) The (normalized) Haar integral on $\mathbb{T}$ is also given by Riemann integration: if $\phi \in C_c(\mathbb{T}) = C(\mathbb{T})$, then 
\[
I(\phi) = \int_{0}^{1} \phi(e^{2\pi it}) \, dt .
\]
(c) Here is perhaps the simplest example of a locally compact group for which left and right Haar measure (or integral) are different: the real “$ax + b$ group.” Let 
\[
G = \left\{ \begin{bmatrix} a & b \\ 0 & 1 \end{bmatrix} : a, b \in \mathbb{R}, a > 0 \right\} .
\]
$G$ is a subgroup of $GL(2, \mathbb{R})$, i.e. is a group under matrix multiplication. $G$ can be identified as a set with the open right half-plane $\mathbb{R}_+ \times \mathbb{R}$ in $\mathbb{R}^2$ by 
\[
\begin{bmatrix} a & b \\ 0 & 1 \end{bmatrix} \leftrightarrow (a, b)
\]
and given the topology from this identification (which agrees with the subspace topology from $GL(2, \mathbb{R})$ regarded as an open subset of $M_2(\mathbb{R}) \cong \mathbb{R}^4$). From this point of view, the group operations are given by 
\[
(a, b)(x, y) = (ax, ay + b)
\]
\[
(a, b)^{-1} = \begin{bmatrix} 1/a & -b/a \\ a & 0 \end{bmatrix}
\]
(cf. ()); the identity is $(1, 0)$. Since these operations are continuous, $G$ is a locally compact group (it is even a Lie group). 

If $g = (a, b) \in G$, left multiplication by $g$ is an affine map $(x, y) \mapsto (ax, ay + b)$ which is differentiable with constant derivative $\begin{bmatrix} a & 0 \\ 0 & a \end{bmatrix}$ and Jacobian $a^2$. 

Consider the linear functional $I$ on $G$ given for $\phi \in C_c(G)$ by 
\[
I(\phi) = \int_{G} \phi(x, y) \frac{dx \, dy}{x^2} = \int_{0}^{+\infty} \int_{-\infty}^{+\infty} \phi(x, y) \frac{dy \, dx}{x^2}
\]
1909
(since the support of \( \phi \) is a compact subset of the open right half-plane, the integral is only really over a sufficiently large closed rectangle on which \( \frac{1}{x^2} \) is bounded, hence is a proper Riemann integral). Then \( I \) is a nonzero positive linear functional on \( C_c(G) \). If \( g = (a, b) \in G \), then by the change-of-variables formula, writing \( u = ax, v = ay + b \), we have

\[
I(g \cdot \phi) = \int_{0}^{+\infty} \int_{-\infty}^{+\infty} \frac{\phi(ax, ay + b)}{x^2} \, dy \, dx = \int_{0}^{+\infty} \int_{-\infty}^{+\infty} \frac{\phi(ax, ay + b)}{a^2 x^2} a^2 \, dy \, dx
\]

\[
= \int_{0}^{+\infty} \int_{-\infty}^{+\infty} \frac{\phi(u, v)}{u^2} \, dv \, du = I(\phi)
\]

(the integrals are actually over suitably large compact regions in \( G \); cf. XVI.2.9.3.). Thus \( I \) is a left Haar integral on \( G \). The corresponding left Haar measure is given by

\[
\mu(A) = \int_{A} \frac{1}{x^2} \, d\lambda(x, y)
\]

for \( A \) a Borel set in \( G \), where \( \lambda \) is Lebesgue measure on \( \mathbb{R}^2 \).

Similarly, right multiplication by \( g = (a, b) \) is given by \((x, y) \mapsto (xa, xb + y)\), with derivative

\[
\begin{bmatrix}
    a & 0 \\
    b & 1
\end{bmatrix}
\]

and Jacobian \( a \). Thus the functional

\[
I_r(\phi) = \int_{0}^{+\infty} \int_{-\infty}^{+\infty} \frac{\phi(x, y)}{x} \, dy \, dx
\]

is a right Haar integral on \( G \), with right Haar measure

\[
\mu(A) = \int_{A} \frac{1}{x} \, d\lambda(x, y)
\]

for \( A \) Borel. Thus left and right Haar measures on \( G \) are different (XVI.2.9.3.).

\( G \) is called the “\( ax + b \) group” since it is isomorphic to the group of all order-preserving invertible affine transformations of \( \mathbb{R} \), i.e. transformations of the form \( f(x) = ax + b, a > 0 \). There is a similar “\( ax + b \) group” for any vector space over any field, or even modules over rings; some of these have topologies making them interesting topological groups (see e.g. [Bla83]).

XVI.2.3. Invariant Measures for Group Actions

XVI.2.4. Properties of Haar Measure

XVI.2.5. The Modular Function

XVI.2.6. Measures on Homogeneous Spaces

XVI.2.7. Extending Haar Measure

XVI.2.8. Measurable Groups

XVI.2.9. Exercises
XVI.2.9.1. Let $G$ be a locally compact group.

(a) Show that there is a neighborhood of $e$ in $G$ which is a compact $G_δ$, which contains a neighborhood of $e$ which is an open Baire set. [Use that $G$ is completely regular.]

(b) Show that if $μ$ is a left Haar measure on $G$, then there is a nonempty open Baire set $V$ in $G$ with $μ(V) < ∞$.

(c) Conversely, if $μ$ is a left invariant Baire measure on $G$ for which there is a nonempty open Baire set $V$ with $μ(V) < ∞$, then $μ(K) < ∞$ for every compact $G_δ$ $K$. [$K$ can be covered by finitely many left translates of $V$.]

Thus condition (ii) in the definition of a left Haar measure can be replaced by

(ii’) There is a nonempty open Baire set $V$ in $G$ with $μ(V) < ∞$.

The same change can be made in the definition of a right Haar measure.

XVI.2.9.2. Here is a warmup for Example XVI.2.2.6.(c). Let $G = \mathbb{R}_+$ be the positive real numbers with multiplication.

(a) Show that the linear functional on $C_c(G)$ given for $ϕ \in C_c(G)$ by

$$I(ϕ) = \int_0^∞ \frac{ϕ(x)}{x} dx$$

is (left and right) invariant, hence is a Haar integral. Write down the corresponding Haar measure.

(b) Show the result of (a) alternately by noting that $x \mapsto e^x$ is a topological isomorphism from $(\mathbb{R}, +)$ to $(\mathbb{R}_+, \cdot)$ and transferring the Haar integral on $\mathbb{R}$ to $\mathbb{R}_+$ using the change-of-variables formula.

XVI.2.9.3. (a) In example XVI.2.2.6.(c), give a more careful argument about regions of integration in the application of the change-of-variables formula in showing $I$ is left invariant.

(b) Show by example that $I$ is not right invariant, i.e. that the left and right Haar integrals for $G$ are truly different. (Caution: this involves more than just showing that $I \neq I_r$.)

XVI.2.9.4. (a) Let $G = GL(2, \mathbb{R})$. Identify $G$ with an open set in $\mathbb{R}^4$ by

$$\begin{pmatrix} x & y \\ z & w \end{pmatrix} \mapsto (x, y, z, w).$$

As in XVI.2.2.6.(c), show that the linear functional defined for $ϕ \in C_c(G)$ by

$$I(ϕ) = \int_G \frac{ϕ(x, y, z, w)}{(xw - yz)^2} d\lambda(x, y, z, w)$$

(the integral is actually a Riemann integral over a suitable compact region) is both a left and right Haar integral for $G$. Note that the denominator is the square of the determinant.

(b) Show similarly that if $G = GL(n, \mathbb{R})$, identified with an open set in $\mathbb{R}^{n^2}$, the left and right Haar integral is given by

$$I(ϕ) = \int_G \frac{ϕ(x_{ij})}{|\text{Det}(x_{ij})|^n} d\lambda(x_{ij})$$

where $(x_{ij})$ symbolically denotes the $n^2$-tupple $(x_{11}, \ldots, x_{nn})$, or the corresponding matrix. (Note that the case $n = 1$ is XVI.2.9.2.)
XVI.3. Lie Groups

A Lie group is a group which is a smooth manifold and whose multiplication and inversion are smooth maps. Since a smooth manifold has an underlying structure as a topological space and smooth functions are continuous, a Lie group has an underlying structure as a topological group (although it is technically not quite correct to say that a Lie group “is” a topological group), which is locally compact. Many of the most familiar and important topological groups are Lie groups. It turns out that every topological group whose topology is locally Euclidean has a unique structure as a Lie group. The theory of Lie groups bridges geometry, topology, linear and abstract algebra, and analysis, and impacts much of modern mathematics.

Lie groups are named in honor of Sophus Lie; note that “Lie” is pronounced “Lee.”

XVI.3.1. The Classical Groups

XVI.3.2. Lie Groups and Lie Algebras

XVI.3.3. Locally Euclidean Groups

XVI.3.3.1. Definition. A locally Euclidean group is a topological group whose topology is locally Euclidean (XI.19.1.1.).

XVI.3.3.2. A locally Euclidean space is $T_1$ (XI.19.1.2. (viii)), and thus a locally Euclidean group $G$ is Hausdorff, hence locally compact. By XI.19.1.2. (vi), XVI.1.2.34., and XVI.1.4.4., the connected component of the identity is an open normal subgroup of $G$ which is $\sigma$-compact. Thus, as a topological space, a locally Euclidean group is a topological manifold (and in particular metrizable; cf. XVI.1.3.7.).

XVI.3.3.3. Definition. Let $G$ be a topological group. Then $G$ has no small subgroups, or is an NSS group, if there is a neighborhood of the identity which contains no nontrivial subgroup of $G$.

An NSS group is Hausdorff, since $\{e\}$ is contained in every neighborhood of $e$ (Exercise XVI.1.7.2.). Any Lie group is an NSS group (). By XVI.1.4.10., a locally compact NSS group is metrizable.

XVI.3.3.4. Hilbert asked in his 1900 problem list (#5) whether every locally Euclidean group is a Lie group (i.e. has a Lie group structure; Hilbert did not state the problem quite so cleanly). This proved to be a difficult problem and was solved in 1952 by A. Gleason, D. Montgomery, and L. Zippin ([Gle52], [MZ52]); special cases had been established by von Neumann (compact groups [vN33]), Pontryagin (abelian groups []), and Chevalley (solvable groups [Che41]). The proof of the general theorem was simplified by H. Yamabe ([Yam53a], [Yam53b]) (although it is still deep and difficult). It is one of the remarkable results of mathematics, often described as “getting something for nothing.”

XVI.3.3.5. Theorem. Let $G$ be a locally compact group. The following are equivalent:

(i) $G$ is locally Euclidean.

(ii) $G$ is an NSS group.

(iii) $G$ has a unique structure as a Lie group.
The proof is far beyond the scope of this book. See e.g. [MZ74] or [Kap71].

“[This result] shows that you can’t have a little bit of orderliness without a lot of orderliness.”

A. Gleason

The implication (ii) ⇒ (i) of XVI.3.3.5. has a generalization due to Gleason and Yamabe:

**XVI.3.3.6. Theorem.** Let $G$ be a locally compact group. Then $G$ has an open subgroup $H$ such that, if $U$ is any neighborhood of $e$ in $G$, there is a compact normal subgroup $K$ of $H$, contained in $U$, such that $H/K$ is locally Euclidean (and thus has a unique structure as a Lie group).

The $K$ cannot be chosen normal in $G$ in general (). But since $H/K$ is a clopen subset of the homogeneous space $G/K$, it follows that $G/K$ is locally Euclidean as a topological space, hence a manifold.

XVI.4. Group Algebras and Unitary Representations

One of the most important applications of the existence of Haar measure on locally compact groups is that certain Banach algebras can be associated to any locally compact group which have the “same” representation theory as the group. These Banach algebras are a crucial tool in showing that locally compact groups have a nice representation theory, and in developing a theory of analysis on locally compact groups (abstract harmonic analysis).

XVI.4.1. The Group Algebra

**XVI.4.2. The $L^1$ Algebra and the C*-Algebra of a Locally Compact Group**

**Caution:** It is common in the literature on representation theory to say that a locally compact group $G$ is “separable” if $L^1(G)$ (or, equivalently, $C^*(G)$) is separable, i.e. if $G$ is second countable. However, this use of the term “separable” can be misleading, since a locally compact group, even a compact abelian group, which is separable in the topological sense of having a countable dense subset is not necessarily “separable” in this sense (a product of $2^\mathbb{N}$ circle groups or nontrivial finite groups is a counterexample; cf. XI.6.1.2.). Thus we will avoid using the term “separable” in any sense for topological groups.

---

1[Yan02, p. 144].
XVI.5. Locally Compact Abelian Groups and Pontryagin Duality

Locally compact abelian groups have special properties which make them an especially attractive class of objects to study, with important applications. There is a beautiful duality theory which leads to, among other things, a general theory of Fourier transform. Analysis on locally compact abelian groups, including the general Fourier transform, is called harmonic analysis.

XVI.5.1. The Dual Group

To each locally compact abelian group $G$ there is associated a dual group $\hat{G}$ which is also a locally compact abelian group. The major result, the Pontryagin Duality Theorem ($\ast$), will be that the dual group $\hat{\hat{G}}$ of $\hat{G}$ is topologically isomorphic to $G$, so there is a true duality between $G$ and $\hat{G}$. In this subsection, we define the dual group and examine some of its properties.

XVI.5.1.1. Definition. Let $G$ be a locally compact abelian group, and $\mathbb{T}$ the circle group ($\ast$). A character of $G$ is a continuous homomorphism $\chi : G \to \mathbb{T}$. If $\chi_1, \chi_2$ are characters, define the product $\chi_1 \chi_2$ by $(\chi_1 \chi_2)(g) = \chi_1(g)\chi_2(g)$ for $g \in G$, where the multiplication is in $\mathbb{T}$ (i.e. the pointwise product as complex-valued functions). Let $\hat{G}$ be the set of all characters of $G$, with the topology of uniform convergence on compact subsets of $G$. $\hat{G}$ is called the dual group, or Pontryagin dual group, of $G$.

The terminology is justified by the following result:

XVI.5.1.2. Theorem. Let $G$ be a locally compact abelian group. Then $\hat{G}$ is a locally compact abelian group under the product and topology of XVI.5.1.1.

Proof: First note that $\hat{G}$ is an abelian group under the product: the product is obviously associative and commutative, the constant function 1 is an identity, and if $\chi \in \hat{G}$, then $\chi^{-1} \in \hat{G}$ defined by $\chi^{-1}(g) = \chi(g)^{-1} = \overline{\chi(g)}$ is an inverse for $\chi$.

To show $\hat{G}$ is a topological group,

It remains to show that $\hat{G}$ is locally compact. 

XVI.5.1.3. Examples. (i) Let $G = \mathbb{Z}$ with the discrete topology. Any homomorphism $\chi$ from $\mathbb{Z}$ to $\mathbb{T}$ is continuous, and completely determined by $\chi(1)$, which can be any element of $\mathbb{T}$; thus $\hat{\mathbb{Z}}$ can be identified as a set with $\mathbb{T}$. The product of two characters is just the product in $\mathbb{T}$ under this identification, so $\hat{\mathbb{Z}} \cong \mathbb{T}$ as a group. The topology on $\hat{\mathbb{Z}}$ is the topology of pointwise convergence since $\mathbb{Z}$ has the discrete topology. If $(\chi_j)$ is a net in $\hat{\mathbb{Z}}$, then $\chi_j \to \chi$ pointwise if and only if $\chi_j(1) \to \chi(1)$. Thus the topology on $\hat{\mathbb{Z}}$ is just the usual topology on $\mathbb{T}$ under the identification, i.e. the identification $\chi \mapsto \chi(1)$ is a topological isomorphism from $\hat{\mathbb{Z}}$ onto $\mathbb{T}$.

(ii) Let $G = \mathbb{R}$ with the usual topology. If $\chi$ is a continuous homomorphism from $\mathbb{R}$ to $\mathbb{T}$, then $\chi$ lifts to a continuous function $\tilde{\chi} : \mathbb{R} \to \mathbb{R}$, and it is easily checked that $\tilde{\chi}$ is a homomorphism. But the only continuous homomorphisms from $\mathbb{R}$ to $\mathbb{R}$ are multiplication by a constant: if $\phi : \mathbb{R} \to \mathbb{R}$ is a continuous homomorphism, then $\phi$ is uniquely determined on $\mathbb{Q}$ by $\phi(1) = \lambda$, and by continuity we must have $\phi(x) = \lambda x$ for all $x \in \mathbb{R}$. Thus, if $\tilde{\chi}(x) = \lambda x$ for fixed $\lambda \in \mathbb{R}$, we must have $\chi(x) = e^{2\pi i \lambda x}$, and we can identify $\chi$ with $\lambda$, i.e. call this character $\chi_\lambda$. The map $\lambda \mapsto \chi_\lambda$ is a group-isomorphism from $\mathbb{R}$ onto $\hat{\mathbb{R}}$. 1914
To show that this is a topological isomorphism, suppose $\chi_\lambda \to \chi_\lambda$ uniformly on compact sets. Then in particular

(iii) Let $G = T$. Suppose $\chi$ is a continuous homomorphism from $T$ to $T$. Compose $\chi$ with the homomorphism $\phi : \mathbb{R} \to T$ with $\phi(x) = e^{2\pi i x}$ to get a character $\tilde{\chi}$ of $\mathbb{R}$, which must be of the form $\tilde{\chi}(x) = e^{2\pi i \lambda x}$ for some $\lambda \in \mathbb{R}$, so we have $\chi(e^{2\pi i x}) = e^{2\pi i \lambda x}$. This function is well defined only if $\lambda \in \mathbb{Z}$. So a continuous homomorphism from $T$ to $T$ can only be of the form $\chi_n(x) = \xi^n$ for some fixed $n \in \mathbb{Z}$, so $T \cong \mathbb{Z}$ as groups. Since $T$ is compact, the topology on $\hat{T}$ is the topology of uniform convergence. But no $\chi_n$ for $n \neq 0$ can be uniformly close to the constant function 1, so the topology on $\hat{T}$ is the discrete topology, i.e. $\hat{T} \cong \mathbb{Z}$ with the discrete topology.

(iv) Let $G = \mathbb{Z}_n$ with the discrete topology. Then any $\chi \in \hat{G}$ is again completely determined by $\chi(1)$. But since 1 has order $n$ in $G$, $\chi(1)$ must have order $n$ in $T$, i.e. $\chi(1)$ must be an $n$’th root of unity. Any $n$’th root of unity defines a character, and the characters multiply like the roots of unity, so we have $\hat{\mathbb{Z}_n} \cong \mathbb{Z}_n$, and the topology on $\hat{\mathbb{Z}}_n$ is obviously also the discrete topology. But there is no natural isomorphism between $\hat{\mathbb{Z}}_n$ and $\mathbb{Z}_n$: any isomorphism requires making a choice of generators for the groups.

XVI.5.1.4. The characters of a locally compact abelian group $G$ are just the one-dimensional unitary representations () of $G$. Every one-dimensional representation is obviously irreducible, and every irreducible unitary representation of an abelian group is one-dimensional (), so $\hat{G}$ is just the set of irreducible representations of $G$. Two one-dimensional representations are equivalent () if and only if they are identical as homomorphisms to $T$, so $\hat{G}$ is just the set of equivalence classes of irreducible representations of $G$, i.e. the notation is consistent with the notation of () . But if $G$ is abelian, $\hat{G}$ has the additional natural structure of a (topological) group; $\hat{G}$ for nonabelian $G$ has no such structure.

XVI.5.1.5. By (), every unitary representation of $G$ defines representations of $L^1(G)$ and $C^*(G)$, and conversely. Thus, if $G$ is locally compact abelian, each character of $G$ defines a (bounded) *-homomorphism from $L^1(G)$ or $C^*(G)$ to $\mathbb{C}$, and these are precisely all the irreducible representations of these group algebras. Thus $\hat{G} \cong L^1(G) = C^*(G)$. The topology on $\hat{G}$ is precisely the hull-kernel topology on $C^*(G) \cong \text{Prim}(C^*(G))$.

Since irreducible representations are separating (), we obtain:

XVI.5.1.6. Proposition. Let $G$ be a locally compact abelian group, and $g \in G$, $g \neq e$. Then there is a character $\chi$ of $G$ with $\chi(g) \neq 1$.

XVI.5.1.7. Definition. If $G$ is a locally compact abelian group and $H$ is a closed subgroup, the annihilator of $H$ in $\hat{G}$ is

$$H^\perp = \{ \chi \in \hat{G} : \chi(h) = 1 \text{ for all } h \in H \} .$$

An element of $H^\perp$ defines a character of $G/H$ in the obvious way. Conversely, every character of $G/H$ can be regarded as a character of $G$ whose kernel contains $H$, i.e. an element of $H^\perp$.

1915
XVI.5.1.8. **Proposition.** Let $G$ be a locally compact group and $H$ a closed subgroup. Then the above correspondence is a topological isomorphism between $H^\perp$ and $G/H$.

XVI.5.1.9. **Theorem.** Let $G$ be a locally compact abelian group. Then

(i) $\hat{G}$ is second countable if and only if $G$ is second countable.

(ii) $\hat{G}$ is compact [resp. discrete] if and only if $G$ is discrete [resp. compact].

If $G$ is discrete (so $\hat{G}$ is compact), there are further topological properties of $\hat{G}$ which reflect algebraic properties of $G$:

XVI.5.1.10. **Proposition.** Let $G$ be a discrete abelian group, and $\hat{G}$ the compact dual group. Then

(i) $\hat{G}$ is connected if and only if $G$ is torsion-free.

(ii) $\hat{G}$ is totally disconnected (zero-dimensional) if and only if $G$ is a torsion group.

XVI.5.2. **Exercises**

XVI.5.2.1. (a) Let $G$ be an abelian group with the discrete topology. Show that the topological dimension (covering dimension $dim$) of the compact group $\hat{G}$ equals the rank () of $G$.

(b) A torsion-free abelian group of finite rank is countable. Hence a connected compact abelian group of finite topological dimension is metrizable.

(c) If $H$ is a connected compact abelian group of topological dimension 1, then $H$ is either a circle or a solenoid (). [Apply (a) to $\hat{H}$.]

(d) The rank 2 torsion-free abelian groups, i.e. the subgroups of $\mathbb{Q}^2$ containing $\mathbb{Z}^2$, are “unclassifiable” (in a technically precise sense, cf. [Tho03]). Thus the connected compact abelian groups of topological dimension 2 (all of which are metrizable) are “unclassifiable” in the same sense. In particular, they can be far more complicated than products of two circles and/or solenoids. The classification problem for rank $n$ becomes strictly more complex as $n$ increases.
Chapter XVII

Addenda
XVII.1. Mathematical Names

One problem not often discussed, which every student and mathematician faces, is learning how to pronounce names of mathematicians when citing or describing their work. I know I have struggled with this on occasion, beginning with my student days, and judging from mispronunciations I have heard from other mathematicians I am hardly alone. Thus I have included this guide as a public service. The information here is correct to the best of my knowledge, but I make no guarantees, and I welcome corrections. I have generally omitted names whose pronunciation should be obvious to English speakers. There are a number of websites such as http://pronouncemath.blogspot.com which may be helpful, but none should be regarded as authoritative.

Since neither I nor most potential readers are professional linguists, I have written the pronunciations using English syllables instead of linguistic symbols. The pronunciations are only approximations, and reflect commonly accepted pronunciations by English-speaking mathematicians rather than exact pronunciations in the original language. Of course, languages vary significantly, particularly in the pronunciation of vowels and r’s, and also l’s, n’s, and other consonants; stress patterns also vary. It is probably better for a mathematician speaking in English to use an English pronunciation instead of an exact original pronunciation anyway.

The English syllables and character combinations are slightly ambiguous in places, but should be pronounced in the usual English way; thus “ch” is always pronounced as in “chair”. One sound not present in English is the German ch or Russian x, pronounced like an English “hi” but farther back in the throat. This sound is written “kh”.

The stressed syllable is written in capital letters.

Spellings of names not originally written in the Latin alphabet are also an issue. This arises most critically with Russian names, but can also occur with Arabic, Chinese, or other names. (It is potentially an issue with Indian and Japanese names, but these seem to have standard and universally-used transliterations into the Latin alphabet.)

Russian names are not always transliterated consistently, and the standard English, French, and German transliteration schemes are rather different; and since much mathematical literature has historically been written in German or French, French- and German-style transliterations have come into common use even in English texts. Thus, for example, the name of the well-known Russian mathematician Тихонов, who originally published his papers in German, is frequently transliterated Tychonoff instead of the proper English transliteration TIKHONOV (this difference is exacerbated by the fact that a final consonant like n in Russian is normally pronounced unvoiced). An initial E in Russian is usually pronounced “yeh”, so should be properly transliterated Ye in this case (the name of the former Russian president Ельциным is transliterated YELTSYN), but Eropo is usually transliterated EGOROV or EGOROFF, not YEGOROV. We have given common spelling variations in the list. Another difficulty is that some Russian mathematicians, especially Jewish ones, have names which were originally German which were transliterated into Russian; there is a question whether these should be retransliterated into English or restored to their original German spellings. For example, Бернштейн (Sergei) is usually written Bernstein, and Урьсон is usually URSOHN. Наимарк is sometimes spelled NAIMARK and sometimes NEUMARK. Yet another gray area concerns Russian mathematicians who emigrate and begin spelling their own names a certain way in the Latin alphabet. The prime example for this book is BESICOVITCH (his spelling). We will regard this example as a voluntary name change and use his spelling.

One last note of caution, more relevant for contemporary names than historical ones: many Americans (and Canadians) are of European or Asian ancestry, and their names are not always pronounced or spelled in the ancestral way (this is even true of BLACKADAR, which was originally BLACKADDER, although not of BBC fame!) There are particularly many German-Americans, Italian-Americans, Polish-Americans, and Chinese-Americans, and Jewish Americans whose names are of German, Polish, or Russian origin. (There are also a
great many Americans with Hispanic names, but unfortunately this group is seriously underrepresented in
the world of mathematics.)

Here are some general pronunciation conventions for some common languages:

**German:** a is normally pronounced “ah”, never “eh” unless it has an umlaut (ä). Other vowels which can
have umlauts are ö and ü, which are hard to pronounce for an English speaker; ö sounds something like “er”,
and ü is something like a deep “ee” with rounded lips. The vowels ä, ö, ü are sometimes written ae, oe, ue
respectively.

Double vowels are just pronounced as longer versions of the corresponding single vowel: aa is pronounced
“ah”, ee is pronounced roughly like the name of the English letter a, and oo is pronounced “oh”, not English
“oo”. (The combination eh is pronounced the same as ee, leading to pun jokes among German students
concerning the word root lehr, “teach”, and leer, “empty”. ah and oh are similarly pronounced like aa and
oo respectively.) A final e is always pronounced, normally as “uh” and not “ee”.

Diphthongs are pronounced as follows: au as “ow”, not “aw”; eu as “oy”, not “oo” or “you”; ie as the
name of the English letter i; ie as “ee”.

The letter v is usually pronounced “f”; the letter w is usually pronounced roughly like English v, but
a little softer with rounded lips. z is pronounced “ts”. The combination th is pronounced “t” (the sound
“th”, voiced or unvoiced, does not occur in German). These letters also sometimes occur consecutively at
the break between parts of a compound word, in which case they are pronounced separately; BEETHOVEN
is an example (although this name is of Flemish origin). st is often, but not always, pronounced separately; the sound “sh” is spelled sch. Thus Monatsheft is pronounced “MOE-nahts-heft”, not “MOE-naht-sheft”. The combination sh usually
only occurs, as here, in compound words where the first part ends in s and the second part begins with h.
This applies to names such as Pringsheim.

**Russian:** a (а) is pronounced “ah” after a consonant, some trace of the “y” usually remains, but it mainly disappears into the preceding consonant (which is technically pronounced soft). There is another letter e (e) which is pronounced without the “y”, but this letter mostly appears in foreign words and rarely if ever in Russian names. Sometimes in a stressed position e is pronounced “yaw” (e pronounced this way should be written è, but the “umlaut” is typically omitted). For example, the names of the former Soviet leaders Хрущев and Горбачев are properly pronounced “khroosch-OFF” and “gar-ba-CHOFF” respectively; the most notable instance among mathematical names is in Chebyshев. When this occurs in the list, it is noted in the pronunciation guide. The letter o (о) is pronounced “ow”, or “uh” (sometimes “ah”) in an unstressed position. The letter u (у) is pronounced “oo”, not “uh”; the soft form io is pronounced “you”. The letter i (и) is pronounced “ee”. There
is another vowel i, the hard version of и, transliterated y, which is pronounced similarly to the German ü
but farther back in the throat. The vowel я, “ya”, is the soft form of a.

There are no diphthongs in Russian: consecutive vowels are pronounced separately. For example,
Воеводский is pronounced “vaw-yeh-VAWD-skee”, and the chemist Менделеев is pronounced “men-del-
YAY-yeff”.

Most Russian consonants have a hard and soft form. The hard form is the “default”, and consonants
become soft only when followed by a soft vowel (я, е, и, ю) or a soft sign (е), which is not pronounced. The
soft sign is sometimes transliterated with an apostrophe (as in OL’SHANSKII), but we have avoided using
this. There is also a “hard sign” or “separative sign” ь, which occurs only rarely in modern Russian and
which now usually has the same pronunciation effect as ь. The letter ь, which occurs only after vowels, is
pronounced with a slight “y” sound and usually transliterated i.

1919
As mentioned earlier, some consonants at the end of words, or before other unvoiced consonants, are pronounced unvoiced.

**Polish:** Polish names are frequently mispronounced badly in English, and some have acquired widely accepted English pronunciations quite different from the Polish ones. This is mainly due to the fact that the Polish spelling conventions for many sounds are different than the English ones. As a result, some Polish names look “unpronounceable” to English speakers not familiar with the Polish conventions. But a little familiarity makes them relatively easy to pronounce, at least approximately.

In Polish, \( w \) is pronounced “v”; \( ł \) is pronounced “w”, \( c \) is pronounced “ts” (except when followed by \( i \) or \( z \)), and \( j \) is pronounced “y”.

The combination \( sz \) is pronounced “sh”, \( cz \) is pronounced “ch”, and \( rz \) is pronounced “zh”. These are hard sounds. The accented letters \( ś \), \( ć \), \( ź \) (si, ci, zi before vowels) are soft forms of \( sz \), \( cz \), and \( rz \) respectively; \( ż \) is pronounced like \( rz \).

The vowel \( ó \) is pronounced “oo”, the same as \( u \). There are also nasal vowels and a nasal \( n \) (\( ň \)), but these are perhaps too arcane to worry about here.

For example, the common first name *Jerzy* is pronounced “YEH-zhee”, not “Jersey”.

In Polish words, including names, the stress is almost always on the next-to-last syllable.

Some Poles (mainly Jews, but not exclusively) have names which are originally German but which are written with Polish spelling conventions. Notable examples are the names *Szulc* and *Sznajder*, which are the same (and pronounced the same) as the German *Schulz* and *Schneider* respectively. Among mathematicians, the names *Aronszajn* and *Szpilrajn* come to mind.

**Hungarian:** Hungarian names also have the reputation of being hard for English speakers to pronounce, and the reason is again differences in spelling conventions. The Hungarian spelling conventions are in some instances the direct opposites of the Polish ones.

The vowels \( a \), \( e \), \( i \), \( o \), \( ö \), \( u \), \( ü \) are pronounced similarly to the corresponding German vowels. An accent denotes a long vowel; \( ť \) and \( ţ \) are the long forms of \( ŏ \) and \( ŭ \) respectively.

Hungarian consonants and combinations are as follows: \( c \) is pronounced “ts”, \( cs \) is “ch”, \( gy \) is a soft “j” (actually similar to the British pronunciation of “due”), \( j \) is like “y”; \( ly \), \( ny \), \( ty \) are soft versions of \( l \), \( n \), \( t \); \( s \) is pronounced “sh” and \( sz \) is pronounced “s”; and \( zs \) is “zh” (hence \( dzs \) is a hard “j”).

The stress in Hungarian words is on the first syllable. Note that an accent on a vowel does *not* indicate stress.

**French:** French names truly are hard for many English speakers to pronounce correctly, although most English speakers know how to make a decent approximation since they are relatively familiar.

**Italian:**

**Japanese:** The syllables of Japanese words are all pronounced with roughly the same stress. However, some syllables are partially swallowed. For example, the name of the city *Fukushima*, the site of the recent nuclear disasters, is pronounced something like “FKOO-shi-muh” (at least it sounds like this to me).

**Chinese:** I will not attempt to describe the proper pronunciation of Chinese names, since it is far beyond my expertise. However, I will recall a conversation I had with a Chinese mathematician, about the Chinese name *Ng* (which is usually pronounced “ing” in English, which is at least better than “nig”). I asked the proper pronunciation, and he replied, “Mm?” I thought he had not understood what I said, so I repeated the question, and he again replied, “Mm?”

Of course, there are many other languages, each with its own peculiarities. For example, consider the name of the eminent, and recently tragically deceased, Danish mathematician *Uffe Haagerup*. Danes pronounce
his last name something like “OR-up”, but somewhat less distinctly. English-speaking mathematicians usually say “HOG-er-up”, which Uffe (“OOF-uh”) didn’t seem to mind too much.

I must say I feel fortunate to be a native English speaker, not just because English has become the international language of mathematics (and many other subjects), but also because I am very happy I didn’t have to learn the language as an adult. It seems to me like a difficult and irregular language, particularly because of the use of articles (very hard for nonnative speakers to get right) and the tenuous relationship between spelling and pronunciation for many words, and I admire the ability of so many of my foreign colleagues to master it quite well. Although it is sometimes said that “the international language of mathematics is bad English,” I find most of it surprisingly good.

“English is weird. It can be understood through tough, thorough thought though.”

Unknown

We could say the same thing about analysis!

Notes:

Dirichlet These pronunciations are almost universally used, but there is some doubt about their correctness. Dirichlet was German, but his family originally came from the town of Richelette in the French-speaking part of Belgium. His full surname was Lejeune Dirichlet, originally Lejeune de Richelette. Even with a French pronunciation the t would be pronounced in this name. The logical pronunciation of Dirichlet should be something like deer-ish-LET. I have been unable to determine how he himself pronounced his name.

Perron Perron was German, but the origin of his surname is obscure.

Zermelo The origin of this name is obscure. Zermelo, who was German (and not Jewish), told people who asked that it was a contraction of Walzermelodie (cf. [Rei70, p. 98]). More serious speculations on an East Prussian origin of the name, apparently also originating with Zermelo himself, can be found in [Ebb07, p. 1].
XVII.1.1. The Greek Alphabet

One thing every mathematics student must learn is the Greek alphabet, or at least most of it. Greek letters are frequently used as mathematical symbols. Many upper-case Greek letters are essentially identical to Latin letters (although not necessarily the equivalent Latin letter!), and these upper-case Greek letters are rarely if ever used as mathematical symbols. The other upper-case letters are commonly used, but the lower-case letters are more common in mathematics. The only lower-case Greek letter I have never seen used as a mathematical symbol is omicron, although upsilon is rarely used since it is hard to distinguish from nu.

1926
XVII.2. Origin of Terms and Notation

I have collected here my best information of when various standard mathematical terms were first introduced. Corrections and additions are solicited. Information is from [Caj93], http://jeff560.tripod.com/mathword.html, and http://jeff560.tripod.com/mathsym.html unless otherwise specified.

Terms

Many of these terms were introduced in languages other than English, in appropriate form. We have given the English form or translation.

algebra: originally *al-jabr* (according to [Str13], Arabic for “restoring”), Al-Khwarizmi, 825. Not used in the modern sense until much later.

algebraic topology: Lefschetz, 1936 [Jam99, p. 570]. Previously usually called “combinatorial topology” (not exactly the same thing; Emmy Noether was instrumental in the transition from “combinatorial topology” to algebraic topology in the late 1920s [Jam99, p. 564-565]).

algorithm: from Al-Khwarizmi, whose book (825) introduced “Arabic” numbers (actually originating in India) and modern calculation methods to Europe. “The method of Al-Khwarizmi” referred to solving a problem by calculation.

Banach space: Fréchet, 1928. Banach spaces were defined by Banach in 1920; he called them espace du type (*B*).

calculus: The term, from the Latin meaning “small pebble,” was used to refer to calculation (word of same origin) since Roman times. The modern usage of *calculus* (*differential calculus*) was introduced by Leibniz around 1680. Newton first used the term in 1691. The original meaning survives in some other mathematical terms such as *functional calculus* and *calculus of residues*.

compact (topology): Fréchet, 1906 (not quite in the modern sense).

complex number: Gauss. He used the term to resolve the ambiguity in the use of *imaginary number* to refer both to nonreal complex numbers and to pure imaginary numbers (an ambiguity which persists to a degree even today).

corollary: from Latin *corolla*, a small wreath; the English word dates from the 14th century and has been used in the modern mathematical sense (a theorem which is an immediate or easy consequence of another theorem) at least since 1669.

derivative: Lagrange, *Théorie des fonctions analytiques*, 1797 [Gra10]. Lagrange’s term (which he used as early as 1772) was *fonction derivée*. Derivatives were previously described as differentials, fluxions, etc.; the general notion of a function was just appearing in Lagrange’s time.

eigenvalue: A hybrid German-English word, apparently first used by A. S. Eddington in 1927. Many mathematicians have rebelled against the term and used alternates, but *eigenvalue* is now firmly established.

ergodic: coined by Boltzmann in 1884.

field (algebra): Dedekind used *Zahlenkörper* in 1858. The English *field* was first used by E. H. Moore in 1893.

geometry: From Greek “measuring the earth.” Used in ancient Greece before Plato.

harmonic analysis: W. Thompson (Lord Kelvin), 1867.

Hilbert space: Erhard Schmidt, *Über die Auflösung linearer Gleichungen mit unendlich vielen Unbekannten*, 1908 (for $\ell^2$). Abstract Hilbert spaces were defined by von Neumann in 1928 [vN30].

homeomorphism: Poincaré, *Analysis Situs*, 1892 (not quite in the modern sense). The modern usage was standard by 1930.

homology: Used by Poincaré in *Analysis Situs*, 1895, but not clearly in the modern sense [Jam99, p. 85]. The word was used in a different sense by James Stirling in 1749.

homotopy: Dehn and Heegaard, *Analysis Situs*, 1907 [Jam99, p. 88]. The concept of homotopy, or continuous deformation, had been around a long time.

imaginary number: Descartes, *La Geometrie*, 1637. Such numbers had long been considered.

integral: Jakob Bernoulli, *Acta eruditorium*, 1690. Johann Bernoulli disputed this (he disputed many things) and claimed originality for the term. Johann Bernoulli first used the term *integral calculus*, and convinced Leibniz to use it too.

linear algebra: the term was used by Bombelli in about 1550, but the modern usage as the subject of vector spaces and linear transformations only dates from about 1950.

logarithm: John Napier, 1614.

manifold: The term was used to denote affine subspaces of $\mathbb{R}^n$ long before the modern definition of manifold was given. First used in something approaching the modern sense by Riemann. The “correct” modern definition was nailed down by Whitney in the 1930s.

mathematics: from Greek *manthanein*, “to learn.” The term *mathematike tekhne*, “mathematical science,” already existed in ancient Greece. The word *mathematics* gradually shifted from a plural noun to a singular one (at least in American English; it is somewhat ambiguous in British English, where it is abbreviated “maths,” and still plural in some other languages).

matrix: Sylvester, 1848. Matrix notation had been recently introduced by Cayley. Determinants (of arrays) were introduced by Cauchy. The older meaning of *matrix* was “the place of origin of something else,” and Sylvester apparently regarded mathematical matrices as the place of origin of determinants.

parallelepiped: Euclid. The only controversy is about pronunciation: the accent is most commonly on the next-to-last syllable, although it is sometimes put on the previous syllable.

pathological: Used in medicine since the 17th century. The first documented use in mathematics is in Murray and von Neumann, *On Rings of Operators*, 1936 (referring to non-type-I factors).

real number: Descartes, *La Geometrie*, 1637.

ring: Dedekind.

set: Apparently first used (German *Menge*) by Bolzano, *Wissenschaftslehre*, 1837 [Fra66, p. 2].

topology: J. Listing, 1847 [Jam99]. The term did not come into general use until the twentieth century; *analysis situs* (introduced by Leibniz, used by Poincaré) predominated.
transcendental number: Leibniz, 1704 [Rib00b]. Transcendental numbers were not proved to exist until 1844 (by Liouville).

trigonometry: Bartholomaeus Pitiscus, 1595.

vector: Used in astronomy to denote a radius vector. First use to denote a point in $\mathbb{R}^3$ by William Rowan Hamilton in 1844. Only gradually became used to denote a point in a general vector space.

vector space: Peano, Formulario mathematico, 1895.

Notation

$a^n$ (exponent): Descartes, 1637 (natural number exponents); Newton, 1676 (negative and fractional exponents). Exponents were first used (with different notation) by Nicole Oresme about 1360.

$|\cdot|$ (absolute value): evidently introduced by Weierstrass.

$\binom{}{}$ (binomial coefficient): Andreas von Ettingshausen, 1826. Euler used this symbol, but with a fraction bar in the middle.

$\mathbb{C}$ (complex numbers): Nathan Jacobson, 1939.

.(decimal point): Unclear. Used by Bartholomaeus Pitiscus in 1612. Popularized by Napier. Decimals had long been used in the Middle East.

$\div$ (division): Johann Rahn, Teutsche Algebra, 1659.

$>$ (greater than): Thomas Harriot, Artis Analyticae Praxis ad Aequationes Algebraicas Resolvendas, 1631. Wallis used the first version of $\geq$ in 1670.

$\delta$ (limit): Cauchy (for différence). Johann Bernoulli used $\delta$ for a difference of functions in 1706.

$e$ (2.718⋅⋅⋅): Euler, 1727. The reason for $e$ is obscure, but it probably was not because of his name.

$<$ (less than): Thomas Harriot, Artis Analyticae Praxis ad Aequationes Algebraicas Resolvendas, 1631. Wallis used the first version of $\leq$ in 1670.

$\epsilon$ (limit): Cauchy (for erreur).

$f(x)$ (function): Euler, Commentarii Academiae Scientarium Petropolitanae, 1734.

$f: X \to Y$ (function): Hurewicz, 1940.

$f'$ (derivative): Lagrange, Théorie des fonctions analytiques, 1797 [Gra10]. The notations $\frac{dy}{dx}$ (Leibniz) and $\dot{x}$ (Newton) previously predominated.

$\emptyset$ (empty set): Bourbaki, 1939. Introduced by Weil from the Norwegian alphabet.

! (factorial): Christian Kramp, Elements d’arithmétique universelle, 1808. The alternate notation $\vdash$, still occasionally seen, is actually newer (Thomas Jarrett, 1827).

$i$ ($\sqrt{-1}$): Euler, 1777. Complex numbers, especially square roots of negative real numbers, had long been considered, although they were still “imaginary.”

$\infty$ (infinity): Wallis, De sectionibus conicis, 1655.

$\lfloor \cdot \rfloor$ (integer part): Kenneth Iverson, 1962. Gauss defined and used this function and denoted it $\lfloor \cdot \rfloor$.

$f$ (integral): Leibniz, 1675. The definite integral notation $\int_a^b$ was first used by Fourier in 1822.

1929
\cap (intersection): Peano, *Formulario mathematico*, 1895.

\lim_{x \to a} \text{ (limit): John Leathem, *Volume and Surface Integrals Used in Physics*, 1905. Weierstrass used } \lim_{x \to a}.

\in (member): Peano, *Formulario mathematico*, 1895.

\neg (minus): Johannes Widmann, 1489.

\mathbb{N} (natural numbers): Dedekind used \( \mathbb{N} \) in *Was sind und was sollen die Zahlen*, 1888.

\mathcal{O} (big-\( \mathcal{O} \)): Paul Bachmann, *Analytische Zahlentheorie*, 1894; but see \( o \).

\( o \) (little-\( o \)): first apparently used in the modern sense by Landau in 1909 (\( O \) and \( o \) are sometimes called Landau symbols). But \( o \) was used by Newton (cf. [?, p. 204] and V.7.).

\( \partial \) (partial): Condorcet, 1768. \( \partial \) was first used by Legendre, 1786. This symbol is an italic Cyrillic \( d \), and this may be the origin of the mathematical symbol (possibly through Euler?)

\( \pi \) (3.14159\ldots): William Jones, 1706 (for *perimeter*). Usage popularized by Euler. The number itself has been known and studied since antiquity.

\( + \) (plus): Nicole Oresme, 1360.

\( \mathbb{Q} \) (rational numbers): Bourbaki introduced \( \mathbb{Q} \) in the 1930s, evidently for *Quotient*.

\( \mathbb{R} \) (real numbers): Dedekind used \( \mathbb{R} \) in *Stetigkeit und irrationale Zahlen*, 1872 (he used \( R \) for the rational numbers). The real numbers as a named set were rarely referred to before this. Use of “blackboard bold” for \( \mathbb{R} \) and other sets of numbers, which is still not universal, is of uncertain origin.

\( / \) (division): Thomas Twinin, 1718.

\( \sqrt{} \) (radical): Christoff Rudolff, *Die Coss*, 1525. Descartes (1637) added the vinculum. The notation \( \sqrt{} \) was suggested by Albert Girard in 1629 and may have been first used by Rolle in *Traité d’Algèbre* in 1690.

\( \sum \) (sum): Euler, *Institutiones calculi differentialis*, 1755.

\( \times \) (multiplication): William Oughtred, 1631.

\( \cup \) (union): Peano, *Formulario mathematico*, 1895.

\( \mathbb{Z} \) (integers): Edmund Landau introduced \( \mathbb{Z} \) (evidently for *Zahl*) in *Grundlagen der Analysis*, 1930. Bourbaki used \( \mathbb{Z} \).
XVII.3. Miscellany

XVII.3.1. Age and Mathematics

“Very few people do anything creative after the age of thirty-five. The reason is that very few people do anything creative before the age of thirty-five.”

Joel Hildebrand

Weierstrass is a notable counterexample to the widely held belief that mathematics is exclusively an enterprise for the young. He never earned a doctorate (he was eventually awarded an honorary one), did not have a university position until age 41, and did most of his work on the foundations of analysis over the next twenty years after that. He did significant mathematical research well into his sixties and perhaps early seventies (he published the Weierstrass Approximation Theorem at age 70), and lectured regularly about his work into his seventies. (He did do important mathematical work in his twenties and thirties while he was employed as a high-school [gymnasium] teacher, but this work was not published or known in the mathematical community until much later.)

Hausdorff did not do much mathematics until he was in his forties (he previously wrote two books on philosophy under the name Paul Mongré).

John Wallis (1616-1703) is perhaps an even more notable example. He continued to produce and write significant mathematics into his eighties, and retained his chair at Oxford until his death at age (almost) 87. (He apparently did not learn or do any serious mathematics until after his Oxford appointment at age 33!) Although he was 27 years older than Newton, he remained active and productive for several years after Newton had ceased to do creative mathematics. When Wallis was 81, Leibniz invited him to Hannover to instruct the Germans on cryptography (he had been England’s Royal cryptographer for decades); Wallis declined for strategic reasons, not because he was physically incapable. (Wallis’s contemporary Thomas Hobbes (1588-1679), a formidable philosopher but a lightweight mathematician, with whom Wallis had a longstanding polemical debate, lived to age 91. Newton lived to age 84 and remained intellectually sharp almost to the end, but produced little new mathematics after a serious illness at age 50, although he did finally publish part of the work he had done decades earlier.)

“. . . no old Men (excepting Dr. Wallis) love Mathematicks.”

Isaac Newton

Leopold Vietoris died in 2002, two months short of his 111th birthday. He was the oldest person in Austria at the time of his death (and the oldest documented Austrian man ever). He published his last research paper at the age of 103. Sergei Nikolskii (1905-2012) also published research papers until age 101. I am not aware of any other mathematician who published a research work after his/her 100th birthday.

“If you live to a hundred you have it made because very few people die past the age of a hundred.”

George Burns

XVII.3.2. The Mathematical Organ

It was fashionable at one time for phrenologists to make studies of the skulls of various classes of people, including mathematicians. The following is adapted from *The Mathematician as a Type*, by William Story.

It has been claimed that a very large number of mathematicians show a striking physiognomic peculiarity called the “mathematical organ.” Franz Joseph Gall, the originator of phrenology, describes it thus:

“The outer part of the roof of the orbita is depressed in such a manner that the upper edge of the hollow of the eye retains its natural arch only on the inner half, and that the outer half becomes a straight line, which runs sloping downward to its outer end. In consequence of this, the outer part of the upper lid falls and covers the eye, more than usually. Still more decided is the character when the lateral part of the orbita is pushed outward, so that the angular process of the frontal bone (the outer upper angle of the edge of the roof) projects sidewise over the front part of the temple.”

Story continues:

“I know a great part of the living mathematicians personally [and] I have studied the busts, and painted and engraved portraits of many others. In all, without exception, I have found the organ described. Consider the portrait of young Colburn; in him the outer part of the orbita is depressed and pushed out in such a way that this peculiarity did not escape the authors of the first notices about the young man in the American newspapers. Consider the portraits of Kepler, Newton, Leibnitz, Huyghens, Descartes, Euler, Roberval, Bernoulli, Lagrange, de la Place, Lalande, Herschell, Olbers, Bessel, Monge, Carnot, etc.”

P. J. Möbius, a psychiatrist and disciple of Gall (and descendent of August Ferdinand Möbius), who published a book on *The Talent for Mathematics*, says:

“Gall’s statements about the mathematical organ are entirely correct, but I have three remarks to make: 1. Nature varies the forms more than might appear from Gall’s description. 2. The mathematical organ is not equally developed on both sides, but as a rule more strongly on the left. 3. The mathematical organ consists in part of a thickening of the soft parts. ... In fact, we find these modifications in almost all great mathematicians. However, sometimes the ridge running downward and backward from the lateral end of the eyebrows is more prominent and sometimes the slope of the outer edge of the orbita. Often the eye stands normally open, often the outer half of the lid hangs down so that the eye is half closed and seems to slant. If we observe the face from in front, it also strikes us that the distance between the outer angle of the eye and the contour of the face is strikingly great. Sometimes the space between the outer angle of the eye and the end of the eyebrow is particularly broad, the distance between the eye and the edge of the forehead magnified. In such cases there is usually neither a distinct ridge nor a slope; the origin is then, so to say, built upward. In individual cases the angular process is uniformly broadened with indefinite outlines, in others it projects with a sharp edge. The description is inaccurate in respect to the variety of nature. A definition that should be in accord with all variations is hard to be found. It would be, perhaps, best to say the mathematical organ consists in an abnormal formation of the angular process that amounts to magnification of the space inclosed by the process. We can say that on no two heads is the organ formed in exactly the same way. ... For the important fact that the mathematical organ is to be found prevalently
on the left, I need only refer to portraits. In the case of only moderate mathematical ability a
distinct modification is usually to be found only on the left. But at times there is scarcely a
perceptible difference between the left and the right, for example, in Leibnitz. At times, again,
the right as well as the left is abnormally formed, but the one is entirely different from the
other, for example, in Gauss. Here, also, the variations are many and it is neither practicable
nor advisable to describe all particular cases in words. . . . Even in considering portraits one
comes to the thought that the prominences are to be referred in part to an abnormally strong
development of the skin. If we examine the living, we can convince ourselves by feeling that a
considerable hyperplasia of the soft part exists. We feel distinctly that the angular process is
indeed uncommonly strongly developed, but also that the skin, more definitely the hypodermal
tissue, is thickened. The skin with an abundant cushion of fat forms a loose sack laid around the
angular process. Very frequently we see also strikingly heavy eyebrows."

With this information, you will undoubtedly be able to recognize the next mathematician you meet on
the street, and even judge the quality of this mathematician at a glance. (Also note that the author has
"strikingly heavy eyebrows," although he lacks an "abundant cushion of fat forming a loose sack laid around
the angular process," making him a good but not great mathematician.)
XVII.3.3. Mathematics and Mental Illness

This is a sensitive subject that I discuss with some hesitation. Mathematicians are often portrayed stereotypically in films and television as social misfits of borderline sanity. There are well-known examples of mathematicians who have suffered from mental illness, such as CANTOR, GÖDEL, and NASH, and other mathematicians whose behavior is at least quite odd by conventional standards (e.g. GROTHENDIECK, PERELMAN). And then there is TED KACZYŃSKI. Popular books, particularly about logic, sometimes suggest that sustained intense thought about mathematics and logic can, and typically will, drive a person insane.

An extreme (and fortunately not so well known) example was ANDRÉ BLOCH, who spent most of his life in an asylum for the criminally insane after killing his brother and two other family members out of fear that they were showing symptoms of hereditary mental illness present in his family history. While in the asylum he did a substantial amount of solid mathematics, particularly in Complex Analysis, and regularly corresponded with leading mathematicians, most of whom apparently did not know he was institutionalized. (He did do odd things such as date all his letters April 1 no matter when they were written.)

But mathematicians in fact appear to be no more, or less, susceptible to mental illness than any other group of people; in any category of people of substantial size, some percentage can be expected to have mental illness. For example, one can easily identify at least as many professional athletes as mathematicians who have had mental health problems, not even counting athletes who suffer brain injuries. Studies have shown that schizophrenics typically have below-average aptitude in mathematics.

Autism is possibly a different matter. There is evidence of positive correlation between autism and some types of mathematical ability. It is likely that some prominent mathematicians (possibly including NEWTON) have been mildly autistic. But the vast majority of mathematicians are in no way autistic.

It is true that many mathematicians are free thinkers who have an unconventional view of the world; one might even expect that the ability to transcend conventional ways of thinking is an important, even necessary, part of being successful in mathematics. And many mathematicians have rather low regard for social customs and norms, although many more are quite conventional socially. Part of the reason many mathematicians are somewhat unconventional may be that they can feel rather free to be so, due to the extreme degree of tolerance in the world of mathematics: mathematicians, probably more than almost any other social group, judge each other to a great extent simply on the quality of their work and ideas and not on social conformity.

“No one ever made a difference by being like everyone else.”

P. T. Barnum

It is also not accurate to characterize mathematicians as misfits who are loners or uncomfortable around others and in social situations. There are some such mathematicians, just as there are such people in most other walks of life, and mathematics may indeed be a comfortable refuge for such a person with sufficient mathematical talent; but most mathematicians are pretty adept and comfortable in social situations (VON NEUMANN was reputedly the life of every party he attended, and he is far from unique among mathematicians in this respect). And mathematicians tend to have broad interests and knowledge, and are not at all single-minded (except when they get working intensively on a mathematical problem, or some other project – mathematicians are very good at focusing their attention when necessary); you will find that mathematicians are often very interesting to talk to about almost any subject.

4Line from the 2017 film The Greatest Showman. There is no documentation that BARNUM actually said it.
Standard Notation in this Book

We will use the following standard (and sometimes not so standard) symbols to denote commonly used mathematical structures. In a few cases, the same letter is used to represent more than one structure; hopefully no confusion will result.

\[B^n\] Closed unit ball in \(\mathbb{R}^n\)

\(\mathbb{C}\) Field of complex numbers

\(\mathbb{D}\)
(1) Ring of dyadic rational numbers ()
(2) Open unit disk in \(\mathbb{R}^2\)

\(\mathbb{F}\) A field, usually \(\mathbb{R}\) or \(\mathbb{C}\)

\(\mathbb{H}\)
(1) Division ring of quaternions ()
(2) Hilbert cube \(\mathbb{I}^N\)

\(\mathbb{I}\) Closed unit interval \([0, 1]\) in \(\mathbb{R}\)

\(\mathbb{J}\) Set of irrational numbers in \(\mathbb{R}\)

\(\mathbb{K}\) C*-Algebra of compact operators on \(\ell^2\)

\(\mathbb{M}_n\) C*-algebra of \(n \times n\) matrices over \(\mathbb{C}\)

\(\mathbb{N}\) Natural numbers (positive integers)

\(\mathbb{Q}\) Field of rational numbers

\(\mathbb{R}\) Field of real numbers

\(\mathbb{R}^n\) Euclidean space of dimension \(n\) (set of \(n\)-tuples from \(\mathbb{R}\))

\(\mathbb{S}^n\) Unit sphere in \(\mathbb{R}^{n+1}\)

\(\mathbb{T}\) Topological group of complex numbers of modulus 1

\(\mathbb{Z}\) Ring of integers

\(\mathbb{Z}_n\) Additive group or ring of integers mod \(n\)

\(\mathbb{Z}_p\)
(1) Additive group or field of integers mod \(p\) (\(p\) prime)
(2) Ring of \(p\)-adic integers ()

The symbol \(\checkmark\) denotes the end of a proof, and \(\mathbb{Q}\) denotes “caution” or, at the end of an argument, “this is not really a proof as it stands.” Other hand symbols occasionally used should have obvious meaning.
XVII.4. Literature Review

“People who like this sort of thing will find this the sort of thing they like.”

Abraham Lincoln

We will give brief reviews here of some of the important books on real analysis and measure theory, and some other topics discussed in this book. In spite of any negative or qualifying comments I make here, almost all of these books are worthwhile to read and study. I have not yet included nearly all the books I am aware of that should be on the list, and I have not included any of the books that should be on the list that I am not aware of.

I generally try to write my own review before looking at any other reviews, and in most cases I have not read any other reviews; in cases where I have and other reviews differ substantially from mine or make additional points, I sometimes add comments to that effect (with attribution).

Undergraduate Analysis

Browder, Mathematical Analysis: An Introduction [Bro96]

This nice book covers undergraduate analysis, both one-variable and multivariable, as well as basic measure theory, and ends with some elementary differential geometry (manifolds and differential forms). Textbooks written by first-rate mathematicians often have a certain quality not found in some other books; the author’s overall approach, insights, and perspectives are quite illuminating. This book covers a lot of ground in a readable way, although some topics covered are not treated in depth.

The author is one of three brothers who are or were all eminent mathematicians. Their father was Earl Browder, a well-known American communist.

Euler, Foundations of Differential Calculus [Eul00]

English translation of the first part of Euler’s 1755 treatise on calculus. Primarily of (considerable) historical interest today, although almost all of the mechanical parts of calculus covered today in first-semester courses are here and treated in a nicely understandable way, if not always too rigorously (this was the first text about which this can be reasonably said), and as in most writings of great mathematicians there is much wisdom and insight in the exposition. And the man certainly could calculate! But, on the other hand, it is remarkable and revealing that even one of the greatest mathematicians had such a degree of misunderstanding about things we today regard as fairly basic, both in mathematics and physics (e.g. Euler seemed to consider it self-evident that matter is infinitely divisible). Throughout this book there is much beating of gums about the nature of infinity and the “infinitely small,” which he repeatedly states is actually zero or nothing while at the same time can be used as a divisor of another infinitely small quantity. This book graphically illustrates how far our understanding of the foundations of analysis has progressed since then.

Fichtenholz, Differential and Integral Calculus [Fic89]

In Russian. This classic three-volume treatise on undergraduate Real Analysis was used as a text by generations of students in the Soviet Union. Far more than just a calculus text. A German translation is available, but not an English one.

5 Book review; cf. R. Byrne, The Third and Possibly the Best 637 Best Things Anybody Ever Said, 514.
Fichtenholz, Foundations of Mathematical Analysis [Fe57]

In Russian. This two-volume set is a reworking of parts of Differential and Integral Calculus, and is aimed at a slightly higher (post-calculus) audience. A generally careful and readable exposition, although it suffers from excessive hand-waving in places (a criticism which can probably be made of most books on this list, including my own). Contains some material and viewpoints not readily found in Western texts. Unfortunately, no translation is available.

Körner, A Companion to Analysis [Kör04]

An insightful and entertainingly written account of undergraduate analysis. Treatment of the topics covered is mostly excellent. Although the mathematics is “honest” and carefully done, it is unsystematic and somewhat informal in places, and not all essential topics are covered, which make the book rather unsuitable as a text. But for its intended purpose as a “companion”, it is excellent.

Krantz, Real Analysis and Foundations [Kra05]

Like “little Rudin,” bridges undergraduate- and graduate-level analysis. I am not terribly impressed with this book, although it has some good features: it is generally pretty solid and complete, and gives a good introduction and motivation for interesting and important applications. But the exposition and organization are of uneven quality, and there are more errors than there should be in a book like this, especially a second edition. (Krantz is very prolific as a writer, but this comes at a price: his writing tends to suffer from a lack of polish and attention to detail, although much of what he writes is pretty good.) He claims that the writing style of this book, unlike older books, speaks to modern-day students in their own language, but I fail to see much difference in style between this book and older books; maybe he simply means the substantial number of statements in the text specifically addressed to the reader, which is indeed rather unusual writing style for a mathematics text but which I don’t imagine makes much practical difference to most readers.

The “preface” is primarily a masterpiece of self-promotion. It also contains the ridiculous assertion (written in 2005) that “real analysis has not appreciably changed in 150 years,” overlooking such fundamental work as that of CANTOR, DEDEKIND, LEBESGUE, . . . , as well as most of the foundational work of WEIERSTRASS (he did not yet even have a university position in 1855) and almost all of topology and functional analysis (and much more). Even the Riemann integral had just barely been developed and was not yet published or widely known. At least half of the present book, and a substantial portion of Krantz’s book, cover real analysis unknown, or at least not properly understood, in 1855.

If he had said “30 years” instead of “150 years,” the statement would have been more defensible, and more in line with what he was claiming in the preface to the first edition: that some other authors of recent analysis books have said that the subject has changed in the last 30 years. But this is a straw man; I am not aware of any author who has made such an assertion.

All in all, this book does not live up to the author’s hype.

The above comments were written about the second edition. A third edition has recently appeared, which has been revised into more of a traditional undergraduate real analysis text: the chapters on Lebesgue measure, wavelets, and differential forms have been removed. A chapter on functional analysis has been added (complete with introductory text directly contradicting the “150 year” statement). The remaining text is a little more refined, but the general comments above still apply. A quick and cursory perusal of the third edition turned up some sample howlers: every metric space is separable (section 13.2 problem 17; he says that this is “fairly tricky to prove” – I’ll say!); every bounded operator on $L^2$ is “essentially” a multiplication operator by the Spectral Theorem (section 14.4 problem 9); and in section 14.6 problem 6, a “norm” is defined which is not a norm (this topological vector space $C^\infty([a,b])$ is in fact not normable,
although it is completely metrizable with a metric defined by a formula similar to the “norm” formula, cf. ()).

There are also a number of inaccurate internal references, which is strange since accurate internal references are so easy in \TeX. Judging by the new preface, the author still has a pretty high opinion of himself and his book. (I should note that the prefaces to some of Krantz’s other books, such as [Kra15], have a far different tone and create a different picture of the author, who I must emphasize I do not know personally.)

Now there is a fourth edition. The slimming down of topics that began in the third edition has continued: for example, the chapter on functional analysis which appeared (with all its difficulties) in the third edition has disappeared just as suddenly. The author says he doesn’t want people to think this is a “high-level” text (I don’t think there is much danger of that; he also says he wants the text “to be the generational touchstone for the subject and the go-to text for developing young scientists” – a laudable but pretentious goal which is not likely either), but he still claims that this book is more rigorous and at the same time more readable than anything else since Little Rudin. But I don’t see either more rigor or more readability than, say, in [Pug15] (or even as much in this case).

For example, the discussion on p. 1 of the inadequacy of \( \mathbb{Q} \) for analysis is logical mush: the claim is that \( \mathbb{Q} \) is “not closed under limits” (apparently meaning limits of sequences) and must be expanded to a number system which is. But this argument presupposes that we already have a (perhaps still ill-defined) larger number system in which limits can be taken: if \( \mathbb{Q} \) is the only number system we have, it is tautologically closed under limits of convergent sequences. And if we want limits of all sequences, \( \mathbb{R} \) is also not closed. He tries to assert that every sequence of real numbers which “should” converge actually does. This is evidently an informal reference to the idea of a Cauchy sequence, a somewhat subtle notion which would certainly not leap to mind for someone (other than a Cauchy) who hadn’t seen it before. Many people would say the sequence \( (1, 2, 3, \ldots) \) “should” converge to \(+\infty\), but \(+\infty \notin \mathbb{R} \), so not every sequence in \( \mathbb{R} \) which “should” converge does, i.e. \( \mathbb{R} \) is not closed under limits either (e.g. in the extended real line). I’m not saying it is easy to give an elementary yet mathematically and logically honest introduction to the notion of completeness, but one can certainly do a lot better than the discussion in the book.

On p. 25, he proves that a sequence in \( \mathbb{C} \) converges if and only if it is Cauchy (after proving this for real sequences) by making the “observation” that a sequence in \( \mathbb{C} \) converges (resp. is Cauchy) if and only if the sequences of real and imaginary parts converge (resp. are Cauchy). There is no previous discussion of anything like this. In fact, both “observations” are propositions which need to be proved. Of course, the proofs are very easy, but they are not trivial, especially for someone who has just seen the definitions of the concepts; at the very least, these should be expressly designated as exercises for the reader, not just “observations.”

On p. 290, it is asserted that “a moment’s thought” shows that an open spherical shell cannot be written as a disjoint union of open balls. Maybe so. But another moment’s thought reveals that this is actually quite nontrivial to prove (and I’m not sure why the question is even relevant to the discussion on that page).

In fact, almost every page I looked at contained something I could quibble with, although many of the criticisms are petty ones concerning the author’s writing style. For example, on p. 19, he says, “If a sequence does not converge then we frequently say that it diverges.” Frequently? When do we not? (OK, I guess we don’t always actually say it diverges, but we could.) Why not just say: “A sequence diverges if it does not converge.”?

I guess someone (other than the author) must like this book, since it has been through four editions.

Pugh, Real Mathematical Analysis [Pug15]

This is overall an excellent book, and is one of the best references for learning and understanding real analysis. The author’s explanations and insights on most topics are outstanding. The book is mathematically honest and generally rigorous. However, many arguments are written a little informally, with some routine
details glossed over; thus a student using this as a textbook might have trouble developing the skill of writing complete rigorous analysis proofs if the book’s proofs are taken as a model (to be sure, there are plenty of proofs in the book written out fully enough to meet anyone’s standards).

Rudin, Principles of Mathematical Analysis [Rud76]

“Little Rudin” or “Baby Rudin.” One of the most widely-used analysis books for a long time, with good reason. Covers pre-measure-theory analysis with a last chapter on Lebesgue measure.

Schumacher, Closer and Closer [?]

A leisurely and non-stressful introduction to undergraduate real analysis. This is a pretty good book, despite its problematic title (cf. IV.1.3.11.); it is nicely written, the mathematics is generally carefully done and is not “dumbed down,” and a surprising amount of material is covered. The discussion of the Implicit Function Theorem is especially good. The treatment is mostly mathematically “honest” (I.7.), although some subtleties, e.g. the Axiom of Choice, are not mentioned. One mistake I noted is the wrong definition of countable compactness (p. 141), confusing countably compact with Lindelöf. The approach is an “active learning” one, based on the Socratic method: some arguments are given in great detail, but many are left as exercises for the reader, often with little hint as to how to proceed. Such an approach is certainly defensible pedagogically. This is a good supplementary text for a reader desiring a gentle but reasonably thorough treatment of the subject.

Stromberg, An Introduction to Classical Real Analysis [Str81]

This is a terrific book (although I would not describe the writing as a literary masterpiece). It is thorough and detailed, but also has much helpful explanatory material. The first few chapters cover standard undergraduate analysis at a similar level to most undergraduate texts, but the pace and depth increase when integration is reached. Riemann integration is not treated, except in passing after the fact; instead, the Riesz-Daniell approach to Lebesgue integration is followed. Some complex analysis is interwoven and integrated into the development at appropriate points. The exercises in this book are especially notable. This is not only a textbook (probably most suited to an honors-level analysis course), but also a great reference work even for mature analysts.

Wade, An Introduction to Analysis [?]

This is a decent book on undergraduate real analysis, covering both the one-variable and multivariable theories, but there are many small things I would wish to do differently. The fourth edition has a number of improvements over the third edition (although the deletion of the chapter on differential forms is not one of them), but the fourth edition seems “cheaper” than the third in both typesetting and binding. The author also did not do a very good job proofreading this edition before publication. There is a long list of typographical errors from the first printing on his website which have been corrected in later printings, but a significant number of typographical and mathematical errors remain.

Real Analysis, Measure Theory, and Integration

These textbooks cover the basic theory of measure and integration, and most also treat the basics of functional analysis.

Many general measure theory texts follow what I call the “reinventing the wheel” plan: first develop Lebesgue measure and integration, then redo everything in general, in many cases just referring back to the
Lebesgue case for proofs of results. This approach is certainly defensible pedagogically, and is preferred by many people, but it is not to my personal taste; I much prefer to start out with general measure theory, spending considerable time discussing and emphasizing the critical special case of Lebesgue measure as I go, as well as discussing other special cases such as probability spaces.

“One of the many fundamental questions which any author on the subject must decide, is whether to begin with ‘general’ measure theory or with ‘Lebesgue’ measure and integration. The point is that Lebesgue measure is rather more than just the most important example of a measure space. It is so close to the heart of the subject that the great majority of the ideas of the elementary theory can be fully realised in theorems about Lebesgue measure. ... If you take the view, as I certainly do when it suits my argument, that the business of pure mathematics is to express and extend the logical capacity of the human mind, and that the actual theorems we work through are merely vehicles for these ideas, then you can correctly point out that all the really important things in [elementary measure theory] can be done without going to the trouble of formulating a general theory of abstract measure spaces; and that by studying the relatively concrete example of Lebesgue measure on \(\mathbb{R}^n\)-dimensional Euclidean space you can avoid a variety of irrelevant distractions.

If you are quite sure, as a teacher, that none of your pupils will wish to go beyond the elementary theory, there is something to be said for this view. I believe, however, that it becomes untenable if you wish to prepare any of your students for more advanced ideas. The difficulty is that, with the best will in the world, anyone who has worked through the full theory of Lebesgue measure, and then comes to the abstract theory of general measure spaces, is likely to go through it too fast, and at the end finds himself uncertain about just which ninety percent of the facts he knows are generally applicable. I believe it is safer to keep the special properties of Lebesgue measure clearly labelled as such from the beginning.”

\[D. \text{ Fremlin}\]

The “reinventing the wheel” approach seems to me like presenting Linear Algebra by first stating and proving all the theorems of the subject for \(\mathbb{R}^n\), and then restating and partially reproving them for general vector spaces.

Bogachev, Measure Theory \[Bog07\]

A very thorough two-volume treatment of measure theory. In order to cover the huge volume of material, many topics, some of them important, are relegated to “exercises” where arguments are only sketched or outlined.

The English translation was apparently done by the author himself. Although this was a commendable effort, and in most places the translation is pretty good, the results are not entirely satisfactory, and in a few places the reader must puzzle out what the author is trying to say (of course, in many books written by native English speakers, probably including my own, the reader must do the same thing!)

Doob, Measure Theory \[Doo94\]

This book, written by an eminent probabilist, is somewhat idiosyncratic, but valuable. It has nice, efficient treatments of a number of topics not readily found in standard texts. The approach is not especially

\[^{6}\ [?] \text{, V. 1, p. 9.}\]
wedded to probability theory, but the chapter on martingales (invented by the author) is especially valuable for probabilists. Many arguments represented as proofs in this book are really only outlines, and need many details to be filled in by the reader (not necessarily a bad thing!)

Dunford and Schwartz, Linear Operators I [DS88]

This first of a three-volume set is usually regarded as an encyclopedic treatise on Operator Theory. But chapters 3 and 4 give an extensive treatment of measure theory and related topics. One of the best places to read about finitely additive measures and integration (from the beginning, a “measure” is a finitely additive complex measure), and vector measures.

Folland, Real Analysis [Fol99]

This is one of my personal favorite Real Analysis texts. It contains elegant and comprehensive treatments of many important topics. However, the basic measure theory part is much too concise to be a good choice as a text for a beginning course, especially for masters students, as I discovered when I tried it. The approach of this book is the exact opposite of the “reinventing the wheel” plan, in my opinion too much so: it treats Lebesgue measure almost as an afterthought, as a special case of Stieltjes (Radon) measures.

Fremlin, Measure Theory [Fre04]–[Fre06]

A monumental five-volume treatise on almost all aspects of the subject. Not suitable as a text, although the first two volumes are designed to be accessible to students, but a detailed and comprehensive reference work.

Halmos, Measure Theory [Ha50]

The first (1950) “modern” treatment of measure theory, and still one of the best. It is an excellent treatment of the basics of measure theory (done from the standpoint of what we call “premeasures on rings”), and includes some more advanced topics such as Haar measure. In fact, one can hardly improve on the exposition of many of the topics covered.

Hewitt and Stromberg, Real and Abstract Analysis [HS75]

A classic book. It is dense in places and not always easy going, but well written and contains a wealth of material.

Lieb and Loss, Analysis [LL97]

This is a valuable book with a little different emphasis than most. The authors’ philosophy is to seamlessly merge classical and functional analysis, which they have done well. The treatments of measure theory and basic functional analysis are rather sketchy, but the coverage of $L^p$-spaces and Sobolev spaces is excellent, among the most complete in any general analysis book. The general approach is a low-tech and computational one, emphasizing inequalities and “hard analysis” arguments rather than abstract general theorems (quite the opposite of Pedersen), an approach which has much merit and should particularly appeal to applied analysts; the primary intended audience for the book is evidently applied mathematicians and mathematical physicists, and there are many physics-related applications woven throughout. The book is written in somewhat of a stream-of-consciousness style, and would have benefited from some more organizational attention and effort on the part of the authors; but on the other hand, it is full of insightful comments and observations. This is not a book I would be likely to use as a text, but it is a great supplementary text.
McDonald and Weiss, A Course in Real Analysis [MW99]

This is overall one of the better measure theory texts, and one that I have used several times. The treatments of most standard subjects range from fairly good to excellent. Some of the writing is somewhat turgid, and some of the definitions (e.g. Borel sets, absolutely continuous functions) are nonstandard but equivalent to the usual ones. A few proofs are more laborious or roundabout than necessary. A few important basic results, e.g. the Lebesgue Density Theorem, are not covered. This text follows the “reinventing the wheel” plan. This book has a lot of exercises, some of which are fairly challenging, but generally with hints and guidance.

Natanson, Theory of Functions of a Real Variable

Another standard Soviet text. Well done, and covers material not found in other books (e.g. the Banach-Tarski paradox). Volume I is pretty routine, but Volume II is more interesting. The English translation leaves something to be desired, and is confusing in places: for example, in several instances the phrase “replace $x$ by $y$” should be “replace $y$ by $x$” (this is simply a translation error; the original Russian text is correct).

Pedersen, Analysis NOW [Ped89]

The author, a specialist in Operator Algebras, takes an uncompromising approach to measure and integration using functional analysis methods (he says the title means “Analysis via norms, operators, and weak topologies”). This is a valid approach with much to recommend it (in my opinion as a fellow Operator Algebraist), but should probably be complemented by a more traditional treatment. The text is clearly written, and witty in places (different readers will have different opinions about the wit).

Royden, Real Analysis [Roy88]

This is one of the “classic” texts (and the one I learned measure theory from as a student). Despite its age, it is still a viable and worthwhile option. The third edition has some additions and improvements, but also more errors than the second edition. This book follows the “reinventing the wheel” plan, to an even greater extent than most. An expanded and updated fourth edition, prepared by M. Fitzpatrick, has recently appeared.

Rudin, Real and Complex Analysis [Rud87]

“Big Rudin.” Also a classic book, widely used. The author rather uniquely covers and integrates Real Analysis (measure and integration) with Complex Analysis. These subjects are usually treated separately, but there is much merit in the author’s approach which highlights the overlap and interplay of the two theories (although I have chosen not to follow this path in this book). Rudin does not follow the “reinventing the wheel” plan; general measure and integration is developed in Chapter 1, and Lebesgue measure is obtained by applying the Riesz Representation Theorem to the Riemann integral.

Saks, Theory of the Integral [Sak64]

This was the first comprehensive book on measure and integration (1933), and is very impressive in its breadth and depth, as well as giving a nice overall view of the logic and philosophy of the subject. While the abstract Lebesgue integral on general measure spaces is treated, it is somewhat in passing and the discussion is practically limited to subsets of Euclidean space. At least half the book is devoted to a study of the interrelated topics of indefinite integration, bounded variation, and absolute continuity. The book
is still well worth careful study. Treatments of some topics have been improved since this book, but many
have not, and indeed this book covers a number of important topics not treated adequately in most newer
references. It is overall quite well written and readable, although dense and detailed. Some of the notation
and terminology is outdated and requires care on the reader’s part to decipher. Definitely a book for adults.

Swartz, Measure, Integration and Function Spaces [Swa94]

This book has a rather unconventional approach to the subject with much to recommend it. It treats
finitely additive, signed, and complex measures from the beginning rather than as an afterthought. It has
a good treatment of limits of measures, the Nikodým Convergence and Boundedness Theorems, and the
Vitali-Hahn-Saks Theorem. The treatment of fundamentals of functional analysis includes ordered vector
spaces.

Taylor, Measure Theory and Integration [Tay06]

A good general treatment of the subject, with topics leading in the direction of geometric measure theory
not well covered in other texts in this group. However, the author is not as careful as he should be in
specifying finite or $\sigma$-finite restrictions in some results and problems (I found several places where such
restrictions are necessary and not mentioned).

Complex Analysis

There are dozens, perhaps hundreds, of complex analysis texts. We will only describe a few of the best.
Many others are at least decent.

Ahlfors, Complex Analysis [Ahl78]

Generally regarded as the classic complex analysis text, and still worth studying.

Brown and Churchill

One of the classic complex analysis texts (I used an early edition as a textbook as a student, when it was
just Churchill). Oriented primarily for nonmathematics students, e.g. physicists and engineers, but unlike
some books of this type it is mathematically solid.

Gamelin, Complex Analysis [Gam01]

One of the very best complex analysis texts.

Greene and Krantz, Function Theory of One Complex Variable [GK06]

I had a somewhat better opinion of this book before I used it (third edition) as a text for a class. It
is overall quite good, especially the later chapters (e.g. the treatment of the Riemann Mapping Theorem is
generally excellent). But the first three chapters with the basic theory are somewhat of an organizational
mess, and some of the exercises are not well thought out (in fact, I had some trouble finding enough good
and suitable exercises for my class). And the authors beat the $\frac{\partial f}{\partial z}$ and $\frac{\partial}{\partial z}$ notation to death, and insist on
writing $\frac{\partial f}{\partial z}$ instead of $f'$ for the derivative of a holomorphic function $f$ throughout most of the book, and
even $\left(\frac{\partial}{\partial z}\right)^n f$ for the $n$’th derivative, making for confusing formulas which are hard to read.
Krantz, Complex Variables, A Physical Approach with Applications and MATLAB

This book seems designed as a modern replacement for Brown and Churchill. It is a rather slow-paced treatment of basic complex analysis aimed at a nonmathematical audience. Far less detailed and sophisticated than [GK06]. Generally well-done, with good insights and explanations of standard results. The MATLAB part (also covering some other similar packages) is not at all deep, barely going beyond how to do complex arithmetic. A good book to read as an introduction to the subject.

Remmert, Theory of Complex Functions [Rem91] and Classical Topics in Complex Function Theory [Rem98]

This is more or less a two-volume sequence, but there is a vast difference in depth and sophistication between the two volumes. The first is a treatment of the basic theory, suitable for undergraduates, and the second is a dense, detailed study of more advanced topics. Both are entertainingly written with extensive historical notes, including anecdotes only loosely related to the subject at hand (such as noting that Pringsheim was at first denied Habilitation “on account of the great ignorance of the candidate”; he apparently refused to explain how to solve quadratic equations.) The books are probably not suitable as primary texts, but are excellent supplemental texts.

Stein and Sakarchi, Complex Analysis [SS03]

Part of the authors’ series of books on analysis. This book stands on its own as well as a volume in the series. Covers basic complex analysis, not as thoroughly as in [Gam01] or [GK06] but well, and then has detailed treatments of number-theoretic functions and the Prime Number Theorem, and of elliptic functions. A very worthwhile addition to the literature, but perhaps not the best choice as a text for an introductory complex analysis course.

Functional Analysis

Kreyszig, Introductory Functional Analysis with Applications [Kre89]

A classic text, and one of the few options for a class without a measure theory prerequisite. It has a vaguely applied orientation, but mainly just covers the basic theory, and covers it well. Still a good choice as a text for an introductory course at the advanced undergraduate level.

Lax, Functional Analysis [Lax02]

This is overall one of the best texts on functional analysis, by one of the leading applied analysts of the 20th century. It includes many topics not covered in other standard texts, and the treatment of most topics is excellent. It has thorough coverage of theoretical functional analysis as well as some applied areas. (There are, however, a rather large number of typographical errors, most of which are inconsequential.) The author’s applied orientation shows through not only in his choice of material, but also in the style and tone of some of the presentation and his notation and terminology; however, this does not make the book less useful or valuable for “pure” mathematicians. Some of the exposition is more reflective of the 1950s than 2002, when the book was published; for one example close to my heart, the antiquated term “B*-algebra” is used, a term I have not otherwise seen since about 1980; specialists in this field have almost universally used the name “C*-algebra” since the 1960s.
**Specialized Topics in Real Analysis**

Diestel and Uhl, Vector Measures [DU77]

Despite the name, only the first two chapters cover the theory of vector measures and integration *per se*; the rest of the book consists of applications to the structure theory of Banach spaces. The first two chapters give a nice introduction to vector measures and Bochner integration. The authors’ personalities and strong opinions make for interesting reading.

König, Measure and Integration [Kön97]

This is a highly original book and contains much material not available elsewhere about construction of measures from primitive data. But the author’s opaque writing style and frequently nonstandard notation and terminology make for tough reading.

Krantz and Parks, The Implicit Function Theorem [KP02a]

The most thorough discussion available of the various versions of the Implicit Function Theorem and Inverse Function Theorem and their histories.

Krantz and Parks, A Primer of Real Analytic Functions [KP02b]

This is a quite thorough treatment of the theory of real analytic functions, covering not only the basic one-variable and multivariable theories, but also more advanced topics such as the Cauchy–Kovalevskaya Theorem, quasi-analytic and Gevrey classes, and the embedding theorem for real analytic manifolds. Complete (or at least semi-complete) proofs are given for most elementary results, but as the topics become more advanced the book becomes more of a survey. Generally well written and readable, although, as with many of Krantz’s books, there is an annoying lack of quality control and attention to detail in places. (I do not mean to slight the contributions of Parks, who has long been an acquaintance of mine.)

Oxtoby, Measure and Category [Oxt71]

This book is rather unique and does not directly overlap with any other books I know of (except for [BJ95], which is a sequel of sorts), although most topics can be found scattered elsewhere. The theme is the duality between the theories of Lebesgue measure and Baire category. Many results in one of these theories have an analog in the other, which is often more than merely an analog. Along the way, topics like the Banach-Mazur game are discussed and woven into the story in an illuminating way.

Schechter, Handbook of Analysis and its Foundations [Sch97]

I think the review of this book on MathSciNet is far too negative. This book, if properly viewed and used, is a valuable resource. Despite the name, not too much classical analysis is covered; instead, the author concentrates on an efficient and logical development of much of the mathematics a modern analyst needs to know, beginning with sets, relations, and orderings, proceeding through algebra and logic, topology and uniformity, and concluding with an extensive treatment of topological vector spaces. This skeleton outline does not do justice to the range of mathematics covered.

Globally, this book is very much in the style of *BOURBAKI* in its organization, attempting to present the most efficient logical path through the development of the material. But the local style is very different: Schechter allows himself much room for motivation, explanation, entertaining writing, and even some humor, things famously and deliberately excluded from *BOURBAKI* (although there is some subtle humor in
Bourbaki reflecting the personalities of the members, beginning with the name itself; indeed, according to [RS09], Grothendieck was not a successful member of Bourbaki in part because he “lacked humor.”

I discovered this book when my manuscript was already well along, and I was struck by how many passages were similar to things I had written, tried to write, or planned to write, often done better than I could have myself. Needless to say, I approve of the author’s views about many things in mathematics. (This is not to say that this book is overall very similar to my own; there are very significant differences.)

That said, I do not think this book would be an appropriate place to learn about most of the material covered; it would be most suitable for someone who had already been introduced to most of the major topics. The author did not assume any prerequisites beyond calculus except for a degree of mathematical maturity, but the book would be best used to fill in holes in one’s background and to see how everything fits together logically.

This book would have been much more effective as an online book with hyperlinks, organized more in the manner I envision for my own manuscript (i.e. less linearly). The author’s logical progression of development means that many results and ideas are introduced before they are actually used, and there are numerous cross-references to other parts of the book. If one simply wants to understand a certain topic or result, a maze of tedious searches through the book via cross-references is often necessary to get the full picture, which would be much more efficient and less annoying if done via hyperlinks. For example, there is a very nice and complete proof of the Brouwer Fixed-Point Theorem contained in the book, but pieces of the proof are scattered through several parts of the book. I hope eventually an online edition of this book can be produced with hyperlinks (there is currently a CD-ROM version, but it appears to be identical to the printed version).

van Rooij and Schikhof, A Second Course on Real Functions [vRS82]

This nice book concentrates on a detailed study of differentiation and integration of functions on the real numbers. The material is restricted in scope, but the treatment is quite complete, containing facts, results, and examples otherwise scattered through the literature.

Measure and Probability

These texts are generally very good, and could serve nicely for a first-semester course in measure theory, as well as for a probability course.

Billingsley, Probability and Measure [Bil95]

A current standard for this genre. Contains a lot of material on probabilistic number theory as well as general measure theory and, of course, standard probability theory.

Dudley, Real Analysis and Probability [Dud02]

An excellent treatment of both measure theory and probability. The two subjects are separated more strictly than in other books of this type, and emphasis is placed on Borel measures on metric spaces, which are especially important in probability. The advanced topics discussed are primarily, but not exclusively, directed towards probability. The writing is clear and readable, and in places rather informal and even chatty, with some important definitions and secondary results buried in passages of text. The writing style somewhat obscures the very careful treatment of the mathematics; I particularly admire the efforts the author made to present the most elegant proofs available of the results. He has a good sense of how to present material in a mathematically honest but non-overwhelming way. There are also extensive and valuable historical notes.

Kingman and Taylor, Introduction to Measure and Probability [KT66]
Geometric Measure Theory

Geometric Measure Theory fairly rapidly splits into two rather distinct parts: “smooth” geometric measure theory and the study of fractals. Some of these references (e.g. Morgan) concentrate on the first, and others (e.g. Edgar) the second. But the basic tools like Hausdorff measures are common to both, and all these references have at least some relevance to both parts.

Edgar, Measure, Topology, and Fractal Geometry [Edg08]

An undergraduate-level introduction to fractals and the tools needed to study them. Contains nice but somewhat “light” (focused on the needs of the book) introductions to metric spaces, topological dimension, and measure theory (Lebesgue and Hausdorff measures). A good place to begin reading about the subjects covered.

Edgar, Integral, Probability, and Fractal Measures [Edg98]

A “sequel” to Measure, Topology, and Fractal Geometry. The title gives a good summary of the topics covered.

Falconer

Descriptive Set Theory

Bartoszyński and Judah, Set Theory: On the Structure of the Real Line [BJ95]

This book more or less picks up where Oxt71 ends. But the treatment is quite technical, and mostly of interest only to specialists in Set Theory.
Kechris, Classical Descriptive Set Theory [Kec95]

The best introductory treatment of Descriptive Set Theory. Covers the basics of the subject thoroughly from many points of view, and makes a convincing case for the importance of the subject and its place in the world of mathematics. More readable than Moschovakis for nonexperts in set theory, although it is more of a complement than a substitute.

Moschovakis, Descriptive Set Theory [Mos80]

The standard treatment of Descriptive Set Theory before Kechris. Requires more detailed familiarity with set theory and logic. Well written and readable, however, and a valuable supplement to Kechris.

Foundations, Set Theory, Logic, Large Cardinals

Kanamori, The Higher Infinite [Kan03]

This is, and will likely remain (additional volumes are planned), the definitive treatment of the theory of large cardinals. Much of the text is tough going for readers not expert in set theory and mathematical logic, but there are also extensive explanations and motivation for important topics and results, so the book is valuable even for nonspecialists. The order of topics follows the historical development, so the origins of the ideas can be traced. There are also numerous and quite candid descriptions and evaluations of the work of individual mathematicians involved in this subject, which make for interesting reading.

Landau, Foundations of Analysis [Lan51]

The first complete treatment of the construction of the real and complex numbers from the Peano axioms (although the various constructions had long since been known and carefully described). The text is rather dry and formal with little explanatory material (although the introduction is engagingly written), but not too much is really necessary and the arguments are easy to follow.

Lawvere and Rosebrugh, Sets for Mathematics

This is an appealing and readable treatment of set theory and the foundations of mathematics using categories, and makes a good case that this is the most natural and fruitful approach to foundations for most working mathematicians. However, I find somewhat unconvincing the authors’ cavalier assertions that category theory and “naive set theory” (which is what is obtained when the category framework is stripped away) as presented in this way are free from logical contradiction and paradox.

Lucas, The Conceptual Roots of Mathematics [Luc00]

This is an entertaining and enlightening book, as well as a good source of pithy quotes. The theme is an argument for a “chastened logicism” as the correct philosophy of mathematics; but there is much more of interest, such as one of the best discussions I have read of second-order logic. I know nothing of the author, but he comes across as something of a character. The quality of both the mathematics and the writing is somewhat uneven, ranging from silly (arguing that Euclidean geometry is “better” than noneuclidean, or invoking stereotypes of Scotsmen and Welshmen to explain some terms) to trenchant.

Nagel and Newman, Gödel’s Proof [NN01]

A nice introduction to Gödel’s Incompleteness Theorem, readable for nonexperts, although it contains a serious misstatement (see H. Putnam’s review in Philos. Sci. 27(1960), p. 205-207).
Potter, Set Theory and its Philosophy [Pot04]

This is an impressive and valuable treatment of set theory which bridges philosophy and mathematics. The mathematical part of the book contains good treatments of the construction of number systems, cardinals, ordinals, and the axiom of choice, as well as set theory itself. Set theory is axiomatized by the theory of levels, but there is also extensive discussion of other systems such as ZF which give theories essentially equivalent for the purposes of providing a foundation for mathematics. Includes extensive historical discussions of the development of the various topics and the philosophy underlying them. Very nicely written, and the philosophical part is varied and balanced. Nonetheless, mathematicians may not agree with all of the philosophical arguments given, and there are a few minor mathematical errors (perhaps no more than in any other book on the list!), such as the formula on p. 232 and accompanying comments.

Sierpiński, Cardinal and Ordinal Numbers [Sie65]

An encyclopedic treatment of ordered sets, ordinals, and cardinals. Contains much material about the order structure of the real line. Interesting reading, with many clever arguments and observations. Some of the language used is a little unusual mathematically, and logically ambiguous in places; for example, a number of results are phrased as “We can prove with the aid of the Axiom of Choice that . . . .” Apparently this language was used because at the time of the publication of this book, it was not definitely established that these results were independent of ZF set theory (most, if not all, have been subsequently shown to be independent).

Smullyan, Gödel’s Incompleteness Theorems [Smi92]

A very readable and mathematically complete treatment of various versions of Gödel’s Incompleteness Theorem. Perhaps the best source to learn about the details of the theorem.

Nonstandard Analysis

Davis, Applied Nonstandard Analysis [Dav77]

Goldblatt, Lectures on the Hyperreals [Gol98]

Hurd and Loeb, An Introduction to Nonstandard Real Analysis [HL85]

Robinson, Non-Standard Analysis [Rob66]

The original treatment of Nonstandard Analysis, and as such of historical and conceptual value. But it is outdated as an exposition of the subject: for example, the hyperreals are constructed using the Compactness Theorem of model theory rather than via ultrafilters (the distinction is more apparent than real, since ultrafilters are used to prove the Compactness Theorem). No longer the best reference for learning about the subject. The last chapter is a discussion of Robinson’s interpretation of the history and philosophy of calculus; while interesting and valuable as motivation for his development of Nonstandard Analysis, some of his opinions are questionable at best.

Constructive Analysis

Bishop and Bridges, Constructive Analysis [BB85]

This is a “second edition” of Bishop’s treatise, largely prepared by Bridges after Bishop’s death.
Bridges and Viţă, Techniques of Constructive Analysis [BV06]

A sequel of sorts to [BB85], although it does not presuppose any knowledge about constructive analysis. It includes much material that postdates the publication of [BB85], and is more reflective of the state of the art in this subject. Nicely written, and a good place to learn about some constructive analysis without becoming embroiled in the philosophical controversies underlying it: the authors present the subject in the right way, in my opinion, as an interesting and useful part of mathematics rather than the only true way to do all of mathematics.

The authors’ presentation does, however, have some foundational obscurities which must be sorted out. In their approach, a “set” is a collection of objects constructed according to some property, from objects which have “already” been constructed [if a construction is done once, is it permanent, or can it be “lost”, e.g. with the death of its constructor?], along with an equivalence relation of “equality” on the objects. In practice the mathematician cannot distinguish between equivalent objects. This approach implicitly presupposes two levels of existence and knowledge: an omniscient level where the objects really exist and where true equality of objects makes sense, and where the equivalence relation can be truly defined, and a lower level of perception on which human mathematicians operate where objects can only be described or distinguished by constructive arguments. Viewed this way, constructive analysis nicely models the way analysis is actually carried out by mathematicians and especially by computers, and the algorithmic arguments forced by this approach are of obvious importance.

From the point of view I take in the last paragraph, what the authors call the “equality” relation should be called “indistinguishability,” and what the authors call “inequality” (constructive proof that two objects are not “equal”) should be called “distinguishability.” But there are still some logical difficulties: for example, in practice it is not obvious that “indistinguishability” is an equivalence relation, specifically that it is transitive. For (perhaps oversimplified) example, suppose we say we can only distinguish real numbers if they differ by at least $10^{-6}$ (this is reasonable from a computer architecture point of view, perhaps with a different constant). We can then have three numbers $a, b, c$ with $a$ and $b$ indistinguishable, $b$ and $c$ indistinguishable, but $a$ and $c$ distinguishable. In fact, any type of archimedean property of the real numbers would seem to be incompatible with indistinguishability being transitive; real numbers indistinguishable from 0 would be analogous to infinitesimals in nonstandard analysis (ironically, constructivists, notably including Bishop [Bis77], are some of the most vocal critics of nonstandard analysis).

Another somewhat jarring feature of the presentation of the book is the rather brief and unmotivated adoption of the set $\mathbb{N}$ as the foundation for all of analysis. The only justification given for this is two quotes from Kronecker and Bishop in effect saying that they regarded $\mathbb{N}$ as a gift from God; the authors seem to suggest that if it was good enough for them, it is good enough for us too. This approach is somewhat of an injustice: in fact, there are reasonable arguments in favor of viewing $\mathbb{N}$ as a starting point, such as ones described in [Hey66]. But I still think the worship of $\mathbb{N}$ as the starting point of mathematics is a philosophical weak point of intuitionism/constructivism.

Heyting, Intuitionism: an Introduction [Hey66]

Number Theory

Baker, Transcendental Number Theory [Bak90]

Perhaps the definitive work on the subject, covering the author’s revolutionary contributions. The techniques cover a broad range, from algebra and number theory to geometry and hard analysis. Worth looking at, if only to get a feeling for the character of the subject.
Hardy and Wright, Introduction to the Theory of Numbers [HW08]

Khinchin, Continued Fractions [Khi97]

This little gem is probably the best introduction to the theory of continued fractions. The first 2/3 of the book is an elementary and very readable introduction to the algebraic theory. The last part is on a considerably more sophisticated level, giving a nice and still very readable treatment of the probabilistic aspects of the theory and full proofs of the author’s important results about the probabilistic distribution of terms in continued fractions.

Niven, Irrational Numbers [Niv56]

Geometry

Berger, Geometry I, II [Ber09]

Originally a single volume in French. A wide-ranging and informative treatment of geometry, including such topics as map projections for the earth.

Blumenthal, Theory and Applications of Distance Geometry [Blu70]

This is an interesting, valuable, and rather unique treatment of geometry from the metric space point of view. The subject matter is covered thoroughly, not only metric characterizations of Euclidean space, but also curvature and elliptic and hyperbolic spaces. Some of the notation and terminology is outdated, and some sections and arguments seem a bit laborious and unfocused. Nonetheless, it is the best reference on these topics, and virtually the only one on some of them.

Greenberg, Euclidean and Non-Euclidean Geometry [Gre93]

An elementary college-level text on axiomatic geometry, with emphasis on the history and nature of the Parallel Postulate. Very readable, and mostly carefully written, although EUCLID’S postulates are rather mangled (they are eventually written properly, but seemingly only as an afterthought).

Hartshorne, Geometry: Euclid and Beyond [Har00]

A careful and comprehensive axiomatic treatment of elementary geometry, both Euclidean and Noneuclidean. Written on a more sophisticated level than Greenberg, but very readable. The connections between geometry and modern algebra are extensively discussed and explained. The author has included nice touches such as hand-drawing most of the diagrams to maintain the spirit of EUCLID.

Moise, Elementary Geometry from an Advanced Standpoint [Moi90]

Topology

Topology, as covered in the literature, seems to be essentially two separate subjects: point-set topology and algebraic topology. Few books treat both parts of topology in any detail. Even within each part, standard references vary greatly in which topics are covered in detail, since the subjects are too large to be covered comprehensively in any one reference. Different standard references are better or more complete for different topics, to a much greater extent than in basic real analysis, and it is not feasible in brief reviews to give a full
summary of which references are good for which topics (and this is a somewhat subjective matter anyway). Readers are encouraged to explore broadly.

Alexandroff (Aleksandrov) and Hopf, Topologie I [AH74]

In German. The first comprehensive book on topology, both point-set and algebraic (1935). I was rather surprised how much of the basics of topology had reached its modern form (some of it for the first time) in this book, since the whole subject had barely begun by the beginning of the twentieth century, although Hausdorff’s book [Hau49] must be regarded as more revolutionary. In particular, much of the topology we cover in this book appears here in essentially modern form. Although this is denoted “Volume I”, there was never a Volume II or, unfortunately, an English translation.

Borsuk, Theory of Retracts [Bor67]

Dugundji, Topology [Dug78]

Engelking, General Topology [Eng89]

The third iteration of this book. This is the most comprehensive text on general topology, and seems to have become the standard reference, although there is essentially no mention of algebraic topology concepts, even the fundamental group (in fact, homotopy is barely mentioned at all). It is also nicely written, with considerable explanation, motivation, and historical notes. However, it is probably too detailed (and esoteric in many places) to be a good text for an introductory course. Copies are also rather difficult and expensive to come by.

Engelking, Theory of Dimensions Finite and Infinite [Eng95]

Revised version of Dimension Theory (available online). A modern version of Hurewicz and Wallman, covering the theory of dimension beyond the separable metric case, and the theory of infinite-dimensional spaces. Nicely written, and a good place to learn about dimension theory even for separable metric spaces, the case of most general interest.

Hatcher, Algebraic Topology [Hat02]

One of the best modern treatments of classical algebraic topology, and freely available online to boot. Very clearly written, with a highly readable exposition of most important basic aspects of algebraic topology. Perhaps the best source for learning the fundamentals of the subject, and a model for what I hope will someday be available online in all parts of mathematics, a goal to which I hope my own book will make a contribution. The author promises additional volumes, which I sincerely hope to see.

Hausdorff, Grundzüge der Mengenlehre [Fundamentals of Set Theory] [Hau49]

This was a path-breaking book (1914), and still merits study. The first half of the book is an exposition of set theory, ordered sets, ordinals, and cardinals; while it is undoubtedly a better treatment of these subjects than was available previously, this part does not really break new ground. But the second half of the book can be fairly regarded as the beginning of the modern subject of point-set topology, although the notion of an abstract topological space was first described by Fréchet in 1906. It contains the first modern definition of a metric space (modeled on previous work of Fréchet as well as Hausdorff himself), and essentially the modern definition of a topological space (there had also been previous work on this, notably by Hilbert). A quite remarkable percentage of the topology we cover in this book appears here. While the topology of
the real numbers and Euclidean space was already well understood (primarily via convergence of sequences and series and continuity of functions), the transition to abstract spaces as we view them today sprang forth rather suddenly in amazingly detailed and polished form in this book.

Later editions of this book (e.g. [Hau44]), and the English translations (e.g. [Hau57]), are considerably abbreviated, leaving out much of the text of the first edition including most of the topology (but with a more refined exposition of what remains), with added material on Descriptive Set Theory. So the later editions are really a different book whose title more accurately describes the contents. This book is mainly of historical interest today, especially the first edition.

Hurewicz and Wallman, Dimension Theory [HW41]
Kelley, General Topology [Kel75]

Kunen and Vaughan, ed., Handbook of Set-Theoretic Topology [KV84]

The title of this collection of articles should be taken seriously (at least the “set-theoretic topology” part; the “handbook” part is pretty misleading – this is a massive 1273-page work which would qualify as a handbook only for the likes of Paul Bunyan, although I note that several “handbooks” of similar size on other subjects are also published by Oxford University Press, so maybe the British have bigger hands). Set-theoretic topology is not quite the same thing as point-set topology; the topology treated in this book is based on the intricacies of set theory, including set-theoretic axioms and large cardinal hypotheses. Almost all the results discussed are either trivial or inapplicable for metrizable spaces, and many of them even for spaces which are separable and/or first countable. The articles seem to be carefully written and comprehensive, but will be of interest primarily to specialists in this field, who would be characterized more as set theorists than mainstream topologists. Even the articles on Borel measures, Banach spaces, and topological groups, which should be of interest to a functional analyst such as myself, have a heavy dose of set-theoretic content, although I found parts of each to be of interest. Besides these, the only article which evinced more than a passing interest from me is P. Nyikos’s discussion of nonmetrizable manifolds, and these still strike me as being mostly a curiosity. Several other articles do have preliminary sections which are well-written overviews of parts of the subject for nonexperts.

Kuratowski, Topology I, II [Kur66], [Kur68]
Massey, Algebraic Topology [Mas77], [Mas91]
Munkres, Algebraic Topology [Mun84]
Munkres, Differential Topology [Mun66]
Munkres, Topology [Mun75]
Seifert and Threlfall, A Textbook of Topology [ST80]

An early (1934) treatment of algebraic topology. Nicely written and still very readable, and of the early topology texts it is the only one which is still worthwhile studying for content instead of just historical value. Parts are rather outdated today; the English translation, published in 1980, describes some but not all of these (and even an exposition current in 1980 is now a bit dated). The small amount of point-set topology covered is particularly rudimentary and outdated. A few things in the exposition are at least misleading if not inaccurate:
In §52, an argument is given that purports to show that every finitely generated group occurs as the fundamental group of a closed 4-manifold (homogeneous 4-complex). But the argument clearly only works as written for finitely \textit{presented} groups, a much smaller class; and in fact the fundamental group of a closed manifold (and, more generally, a compact metrizable ANR, cf. ()), is always finitely presented. Actually the statement in the book is somewhat ambiguous since their complexes are not required to be finite; the question of whether every finitely generated group, or more generally any countable group, occurs as the fundamental group of a (possibly noncompact) 4-manifold appears to be up in the air, but the answer is positive for open subsets of $\mathbb{R}^5$; cf. \url{http://math.stackexchange.com/questions/1362655/fundamental-group-of-open-subsets-of-mathbb{R}^5}.

The definition of “manifold” in the book is what is now called a \textit{combinatorial homology manifold}, which is significantly different from a topological manifold: a combinatorial homology manifold is compact, with no boundary, triangulable, but not necessarily homogeneous. Thus only closed manifolds are combinatorial homology manifolds, and only those which can be triangulated, but on the other hand there are combinatorial homology manifolds which are not manifolds, such as the suspension of the Poincaré homology 3-sphere ().

Spanier, Algebraic Topology [Spa81]

My immediate impression of this book when I first picked it up as a student was that it is quite heavy for its size. When I started reading it, this impression persisted in a metaphorical sense: it is pretty dense and detailed. But it is also pretty readable, and it was a standard reference and text at that time for good reason. It may not still be state of the art, but it is still a worthwhile reference.

Willard, General Topology [Wil04]

\textbf{Numerical Analysis}

Acton, Numerical Methods That (Usually) Work [Act90]

A lively and informative book. The contents could be uncharitably described as a large bag of tricks, but the book is really much more than that: it is a detailed discussion of the art of computation (with emphasis on the \textit{art}), meaning finding, adapting, and using appropriate numerical procedures for computational problems. The author was an engineer, with a fairly typical engineering perspective on mathematics, but informed by extensive experience in computation, and there is much wisdom and common (even uncommon) sense here. His writing style is refreshing and somewhat self-effacing; although he was an acknowledged expert in computation, he never talks down to the reader. For example, he states, “I have tried to make my explanations clear, but sad experience has shown that you will not really understand what I am talking about until you have made some of the same mistakes that I have made.” There is not much attention to mathematical rigor, and even the mathematical details of standard procedures are not discussed in depth, but there are beautiful heuristic descriptions of many procedures. This book is a must-read for anyone preparing to work in computation.

Hamming, Numerical Methods for Scientists and Engineers [Ham86]

As a nonexpert in numerical analysis, I found this to be one of the most valuable books for understanding the philosophy of the subject. While many of the nuts and bolts of numerical analysis are treated in detail, and in a way I mostly found mathematically satisfactory, the book’s main strength is extensive explanations
of *why* things are done as they are, from the point of view of the user. Pure (and even applied) mathematicians may be occasionally offended by sarcastic comments of the author (his colleague BRIAN KERNIGHAN has fondly called Hamming a “classic curmudgeon”). For example, he describes the difference between Numerical Analysis and Numerical Methods thus:

> “Numerical analysis seems to be the study in depth of a few, somewhat arbitrarily selected, topics and is carried out in a formal mathematical way devoid of relevance to the real world. Numerical methods, on the other hand, try to meet the need for methods to cope with the potentially infinite variety of problems that can arise in practice. The methods given are generally chosen for their wide applicability in creating formulas and algorithms as well as for the particular result being found at that point.”

(In fact, I disagree with much of the author’s philosophy of mathematics as described in [Ham98], although I appreciate his point of view.) But from this book one really gets a feeling for how engineers and other consumers of numerical analysis view the subject and how their needs are accommodated. The author’s stated motto is “The purpose of computing is insight, not numbers,” and he delivers on this goal.

**Miscellaneous Topics**

Wagon, The Banach-Tarski Paradox [Wag93]

This is one of the best mathematics books I have read. It covers an enormous range of fascinating topics in a very engaging way, and has succeeded in giving a quite readable treatment of some deep topics without pulling punches. Not all of the topics covered are directly related to measure theory, but many are, sometimes in surprising ways. This book really gives the reader a feeling for the way many diverse parts of mathematics fit together and interact.

**History of Mathematics**

Ball, A Short Account of the History of Mathematics [Bal60]

This book, first published in 1891, is badly out of date and inconsistent with modern historical scholarship in many parts; thus its modern-day value as a serious historical work is limited. It is still interesting reading, however, with many personal tidbits which are generally more reliable than those in bell’s books.

Bell, The Development of Mathematics [Bel92]

This is a more solid and serious book than *Men of Mathematics*, and has been generally praised by historians of mathematics, although the early chapters have faced some criticism. It is written in an engaging style, with many interesting insights and strong opinions. But it should not be the only book one reads about the history of mathematics.

Boyer, A History of Mathematics [Boy89]

Eves, An Introduction to the History of Mathematics [Eve90]

---

The thesis of this book is that “Name Worshipping,” a sect of the Russian Orthodox Church, played a significant role in the mathematical careers of Dmitri Egorov and Nikolai Luzin, and in the development of Descriptive Set Theory by the Moscow school. Part of the book is a detailed account of the lives of these mathematicians and their colleagues and students, which is one of the most detailed studies yet of the important group in Moscow commonly called “Lusitania.” Other parts describe the practice of Name Worshipping and attempt to make the connection with the mathematical philosophies of Egorov and, especially, Luzin.

I found the book somewhat disappointing until I reached the last chapter, where the authors put things together nicely; this chapter is a glimpse of what the earlier part of the book could have been. Unfortunately, it seems that the authors, who are themselves certainly well versed in mathematics, shied away from depth and technicalities in most of the book in a misguided effort to make it accessible and interesting to non-mathematicians, and thus made their arguments less convincing to mathematicians. I found many of their arguments in the earlier part of the book strained and unconvincing. For example, they often seem to argue that due to the Name Worshipping philosophy, Luzin et al. conflated naming mathematical objects with establishing their existence. No one with a significant background in mathematics could accept this, and it is clear from a quote of Luzin in the Appendix that this was not what he thought (the authors also explain in the last chapter that they did not believe this argument or intend to make it). Several analogies proposed such as the comparison with Grothendieck are quite strained: Grothendieck’s talent described in the book (only one of his many talents) was his ability to come up with good names for mathematical objects which would inform and inspire himself and others; in the philosophy described in the book, where simply naming or explicitly describing mathematical objects was the crucial matter, the quality of the names chosen would seem to be irrelevant. And although the book draws extensive comparisons between the mathematics in Moscow and developments in France during the same period and immediately preceding, I was surprised that the religious influences on the work and philosophy of Cantor, who got the whole subject of set theory going, were almost totally ignored (it seems clear from other sources that Cantor was indeed significantly influenced by Christian theology and/or Jewish traditions).

This is overall an interesting book to read, but it could have been a lot better.
the principal remaining parts of traditional real analysis with an active research component (one might add probability). In addition, we now have an ever-increasing collection of things regarded by at least some mathematicians as specific concrete objects, e.g. manifolds, well-ordered sets, Hilbert space. But even the subjects superficially unchanged from 200 years ago, such as number theory and differential equations, use a range of techniques far expanded from the traditional ones which could be developed or even contemplated only as a result of the modernist revolution. For example, the modern study of differential equations heavily uses methods from functional analysis, listed by the author as one of the shining examples of modernist mathematics. (Of course, traditional techniques also continue to be used; after all, even calculus as known and understood in the eighteenth century is still extremely important and useful.) The subject of differential equations also heavily uses sophisticated modeling and simulation techniques made possible by the existence of powerful computers, a development not anticipated even at the end of the modernist revolution; the present use of computation in mathematics may mark another revolution which will turn out to be as profound as the modernist one.

Although parts of this book are dense and a challenge to slog through, it is highly recommended.

Jahnke (Ed.), A History of Analysis [Jah03]

Kline, Mathematical Thought from Ancient to Modern Times [Kli72]

This is Kline’s *magnum opus* and principal scholarly work on the history of mathematics; he has a number of other books written more at the popular level. In this, as well as his other books, there is an undercurrent of Kline’s philosophy of mathematics which I personally take some issue with, although this does not seriously undercut the value of these books as historical works. There are also small doses of sexism here and there in Kline’s books.

Moore, Zermelo’s Axiom of Choice [Moo82]

A careful and thorough study of the Axiom of Choice – its prehistory, history, controversy, variations, and intimate connections with the very nature of modern mathematics.

Pier, Mathematical Analysis During the 20th Century [Pie01]

The author has set himself a monumental and perhaps impossible task in trying to summarize and organize the development of analysis during the twentieth century, and he has partially succeeded, perhaps as well as any one individual could in a book of this length published at the immediate end of the period studied (he is well aware of the inherent problems of such a project, and indeed divides his description of each part of analysis into “evolution” covering the period 1900-1950 and “flashes” covering 1950-2000). But due to the sheer volume and scope of the material, the coverage is necessarily rather shallow, and the author’s judgment about what the most important developments were is highly subjective. For example, in the area I personally know best, operator algebras, he hits some of the high points of the subject (with occasionally muddled description) but misses others, instead discussing some developments at length which are generally regarded as peripheral, such as the axioms for a C*-algebra; I doubt that any leading operator algebra specialist would regard the author’s treatment as an adequate or satisfactory history of the subject of operator algebras during the 20th century. (To be fair, he seems to have done a more accurate and thorough job on some other parts of analysis he may be more personally familiar with.)

One of the most interesting parts of the book is the introduction, where the definition, meaning, and scope of the term “analysis” is discussed. The author then takes a fairly broad interpretation of its meaning, including subjects from topology to algebraic geometry under the umbrella of 20th century “analysis.”
Much of the material is presented via extensive quotations from the writing of leading mathematicians. These make for interesting and thought-provoking reading. The book is very helpful in giving the reader a feeling for the overall flavor of twentieth-century analysis, although it is far from a definitive study.

Roberts, King of Infinite Space [Rob06]

A biography of Donald Coxeter. This was a more engaging book than I expected. It is nicely written, and the author has really done her homework, with extensive and trenchant quotes from many leading mathematicians she apparently interviewed. The mathematics is pretty much right, both in detail and philosophical form, especially impressive from an author who does not claim any particular expertise in mathematics; it is conveyed more accurately than by some highly-trained authors who should know better. The general theme of the book, which I think is slightly (but only slightly) overblown, is that classical geometry was a dying subject kept alive primarily by Coxeter before finding a renaissance in such modern areas as computer graphics. A subplot which is greatly oversimplified and rather inaccurate, in my opinion, is that there was a war between formal and visual mathematics in the twentieth century, which is roughly characterized as Bourbaki vs. Coxeter. Bourbaki was indeed a champion of a formal, logical approach to mathematics, but it would be totally wrong to claim that the members of Bourbaki (even Dieudonné, portrayed as the principal villain) did not approve of use of pictures, diagrams, and other visual aids in understanding and creating mathematics; they just felt that the ultimate logical justification for results which may have been found by such methods must be done formally, a sentiment with which even Coxeter would have largely agreed. And it is quite another matter that Bourbaki chose to leave pictures and diagrams almost completely out of their exposition of mathematics, which was never intended to supplant all other approaches. Blaming Bourbaki for the failures of the “new math” is about as misguided as blaming Jesus for present-day fundamentalist Christianity. A new exposition of part of mathematics can never be a negative, except possibly if it is mathematically incorrect; it can only help a competent reader, in combination with other expositions, gain a better understanding of the subject. The problem comes when some people who lack the vision and expertise of the authors decide that a particular work is gospel and should be followed (often with a twisted interpretation due to a lack of understanding) to the exclusion of all others, and a fashion (which mathematics is certainly not immune from) is established. This was the principal problem with the “new math,” and even (as the author points out) with the mathematics curriculum at some leading universities, although it is questionable whether all these problems were even directly a result of the influence of Bourbaki. In any event, it is nice to see that visual mathematics is making a comeback, and while Coxeter was probably not as single-handedly responsible as this book portrays, he was certainly a major influence.

Struik, A Concise History of Mathematics [Str87]

Philosophy of Mathematics

Some of the books in other sections above are partially concerned with the philosophy of mathematics.

Chaitin, Information-Theoretic Incompleteness [Cha92] and The Unknowable [Cha99]

Entertainingly written accounts of Chaitin’s philosophy of mathematics and knowledge, focusing on complexity. The presentation is unusual, intermixing autobiographical passages with the mathematics. It is easy to dismiss the autobiographical parts as egotistical self-promotion (e.g. “Gödel discovered incompleteness, Turing discovered uncomputability, and I discovered randomness”), but, although I have no personal knowledge about the author, I see a certain naiveté about the stories that suggests such a conclusion may
be unfair. The mathematical part is heavy stuff, and I do not feel comfortable with my own understanding of it, but it is certainly a lot of food for thought.

Corfield, Towards a Philosophy of Real Mathematics [Cor03]

This is not the first criticism of the preoccupation of philosophers of mathematics with foundations at the expense of studying its actual practice, but it is the most detailed and articulate one to date. The author’s knowledge and understanding of mathematics is clearly much broader and deeper than that of most other philosophers of mathematics, and is quite impressive. He makes a compelling case against traditional philosophy of mathematics, but I have a hard time figuring out exactly what he proposes as a replacement: he says he is arguing for a Bayesian theory, but spends a good bit of time pointing out the absurdities of a strict Bayesian interpretation of mathematics and science (e.g. that existing evidence cannot help confirm the plausibility of a new theory that explains it). In any event, as evidenced by his choice of title, he clearly thinks that answering the questions he raises is a work in progress. Although this cannot be considered the definitive work on the subject, it is a significant and thought-provoking contribution to the process.

Lakatos, Proofs and Refutations [Lak76]

A thought-provoking discussion of Lakatos’ ideas on the nature of mathematical proof, and by transfer his whole philosophy of mathematics. Written primarily as a dialog based around Euler’s formula for the relation of the number of vertices, edges, and faces of a polyhedron \((V - E + F = 2)\). Interesting reading even for those, like me, who are somewhat skeptical of his conclusions. See [] and [Cor03] for detailed analyses of Lakatos’ work.

Nontechnical and Popular Books

Klein, Elementary Mathematics from an Advanced Standpoint: Arithmetic, Algebra, Analysis [Kle04]

This is not intended to be a popular book, and is not exactly nontechnical. Its goal was twofold: to describe Klein’s ideas on how mathematics should be presented and taught in schools, and to give schoolteachers knowledge and insight on the true nature of the mathematics they teach (he says on p. 162: “. . . the teacher’s knowledge should be far greater than that which he presents to his pupils. He must be familiar with the cliffs and the whirlpools in order to guide his pupils safely past them.”) Although it was written more than a hundred years ago, most of it is as relevant today as when it first appeared, and it is full of valuable insights even today from a first-rate mathematical mind which paid unusually great attention to how mathematics should be taught. I myself learned some things about mathematics and its development, such as a beautiful proof of Taylor’s theorem with Lagrange remainder via difference calculus, regarded by Klein as the best and most natural proof of the theorem (and the way Taylor himself found the theorem, although he did not come close to giving what would be today recognized as a proof), which I have not found in modern texts, probably because difference calculus is rarely discussed except in numerical analysis texts. See () for the argument. And Hilbert in his Grundlagen der Geometrie described something close to the nonstandard real numbers (they may have even been found earlier by someone else). This book is well worth reading and studying by any potential mathematician or mathematics teacher. The reader is cautioned that the English translation in this edition contains an unusually large number of misprints, most of which are harmless.

Livio, Is God a Mathematician? [Liv09]

This is generally a well-written, informative, and entertaining study of the “unreasonable effectiveness of mathematics” as a basis for science and the underlying principles of the universe. There is little actual religious content, mainly just a discussion of the religious beliefs of major figures such as Galileo, Descartes,
Rucker, Infinity and the Mind \[\text{Ruc82}\]

In my opinion, the most interesting of Rucker’s books. Contains accurate and readable, although non-rigorous, treatments of the theory of ordinals and of Gödel’s Incompleteness Theorem.

Smullyan, The Lady or the Tiger? \[?\]

The first half of this book is a collection of Smullyan’s famous logic puzzles. The second half is a delightful treatment of Gödel’s Incompleteness Theorem in the form of a “mathematical novel.”

Smullyan, Forever Undecided \[?\]

This book falls somewhere between The Lady or the Tiger? and Gödel’s Incompleteness Theorems. It is not a technical book, although it covers some symbolic logic, but it is also not nearly as lighthearted as Smullyan’s other popular books. The topics discussed and explained are somewhere between philosophy and mathematics, based on various versions of Gödel’s Incompleteness Theorem.

The two books The Lady or the Tiger? and Forever Undecided are available together in a single paperback volume.

Books to be Wary of

Alexander, Infinitesimal: How a Dangerous Mathematical Theory Shaped the Modern World \[\text{Ale15}\]

The theme of this book is that the mathematical “theory of indivisibles” precipitated an intense battle in the sixteenth and seventeenth centuries, not just among mathematicians but even among political and social theorists. Throughout the book the author tries to characterize the opposition to the theory of indivisibles as a manifestation of a rigid, authoritarian social philosophy, and the belief in the theory of indivisibles as representing ideals of free inquiry and, ultimately, democracy. While this may be somewhat of a stretch, oversimplification, or extrapolation, it certainly has an element of truth, and the historical events are engagingly described in considerable detail in support of the thesis.

I saw and browsed this book in a bookstore and it looked interesting, so I got a copy and began reading it systematically. I could hardly get past the introduction, since it was so full of mathematical misconceptions. The most egregious, affecting the entire thesis of the book, is confusion of the mathematical terms indivisible and infinitesimal (which mean entirely different things – whatever an infinitesimal is, it is not indivisible! Granted, before the late seventeenth century the difference was not well understood even by mathematicians.

and Newton. The author is an astrophysicist and not a mathematician, and his primary interest (at least in this book) is the relation between mathematics and science; but he has deep knowledge and understanding of mathematics and gets it almost all right. There are a few misstatements, such as that “a fully consistent theory of analysis was only formulated in the 1960s” (an apparent reference to nonstandard analysis), and the crucial words finitely describable (technically, recursively axiomatizable) are omitted from the statements of Gödel’s theorems (he is hardly the first author to make this mistake, and in his case it may well be an inadvertent error rather than a misunderstanding). His discussion of the philosophy of mathematics is extensive and intelligently argued, although he repeatedly makes rather unconvincing arguments against Platonism, and he rather too glowingly refers to [\text{LN00}], which in my opinion is hardly more than a work of fiction. He buys a little too much into the “crisis” characterization of the modernist revolution precipitated by the discovery of noneuclidean geometry, but his discussion of this subject is more accurate and intelligent than many others. He does not pretend to have the answers to the main questions he discusses (no one else does either), but makes worthwhile contributions to the discussion.
See [She18] for a detailed study.) In fact, the book probably should have been titled *Indivisible*, since this term is the one causing most of the controversy discussed in the book. The only mention of infinitesimals as mathematicians since Archimedes have almost always thought of them is a few oblique references to the development of calculus, which really has nothing to do with the theory of indivisibles; the only relevance to the book’s thesis is that (early) calculus was based on controversial (although not actually new) ideas which were not rigorously established.

But there are other serious mathematical inadequacies, such as the attempt to describe what the theory of indivisibles means (it essentially means that a line is a set of points, or, what is not exactly the same thing, that a line is “made up” of a collection of points, and similarly a plane figure is “made up” of a collection of parallel line segments, etc., not that a line segment is actually indivisible). The author is a historian, not a mathematician, and it is perhaps unrealistic to expect him to get the mathematics right, but many authors of other books about mathematics have done better with no more formal mathematical training. Perhaps he was simply presenting the idea as it was (mis)understood by people like Renaissance Jesuits as well as many mathematicians of the time, but if so he should have said so and pointed out the misconception. And he never mentioned the resolution of the paradoxes discussed, not found until the twentieth century using measure theory and the difference between countably and uncountably infinite sets (see I.3.1.2. for a discussion). The author seems to subscribe to the common picture of a line as a string of beads, each point having a “next” point, a picture every modern mathematician has had to try to correct in the classroom. This picture was common at one time even among mathematicians: Galileo believed that a line segment was made up of infinitely many infinitely small points separated by infinitely many infinitely small gaps.

Pushing on, I found the rest of the book more interesting, with much detailed history I didn’t know which I assume is accurately portrayed since this should be the author’s forte. The book traces the formation of the Jesuit order of the Catholic Church, largely as a response to the Reformation and resulting loss of influence and control of the Church, and the incorporation of mathematics into the curriculum of the Jesuit colleges and, more generally, as a subject as worthy of study as philosophy and theology. Mathematics as taught by the Jesuits was in a form compatible with overall Jesuit philosophy, as a body of eternal truths and not as an intellectual pursuit in which new ideas were sought or even tolerated. As the author puts it on p. 78:

“But why study mathematics? Only because it provided a model of perfect rational order and certainty, and an example of how universal truths governed the world. If mathematics was to become a field of far-reaching innovation, in which new truths were proposed and then subjected to challenge and debate, then it would be worse than useless. It would be dangerous, as it would compromise the very foundations of the truth it was meant to buttress.”

The Jesuits had enormous influence on the intellectual life of continental Europe in the sixteenth and seventeenth centuries, partially through their colleges, which were in some respects the best system of higher education at the time.

A good deal of the book is devoted to Thomas Hobbes and John Wallis. The mathematical part of their longstanding intellectual battle (there was a considerable nonmathematical component too) is described as being mainly a disagreement about mathematical philosophy. While there is probably some truth to this, I think there is a more important reason. The author does point out that Hobbes’s (later) mathematical work was not taken seriously by the English mathematical establishment, but attributes this to political prejudice. In fact, Hobbes was a hopeless mathematical charlatan, and his mathematical work was no more worthy of being taken seriously than that of modern-day cranks (cf. Figure I.8). Wallis was an excellent mathematician, one of the world’s leading mathematicians of the seventeenth century (although overshadowed in Britain by Newton and Gregory), and very likely had the attitude widespread among mathematicians of not suffering fools gladly. The author may perhaps again be excused for not having the

1962
ability to make a judgment about the quality of Hobbes’s mathematics. The statement on p. 213 that Hobbes was “one of the most respected English mathematicians of the day” [1640] is highly doubtful; I am not aware of a single (correct) original contribution he made to mathematics.

The author’s assertion that Wallis created a new kind of experimental mathematics, and especially that he did so to conform to the philosophy of the Royal Society, is nonsense. All mathematics is experimental when first being developed, and mathematical results have been found by induction since ancient Greece and even earlier. Wallis used techniques going back to Archimedes and probably even Euclid’s predecessors (ancient Greeks apparently did not record how they obtained their results, and in any event knowledge about their methods has been lost). Wallis may not have paid sufficient attention to carefully proving his results, but he undoubtedly could have (and probably did mentally) in many cases using the elaborate double *reductio ad absurdum* technique of Archimedes, but evidently was more interested in using his time and effort to explore new things. He was surely aware, as contemporaries like Newton were, that some of the techniques did not (at that time) have a sound logical footing, but these mathematicians had strong intuition and their results invariably turned out to be correct and logically justifiable (unlike Hobbes). It seems farfetched that Wallis declined to try to prove his results simply in order to adhere to the Royal Society philosophy. The author seems to be obsessively insistent on attributing the primary motivation for every mathematical or scientific study to adherence to one side or the other of the philosophical dichotomy which is the theme of the book.

Incidentally, Wallis did not initiate the idea that mathematical objects exist and only need to be explored, and that mathematical truths are discovered; this philosophy of mathematics is called Platonism since it goes back (at least) to Plato. (Hobbes was also a Platonist and, contrary to what is suggested in the book, Euclid probably was too.)

There is at least one historical inaccuracy I noticed. On p. 290, it is stated:

“Following the war over the infinitely small, advanced mathematics in Italy came to a standstill, whereas English mathematics quickly became one of the dominant national traditions in Europe, rivaled only by the French.”

This may be an accurate assessment about Italy. But although England in many respects, including technology, industrialization, and certain intellectual and social areas, became a world leader, it notably remained a mathematical backwater for nearly 200 years after Newton, particularly in analysis. In fact, there was a nineteenth century analysis renaissance in Italy before there was one in England. It was French, Swiss, and German mathematicians, not English, who were at the forefront of analysis in the eighteenth and nineteenth centuries (I count Lagrange as French although he was actually born in Italy).

There have been criticisms of the reasons the author attributes for the Jesuit opposition to the theory of indivisibles, that it is inconsistent with Aristotle and Euclid and the notion that mathematics represents eternal truth. In [She18] (which I find an articulate criticism of much of Alexander’s book, although I cannot evaluate the historical aspects), it is argued that the principal reason for the opposition was that it contradicted the Catholic doctrine of transubstantiation of Christ’s body and blood in the Eucharist (this idea was first presented in [Red87]). Note that I only discovered and read these other references after I had written this review.

It is remarkable that so many people, both mathematicians and nonmathematicians, spent so much time and effort and generated such acrimony over a dispute of such little ultimate (mathematical) consequence, with both sides advancing arguments which today would be regarded as foolishly misguided. I wish the author had been able to convey the obsolescence better. The book is worth reading for its historical content, as long as the author’s attributions and conclusions are taken with a degree of skepticism.
Bell, Men of Mathematics [?]

This book is entertaining reading, but unreliable as history; some parts are downright fanciful. The chapters on Galois and Cantor are the worst from the standpoint of historical accuracy. Although Bell was a respectable mathematician, some critics have asserted that as a biographer he seems to have been the type of writer who never lets the facts get in the way of a good story. Overall, however, the book is not nearly as bad as these critics have made it out to be: the vast majority of the book is factually accurate, and the errors appear to be entirely the result of careless or inadequate research and unwarranted extrapolation rather than deliberate falsification; the accounts are much closer to the actual events than in many modern “historical” movies. In fact, the author has gone to some pains to qualify historical assertions he felt were not adequately established. Despite the title, the book does not have a sexist tone, and in fact was fairly progressive for its time (1937), giving sympathetic treatment to several women mathematicians and the obstacles they faced; for example, Bell gave the first popular (if dated and flawed) account of Sofia Kovalevskaya. There is some gratuitous antisemitism in the chapter on Cantor (there is controversy over to what degree, if any, Cantor himself was Jewish, although he clearly had at least some Jewish ancestry). This book may be inspiring to a young reader who is aware of its historical inaccuracies, and it also serves a useful purpose in countering the stereotype of mathematicians as nerds of borderline sanity and little personality or variety. The description of Bell in [New88] seems fairly apt: “lively, stimulating, inoffensively crotchety and opinionated, with a good sense of historical circumstance, a fine impatience with humbug, a sound grasp of the entire mathematical scene, and a gift for clear and orderly explanation.”

Griffiths and Hilton, A Comprehensive Textbook of Classical Mathematics [GH78]

This book is hard to categorize. The aim is to give a unified exposition of “classical mathematics” (or what may be loosely described as “undergraduate mathematics”) from a modern perspective: logic and set theory, abstract algebra, elementary geometry and topology, and undergraduate analysis. Some things (generally simpler ones) are proved in detail, but most of the deeper or more difficult results are just stated with some informal or intuitive justification given (which is clearly represented as such; the book is pretty honest mathematically). I would not describe the treatment as inspired, and it is generally pretty conventional, but there is much wisdom and insight in the descriptions. And, importantly, the authors explicitly describe, and follow, what they call the spiral principle, which underlies both the historical development of mathematics and the way it is, or should be, taught: fundamental topics and principles are first introduced and developed in a natural and intuitive way, and after they have become somewhat familiar are redeveloped in a more careful way. This is nicely summarized in this statement from p. 249, in the chapter “The Logic of Geometry”, after Euclid’s geometry (with modern improvements) is described:

“A person might object to all this procedure on the grounds that the definitions given are artificial without a prior knowledge of Euclidean geometry; to which we can only reply that once they are given, a logically watertight system of geometry can be developed, and it matters not a whit how the definitions happened to be suggested. This is typical of the way in which a great deal of mathematics has grown. First a terminology and body of results is obtained by logically unsatisfactory (but often aesthetically pleasing) methods. Then the theory is seen to have flaws which prevent further progress. Finally the theory is reset in a possibly different language, and derived in a correct logical manner, usually gaining greater power.”

On the other hand, the book contains surprisingly many (especially for an apparently revised second edition) missteps, most of which are fairly minor and many of little real consequence; I think at least nearly all of them could be described as “careless.” For example, both the statement of the Implicit Function
Theorem (37.4.2) and Theorem 15.5.2 are false as stated; additional hypotheses are needed (continuity of the relevant derivatives suffices). In contrast, the statement of the Mean Value Theorem, or more accurately of “Rolle’s conditions” on p. 483 (ROLLE never stated, and probably never considered, such conditions), contains a superfluous continuity assumption on the derivative, which is not used in the proof or mentioned when the theorem is quoted in several other places. It is stated that the definition of “finite set” in 7.2.4 (what is usually called Dedekind-finite) is equivalent to the one in 7.1.4 (apparently meaning 2.11.1), but some form of the Axiom of Choice, which is only mentioned later, is needed. (Theorem 7.1.4 also has an obvious superfluous assumption.) And the authors seem to like to invent their own terminology, which is sometimes at odds with convention. Some of this invented terminology is picturesque, such as their name “mostest theorem” for what is normally called the Extreme Value Theorem, but some is not an improvement, such as “flat” for “affine subspace” or “laws of indices” for “rules of exponents” (maybe some of their terms are in more general use in Britain than in the U.S.). And what they call the “Axiom of Choice” (that an element can be chosen out of one nonempty set) is either trivial or a nonmathematical assertion depending on one’s point of view (cf. II.6.1.6.); what is usually called the Axiom of Choice is called the “Strong Axiom of Choice”.

This book could be quite helpful to an advanced undergraduate or knowledgeable nonmathematician in helping to “put the pieces together”, somewhat in the manner of [Sch97] (although the books are very different), as long as it is recognized that the small inaccuracies mean that the details of the exposition must be regarded with a degree of skepticism. But, although this book is described and clearly intended as a textbook, I find it hard to think it could be suitable as a textbook for a course it would be worthwhile for a mathematics student to take; it might be suitable for a “capstone” course for students preparing to be math teachers at the high-school or community college level.

Guillen, Bridges to Infinity [Gui83]

This book is not entirely about mathematics, and I will not pass judgment on the nonmathematical part. But it is so riddled with mathematical errors and misconceptions that the credibility of the entire work is questionable. There are also sloppy historical errors, such as calling von Neumann a “German mathematician.”

Lakoff and Nuñez, Where Mathematics Comes From [LN00]

This book purports to be a study of how the human mind perceives and understands mathematics. But the authors, a linguist and a cognitive psychologist, repeatedly demonstrate an embarrassing lack of understanding of basic undergraduate mathematics (e.g. limits); they would be well advised to study a book like Closer and Closer to see what they are missing. They regard the equation $e^{i\pi} = -1$ as “one of the deepest equations in all of mathematics,” and suggest that even most modern mathematicians do not understand it. There is also much discussion of the philosophy of mathematics, which is shallow and logically flawed, sometimes with a vicious undertone. While I cannot evaluate the authors’ cognitive psychology arguments, this is not a book that mathematicians should take very seriously. See () for a more extensive review.

Polya, Induction and Analogy in Mathematics [Pól90a] and Patterns of Plausible Inference [Pól90b]

This two-volume work is in many ways an admirable book. It is a thorough discussion of mathematical reasoning and problem solving by one of the masters, and it is filled with solid and valuable advice on how to approach and solve mathematical problems. The techniques are illustrated by numerous examples, containing clever and insightful arguments (originally dating back as far as ancient Greece) from which much can be learned.
But the book is unfortunately riddled with what I call “mathematical dishonesty.” Many of the arguments represented as proofs are logically incomplete or nonrigorous (see 1.5.1.5. for a discussion of some of these; earlier, he seems to represent the principle of induction as so self-evident that it merits no comment.) This is a much more serious problem in a book of this sort than in books like [Doo94] or [Mor09] (where there are gaps in arguments but no attempt is made to hide them, and the gaps are generally routine to fill in), since the main subject of this book is mathematical reasoning. Polya himself certainly knew better. Some rather minor changes in the language used, and a few added comments, could have maintained mathematical honesty while still making the main points the author wanted to convey. But he seemed to deliberately go out of his way to obscure or gloss over some of the mathematical difficulties in his arguments, and as a result many readers could be misled about the nature of full demonstrations in mathematics.
