VI.2.1.4. A “distance function” \( \rho \) on a set \( X \) satisfying (i), (iii), and (iv) is called a \textit{pseudometric}. Pseudometrics play an important role in more advanced parts of analysis.

VI.2.2. \textbf{Balls, Limit Points, and Closures}

VI.2.2.1. \textbf{Definition.} Let \((X, \rho)\) be a metric space, and \( x_0 \in X \). If \( r > 0 \), the \textit{(open) ball of radius} \( r \) \textit{around} \( x_0 \) (or \textit{centered at} \( x_0 \)) is
\[ B_r^o(x_0) = \{ x \in X : \rho(x_0, x) < r \} \]
(the \( \rho \) is often omitted if the metric is understood and there is no possibility of confusion.) The \textit{closed ball of radius} \( r \) \textit{around} \( x_0 \) is
\[ B_r^c(x_0) = \{ x \in X : \rho(x_0, x) \leq r \} \].

VI.2.2.2. The term “ball” is a standard term even though \( B_r(x_0) \) need not look anything like a geometric ball. (In fact, there is usually no geometric interpretation of distance in a general metric space; see Exercise (v), for example, for interpretations of \( \rho_1 \) and \( \rho_\infty \) on \( \mathbb{R}^2 \).) The term “ball” without the qualification “closed” will always mean “open ball”.

726
VI.2.2.3. Examples.

(i) In \( \mathbb{R} \) with the usual metric, the open ball of radius \( r \) around \( x_0 \) is the open interval of length \( 2r \) centered at \( x_0 \); \( B_r(x_0) \) is the closed interval of length \( 2r \) centered at \( x_0 \).

(ii) In \( (\mathbb{R}^2, \rho_2) \), \( B_r(x_0) \) is an open disk centered at \( x_0 \). In \( (\mathbb{R}^3, \rho_2) \), \( B_r(x_0) \) is the usual geometric open ball of radius \( r \) centered at \( x_0 \). The closed balls have a similar interpretation.

(iii) In \( (\mathbb{R}^2, \rho_1) \), balls (open or closed) are square diamonds; in \( (\mathbb{R}^2, \rho_\infty) \) they are squares with horizontal and vertical sides (see Exercise ().)

(iv) There is a geometric interpretation of balls in \( C[a,b] \) for the \( \rho_\infty \) metric. Fix \( f_0 \in C[a,b] \), and \( r > 0 \). Draw the graphs of the functions \( f(t) - r \) and \( f(t) + r \) (Figure ().) Then \( B^{\rho_\infty}_{r}(f_0) \) consists of all functions in \( C[a,b] \) whose graph lies within the strip strictly between the top and bottom curves. \( \bar{B}^{\rho_\infty}_{r}(f_0) \) consists of the functions whose graphs lie in the closed strip including the two boundary functions.

(v) If \( \rho \) is the discrete metric on a set \( X \), and \( x_0 \in X \), then \( B^{\rho}_{r}(x_0) = \{x_0\} \) if \( r \leq 1 \), and \( B^{\rho}_{r}(x_0) = X \) if \( r > 1 \). \( B^{\rho}_{r}(x_0) = \{x_0\} \) if \( r < 1 \) and \( \bar{B}^{\rho}_{r}(x_0) = X \) if \( r \geq 1 \). Thus \( B^{\rho}_{1}(x_0) = \{x_0\} \) but \( \bar{B}^{\rho}_{1}(x_0) = X \), so \( B_r(x_0) \) can be much larger than the “closure” of \( B_r(x_0) \) in general (this will be made precise in ().)

VI.2.2.4. Definition. Let \((X, \rho)\) be a metric space, and \( A \subseteq X \). A point \( x \in X \) is a limit point (or point of closure) of \( A \) (with respect to \( \rho \)) if every ball centered at \( x \) contains at least one point of \( A \), i.e., if, for every \( \epsilon > 0 \), there is a point \( y \in A \) with \( \rho(x,y) < \epsilon \). The closure of \( A \) (with respect to \( \rho \)), denoted \( \bar{A} \), is the set of all limit points of \( A \). The set \( A \) is closed if \( A = \bar{A} \).

When there is any possibility of confusion about which metric is being used, we will use the terms \( \rho \)-limit point and \( \rho \)-closed set.

VI.2.2.5. Note that a limit point of \( A \) is not an element of \( A \) in general: for example, 0 and 1 are limit points of \((0,1)\) in \( \mathbb{R} \). But a point of \( A \) is always a limit point of \( A \), so \( A \subseteq \bar{A} \) for any \( A \). If \( A \subseteq B \), then \( \bar{A} \subseteq B \). We also have that \( \emptyset = \emptyset \) and \( \bar{X} = X \), i.e. \( \emptyset \) and \( X \) are closed sets in \( X \).

VI.2.2.6. Proposition. Let \((X, \rho)\) be a metric space, and \( A \subseteq X \). Then every limit point of \( \bar{A} \) is a limit point of \( A \), i.e. \( \bar{A} = \bar{A} \), so \( A \) is closed.

Proof: Suppose \( x \) is a limit point of \( \bar{A} \), and \( \epsilon > 0 \). We must show that there is a \( z \in A \) with \( \rho(x,z) < \epsilon \). But \( x \) is a limit point of \( \bar{A} \), so there is a \( y \in \bar{A} \) with \( \rho(x,y) < \epsilon/2 \); and there is a \( z \in A \) with \( \rho(y,z) < \epsilon/2 \). By the triangle inequality, \( \rho(x,z) < \epsilon \).

The complement of a \( \rho \)-closed set is called an open set (with respect to \( \rho \), or \( \rho \)-open set). The next proposition gives two other useful characterizations of open sets:
VI.2.2.7. **Proposition.** Let \((X, \rho)\) be a metric space, and \(U \subseteq X\). Then the following are equivalent:

(i) \(U\) is an open set.

(ii) \(U\) is a union of open balls.

(iii) For every \(x \in U\), there is an \(\epsilon > 0\) such that \(B_\epsilon(x) \subseteq U\).

**Proof:**

(i) \(\Rightarrow\) (iii): If \(x \in U\), then \(x\) is not a limit point of \(U^c\) since \(U^c\) is closed. Thus, there is an \(\epsilon > 0\) such that \(B_\epsilon(x) \subseteq U\), i.e. \(B_\epsilon(x) \subseteq U\).

(iii) \(\Rightarrow\) (i): If \(x \in U\), then there is an \(\epsilon > 0\) such that \(B_\epsilon(x) \subseteq U\), hence \(B_\epsilon(x) \subseteq U\) and \(x\) is not a limit point of \(U^c\). Thus \(U^c\) is closed.

(ii) \(\Rightarrow\) (iii): Suppose \(x \in U\). Then \(x \in B_r(y) \subseteq U\) for some \(r\) and \(y\), since \(U\) is a union of open balls. Set \(\epsilon = r - \rho(x, y)\). Then by the triangle inequality, \(B_\epsilon(x) \subseteq B_r(y) \subseteq U\).

(iii) \(\Rightarrow\) (ii) is obvious. \(\blacksquare\)

In particular, every open ball is an open set.

VI.2.2.8. **Corollary.** An arbitrary union of open sets is open. A finite intersection of open sets is open.

An arbitrary intersection of closed sets is closed. A finite union of closed sets is closed.

**Proof:** It is obvious from either (ii) or (iii) that an arbitrary union of open sets is open. To prove that a finite intersection of open sets is open, use (iii): if \(U_1, \ldots, U_n\) are open and \(x \in U_1 \cap \cdots \cap U_n\), choose \(\epsilon_1, \ldots, \epsilon_n > 0\) with \(B_{\epsilon_k}(x) \subseteq U_k\) for each \(k\). Set \(\epsilon = \min(\epsilon_1, \ldots, \epsilon_n)\); then \(\epsilon > 0\) and \(B_\epsilon(x) \subseteq U_1 \cap \cdots \cap U_n\).

The statements about unions and intersections of closed sets are obtained by taking complements. \(\blacksquare\)

VI.2.2.9. **Note** that an intersection of infinitely many open sets is not open in general: for example, \(\cap_{n=1}^{\infty} B_{1/n}(x) = \{x\}\), which is rarely an open set (\(\{x\}\) is actually a closed set for any \(x\)). Similarly, an arbitrary union of closed sets is not closed in general: in fact, every subset of \(X\) is a union of singleton subsets, which are closed.

VI.2.2.10. **Note** that not every subset of a metric space is either open or closed; in fact, this is far from true in most metric spaces.

"Most sets, like doors, are neither open nor closed, but ajar."

C. Pugh\(^1\)

\(\uparrow\)\[Pug15, p. 60]\]

In fact, the "most" can be precisely quantified: in \(\mathbb{R}\) (and in most other metric spaces encountered in analysis), there are \(2^{2^{\aleph_0}}\) subsets in all, but only \(2^{\aleph_0}\) open sets and \(2^{\aleph_0}\) closed sets (\(\{\\}\)), so there are \(2^{2^{\aleph_0}}\) subsets which are "ajar." Although "most" of these subsets are rather bizarre and cannot be even explicitly described, many frequently encountered and easily described sets are ajar, such as half-open intervals of the form \((a, b]\) or \([a, b)\), or the rational numbers \(\mathbb{Q}\).
VI.2.3. Limits and Continuity

Convergence of sequences and limits and continuity of functions work in any metric space almost exactly as in \( \mathbb{R} \). The statements and proofs are essentially identical to the case of \( \mathbb{R} \); all that is needed is to “redecorate” using the metric distance in place of the absolute value. We will do a few examples of redecoration in proofs, and leave others as exercises.

Limits of Sequences

VI.2.3.1. Definition. Let \((X, \rho)\) be a metric space, \(x \in X\), and \((x_n)\) a sequence in \(X\). Then \((x_n)\) converges to \(x\) (with respect to \(\rho\)), or \(x\) is the limit of the sequence \((x_n)\), written \(x_n \to x\) or \(x = \lim_{n \to \infty} x_n\), if for every \(\epsilon > 0\) there is an \(n_0 \in \mathbb{N}\) such that \(\rho(x_n, x) < \epsilon\) for all \(n \geq n_0\).

Where it is necessary to explicitly specify the metric \(\rho\), or where there is any chance of confusion, we will say that \((x_n)\) \(\rho\)-converges to \(x\), or \(x\) is the \(\rho\)-limit of \((x_n)\), written \(x_n \to_\rho x\) or \(x = \rho\lim_{n \to \infty} x_n\).

As in \(\mathbb{R}\), limits of sequences are unique:

VI.2.3.2. Proposition. Let \((X, \rho)\) be a metric space, \(x, y \in X\), and \((x_n)\) a sequence in \(X\). If \(x_n \to x\) and \(x_n \to y\), then \(x = y\).

Proof: If \(x \neq y\), set \(\epsilon = \rho(x, y)/3 > 0\), and choose \(n_1, n_2 \in \mathbb{N}\) with \(\rho(x_n, x) < \epsilon\) for all \(n \geq n_1\) and \(\rho(x_n, y) < \epsilon\) for all \(n \geq n_2\). Then, if \(n \geq \max(n_1, n_2)\),

\[
\rho(x, y) \leq \rho(x, x_n) + \rho(x_n, y) < 2\epsilon = 2\rho(x, y)/3 < \rho(x, y)
\]

which is a contradiction. ☐

VI.2.3.3. Proposition. Let \((X, \rho)\) be a metric space, \(x \in X\), and \((x_n)\) a sequence in \(X\). If \(x_n \to x\), then every subsequence of \((x_n)\) also converges to \(x\).

There is also a notion of a cluster point of a sequence in a metric space:

VI.2.3.4. Definition. Let \((X, \rho)\) be a metric space, \(x \in X\), and \((x_n)\) a sequence in \(X\). Then \(x\) is a cluster point of the sequence \((x_n)\) if for every \(\epsilon > 0\) and \(n_0 \in \mathbb{N}\), \(\rho(x_n, x) < \epsilon\) for some \(n \geq n_0\). (Equivalently, \(\rho(x_n, x) < \epsilon\) for infinitely many \(n\).) When \(\rho\) needs to be specified, we say \(x\) is a \(\rho\)-cluster point of \((x_n)\).

If \(x_n \to x\), then \(x\) is a cluster point of \((x_n)\), but the converse is generally not true. A sequence can have many cluster points.

VI.2.3.5. The term “limit point” is sometimes used in place of “cluster point”, but this can lead to confusion, so we will use the term “limit point” only in reference to a set, and “cluster point” in reference to a sequence. If \(x\) is a cluster point of a sequence \((x_n)\), then \(x\) is a limit point of the set \(\{x_n : n \in \mathbb{N}\}\), but the converse is not necessarily true: each term \(x_k\) is a limit point of \(\{x_n : n \in \mathbb{N}\}\), but \(x_k\) is usually not a cluster point of \((x_n)\). In fact, we have:
VI.2.3.6. Proposition. Let \((x_n)\) be a sequence in a metric space \((X, \rho)\), and let \(x \in X\). Then \(x\) is a cluster point of \((x_n)\) if and only if \(x\) is a limit point of
\[
A_k = \{x_n : n \geq k\}
\]
for every \(k \in \mathbb{N}\).

This proposition is an immediate consequence of the definitions, and the proof is left as an exercise.

Cluster points can also be characterized using subsequences:

VI.2.3.7. Proposition. Let \((x_n)\) be a sequence in a metric space \((X, \rho)\), and let \(x \in X\). Then \(x\) is a cluster point of \((x_n)\) if and only if there is a subsequence \((x_{k_n})\) which converges to \(x\).

Proof: Suppose there is a subsequence of \((x_n)\) converging to \(x\). Then, for any \(\epsilon > 0\), infinitely many terms of the subsequence lie within \(\epsilon\) of \(x\), so \(x\) is a cluster point of \((x_n)\). Conversely, if \(x\) is a cluster point of \((x_n)\), then set \(k_1 = 1\) and inductively let \(k_{n+1} \geq k_n + 1\) for which \(\rho(x_{k_{n+1}}, x) < 1/(n+1)\). Then \(x_{k_n} \to x\).

A related result about subsequences has a somewhat complicated statement, but is frequently useful:

VI.2.3.8. Proposition. Let \((X, \rho)\) be a metric space, \(x \in X\), and \((x_n)\) a sequence in \(X\). Then \(x_n \to x\) if and only if \(x\) is a cluster point of every subsequence of \((x_n)\).

Proof: If \(x_n \to x\), then every subsequence \((x_{k_n})\) of \((x_n)\) also converges to \(x\) (), hence \(x\) is a cluster point of \((x_{k_n})\). Conversely, suppose \((x_n)\) does not converge to \(x\). Then there is an \(\epsilon > 0\) such that, for every \(n_0 \in \mathbb{N}\), there is an \(n \geq n_0\) with \(\rho(x_n, x) \geq \epsilon\). Let \(k_1 = 1\), and inductively choose \(k_{n+1} \geq k_n + 1\) with \(\rho(x_{k_{n+1}}, x) \geq \epsilon\). Then \(x\) is not a cluster point of the subsequence \((x_{k_n})\).

Limits of sequences and functions, continuity, sequential criterion, dependence on metric; cluster points; subsequences; closure in terms of sequences; uniform continuity; mean and mean-square convergence

Dominant and Equivalent Metrics

It is sometimes important to compare two or more metrics on the same set. The next definition is reminiscent of the definition of continuity, and is in fact very closely related ().

VI.2.3.9. Definition. Let \(\rho\) and \(\sigma\) be metrics on the same set \(X\). Then \(\rho\) dominates \(\sigma\) if, for every \(x_0 \in X\) and \(\epsilon > 0\), there is a \(\delta > 0\) such that \(\sigma(x, x_0) < \epsilon\) whenever \(x \in X\) and \(\rho(x, x_0) < \delta\). The metric \(\rho\) uniformly dominates \(\sigma\) if, for every \(\epsilon > 0\), there is a \(\delta > 0\) such that \(\sigma(x, y) < \epsilon\) whenever \(x, y \in X\) and \(\rho(x, y) < \delta\).

The metrics \(\rho\) and \(\sigma\) are equivalent if each dominates the other, and uniformly equivalent if each uniformly dominates the other.

The metrics \(\rho\) and \(\sigma\) are incomparable if neither one dominates the other.
VI.2.3.10. Roughly speaking, “ρ dominates σ” means that \( \sigma(x, y) \) is small whenever \( \rho(x, y) \) is small. The most common way a metric ρ uniformly dominates another metric σ is if there is a \( C > 0 \) with \( \sigma(x, y) \leq C\rho(x, y) \) for all \( x, y \in X \).

VI.2.3.11. Proposition. Let \( \rho \) and \( \sigma \) be metrics on a set \( X \). Then the following are equivalent:

(i) \( \rho \) dominates \( \sigma \).

(ii) The identity function from \((X, \rho)\) to \((X, \sigma)\) is continuous.

(iii) Whenever \((x_n)\) is a sequence in \( X \) converging to a limit \( x \) with respect to \( \rho \) (i.e. \( \lim_{n \to \infty} \rho(x_n, x) = 0 \)), \((x_n)\) also converges to \( x \) with respect to \( \sigma \) (i.e. \( \lim_{n \to \infty} \sigma(x_n, x) = 0 \)).

(iv) Every set which is \( \sigma \)-closed is also \( \rho \)-closed.

(v) Every set which is \( \sigma \)-open is also \( \rho \)-open.

Paraphrasing (iii)–(v), if \( \rho \) dominates \( \sigma \), it is easier for a set to be \( \rho \)-open (or \( \rho \)-closed) than \( \sigma \)-open (or \( \sigma \)-closed), but harder for a sequence to converge with respect to \( \rho \) than with respect to \( \sigma \).

Proof: (i) \( \iff \) (ii) is a straightforward comparison of definitions, and is left to the reader. (ii) \( \iff \) (iii) is the Sequential Criterion for continuity.

(iii) \( \Rightarrow \) (iv): Suppose \( A \subseteq X \) is \( \sigma \)-closed, and \( x \) is a \( \rho \)-limit point of \( A \). We must show that \( x \in A \). But by the Sequential Criterion for limit points, there is a sequence \((x_n)\) in \( A \) with \( x_n \to x \) with respect to \( \rho \). By (iii), \( x_n \to x \) with respect to \( \sigma \), so \( x \in A \) because \( A \) is \( \sigma \)-closed.

(iv) \( \iff \) (v) by taking complements. (v) \( \Rightarrow \) (ii) by ??.

Similarly, we obtain:

VI.2.3.12. Proposition. Let \( \rho \) and \( \sigma \) be metrics on a set \( X \). Then \( \rho \) uniformly dominates \( \sigma \) if and only if the identity function from \((X, \rho)\) to \((X, \sigma)\) is uniformly continuous.

VI.2.3.13. Examples.

(i) On \( \mathbb{R}^n \), the metrics \( \rho_2, \rho_1, \) and \( \rho_\infty \) are uniformly equivalent since, for any \( x, y \in \mathbb{R}^n \),

\[
\rho_\infty(x, y) \leq \rho_2(x, y) \leq \rho_1(x, y) \leq n\rho_\infty(x, y) \leq n\rho_2(x, y)
\]

(the inequality \( \rho_2(x, y) \leq \rho_1(x, y) \) is the only one which is not obvious; see Exercise ()).

(ii) On \( C[a, b] \), \( \rho_\infty \) uniformly dominates \( \rho_1 \) and \( \rho_2 \) since \( \rho_1(f, g) \leq (b - a)\rho_\infty(f, g) \) and \( \rho_2(f, g) \leq (b - a)^{1/2}\rho_\infty(f, g) \) for any \( f, g \). Actually, \( \rho_1(f, g) \leq (b - a)^{3/2}\rho_2(f, g) \) for any \( f, g \in C[a, b] \) (Exercise ()), so \( \rho_2 \) also uniformly dominates \( \rho_1 \).

However, none of the three are equivalent. For example, let \( f_n \) be the function whose graph is in Figure ().
Then
\[ \lim_{n \to \infty} \rho_1(f_n, 0) = \lim_{n \to \infty} \rho_2(f_n, 0) = 0, \]
but \( \rho_\infty(f_n, 0) = 1 \) for all \( n \). Apply the criterion of VI.2.3.11.(iii) to conclude that \( \rho_1 \) and \( \rho_2 \) do not dominate \( \rho_\infty \). See Exercise () for a proof that \( \rho_1 \) does not dominate \( \rho_2 \).

(iii) Let \( \rho \) be a metric on \( X \), and for \( x, y \in X \), set \( \sigma(x, y) = \min(\rho(x, y), 1) \). Then \( \sigma \) is a bounded metric on \( X \) which is uniformly equivalent to \( \rho \) [it is obvious that \( \rho \) uniformly dominates \( \sigma \); to prove that \( \sigma \) uniformly dominates \( \rho \), for any \( \epsilon > 0 \) choose \( \delta = \min(\epsilon, 1) \).

(iv) Let \( \rho \) be the usual metric on \( \mathbb{R} \), \( \rho(x, y) = |x - y| \), and let \( \sigma(x, y) = |\arctan x - \arctan y| \). Then \( \sigma \) is a metric on \( \mathbb{R} \), and \( \rho \) uniformly dominates \( \sigma \) (in fact, \( \sigma(x, y) \leq \rho(x, y) \) for all \( x, y \in \mathbb{R} \).) Conversely, \( \sigma \) dominates \( \rho \) by continuity of the tangent function, but not uniformly since \( \sigma(n, n + 1) \to 0 \) as \( n \to \infty \); so \( \rho \) and \( \sigma \) are equivalent but not uniformly equivalent.

(v) The discrete metric on a set \( X \) uniformly dominates any other metric on \( X \) [for any \( \epsilon > 0 \) we can choose \( \delta = 1 \).]

(vi) If \( \rho \) is a metric on \( X \), then \( c\rho \) is a metric which is uniformly equivalent to \( \rho \), for any \( c > 0 \).

(vii) If \( \rho \) and \( \sigma \) are metrics on a set \( X \), then \( \rho + \sigma \) (defined by \( (\rho + \sigma)(x, y) = \rho(x, y) + \sigma(x, y) \)) and \( \max(\rho, \sigma) \) are uniformly equivalent metrics which uniformly dominate both \( \rho \) and \( \sigma \). If \((\rho_n)\) is a sequence of metrics on \( X \), set \( \sigma_n = \min(\rho_n, 1) \) for all \( n \) (cf. (iii)), and define \( \rho \) by
\[ \rho(x, y) = \sum_{n=1}^{\infty} 2^{-n} \sigma_n(x, y). \]

Then \( \rho \) is a metric which uniformly dominates all the \( \rho_n \)'s.

732
VI.2.4. Extended Metrics

It turns out to be quite harmless to allow a metric to also take the value $\infty$ ($+\infty$), i.e. to allow points to be an infinite distance apart.

VI.2.4.1. **Definition.** An *extended metric* on a set $X$ is a function $\rho : X \times X \to [0, \infty]$ satisfying:

(i) $\rho(x, y) \geq 0$ for all $x, y \in X$.

(ii) $\rho(x, y) = 0$ if and only if $x = y$ (*definiteness*).

(iii) $\rho(x, y) = \rho(y, x)$ for all $x, y \in X$ (*symmetry*).

(iv) $\rho(x, z) \leq \rho(x, y) + \rho(y, z)$ for all $x, y, z \in X$ (*triangle inequality*).

A pair $(X, \rho)$, where $X$ is a set and $\rho$ is a metric on $X$, is called an *extended metric space*.

In the definition, we take the usual order on $[0, \infty]$, i.e. $x < \infty$ for all $x \in \mathbb{R}$, and $x + \infty = \infty$ for any $x \in [0, \infty]$. Note that any metric is an extended metric. We may also consider extended pseudometrics which have all the properties except (ii).

VI.2.4.2. All the results of this section hold for extended metrics with no modifications. If $\rho$ is an extended metric on $X$, define $\tilde{\rho}$ by $\tilde{\rho}(x, y) = \min(\rho(x, y), 1)$; then $\tilde{\rho}$ is a metric on $X$ which is equivalent to $\rho$, so if desired any extended metric can be converted to a metric without changing the topology.

VI.2.4.3. **Definition.** Let $(X, \rho)$ be an extended metric space, and $x \in X$. The *galaxy* of $x$ in $X$ is

$$\{y \in X : \rho(x, y) < \infty\}.$$ 

The proof of the next simple proposition is left as an exercise for the reader.

VI.2.4.4. **Proposition.** Let $(X, \rho)$ be an extended metric space. Then

(i) Any two distinct galaxies in $X$ are disjoint. Thus $X$ partitions into a disjoint union of galaxies. Any points in distinct galaxies are an infinite distance apart.

(ii) Each galaxy is a clopen set in $X$.

(iii) As a topological space, $X$ is the separated union () of its galaxies.

(iv) The restriction of $\rho$ to any galaxy is a metric.

A metric space is just an extended metric space with only one galaxy.

Maximal Metrics

The next simple but important observation is most naturally phrased using extended metrics:
Proposition. Let $X$ be a set, $\{\rho_i : i \in I\}$ a collection of extended pseudometrics on $X$. For $x, y \in X$, set 
\[ \tilde{\rho}_I(x, y) = \sup_{i \in I} \rho_i(x, y). \]
Then $\tilde{\rho}_I$ is an extended pseudometric on $X$.

Proof: The only thing that needs to be checked is the triangle inequality. If $x, y, z \in X$, then, by (i), 
\[ \tilde{\rho}_I(x, z) = \sup_i \rho_i(x, z) \leq \sup_i [\rho_i(x, y) + \rho_i(y, z)] \leq \sup_i \rho_i(x, y) + \sup_i \rho_i(y, z) = \tilde{\rho}_I(x, y) + \tilde{\rho}_I(y, z). \]

VI.2.4.6. If the $\rho_i$ are separating (in particular, if at least one $\rho_i$ is an extended metric), then $\tilde{\rho}_I$ is an extended metric. The metric $\tilde{\rho}_I$ dominates each $\rho_i$; i.e., the $\tilde{\rho}_I$ topology is stronger than all the $\rho_i$ topologies, but it might not be the weakest topology stronger than all the $\rho_i$ topologies. For a simple example, let $\sigma$ be a metric on $X$, and for each $n$ let $\rho_n = n\sigma$. Then all the $\rho_n$ are equivalent to $\sigma$, but $\tilde{\rho}_I$ is the discrete extended metric. (For an actual metric version, set $\rho_n(x, y) = \min(1, n\sigma(x, y))$ for $x, y \in X$.) If $I$ is finite, then the $\tilde{\rho}_I$ topology is indeed the weakest topology stronger than all the $\rho_i$ topologies.

VI.2.4.7. A particularly important example (cf. XI.8.4.2.) comes from a bound function. Let $X$ be a set, and $\beta : X \times X \to [0, +\infty]$ a function. Let $I$ be the set of all pseudometrics $\sigma$ on $X$ such that $\sigma(x, y) \leq \beta(x, y)$ for all $x, y \in X$ ($I$ is nonempty since the zero pseudometric is in $I$; one could also allow extended pseudometrics without affecting the construction). Set $\rho_\beta = \tilde{\rho}_I$. The extended pseudometric $\rho_\beta$ is called the maximal pseudometric of $\beta$; it is the largest pseudometric $\rho$ satisfying $\rho(x, y) \leq \beta(x, y)$ for all $x, y \in X$.

VI.2.5. Cauchy Sequences

VI.2.6. Normed Vector Spaces

Many of the important metric spaces in analysis are vector spaces in which the metric comes from a norm.

VI.2.6.1. Definition. Let $X$ be a vector space over $\mathbb{R}$ or $\mathbb{C}$. A norm on $X$ is a function $x \mapsto \|x\|$ from $X$ to $\mathbb{R}$ satisfying

(i) $\|x\| \geq 0$ for all $x \in X$.

(ii) $\|x\| = 0$ if and only if $x = 0$ (definiteness).

(iii) $\|\alpha x\| = |\alpha|\|x\|$ for all $x \in X$ and all scalars $\alpha$ (homogeneity).

(iv) $\|x + y\| \leq \|x\| + \|y\|$ for all $x, y \in X$ (triangle inequality).

VI.2.6.2. A norm on a vector space $X$ defines a metric on $X$ by $\rho(x, y) = \|x - y\|$. The metrics in VI.2.1.3.(i)–(iv) arise this way:
VI.2.6.3. Examples.

(i) The usual metric on \( \mathbb{R} \) comes from the norm \( \|x\| = |x| \).

(ii) The metric \( \rho_2 \) on \( \mathbb{R}^n \) comes from \( \|x\|_2 = \sqrt{x_1^2 + \cdots + x_n^2} \).

(iii) The metrics \( \rho_1 \) and \( \rho_\infty \) on \( \mathbb{R}^n \) also come from norms:
\[
\|x\|_1 = |x_1| + \cdots + |x_n| \\
\|x\|_\infty = \max(|x_1|, \ldots, |x_n|)
\]

(iv) The metrics \( \rho_2, \rho_1, \rho_\infty \) on \( C([a,b]) \) come from norms
\[
\|f\|_2 = \left[ \int_a^b (f(t))^2 \, dt \right]^{1/2} \\
\|f\|_1 = \int_a^b |f(t)| \, dt \\
\|f\|_\infty = \max_{a \leq t \leq b} |f(t)|
\]

(See Exercise (i) or (ii) for a proof that \( \| \cdot \|_2 \) satisfies the triangle inequality.)

(v) On \( \mathbb{C}^n \), the same formulas as in (ii) and (iii) define norms, except that the 2-norm must be written
\[
\|x\|_2 = \sqrt{|x_1|^2 + \cdots + |x_n|^2}.
\]

VI.2.6.4. The metric \( \rho \) induced by a norm is translation-invariant, i.e. \( \rho(x + z, y + z) = \rho(x, y) \) for all \( x, y, z \in X \), and homogeneous, i.e. \( \rho(\alpha x, \alpha y) = |\alpha| \rho(x, y) \) for all \( x, y \in X \) and all scalars \( \alpha \). A consequence of translation-invariance is that \( B_r(z) = z + B_r(0) \) for any \( r > 0, z \in X \), and \( B_{r \alpha}(0) = \alpha B_r(0) \) for any \( \alpha, r > 0 \). Thus all balls in a normed vector space “look the same” up to scaling and translation.

Another consequence of homogeneity is:

VI.2.6.5. Proposition. Let \( X \) be a vector space, \( \| \cdot \| \) and \( \| \cdot \|' \) norms on \( X \), \( \rho \) and \( \sigma \) the associated metrics. Then the following are equivalent:

(i) \( \rho \) dominates \( \sigma \).

(ii) \( \rho \) uniformly dominates \( \sigma \).

(iii) There is a \( C > 0 \) such that \( \|x\|' \leq C \|x\| \) for all \( x \in X \).
This is actually a special case of a fundamental principle about operators between normed vector spaces.

**Proof:** (iii) $\Rightarrow$ (ii) $\Rightarrow$ (i) are trivial, so we need only prove (i) $\Rightarrow$ (iii). Choose $\delta > 0$ so that $\|x\| = \rho(x, 0) < \delta$ implies $\|x\|' = \sigma(x, 0) < 1$, for any $x \in X$, and set $C = 1/\delta$. Then $\|x\| < 1$ implies that $\|x\|' < C$. If $x \in X$ and $\|x\|' > C\|x\|$, choose $\alpha \in \mathbb{R}$ with

$$\frac{C}{\|x\|'} < \alpha < \frac{1}{\|x\|}$$

and then $\|\alpha x\| < 1$ but $\|\alpha x\|' > C$, a contradiction; so there can be no such $x$, proving (iii).

[Move to later section]

**Theorem.** Let $X$ and $Y$ be vector spaces (over the same field, $\mathbb{R}$ or $\mathbb{C}$), with norms $\|\cdot\|_X$ and $\|\cdot\|_Y$ respectively, and let $T : X \to Y$ be a linear operator. Then the following are equivalent:

(i) $T$ is continuous at 0.

(ii) $T$ is continuous.

(iii) $T$ is uniformly continuous.

(iv) There is a constant $K \geq 0$ such that $\|Tx\|_Y \leq K\|x\|_X$ for all $x \in X$.

If $T$ satisfies (iv), $T$ is said to be bounded; the smallest such $K$ is called the operator norm of $T$, denoted $\|T\|_{op}$ or usually just $\|T\|$.  

**Seminorms**

**Banach Spaces**

**VI.2.7. Exercises**

1. Here are physical interpretations of $\rho_1$ and $\rho_\infty$ on $\mathbb{R}^2$.

(a) The metric $\rho_1$ is often called the city metric or driving metric. Imagine a city in which all streets run north-south or east-west. Then the $\rho_1$-distance between two points located on streets is the shortest driving distance between the points (ignoring one-way streets, etc.)

(b) There is a similar, though perhaps less satisfactory, interpretation of $\rho_\infty$. In this city, there are buses on each street. The fare structure is unusual: the cost of riding a bus is strictly proportional to the distance traveled, say $1$ per mile. However, a rider also receives a transfer good for a free ride on a bus in the perpendicular direction, of length not exceeding the length of the paid ride. The $\rho_\infty$ distance between two points on streets is then the minimum cost of a bus ride between the two points.

2. Show that $\rho_1$, $\rho_2$, and $\rho_\infty$ are equivalent metrics on $\mathbb{R}^n$.

3. (a) If $x_1, \ldots, x_n$ are nonnegative real numbers, show that

$$\sum_{k=1}^{n} x_k^2 \leq \left(\sum_{k=1}^{n} x_k\right)^2.$$

[Hint: Multiply out the right side.] Give a careful proof by induction on $n$.  

736
(b) If $x_1, x_2$ are real numbers, show that $(x_1 + x_2)^2 \leq 2(x_1^2 + x_2^2)$. [Hint: $(x_1 - x_2)^2 \geq 0$.]

(c) If $x_1, \ldots, x_n$ are arbitrary real numbers, and $n = 2^m$, show by induction on $m$ that
\[
\left( \sum_{k=1}^{n} x_k \right)^2 \leq n \sum_{k=1}^{n} x_k^2.
\]

(d) Let $f$ be Riemann integrable on $[a, b]$ (e.g. $f \in C[a, b]$.) Show that
\[
\left( \int_a^b |f(t)| \, dt \right)^2 \leq (b - a) \int_a^b |f(t)|^2 \, dt .
\]
[Hint: approximate the integrals by Riemann sums, dividing the interval into $2^n$ subintervals of equal length, and apply (c).]

(e) Show that the inequality in (c) is also true if $n$ is not a power of 2. [Given $x_1, \ldots, x_n$, let $f$ be the function on $[0, n]$ with $f(t) = x_k$ if $k - 1 \leq x < k$. Apply (d).]

The inequalities in (b)–(e) are special cases of Jensen’s Inequality. See also VI.2.7. for an alternate proof of (c) for general $n$.

4. (a) Show that on $C[a, b]$, the $\infty$-norm dominates the 2-norm, and the 2-norm dominates the 1-norm.

(b) Let $g_n$ be the function whose graph is given in Figure (a), and $h_n = \sqrt{g_n}$.

\[\text{Figure VI.2: The graph of } g_n\]

Then $\rho_1(h_n, 0) < n^{-1/2}$, so $\lim_{n \to \infty} \rho_1(h_n, 0) \to 0$. However, for any $n$,
\[
\rho_2(h_n, 0) = \left( \int_a^b g_n(t) \, dt \right)^{1/2} = \frac{1}{\sqrt{2}}.
\]
so $\rho_2(h_n, 0) \neq 0$.

5. Give a direct proof (not involving taking complements) that the collection of closed sets in a metric space is closed under arbitrary intersections and under finite unions.

The graph of the Cantor function is given in Figure VI.4.

![The Cantor function graph](image-url)

Figure VI.3: The Cantor function

[Move to later section]

6. Let $x_1, \ldots, x_n, y_1, \ldots, y_n$ be real numbers. Show that

$$(x_1 + \cdots + x_n)(y_1 + \cdots + y_n) \leq n \sqrt{x_1^2 + \cdots + x_n^2} \sqrt{y_1^2 + \cdots + y_n^2}.$$  

[Hint: let $\mathbf{x} = (x_1, \ldots, x_n)$, and for $1 \leq k \leq n$ let

$$y^{(k)} = (y_k, y_k+1, \ldots, y_n, y_1, \ldots, y_{k-1}).$$

Then $(x_1 + \cdots + x_n)(y_1 + \cdots + y_n) = \mathbf{x} \cdot \mathbf{y}^{(1)} + \cdots + \mathbf{x} \cdot \mathbf{y}^{(n)}$. Apply the CBS inequality.] In particular, $(x_1 + \cdots + x_n)^2 \leq n(x_1^2 + \cdots + x_n^2)$. The $n$ in this inequality is the best possible constant in general: if all the $x_i$ and $y_j$ are equal, we have equality.
Figure VI.4: The Cantor Function
VI.2.8. How Many Separable Metric Spaces Are There?

In this subsection, we answer the following two questions:

VI.2.8.1. Question. How many separable metric spaces are there?

VI.2.8.2. Question. How many separable complete metric spaces are there?

VI.2.8.3. These questions are meaningless unless we specify a notion of equivalence. After all, there are as many one-point metric spaces as there are sets! (For a similar reason, it is meaningless to ask how many metric spaces there are, even up to isometry: any set with the discrete metric is a (complete) metric space.)

The two obvious notions of equivalence are homeomorphism and isometry. Isometry is a much finer equivalence: each homeomorphism class of metric spaces (with more than one point) includes many isometry classes. Thus we will obtain, and answer, four questions by inserting the phrase “up to homeomorphism” or “up to isometry” in each. The answers, however, will turn out not to depend on which equivalence we take: the answer to VI.2.8.1. in both cases is $2^\aleph_0$, and to VI.2.8.2. in both cases is $2^\aleph_0$.

VI.2.8.4. Proposition. There are exactly $2^\aleph_0$ functions from $\mathbb{N} \times \mathbb{N}$ to $\mathbb{R}$.

VI.2.8.5. Corollary. There are at most $2^\aleph_0$ metrics on $\mathbb{N}$. Hence up to isometry there are at most $2^\aleph_0$ countable metric spaces.

In fact, it is easily seen that there are at least $2^\aleph_0$ metrics on $\mathbb{N}$ (the distance between 1 and 2 can be any positive number), hence exactly $2^\aleph_0$. (One should also consider finite metric spaces: there are clearly exactly $2^\aleph_0$ metrics on a finite set with more than one element.)

VI.2.8.6. Corollary. Up to isometry, there are at most $2^\aleph_0$ separable complete metric spaces.

Proof: Every separable complete metric space is isometric to the completion of a countable metric space, and the completion of a metric space is unique up to isometry.

VI.2.8.7. There are $2^\aleph_0$ topologically distinct compact subsets of $\mathbb{R}^2$ (XI.18.4.1.; there are even $2^\aleph_0$ topologically distinct compact subsets of $\mathbb{R}$ – see XI.18.4.2.), each of which is a separable complete metric space. Thus up to homeomorphism, there are at least $2^\aleph_0$ compact metric spaces, each of which is separable and complete (). Thus we obtain the answer to Question VI.2.8.2.:
VI.2.8.8. THEOREM. (i) Up to homeomorphism, there are exactly $2^{\aleph_0}$ compact metric spaces.
(ii) Up to isometry, there are exactly $2^{\aleph_0}$ compact metric spaces.
(iii) Up to homeomorphism, there are exactly $2^{\aleph_0}$ separable complete metric spaces.
(iv) Up to isometry, there are exactly $2^{\aleph_0}$ separable complete metric spaces.

Recall () that a Polish space is a topological space which is homeomorphic to a separable complete metric space. Thus we can rephrase (iii):

VI.2.8.9. COROLLARY. Up to homeomorphism, there are exactly $2^{\aleph_0}$ Polish spaces.

We can now answer Question VI.2.8.1.:

VI.2.8.10. THEOREM. (i) Up to homeomorphism, there are exactly $2^{2^{\aleph_0}}$ separable metric spaces.
(ii) Up to isometry, there are exactly $2^{2^{\aleph_0}}$ separable metric spaces.

Proof: Every separable metric space is isometric to a subset of a separable complete metric space. Every separable complete metric space has cardinality $\leq 2^{\aleph_0}$ (XI.7.8.5.(c)) (in fact, exactly $2^{\aleph_0}$ if uncountable; cf. XII.3.1.10.). Thus a separable complete metric space has at most $2^{2^{\aleph_0}}$ subsets. Since there are $2^{\aleph_0}$ separable complete metric spaces up to isometry (VI.2.8.8.), there are up to isometry at most $2^{\aleph_0} \cdot 2^{2^{\aleph_0}} = 2^{2^{\aleph_0}}$ subsets of complete metric spaces. Hence there are at most $2^{2^{\aleph_0}}$ separable metric spaces up to isometry.

Conversely, there are $2^{2^{\aleph_0}}$ topologically distinct subsets of $\mathbb{R}$ (XI.18.4.42.), each of which is a separable metric space. Thus there are at least $2^{2^{\aleph_0}}$ separable metric spaces up to homeomorphism.

VI.2.9. The Banach Fixed-Point Theorem

There are many fixed-point theorems in topology, which assert that under certain conditions a function from a topological space to itself sends at least one, or exactly one, point to itself. Perhaps the simplest example is (); other examples are XI.20.1.2. Here we discuss a fairly elementary but very useful example, the Banach fixed-point theorem, sometimes called the Contraction Mapping Theorem.

VI.2.9.1. Definition. Let \((X, \rho)\) be a metric space. A function \(T : X \to X\) is a strict contraction if there is an \(\alpha, 0 < \alpha < 1\), such that \(\rho(T(x), T(y)) \leq \alpha \rho(x, y)\) for all \(x, y \in X\).

A strict contraction is obviously a (uniformly) continuous function from \(X\) to \(X\).

VI.2.9.2. Caution: For \(T\) to be a strict contraction, it is not sufficient that \(\rho(T(x), T(y)) < \rho(x, y)\) whenever \(x \neq y\); the distance must decrease by at least a constant factor less than 1. See VI.2.9.6.

VI.2.9.3. Theorem. [Banach Fixed-Point Theorem] Let \((X, \rho)\) be a complete metric space, and \(T : X \to X\) a strict contraction. Then \(T\) has a unique fixed point: there is a unique point \(p \in X\) with \(T(p) = p\). If \(x\) is any point of \(X\), then the sequence \((T^n(x))\) converges to \(p\).

Proof: Fix \(x \in X\). Inductively set \(x_0 = x\) and \(x_{n+1} = T(x_n)\) for all \(n\). We claim \((x_n)\) is a Cauchy sequence. By induction, we have \(\rho(x_n, x_{n+1}) \leq \alpha^n \rho(x_0, x_1)\) for all \(n\). Thus, if \(n < m\), by the triangle inequality we have

\[
\rho(x_n, x_m) \leq \rho(x_0, x_1) \sum_{k=n}^{m-1} \alpha^k.
\]

The sum is a tail sum of the convergent geometric series \(\sum_{k=1}^{\infty} \alpha^k\), hence is arbitrarily small if \(n\) is large enough. Thus \((x_n)\) is a Cauchy sequence and therefore converges to a point \(p \in X\). Then \(T(x_n) \to T(p)\) since \(T\) is continuous; but \(T(x_n) = x_{n+1}\), so \(T(x_n) \to p\), i.e. \(T(p) = p\) by uniqueness of limits in a metric space.

If \(q\) is any fixed point of \(T\), then

\[
\rho(p, q) = \rho(T(p), T(q)) \leq \alpha \rho(p, q)
\]

which can only hold if \(\rho(p, q) = 0\), i.e. \(q = p\). Thus \(p\) is the only fixed point of \(T\).

VI.2.9.4. The proof of the theorem is constructive: the sequence of iterates of any starting point converges to the fixed point, i.e. the fixed point is a “universal attractor.” Thus the fixed point can be found by an explicit iterative algorithm of successive approximation.

VI.2.9.5. If \((X, \rho)\) is not complete, a strict contraction on \(X\) need not have a fixed point (VI.2.10.1). However, if it does, the argument of the proof shows that the fixed point is unique (this part of the proof does not require completeness). And if \(p\) is a fixed point of \(T\), then for any \(x \in X\) we have \(\rho(T^n(x), p) = \rho(T^n(x), T^n(p)) \leq \alpha^n \rho(x, p) \to 0\), so \(T^n(x) \to p\). Alternatively, any strict contraction on \((X, \rho)\) extends uniquely to a strict contraction \(\bar{T}\) on the completion \((\bar{X}, \bar{\rho})\) of \((X, \rho)\) by uniform continuity (); if \(T\) has a fixed point, it must be the unique fixed point of \(\bar{T}\) and we have \(T^n(x) \to p\) for any \(x \in X\).
VI.2.9.6. Example. To obtain a fixed point, it does not suffice to simply have \( \rho(T(x), T(y)) < \rho(x, y) \) for \( x \neq y \); this condition is not enough to insure that \( (T^n(x)) \) is a Cauchy sequence for any \( x \). For example, let \( T : [1, +\infty) \to [1, +\infty) \) be defined by \( T(x) = x + \frac{1}{x} \). Then \( T \) is differentiable everywhere and \( 0 < T'(x) < 1 \) for \( 1 < x < +\infty \), so by the MVT \( |T(x) - T(y)| < |x - y| \) for \( x, y \in [1, +\infty) \), \( x \neq y \) (this also has an elementary proof not requiring calculus). But \( T \) has no fixed point.

Continuity of Fixed Points

If two strict contractions are uniformly close, their fixed points must be close:

VI.2.9.7. Proposition. Let \( (X, \rho) \) be a metric space, and \( S, T \) strict contractions on \( X \), i.e. there are \( 0 \leq \alpha, \beta < 1 \) such that \( \rho(S(x), S(y)) \leq \alpha \rho(x, y) \) and \( \rho(T(x), T(y)) \leq \beta \rho(x, y) \) for all \( x, y \in X \). Let \( p \) and \( q \) be (unique) fixed points of \( S \) and \( T \) respectively. If \( S \) and \( T \) are uniformly close within \( \epsilon > 0 \), i.e. \( \rho(S(x), T(x)) < \epsilon \) for all \( x \in X \), then \( \rho(p, q) < \frac{\epsilon}{1 - \gamma} \), where \( \gamma = \min(\alpha, \beta) \).

Proof: We have \( \lim_{n \to \infty} S^n(q) = p \), and by the triangle inequality we have, for each \( n \),

\[
\rho(q, S^n(q)) = \rho(q, S(q)) + \rho(S(q), S^2(q)) + \cdots + \rho(S^{(n-1)}(q), S^n(q)) \\
\leq (1 + \alpha + \cdots + \alpha^{n-1})\rho(q, S(q)) = \frac{1 - \alpha^n}{1 - \alpha}\rho(q, S(q)) < \frac{1}{1 - \alpha}\rho(q, S(q))
\]

and thus, letting \( k \to \infty \),

\[
\rho(q, p) \leq \frac{1}{1 - \alpha}\rho(q, S(q)) = \frac{1}{1 - \alpha}\rho(T(q), S(q)) < \frac{\epsilon}{1 - \alpha}.
\]

Similarly, we have \( \rho(p, q) = \lim_{n \to \infty} \rho(p, T^n(p)) < \frac{\epsilon}{1 - \gamma} \).

Strict Power Contractions and the Extended Banach Fixed-Point Theorem

There is a substantial extension of the Banach Fixed-Point Theorem.

VI.2.9.8. Definition. Let \( (X, \rho) \) be a metric space. A function \( T : X \to X \) is a strict power contraction if \( T^n \) is a strict contraction for some \( n \in \mathbb{N} \).

VI.2.9.9. Example. A strict power contraction is not necessarily a strict contraction. It is not necessarily even continuous! Let \( X = \mathbb{R} \) with its usual metric, and define \( T : \mathbb{R} \to \mathbb{R} \) by

\[
T(x) = \begin{cases} 
\frac{x}{2} & \text{if } x \in \mathbb{Q} \\
-x/2 & \text{if } x \notin \mathbb{Q}
\end{cases}
\]

Then \( T \) is not continuous, but \( T^2 \) is a strict contraction, so \( T \) is a strict power contraction. Note that \( T \) has a unique fixed point 0, and is continuous at 0 (and only at 0).
VI.2.9.10.  **Theorem.** [Extended Banach Fixed-Point Theorem] Let \((X, \rho)\) be a complete metric space, and \(T : X \to X\) a strict power contraction. Then \(T\) has a unique fixed point \(p\). If \(x\) is any point of \(X\), then the sequence \((T^n(x))\) converges to \(p\).

**Proof:** Suppose \(T^n\) is a strict contraction. Then \(T^n\) has a unique fixed point \(p\) by Theorem VI.2.9.3. We have
\[
T^n(T(p)) = T^{n+1}(p) = T(T^n(p)) = T(p)
\]
so \(T(p)\) is also a fixed point of \(T^n\); thus \(T(p) = p\) by uniqueness, and \(p\) is a fixed point of \(T\). If \(q\) is any fixed point of \(T\), then \(q\) is also a fixed point of \(T^n\), hence \(q = p\) by uniqueness, so \(T\) has a unique fixed point.

Fix \(x \in X\). Then \(\lim_{k \to \infty} T^{kn}(x) = p\). Also, for each \(j\), \(T^{kn+j}(x) = T^{kn}(T^j(x)) \to p\) as \(k \to \infty\). It follows that \(\lim_{m \to \infty} T^m(x) = p\). \(\blacksquare\)

VI.2.9.11.  If \((X, \rho)\) is not complete, a strict power contraction on \(X\) need not have a fixed point (VI.2.10.1). However, if it does, the fixed point is unique (VI.2.9.5), and the proof shows that \(T^n(x) \to p\) for any \(x \in X\) (this part of the proof does not require completeness). The alternate argument of VI.2.9.5 does not work, however, since in general there is no reasonable way to extend a power contraction to the completion.

VI.2.10.  **Exercises**

VI.2.10.1.  Let \(X = \mathbb{Q} \cap [1, 2]\) with the usual metric, and define \(T : X \to X\) by
\[
T(x) = \frac{1}{2} \left( x + \frac{2}{x} \right).
\]

(a) Show that \(T\) is a strict contraction on \(X\).
(b) Show that \(T\) has no fixed point in \(X\).
(c) Identify \(X\) with \([1, 2]\) with the usual metric, and \(\bar{T}\) with the function from \(X\) to \(\bar{X}\) defined by the same formula as \(T\). Find the fixed point of \(\bar{T}\).

VI.2.10.2.  A strict power contraction does not have to be continuous (VI.2.9.9). If it has a fixed point (e.g. if the metric space is complete), does it have to be continuous at the fixed point? Give a proof or counterexample.

VI.2.10.3.  Discuss the difficulties in trying to extend VI.2.9.7. to power contractions. Is there any reasonable result?
VI.3. Euclidean Space

VI.3.1. Metric Axiomatization of Euclidean Space

There are several approaches one can take to defining \( n \)-dimensional Euclidean space. We can just define it to be \( \mathbb{R}^n \) (with the standard metric \( \rho_2 \)). We will eventually take this approach, but it is worth noting that Euclidean space can be defined in a more abstract manner and shown to be effectively the same as \( \mathbb{R}^n \).

There are two such approaches possible, characterizing \( \mathbb{R}^n \) directly as a metric space, and giving a set of purely geometric axioms. Since this is a book about analysis, we will take the metric space approach, which may be rather unsatisfying to geometers. The metric approach is, however, quite elegant (although some of the proofs are rather involved), and not as well known as it should be. Our exposition is adapted from [Blu70] (cf. also [Blu75]), where the history of various metric approaches is discussed. For the purely geometric approach, see [Gre93], [Har00], and/or [Moi90].

VI.3.1.1. One easy metric approach is to define \( n \)-dimensional Euclidean space to be a metric space isometric to \( \mathbb{R}^n \). Since the isometries of \( \mathbb{R}^n \) can be nicely described (XV.1.2.4.), and preserve the affine structure, an isometry from an abstract metric space \( E \) to \( \mathbb{R}^n \) is almost unique (up to a choice of origin and an ordered orthonormal basis) and can be used to transfer the structure of \( \mathbb{R}^n \) to \( E \). We will regard a choice of an isometry of \( E \) with \( \mathbb{R}^n \) to be a choice of a coordinate system in \( E \). By choosing a coordinate system, we can identify \( E \) with \( \mathbb{R}^n \) and all analysis we do on \( E \) can be described using the chosen coordinates; it will all turn out to be independent of the coordinate system chosen in an appropriate sense ( ).

VI.3.1.2. We can, however, characterize \( n \)-dimensional Euclidean space abstractly as a metric space by three axioms (VI.3.1.43.), or four simpler axioms plus completeness (VI.3.1.44.). These axioms will presuppose having \( \mathbb{R} \) available by some previous construction; this is undesirable from a geometric point of view, but necessary from the metric standpoint (indeed, the definition of a metric space itself depends on already having \( \mathbb{R} \), or at least \( \mathbb{R}_+ \)). \( \mathbb{R} \) is always assumed to have its usual metric.

We will give the three axioms for a metric space \( (E, \rho) \), and discuss some variations and equivalent versions of them.

The Line Axiom

VI.3.1.3. Definition. A subset \( L \) of a metric space \( (E, \rho) \) is a line if \( L \) is isometric to \( \mathbb{R} \). A subset of \( E \) isometric to a closed bounded interval \( [\alpha, \beta] \) in \( \mathbb{R} \) is called a line segment in \( E \), with the points corresponding to \( \alpha \) and \( \beta \) the endpoints. A subset of \( E \) isometric to \( [0, \infty) \) is called a ray in \( E \), beginning at (or with endpoint) the point corresponding to \( 0 \).

VI.3.1.4. Line Axiom: For any two points \( a, b \in E \) there is a line in \( E \) containing \( a \) and \( b \).

Such a subset is called a line through \( a \) and \( b \). Note that no uniqueness is required as part of the axiom (uniqueness will follow from the second axiom; cf. VI.3.1.27.). A metric space in which each pair of distinct points lies on a unique line will be said to satisfy the Unique Line Axiom. Similarly:

VI.3.1.5. Line Segment Axiom: For any two (distinct) points \( a, b \in E \) there is a line segment in \( E \) with endpoints \( a \) and \( b \).
A metric on a set which satisfies the Line Segment Axiom is called a *strictly intrinsic metric*. See () for an explanation of this terminology from metric geometry. The Line Axiom is more important than the Line Segment Axiom in this section, but the Line Segment Axiom is central in metric geometry ().

**VI.3.1.6. Examples.** (i) \((\mathbb{R}^2, \rho_\infty)\) () satisfies the Line Axiom (as does any normed real vector space viewed as a metric space). But lines through two given points are not unique in general: for example, the graph of any Lipschitz function from \(\mathbb{R}\) to \(\mathbb{R}\) () with Lipschitz constant \(\leq 1\) (contractive function), regarded as a subset of \(\mathbb{R}^2\) in the usual way, is a line in this metric space.

(ii) Any convex set in \(\mathbb{R}^n\) (or any normed vector space) satisfies the Line Segment Axiom. Again the line segment need not be unique.

(iii) A circle with the arc length metric satisfies the Line Segment Axiom, as does a 2-sphere with the great circle arc length metric. The line segment is not unique for diametrically opposed points. They do not satisfy the Line Axiom.

If the metric space \((E, \rho)\) is assumed to be complete, an apparently much weaker assumption implies the Line Axiom. We first make a definition:

**VI.3.1.7. Definition.** Let \(a, c \in E\). A point \(b \in E\) is *between* \(a\) and \(c\) if \(b \neq a, b \neq c\, \text{and} \, \rho(a, c) = \rho(a, b) + \rho(b, c)\).

In \(\mathbb{R}\), \(b\) is between \(a\) and \(c\) in this sense if and only if \(b\) is between \(a\) and \(c\) with respect to the usual ordering on \(\mathbb{R}\). More generally, if \(L\) is a line in a metric space, then the various isometries of \(L\) with \(\mathbb{R}\) give two orderings on \(L\), and if \(a, b, c \in L\), then \(b\) is between \(a\) and \(c\) in the sense of VI.3.1.7. if and only if \(b\) is between \(a\) and \(c\) with respect to either (both) of these orderings. In particular, if \(a, b, c\) are distinct points on a line in a metric space, exactly one of the points is between the other two.

Note, however, that the set of points between two given points in a metric space need not look anything like a line segment (cf. Exercise VI.3.3.1); indeed, this set can easily be empty or finite.

There is a limited sense in which betweenness is transferable:

**VI.3.1.8. Proposition.** Let \(a, b, c, d\) be points in a metric space \((E, \rho)\). If \(b\) is between \(a\) and \(d\) and \(c\) is between \(b\) and \(d\), then \(c\) is between \(a\) and \(d\) and \(b\) is between \(a\) and \(c\).

**Proof:** We have
\[
\rho(a, d) = \rho(a, b) + \rho(b, d) = \rho(a, b) + \rho(b, c) + \rho(c, d)
\]
and since \(\rho(a, d) \leq \rho(a, c) + \rho(c, d)\) by the triangle inequality, we have
\[
\rho(a, c) \geq \rho(a, b) + \rho(b, c)
\]
by subtraction; the opposite inequality holds by the triangle inequality, so
\[
\rho(a, c) = \rho(a, b) + \rho(b, c)
\]
and \(c\) is between \(a\) and \(b\). Then we have
\[
\rho(a, d) = \rho(a, b) + \rho(b, c) + \rho(c, d) = \rho(a, c) + \rho(c, d)
\]
so \(c\) is between \(a\) and \(d\).  

746
VI.3.1.9. Care must be exercised in combining betweenness relations, however; overlapping relations cannot be combined in general (betweenness is not “transitive”). For example, if $(E;\rho) = ((0,0), (1,1), (2,0), (1,-1))$, then $b$ is between $a$ and $c$ and $c$ is between $b$ and $d$, but neither $b$ nor $c$ is between $a$ and $d$.

There is a useful consequence of VI.3.1.8.: 

VI.3.1.10. Corollary. Let $(E;\rho)$ be a metric space, $a,b,c \in E$, $S_1$ a line segment with endpoints $a$ and $b$, and $S_2$ a line segment with endpoints $b$ and $c$. Then $S = S_1 \cup S_2$ is a line segment with endpoints $a$ and $c$ if and only if $b$ is between $a$ and $c$.

Proof: If $S$ is a line segment, then $b$ is clearly between $a$ and $c$. Conversely, if $b$ is between $a$ and $c$, to show $S$ is a line segment it suffices to show that if $x \in S_1$, $y \in S_2$, $x \neq b$, $y \neq b$, then $\rho(x,y) = \rho(x,b) + \rho(b,y)$, i.e. that $b$ is between $x$ and $y$. Apply VI.3.1.8. to $a,b,y,c$ to conclude that $b$ is between $a$ and $y$, and then apply VI.3.1.8. again to $y,b,x,a$ to conclude that $b$ is between $y$ and $x$. ☐

VI.3.1.11. Between Axiom: If $a,c \in E$, $a \neq c$, then there is a $b \in E$ which is between $a$ and $c$.

VI.3.1.12. Extension Axiom: If $a,b \in E$, $a \neq b$, then there is a $c \in E$ such that $b$ is between $a$ and $c$.

In metric geometry (e.g. in [Blu70]), a metric space satisfying the Between Axiom is often called metrically convex, and a metric space satisfying the Extension Axiom is called externally convex. We have not used these terms since they do not seem appropriate in general: for example, the subset $[0,1) \cup \{2\}$ of $\mathbb{R}$ satisfies the Between Axiom, and $\mathbb{Z}$ satisfies the Extension Axiom, but neither resembles a convex set in the usual sense (). However, the two axioms together, along with completeness, are quite powerful:

VI.3.1.13. Theorem. Let $(E,\rho)$ be a complete metric space satisfying the Between Axiom and the Extension Axiom. Then $(E,\rho)$ satisfies the Line Axiom.

Completeness is essential for this result: the subsets $\mathbb{Q}$ and $(0,1)$ of $\mathbb{R}$ each satisfy both the Between Axiom and the Extension Axiom, but not the Line Axiom. Note also that even for complete metric spaces, neither axiom implies the other: consider $[0,1]$ and $\mathbb{Z}$.

The proof of VI.3.1.13. consists of three lemmas.

VI.3.1.14. Lemma. Let $(E,\rho)$ be a complete metric space satisfying the Between Axiom. Then $(E,\rho)$ satisfies the Line Segment Axiom.

Proof: We give a simple proof using Zorn’s Lemma. A somewhat more complicated proof can be given which requires only the Axiom of Dependent Choice; cf. [Blu70, Theorem 14.1] and Exercise VI.3.3.8..

Let $\mathcal{X}$ be the set of all subsets of $E$ containing $a$ and $b$ and isometric to a subset of $[0,\lambda]$, where $\lambda = \rho(a,b)$, ordered by inclusion. (Note that $\{a,b\} \in \mathcal{X}$, so $\mathcal{X}$ is nonempty.) For every set $X \in \mathcal{X}$, there is a unique
isometry \( \phi_X \) from \( X \) to \([0, \lambda]\) with \( \phi_X(a) = 0 \) and \( \phi_X(b) = \lambda \). If \( \{X_i\} \) is a chain in \( X \), and \( X = \bigcup X_i \), define \( \phi_X : X \to [0, 1] \) by \( \phi_X(x) = \phi_X(x') \) for \( x \in X_i \); this is well defined by uniqueness of the \( \phi_X \): if \( X_i \subseteq X_j \), then \( \phi_X|_{X_i} = \phi_X |_{X_i} \). Then \( \phi_X \) is an isometry since if \( x, y \in X \), then \( x, y \in X_i \) for some \( i \).

If \( X \in \mathcal{X} \), then since \( \phi_X \) is an isometry it extends to an isometry from the closure \( \overline{X} \) in \( E \) to \([0, \lambda]\), and hence \( \overline{X} \in \mathcal{X} \).

Let \( X \) be a maximal element of \( \mathcal{X} \). Then \( X \) is closed in \( E \), and hence complete; thus \( K = \phi_X(X) \) is complete, hence closed in \([0, \lambda]\). If \( K \neq [0, \lambda] \), there is an interval \([\alpha, \beta] \subseteq [0, \lambda] \) with \( \alpha, \beta \in K \) and \((\alpha, \beta) \cap K = \emptyset \). Let \( c, d \in X \) with \( \phi_X(c) = \alpha \), \( \phi_X(d) = \beta \). There is a \( p \in E \) between \( c \) and \( d \). Since \( c \) and \( d \) are between \( a \) and \( b \), by VI.3.1.8. we have \( p \) between \( a \) and \( b \). Then \( p \notin X \) since \( \rho(a, p) \in (\alpha, \beta) \). If \( x \) is any element of \( X \), then \( x \) is either between \( a \) and \( c \) or between \( d \) and \( b \); it follows from VI.3.1.8. that if \( x, y \in X \), then one of \( x, y, p \) is between the other two. Thus \( \phi_X \) extends to an isometry of \( X \cup \{p\} \) to \([0, \lambda]\), contradicting maximality of \( X \). Thus \( K = [0, \lambda] \) and \( X \) is a line segment with endpoints \( a \) and \( b \). \( \diamond \)

Now we turn to the procedure of extending line segments.

**VI.3.1.15. Lemma.** Let \((E, \rho)\) be a complete metric space satisfying the Extension Axiom, and let \( a, b \in E \). Then

\[
\sup \{\rho(a, c) : c \in E, b \text{ is between } a \text{ and } c \} = +\infty.
\]

**Proof:** Suppose \( \lambda_1 = \sup \{\rho(a, c) : c \in E, b \text{ is between } a \text{ and } c \} \) is finite. Let \( c_1 \in E \) with \( b \) between \( a \) and \( c_1 \) and \( \rho(a, c_1) > \lambda_1 - 1 \). If \( c \in E \) and \( c_1 \) is between \( a \) and \( c \), then \( b \) is between \( a \) and \( c \) by VI.3.1.8. Thus \( \lambda_2 = \sup \{\rho(a, c) : c \in E, c_1 \text{ is between } a \text{ and } c \} \) is finite and \( \lambda_2 \leq \lambda_1 \). Inductively let

\[
\lambda_{n+1} = \sup \{\rho(a, c) : c \in E, c_n \text{ is between } a \text{ and } c \} \leq \lambda_n
\]

and let \( c_{n+1} \) be a point of \( E \) with \( c_n \) between \( a \) and \( c_{n+1} \) (hence by VI.3.1.8. \( b \) is between \( a \) and \( c_{n+1} \)) and \( \rho(a, c_{n+1}) > \lambda_{n+1} - \frac{1}{n+1} \).

Set \( \lambda = \inf \lambda_n = \lim \lambda_n \). If \( n < m \), we have \( c_n \) between \( a \) and \( c_m \), hence

\[
\lambda_n - \frac{1}{n} < \rho(a, c_n) < \rho(a, c_m) \leq \lambda_n
\]

so \( \rho(c_n, c_m) < \frac{1}{n} \) for \( n < m \) and thus \( (c_n) \) is a Cauchy sequence in \( E \). By completeness, \( (c_n) \) converges to some \( c \in E \), and we have

\[
\lambda_n - \frac{1}{n} < \rho(a, c) \leq \lambda_n
\]

for all \( n \); thus \( \rho(a, c) = \lambda \) by the Squeeze Theorem (). By continuity, \( b \) and \( c_n \) are between \( a \) and \( c \) for all \( n \).

Choose \( d \in E \) with \( c \) between \( a \) and \( d \). Then \( \rho(a, d) > \lambda \), so \( \rho(a, d) > \lambda_n \) for some \( n \). But \( c_n \) is between \( a \) and \( d \), so this contradicts the definition of \( \lambda_n \). Thus the assumption that \( \lambda_1 < +\infty \) is false. \( \diamond \)
VI.3.1.16.  **Lemma.** Let \((E, \rho)\) be a complete metric space satisfying the Between and Extension Axioms. Then

(i) \((E, \rho)\) satisfies the Line Axiom.

(ii) Every line segment in \(E\) can be extended to a line in \(E\).

(iii) If \(a, b \in E\), and \(x_1, \ldots, x_n\) are points of \(E\) between \(a\) and \(b\), with \(x_k\) between \(a\) and \(x_{k+1}\) for \(1 \leq k \leq n-1\), then there is a line in \(E\) containing \(a\), \(b\), and all the \(x_k\).

**Proof:** For (i), let \(a, b \in E\). By Lemma VI.3.1.14., there is a line segment \(S_0\) with endpoints \(a\) and \(b\). For (ii), let \(S_0\) be a line segment in \(E\), and let \(a\) and \(b\) be its endpoints. For (iii), there is a line segment with endpoints \(a\) and \(x_1\), for each \(k < n\) a line segment with endpoints \(x_k\) and \(x_{k+1}\), and a line segment with endpoints \(x_n\) and \(b\). By repeated use of VI.3.1.10., the union of these segments is a line segment \(S_0\) with endpoints \(a\) and \(b\) containing all the \(x_k\).

In each case, begin with the segment \(S_0\). By Lemma VI.3.1.15. there is a \(c_1 \in E\) with \(b\) between \(a\) and \(c_1\) and \(\rho(a, c_1) \geq 2\rho(a, b)\). By Lemma VI.3.1.14. there is a line segment \(S_1\) in \(E\) with endpoints \(b\) and \(c_1\). Since \(b\) is between \(a\) and \(c_1\), \(S_0 \cup S_1\) is a line segment with endpoints \(a\) and \(c_1\) by VI.3.1.10.. Now let \(c_2 \in E\) with \(a\) between \(c_1\) and \(c_2\) and \(\rho(c_1, c_2) \geq 2\rho(a, c_1)\), and let \(S_2\) be a line segment with endpoints \(a\) and \(c_2\). Then \(S_0 \cup S_1 \cup S_2\) is a line segment in \(E\) with endpoints \(c_1\) and \(c_2\). Now let \(c_3 \in E\) with \(c_1\) between \(c_2\) and \(c_3\) and \(\rho(c_2, c_3) \geq 2\rho(c_1, c_2)\), and let \(S_3\) be a line segment between \(c_1\) and \(c_3\). Continue inductively placing \(c_{n+1}\) at the \(c_{n-1}\) end of the already constructed segment with endpoints \(c_{n-1}\) and \(c_n\). Then \(\cup_{k=0}^{n+1} S_k\) is a line segment between \(c_n\) and \(c_{n+1}\) extending the previous segment, and the length of this segment is at least \(2^{n+1}\rho(a, b)\). The union of the \(S_n\) is a line in \(E\) through \(a\) and \(b\). 

This completes the proof of Theorem VI.3.1.13.

Here are variations of the Between and Extension Axioms which are sometimes useful:

VI.3.1.17. **Definition.** If \(a, b \in E\), then \((a, b)\) has the Interpolation Property if for each \(t \in [0, 1]\) there is a point \(c \in E\) such that

\[\rho(a, c) = t\rho(a, b) \quad \text{and} \quad \rho(b, c) = (1-t)\rho(a, b)\ .\]

If \(a, b \in E\), and \(t \in \mathbb{R}\), then \((a, b)\) has the Extrapolation Property if for each \(t \geq 1\) there is a point \(c \in E\) such that

\[\rho(a, c) = t\rho(a, b) \quad \text{and} \quad \rho(b, c) = (t-1)\rho(a, b)\ .\]

The pair \((a, b)\) has the Unique Interpolation Property (resp. the Unique Extrapolation Property) if the \(c\) is unique.

The Interpolation Property is symmetric in \(a\) and \(b\), but the Extrapolation Property is not.
VI.3.1.18. If there is a line segment in $E$ with endpoints $a$ and $b$, then $(a, b)$ has the Interpolation Property. But even the Unique Interpolation Property for $(a, b)$ does not imply that there is a line segment in $E$ with endpoints $a$ and $b$ (Exercise VI.3.3.3.). Similarly, if there is a ray from $a$ through $b$, then $(a, b)$ has the Extrapolation Property; but even the Unique Extrapolation Property does not imply existence of a ray.

A metric space with the Interpolation Property satisfies the Between Axiom; the converse is false in general if the space is incomplete (e.g. $\mathbb{Q}$). Similarly, the Extrapolation Property implies the Extension Axiom, but not conversely (e.g. $\mathbb{Z}$).

Here is a result which, among other things, can substitute for completeness in yielding the Line Axiom:

VI.3.1.19. Theorem. (i) If every pair $(a, b)$ of points in $E$ has the Unique Interpolation Property, then for every $a, b \in E$, $a \neq b$, there is a unique line segment in $E$ with endpoints $a$ and $b$.

(ii) If every pair $(a, b)$ of points in $E$ has the Unique Interpolation Property and the Unique Extrapolation Property, then through any two distinct points of $E$ there is a unique line.

See Exercise VI.3.3.7. for the proof.

The Pythagorean Axiom

The second axiom for Euclidean space has several equivalent forms, at least in the presence of the Line Axiom.

VI.3.1.20. Weak Euclidean Four-Point Axiom: If $a, b, c, d \in E$, and $b, c, d$ lie on a line in $E$, then $\{a, b, c, d\}$ is isometric to a set of four points in $\mathbb{R}^2$ (with the usual Euclidean metric).

The stronger Euclidean Four-Point Axiom is the same without the requirement that three of the points lie on a line, and $\mathbb{R}^2$ replaced by $\mathbb{R}^3$. These axioms trivially hold in $\mathbb{R}^n$ (four points in $\mathbb{R}^n$ generate an affine subspace of dimension $\leq 3$).

One can similarly define the Euclidean $n$-Point Axiom for any $n$. Note that every metric space satisfies the Euclidean Three-Point Axiom, since if $\alpha, \beta, \gamma$ are any positive real numbers with each less than or equal to the sum of the other two, there is a (possibly degenerate) triangle in $\mathbb{R}^2$ with sides $\alpha, \beta, \gamma$. It turns out that the Weak Euclidean Four-Point Axiom along with the Line Axiom implies the Euclidean $n$-Point Axiom for all $n$ (VI.3.1.27., VI.3.1.35.).

VI.3.1.21. Definition. Let $(E, \rho)$ be a metric space and $a, b$ distinct points of $E$. A point $m$ in $E$ is a midpoint for $a$ and $b$ if $\rho(a, m) = \rho(m, b) = \frac{1}{2}\rho(a, b)$. A midpoint $m$ is a linear midpoint if there is a line in $E$ containing $a$, $b$, and $m$.

A midpoint for $a$ and $b$ is obviously between $a$ and $b$. Each line through $a$ and $b$ contains a unique midpoint of $a$ and $b$; however, if lines are not unique, (linear) midpoints may not be unique either (Exercise VI.3.3.2.).

If $(E, \rho)$ is complete and satisfies the Between and Extension Axioms, then any midpoint $m$ for $a$ and $b$ automatically lies on a line through $a$ and $b$ (VI.3.1.16.(iii)) and is thus a linear midpoint. The Line Axiom is not enough to guarantee this, however (?).
VI.3.1.22. **Parallelogram Axiom:** If \( a, b, c \in E \), and \( m \) is a linear midpoint of \( b \) and \( c \), then

\[
2 \left[ \rho(a, b)^2 + \rho(a, c)^2 \right] = \rho(b, c)^2 + 4\rho(a, m)^2.
\]

This law expresses the familiar geometric fact that the sum of the squares of the lengths of the diagonals of a parallelogram equals the sum of the squares of the lengths of the sides. (The fourth vertex of the “parallelogram” would be a point \( d \) for which \( m \) is also a midpoint for \( a \) and \( d \). In the presence of the Line Axiom, it will follow that there is a unique such \( d \), and opposite sides of the resulting figure are automatically equal length.) This axiom holds in \( \mathbb{R}^n \) (XV.9.2.6.).

VI.3.1.23. **Definition.** Let \( S \) be a subset of a metric space \((E, \rho)\), and \( a \) a point of \( E \). A foot of \( a \) on \( S \) is a point \( f \) of \( S \) such that \( \rho(a, f) = \rho(a, S) = \min\{\rho(a, c) : c \in S\} \).

If \( a \in S \), then \( a \) itself is a foot of \( a \) on \( S \) (and is the only foot of \( a \) on \( S \)). The concept of foot is only interesting if \( \rho(a, S) > 0 \).

VI.3.1.24. **Proposition.** Let \((E, \rho)\) be a metric space, \( S \) a subset of \( E \) with the Bolzano-Weierstrass property () (e.g. a subset of \( E \) isometric to \( \mathbb{R}^n \) for some \( n \)), and \( a \) a point of \( E \). Then there exists a foot of \( a \) on \( S \).

**Proof:** Let \( c \) be an element of \( S \). Let

\[
K = \{ x \in S : \rho(x, c) \leq 2\rho(a, c) \}.
\]

Then the triangle inequality implies that if \( e \) is a point of \( L \) which is not in \( K \), then \( \rho(a, e) > \rho(a, c) \). So we have \( \rho(a, S) = \rho(a, K) \), and \( K \) is closed and bounded in \( E \), hence compact, so the distance is minimized at some point of \( K \). \( \square \)

VI.3.1.25. In particular, if \( L \) is a line in \( E \), and \( a \) a point of \( E \), then \( a \) has a foot on \( L \). A foot of a point \( a \) on a line \( L \) need not be unique in general. For example, in \((\mathbb{R}^2, \rho_\infty)\), if \( L \) is the \( x \)-axis and \( a = (0, 1) \), then any point \( (t, 0) \) with \( |t| \leq 1 \) is a foot of \( a \) on \( L \).

VI.3.1.26. **Pythagorean Axiom:** If \( L \) is a line in \( E \), and \( a \) a point of \( E \), and \( f \) is a foot of \( a \) on \( L \), then for any \( c \in L \) we have

\[
\rho(a, c)^2 = \rho(a, f)^2 + \rho(f, c)^2.
\]

The Pythagorean Axiom holds in \( \mathbb{R}^n \). It obviously implies that the foot of a point on a line is unique.

VI.3.1.27. **Theorem.** Let \((E, \rho)\) be a metric space satisfying the Line Axiom. The following are equivalent:

(i) \((E, \rho)\) satisfies the Weak Euclidean Four Point Axiom.

(ii) \((E, \rho)\) satisfies the Parallelogram Axiom.

(iii) \((E, \rho)\) satisfies the Pythagorean Axiom.
(iv) If \( L \) is a line in \( E \) and \( a \) a point of \( E \) not on \( L \), then \( L \cup \{a\} \) can be isometrically embedded in \( \mathbb{R}^2 \) (with the usual metric).

These conditions imply that there is a unique line through any two distinct points of \( E \).

**Proof:** (iv) \( \Rightarrow \) (i) \( \Rightarrow \) (ii) and (iv) \( \Rightarrow \) (iii) are trivial. We will prove (iii) \( \Rightarrow \) (ii) \( \Rightarrow \) (iv). (In fact, the Line Axiom is only needed for (iv) \( \Rightarrow \) (i) and for the last assertion.) \( \diamondsuit \)

**VI.3.1.28. Lemma.** Let \((E, \rho)\) be a metric space satisfying the Pythagorean Axiom. Then \( E \) satisfies the Parallelogram Axiom.

**Proof:** Let \( a, b, c \in E \) and \( L \) a line through \( b \) and \( c \). Let \( m \) be the midpoint of \( b \) and \( c \) on \( L \), and let \( f \) be the foot of \( a \) on \( L \). Set \( \alpha = \rho(a,c), \beta = \rho(a,b), \gamma = \rho(b,c) \). There are two cases to consider: (1) \( f = b, f = c, \) or \( f \) is between \( b \) and \( c \), and (2) \( c \) is between \( b \) and \( f \) (the case where \( b \) is between \( f \) and \( c \) is symmetric and handled by interchanging \( b \) and \( c \)). See Figure (), although the reader is cautioned that since the points are in \( E \) and not in \( \mathbb{R}^2 \), the accuracy of the picture cannot (yet) be justified and it should be used only as a visual aid in following the proof (this is usually a good attitude to take with any picture or diagram).

Consider case (1). By interchanging \( b \) and \( c \) if necessary, we may assume that \( f = c, f = m, \) or \( f \) is between \( m \) and \( c \). Then there is a \( t, 0 \leq t \leq \frac{1}{2}, \) such that \( \rho(f,c) = t \gamma, \rho(m,f) = (\frac{1}{2} - t) \gamma, \rho(b,f) = (1-t) \gamma. \) Set \( \eta = \rho(a,f) \) and \( \zeta = \rho(a,m) \). By the Pythagorean Axiom we have

\[
\alpha^2 = \eta^2 + t^2 \gamma^2 \\
\beta^2 = \eta^2 + (1-t)^2 \gamma^2 = \eta^2 + \gamma^2 - 2t \gamma^2 + t^2 \gamma^2 \\
\zeta^2 = \eta^2 + \left(\frac{1}{2} - t\right)^2 \gamma^2 = \eta^2 + \frac{1}{4} \gamma^2 - t \gamma^2 + t^2 \gamma^2
\]

so we have

\[
2\alpha^2 + 2\beta^2 = 2\eta^2 + 2t^2 \gamma^2 + 2\eta^2 + 2\gamma^2 - 4t \gamma^2 + 2t^2 \gamma^2 = 4\eta^2 + 2\gamma^2 - 4t \gamma^2 + 4t^2 \gamma^2 \\
4\zeta^2 + \gamma^2 = 4\eta^2 + \gamma^2 - 4t \gamma^2 + 4t^2 \gamma^2 + \gamma^2 = 2\alpha^2 + 2\beta^2
\]

which is the Parallelogram formula.

Now consider case (2). There is a \( t \geq 0 \) such that \( \rho(f,c) = t \gamma, \rho(f,m) = (\frac{1}{2} + t) \gamma, \rho(f,b) = (1+t) \gamma. \) Again by the Pythagorean Axiom

\[
\alpha^2 = \eta^2 + t^2 \gamma^2 \\
\beta^2 = \eta^2 + (1+t)^2 \gamma^2 = \eta^2 + \gamma^2 + 2t \gamma^2 + t^2 \gamma^2 \\
\zeta^2 = \eta^2 + \left(\frac{1}{2} + t\right)^2 \gamma^2 = \eta^2 + \frac{1}{4} \gamma^2 + t \gamma^2 + t^2 \gamma^2
\]

so we have

\[
2\alpha^2 + 2\beta^2 = 2\eta^2 + 2t^2 \gamma^2 + 2\eta^2 + 2\gamma^2 + 4t \gamma^2 + 2t^2 \gamma^2 = 4\eta^2 + 2\gamma^2 + 4t \gamma^2 + 4t^2 \gamma^2 \\
4\zeta^2 + \gamma^2 = 4\eta^2 + \gamma^2 + 4t \gamma^2 + 4t^2 \gamma^2 + \gamma^2 = 2\alpha^2 + 2\beta^2
\]

which is the Parallelogram formula. \( \diamondsuit \)
VI.3.1.29. Lemma. Let \((E, \rho)\) be a metric space satisfying the Parallelogram Axiom. Let \(L\) be a line in \(E, b, c\) points on \(L\), and \(a\) a point not on \(L\). Set \(\alpha = \rho(a, c), \beta = \rho(a, b), \gamma = \rho(b, c)\). Then for any \(t \in \mathbb{R}\), if \(d_t\) is the unique point on \(L\) with \(\rho(b, d_t) = |t|\gamma\) and \(\rho(d, c) = |1 - t|\gamma\), we have
\[
\rho(a, d_t)^2 = t\alpha^2 + (1 - t)\beta^2 - t(1 - t)\gamma^2.
\]

Proof: By continuity, it suffices to prove the formula if \(t\) is a dyadic rational number. The formula is trivially true if \(t = 0\) or \(t = 1\) (and the case \(t = \frac{1}{2}\) is the Pythagorean Axiom, although we do not explicitly need this case).

We first show that if the formula holds for \(t\), it also holds for \(-t\). Set \(\rho(a, d_t) = \eta\). By assumption,
\[
\eta^2 = t\alpha^2 + (1 - t)\beta^2 - t(1 - t)\gamma^2.
\]
Since \(\rho(d_t, d_{-t}) = 2|t|\gamma\) and \(b\) is the midpoint of \(d_t\) and \(d_{-t}\) on \(L\), by the Parallelogram Axiom we have
\[
2\rho(a, d_{-t})^2 + 2\eta^2 = 4\beta^2 + 4t^2\gamma^2
\]
so the formula holds for \(-t\).

Similarly, we show that if the formula holds for \(t\), it holds for \(2t\). Again let \(\eta = \rho(a, d_t)\). Since \(\rho(b, d_{2t}) = 2|t|\gamma\) and \(d_t\) is the midpoint of \(b\) and \(d_{2t}\) on \(L\), by the Parallelogram Axiom we have
\[
2\rho(a, d_{2t})^2 + 2\eta^2 = 4\beta^2 + 4t^2\gamma^2
\]
so the formula holds for \(2t\).

Finally, suppose \(s, t \in \mathbb{R}\) and the statement is true for \(s\) and \(t\). We will show that the statement is also true for \(r = \frac{s + t}{2}\). Let \(d_s, d_t, d_r\) be the points of \(L\) corresponding to \(s, t, r\) respectively, and set \(\eta = \rho(a, d_t), \zeta = \rho(a, d_s)\). Then by assumption
\[
\eta^2 = t\alpha^2 + (1 - t)\beta^2 - t(1 - t)\gamma^2
\]
and, since \(\rho(d_t, d_s) = |s - t|\gamma\) and \(d_r\) is the midpoint of \(d_t\) and \(d_s\) on \(L\), by the Parallelogram Axiom we have
\[
\rho(a, d_r)^2 = \frac{1}{2}[(\zeta^2 + \eta^2) - \frac{1}{4}(s - t)^2\gamma^2]
\]
so the formula holds for \(r\) too. Therefore the formula holds for all dyadic rational \(t\).
VI.3.1.30. Corollary. Let \((E, \rho)\) be a metric space satisfying the Parallelogram Axiom. Let \(L\) be a line in \(E\), and \(a\) a point of \(E\). Then there is an isometry from \(L \cup \{a\}\) to \(\mathbb{R}^2\). If \(b, c \in L\) and \(\{a', b', c'\}\) is a subset of \(\mathbb{R}^2\) isometric to \(\{a, b, c\}\), then there is an isometry \(\phi\) from \(L \cup \{a\}\) to \(\mathbb{R}^2\) with \(\phi(a) = a'\), \(\phi(b) = b'\), \(\phi(c) = c'\).

Proof: Let \(b\) and \(c\) be two distinct points on \(L\). Let \(\{a', b', c'\}\) be three points in \(\mathbb{R}^2\) isometric to \(\{a, b, c\}\), and \(L'\) the line in \(\mathbb{R}^2\) through \(b'\) and \(c'\). If \(d\) is any point on \(L\) and \(d'\) the point on \(L'\) with \(\rho_2(b', d') = \rho(b, d)\) and \(\rho_2(c', d') = \rho(c, d)\), then applying Lemma VI.3.1.29. in both \(E\) and \(\mathbb{R}^2\) we obtain \(\rho_2(a', d') = \rho(a, d)\). Thus \(L\) and \(\{a\}\) isometric to \(L' \cup \{a'\}\) under an isometry \(\phi\) with \(\phi(a) = a'\), \(\phi(b) = b'\), \(\phi(c) = c'\). \(\blacksquare\)

VI.3.1.31. Lemma. Let \((E, \rho)\) be a metric space satisfying the Parallelogram Axiom. Let \(a, b, c\) be points of \(E\) with \(a \neq b\) and \(a \neq c\), and let \(L_1\) be a line in \(E\) through \(a\) and \(b\), and \(L_2\) a line in \(E\) through \(a\) and \(c\). If \(\phi\) is an isometry of \(\{a, b, c\}\) with \(\{a', b', c'\}\) \(\subseteq \mathbb{R}^2\), then \(\phi\) extends uniquely to an isometry from \(L_1 \cup L_2\) to \(\mathbb{R}^2\).

Proof: Let \(L_1'\) be the (unique) line in \(\mathbb{R}^2\) through \(a'\) and \(b'\), and \(L_2'\) the line in \(\mathbb{R}^2\) through \(a'\) and \(c'\). There is a unique isometry \(\phi_1\) from \(L_1\) to \(L_1'\) with \(\phi_1(a) = a'\) and \(\phi_1(b) = b'\), since if \(x \in L_1\), \(x\) is uniquely determined by \(\rho(x, a)\) and \(\rho(x, b)\), and similarly for \(L_1'\). In the same way, there is a unique isometry \(\phi_2\) from \(L_2\) to \(L_2'\) with \(\phi_2(a) = a'\), \(\phi_2(c) = c'\). It suffices to show that if \(x \in L_1\) and \(y \in L_2\), and \(x' = \phi_1(x), y' = \phi_2(y)\), then \(\rho_2(x', y') = \rho(x, y)\). We may assume \(x \neq a\) and \(y \neq a\).

By VI.3.1.30., there is an isometry \(\psi\) from \(L_1 \cup \{a\}\) to \(\mathbb{R}^2\) with \(\psi(a) = a', \psi(b) = b', \psi(c) = c'\), and we must have \(\psi|_{L_1} = \phi_1\), so \(\psi(x) = x'\). Thus \(\rho_2(x', c') = \rho(x, c)\), so by VI.3.1.30. there is an isometry \(\theta\) from \(L_2 \cup \{x\}\) to \(\mathbb{R}^2\) with \(\theta(a) = a', \theta(c) = c', \theta(x) = x'\). We must have \(\theta|_{L_2} = \phi_2\), so \(\theta(y) = y'\) and we have \(\rho_2(x', y') = \rho(x, y)\). \(\blacksquare\)

VI.3.1.32. Corollary. Let \((E, \rho)\) be a metric space satisfying the Parallelogram Axiom, and let \(a\) and \(b\) be distinct points of \(E\). Then there is at most one line in \(E\) through \(a\) and \(b\).

Proof: If \(L_1\) and \(L_2\) are lines in \(E\) through \(a\) and \(b\), set \(c = b\) and apply VI.3.1.31.. \(\blacksquare\)

This completes the proof of Theorem VI.3.1.27..

Affine Subspaces

It would seem to make sense to define an \(n\)-dimensional affine subspace of a metric space to be a subset isometric to \(\mathbb{R}^n\). But it will turn out to be more convenient to make the following unorthodox inductive definition, which is equivalent (VI.3.1.35.) in the presence of the Line and Parallelogram Axioms:

VI.3.1.33. Definition. Let \((E, \rho)\) be a metric space satisfying the Line Axiom and the Parallelogram (or Pythagorean) Axiom.

(i) A zero-dimensional affine subspace of \(E\) is a single point.
(ii) If \( n \geq 1 \), an \( n \)-dimensional affine generator in \( E \) is a subset \( G(L, a) \) consisting of all points \( x \) lying on a line through \( a \) and a point of \( L \), where \( L \) is an \( (n-1) \)-dimensional affine subspace of \( E \) and \( a \) is a point of \( E \) not in \( L \).

(iii) If \( n \geq 1 \), an \( n \)-dimensional affine subspace of \( E \) is the closure of an \( n \)-dimensional affine generator in \( E \).

(iv) A set \( \{x_0, \ldots, x_n\} \) of \( n+1 \) points of \( E \) is independent if it is not contained in any \( (n-1) \)-dimensional affine subspace of \( E \).

It is easy to verify that the one-dimensional affine subspaces of \( E \) are precisely the lines in \( E \).

**VI.3.1.34.** Proposition. Let \((E, \rho)\) be a metric space satisfying the Line Axiom and the Parallelogram (or Pythagorean) Axiom, and \( L \) a subset of \( E \) isometric to \( \mathbb{R}^n \). Then \( L \) is an \( n \)-dimensional affine subspace of \( E \).

Proof: This is easily seen by induction, since if \( L \) is an \((n-1)\)-dimensional affine subspace of \( \mathbb{R}^n \) (in the usual sense, hence by the inductive hypothesis in the sense of VI.3.1.33.), and \( a \) is a point of \( \mathbb{R}^n \) not on \( L \), then \( G(L, a) \) consists of all points of \( \mathbb{R}^n \) not in the affine subspace through \( a \) parallel to \( L \), along with \( a \), and this set is dense in \( \mathbb{R}^n \).

The next theorem, essentially the converse of VI.3.1.34., is perhaps the most important result of this section.

**VI.3.1.35.** Theorem. Let \((E, \rho)\) be a metric space satisfying the Line Axiom and the Parallelogram (or Pythagorean) Axiom, and \( n \in \mathbb{N} \). Then

(i) Every \( n \)-dimensional affine subspace of \( E \) is isometric to \( \mathbb{R}^n \).

(ii) If \( \{x_0, \ldots, x_n\} \) is an independent set of \( n+1 \) points of \( E \), then there is a unique \( n \)-dimensional subspace of \( E \) containing \( \{x_0, \ldots, x_n\} \).

Proof: The proof is by induction on \( n \). The case \( n = 1 \) is obvious from VI.3.1.27.. For the inductive step, we suppose that the statement is true for \( n \) for any metric space satisfying the hypotheses. Then let \((E, \rho)\) be a metric space satisfying the hypotheses. Proofs of (i) and (ii) for \( n + 1 \) will be done in parallel. To set up the proof, we make notational definitions for the two cases.

To prove (i), let \( L_{n+1} \) be an \((n+1)\)-dimensional affine subspace of \( E \), and let \( L_n \) be an \( n \)-dimensional affine subspace of \( E \) and \( a \) a point of \( E \) such that \( L_{n+1} \) is the closure of \( G(L_n, a) \). To prove (ii), let \( \{x_0, \ldots, x_{n+1}\} \) be an independent set of \( n+2 \) points of \( E \). If \( \{x_0, \ldots, x_n\} \) is contained in an affine \((n-1)\)-dimensional subspace \( L_{n-1} \), then \( \{x_0, \ldots, x_{n+1}\} \) is contained in the \( n \)-dimensional affine subspace which is the closure of \( G(L_{n-1}, x_{n+1}) \), a contradiction. Thus \( \{x_0, \ldots, x_n\} \) is independent and contained in a unique \( n \)-dimensional affine subspace \( L_n \) of \( E \). Let \( a = x_{n+1} \) and let \( L_{n+1} \) be the closure of \( G(L_n, a) \).

In both cases we have an \((n+1)\)-dimensional affine subspace \( L_{n+1} \) which is the closure of an \((n+1)\)-dimensional generator \( G(L_n, a) \), where \( L_n \) is an \( n \)-dimensional affine subspace of \( E \) and \( a \) a point of \( E \) not in
$L_n$. By the inductive hypothesis, $L_n$ is isometric to $\mathbb{R}^n$, hence is complete and has the Bolzano-Weierstrass property, and satisfies the Line Axiom, i.e. if $b, c \in L_n$, then the unique line in $E$ through $b$ and $c$ is contained in $L_n$.

By VI.3.1.24., there is a foot $f$ of $a$ on $L_n$. If $g$ is another foot of $a$ on $L_n$, let $L$ be the line in $L_n$ through $f$ and $g$; then both $f$ and $g$ are feet of $a$ on $L$, impossible by the Pythagorean Axiom if $f \neq g$. Thus $f$ is the unique foot of $a$ on $L_n$, and $f$ is the foot of $a$ on any line in $L_n$ through $f$. So if $b$ is any point of $L_n$, we have

$$\rho(a, b)^2 = \rho(a, f)^2 + \rho(f, b)^2.$$  

In $\mathbb{R}^{n+1}$, let $L'_n$ be the $n$-dimensional subspace of points with last coordinate $0$, and let $a' = (0, \ldots, 0, \lambda)$, where $\lambda = \rho(a, f)$. Let $\phi$ be an isometry of $L_n$ onto $L'_n$ sending $f$ to the origin. Then if $b \in L_{n+1}$, we have

$$\rho_2(a', \phi(b))^2 = \lambda^2 + \rho(0, \phi(b))^2$$

so by the previous calculation $\rho_2(a', \phi(b)) = \rho(a, b)$, and $\phi$ extends to an isometry from $L_n \cup \{a\}$ to $L'_n \cup \{a'\}$, also denoted $\phi$.

We next show that $\phi$ can be extended to an isometry from $G(L_n, a)$ to $G(L'_n, a')$, which consists of all the points of $\mathbb{R}^{n+1}$ whose last coordinate is not $\lambda$, along with $a'$ (i.e. $\mathbb{R}^{n+1}$ with the horizontal hyperplane through $a'$, except $a'$ itself, removed).

Let $x \in G(L_n, a), x \neq a$. Then there is a unique $b \in L_n$ such that $x$ is on the line through $a$ and $b$. Let $\phi(x)$ be the corresponding point on the line through $a'$ and $\phi(b)$ in $\mathbb{R}^{n+1}$. If $y$ is another point in $G(L_n, a), y \neq a$, let $y$ be on the line through $a$ and $c \in L_n$. If the plane through $a', \phi(b), \phi(c)$ in $\mathbb{R}^{n+1}$ is identified with $\mathbb{R}^2$, then by VI.3.1.31. the isometry $\phi$ from $\{a, b, c\}$ to $\{a', \phi(b), \phi(c)\}$ extends uniquely to the lines through $a$ and $b$ and through $a$ and $c$; hence in particular $\rho_2(\phi(x), \phi(y)) = \rho(x, y)$ and the $\phi$ we have defined is an isometry from $G(L_n, a)$ into $G(L'_n, a')$. To see that it is surjective, let $x' \in G(L'_n, a') x' \neq a'$, and let $b'$ be the point of $L'_n$ on the line through $a'$ and $x'$ (a' and $x'$ have different last coordinates, so there is a unique point on this line with last coordinate $0$). Then $b' = \phi(b)$ for some $b \in L_n$, and there is a (unique) point $x$ on the line in $E$ through $a$ and $b$ with $x' = \phi(x)$, and $\phi$ maps $G(L_n, a)$ onto $G(L'_n, a')$.

Thus $\phi$ extends to an isometry from $L_{n+1}$ into $\mathbb{R}^{n+1}$, also denoted $\phi$. We show that this $\phi$ is surjective. (This would be immediate if $(E, \rho)$ is complete, but $(E, \rho)$ need not be complete.) We must show that if

$$m' = (\alpha_1, \ldots, \alpha_n, \lambda) \in \mathbb{R}^n \setminus G(L'_n, a')$$

then there is an $m \in E$ with $\phi(m) = m'$. Let $b' = (\alpha_1, \ldots, \alpha_n, 0)$ and $c' = (\alpha_1, \ldots, \alpha_n, 2\lambda)$ in $\mathbb{R}^{n+1}$, and let $b = \phi^{-1}(b')$, $c = \phi^{-1}(c')$, and let $m$ be the midpoint of the line segment in $E$ with endpoints $a$ and $b$. It suffices to show that $m \in L_{n+1}$, for then necessarily $\phi(m) = m'$. But if $t \in (0, 1)$, $t \neq \frac{1}{2}$, then the point

$$d'_t = (\alpha_1, \ldots, \alpha_n, 2t\lambda) \in G(L'_n, a')$$

is between $b'$ and $c'$, hence $d_t = \phi^{-1}(d'_t) \in G(L_n, a)$ is between $b$ and $c$; hence all the points of the line segment between $b$ and $c$ other than $m$ are in $G(L_n, a)$, so $m$ is in the closure of $G(L_n, a)$.

We have now proved (i) for $n + 1$, and proved all of (ii) except uniqueness. For uniqueness, let $\hat{L}_{n+1}$ be any $(n + 1)$-dimensional affine subspace of $E$ containing $\{x_0, \ldots, x_{n+1}\}$. Then by (i) $\hat{L}_{n+1}$ is isometric to $\mathbb{R}^{n+1}$ and hence satisfies the Line Axiom. Any $k$-dimensional affine subspace of $\hat{L}_{n+1}$ ($k \leq n + 1$) is a $k$-dimensional affine subspace of $E$ by VI.3.1.34.. Thus $\{x_0, \ldots, x_n\}$ is independent as a subset of $\hat{L}_{n+1}$, so by the inductive hypothesis applied to $\hat{L}_{n+1}$, $\{x_0, \ldots, x_n\}$ is contained in a unique $n$-dimensional affine subspace of $\hat{L}_{n+1}$. But $L_n$ is the unique $n$-dimensional affine subspace of $E$ containing $\{x_0, \ldots, x_n\}$, so $L_n \subseteq \hat{L}_{n+1}$. Then $G(L_n, x_{n+1}) \subseteq \hat{L}_{n+1}$ since $\hat{L}_{n+1}$ contains the line in $E$ through any two of its points.

756
Thus the closure $L_{n+1}$ of $G(L_n, x_{n+1})$ is contained in $\hat{L}_{n+1}$ since $\hat{L}_{n+1}$ is closed in $E$. But this implies that $L_{n+1} = \hat{L}_{n+1}$ since $\mathbb{R}^{n+1}$ has no proper $(n + 1)$-dimensional affine subspaces.

This completes the proof of Theorem VI.3.1.35.

VI.3.1.36. **Corollary.** Let $(E, \rho)$ be a metric space satisfying the Line and Parallelogram (or Pythagorean) Axioms, and $S = \{x_0, \ldots, x_m\}$ a subset of $E$ with $n + 1$ points. Then, for some $m \leq n$, there is a (unique) $m$-dimensional affine subspace of $E$ containing $S$ which is the smallest affine subspace of $E$ containing $S$, called the affine subspace of $E$ spanned by $S$, denoted $\text{span}(S)$; $m = n$ if and only if $S$ is independent. Any subset of an independent set is independent.

Any real inner product space with the induced metric satisfies all the axioms considered so far. Conversely:

VI.3.1.37. **Theorem.** Let $(E, \rho)$ be a metric space satisfying the Line Axiom and the Parallelogram (or Pythagorean) Axiom, and let $a \in E$. Then

(i) There is a unique real vector space structure on $E$ with $a$ the zero vector, and a unique inner product on this vector space, such that $\rho$ is the metric induced by the inner product.

(ii) Every subset of $E$ satisfying the Line Axiom (in particular, every $n$-dimensional affine subspace in the sense of VI.3.1.33.) is an affine subspace in the linear algebra sense.(

(iii) If $S = \{x_0, \ldots, x_n\}$ is a finite subset of $E$, then the span of $S$ in the sense of VI.3.1.36. is the linear span of $S$ in the vector space structure on $E$ with zero vector $x_0$. The set $S$ is independent in the sense of VI.3.1.33. if and only if $\{x_1, \ldots, x_n\}$ is linearly independent in this vector space structure on $E$.

Combining this with VI.3.1.13., we obtain:

VI.3.1.38. **Corollary.** Let $(E, \rho)$ be a complete metric space satisfying the Between, Extension, and Parallelogram (or Pythagorean) Axioms. Then $(E, \rho)$ is isometric to a real Hilbert space.(

**Proof:** The proof of VI.3.1.37. follows easily from VI.3.1.35. Fix $a \in E$. If $b, c \in E$, there is an isometry from the span of $\{a, b, c\}$ to $\mathbb{R}^n$ for some $n \leq 2$ sending $a$ to 0, and we define vector addition, scalar multiplication, norm, and inner product for $b, c$ via this isometry. Since an isometry of $\mathbb{R}^n$ fixing the origin is linear and orthogonal, these operations are well defined. All except the inner product have simple intrinsic characterizations. (The inner product can be recovered from the norm by polarization.) We have $\|b\| = \rho(a, b)$. If $a \in \mathbb{R}$ and $b \neq a$, then $ab$ is the unique element $c$ on the line in $E$ through $a$ and $b$ with $\rho(a, c) = |a|\rho(a, b)$ and $a$ between $c$ and $b$ if and only if $a < 0$. If $m$ is the midpoint of $b$ and $c$ in $E$, then $b + c = 2m$. Thus this structure is the only possible vector space structure and norm compatible with $\rho$.

To verify that $E$ is a normed vector space with these operations, the only axiom which is not obviously satisfied is associativity of vector addition. But if $b, c, d \in E$, then the span of $\{a, b, c, d\}$ is isometric to $\mathbb{R}^n$ for some $n \leq 3$, and the vector addition in $E$ restricted to this subspace agrees with vector addition in this $\mathbb{R}^n$ if an isometry is chosen sending $a$ to the origin, and associativity of vector addition follows.

Parts (ii) and (iii) are immediate from (i).
The Dimension Axiom

Thus, to characterize $\mathbb{R}^n$ as a metric space, we need only one additional axiom insuring that the space is $n$-dimensional. The simplest way to do this is

**VI.3.1.39. Dimension $n$ Axiom:** There is an independent set of $n + 1$ elements of $E$ which spans $E$.

The Dimension $n$ Axiom can be rephrased in a purely metric way not requiring reference to the Unique Line Axiom.

**VI.3.1.40. Definition.** Let $(E, \rho)$ be a metric space, and $(a_0, \ldots, a_m)$ an $(m + 1)$-tuple of points in $E$. The Cayley-Menger determinant $D(a_0, \ldots, a_m)$ of $(a_0, \ldots, a_m)$ is the determinant of the $(m + 2) \times (m + 2)$ matrix

$$
\begin{vmatrix}
0 & 1 & 1 & \cdots & 1 \\
1 & 0 & \rho(a_0, a_1)^2 & \cdots & \rho(a_0, a_n)^2 \\
1 & \rho(a_1, a_0)^2 & 0 & \cdots & \rho(a_1, a_m)^2 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
1 & \rho(a_m, a_0)^2 & \rho(a_m, a_1)^2 & \cdots & 0
\end{vmatrix}
$$

**VI.3.1.41.** If $E = \mathbb{R}^n$, there is a constant $c_m = \frac{(-1)^{n+1}}{2^n(n!)^2}$ depending only on $m$ such that $c_m D(a_0, \ldots, a_m)$ is the square of the $m$-dimensional volume of the parallelepiped with edges $a_1 - a_0, \ldots, a_m - a_0$. In particular, it is nonzero if and only if the set $\{a_1 - a_0, \ldots, a_m - a_0\}$ is linearly independent. (The constant is not relevant for our uses of the Cayley-Menger determinant in this section, since we will be concerned only whether it is 0.)

**VI.3.1.42. $n$-Determinant Axiom:** The space $E$ has an $(n+1)$-tuple $(a_0, \ldots, a_n)$ with $D(a_0, \ldots, a_n) \neq 0$, but $D(b_0, \ldots, b_{n+1}) = 0$ for any $(n + 2)$-tuple $(b_0, \ldots, b_{n+1})$ in $E$.

The Characterization Theorems

The main result of this section is:

**VI.3.1.43. Theorem.** Let $(E, \rho)$ be a metric space satisfying the Line Axiom and the Parallelogram (or Pythagorean) Axiom. Then the following are equivalent:

(i) $(E, \rho)$ satisfies the Dimension $n$ axiom.

(ii) $(E, \rho)$ satisfies the $n$-Determinant Axiom.

(iii) $(E, \rho)$ is isometric to $(\mathbb{R}^n, \rho_2)$.

**Proof:** (i) $\Rightarrow$ (iii) is VI.3.1.35., (iii) $\Rightarrow$ (ii) and the equivalence of (i) and (ii) for $\mathbb{R}^n$ is VI.3.1.41.. $\diamond$

Combining this result with VI.3.1.13., we obtain perhaps the nicest metric characterization of $n$-dimensional Euclidean space:

758
VI.3.1.44. **Corollary.** Let \((E, \rho)\) be a complete metric space satisfying the Between, Extension, Parallelogram (or Pythagorean), and \(n\)-Determinant Axioms. Then \((E, \rho)\) is isometric to \((\mathbb{R}^n, \rho_2)\).

In fact, the Parallelogram Axiom can be replaced with a more complicated condition involving Cayley-Menger determinants of smaller order. This was the original metric characterization of \(\mathbb{R}^n\) obtained by K. Menger in 1928. See [Blu70, Theorem 48.2].

VI.3.2. \(\mathbb{R}^n\) is \(n\)-Dimensional

Everyone “knows” that \(\mathbb{R}^n\) is \(n\)-dimensional. But what does this mean? Specifically, what does “dimension” mean? And how can \(\mathbb{R}^n\) be distinguished from \(\mathbb{R}^m\) for \(m \neq n\) by its properties?

\(\mathbb{R}^n\) is a set with several types of structure: algebraic, geometric, topological, and analytic. Efforts have been made to define and/or describe the “dimension” of \(\mathbb{R}^n\) in terms of each of these types of structure, and various theories of dimension have been studied in different contexts; the only thing these various theories have in common is that they all assign the same number \(n\) to \(\mathbb{R}^n\), justifying the use of the name “dimension” for all of them.

VI.3.2.1. Specifically, we have:

(i) The vector space dimension \((\cdot)\) of \(\mathbb{R}^n\) as a real vector space is \(n\).

(ii) The topological dimension \((\cdot)\) of \(\mathbb{R}^n\) as a topological space is \(n\). (In fact, there are several notions of topological dimension, all of which give dimension \(n\) to \(\mathbb{R}^n\).)

(iii) The Hausdorff dimension \((\cdot)\) of \(\mathbb{R}^n\) is \(n\).

VI.3.2.2. There is one respect in which all Euclidean spaces are the same, however: cardinality. Contrary to Cantor’s expectations (he first thought the cardinality of \(\mathbb{R}^n\) should be \(\aleph_n\)), the cardinality of \(\mathbb{R}^n\) is \(2^{\aleph_0}\) for all \(n\). Thus some additional structure beyond set theory is needed to distinguish \(\mathbb{R}^n\) from \(\mathbb{R}^m\) for \(n \neq m\).

VI.3.3. Exercises

VI.3.3.1. Let \(X\) be a set, and \(a, b \in X\). Define a metric \(\rho\) on \(X\) by \(\rho(a, b) = 2\) and \(\rho(x, y) = 1\) for all other distinct pairs \(x, y\). Then every element of \(X \setminus \{a, b\}\) is between \(a\) and \(b\).

VI.3.3.2. In \((\mathbb{R}^2, \rho_\infty)\), the set of points between \(a = (0, 0)\) and \(b = (2, 0)\) is

\[\{(t, s) : 0 < t < 2, |s| \leq \min(t, 2 - t)\}\]

which is the “diamond” with corners \(a, b, (1, 1)\), and \((1, -1)\).

VI.3.3.3. Let \((E, \rho)\) be the subset

\[\{(t, t) : 0 \leq t \leq 1\} \cup \{(t, t - 2) : 1 < t \leq 2\}\]

of \((\mathbb{R}^2, \rho_\infty)\). If \(a = (0, 0)\) and \(b = (2, 0)\), then for every \(t, 0 \leq t \leq 2\), there is a unique \(c_t\) between \(a\) and \(b\) with \(\rho(a, c_t) = t\) and \(\rho(c_t, b) = 2 - t\) (i.e. \(E\) has the Unique Interpolation Property), but there is no line segment in \(E\) with endpoints \(a\) and \(b\).
VI.3.3.4. Let $E$ be the unit sphere in $\mathbb{R}^3$.

(a) If $E$ is given the induced metric from $\mathbb{R}^3$ (sometimes called the chord metric), and $a, b \in E$, then there are no points of $E$ between $a$ and $b$.

(b) If the distance between points $a$ and $b$ is defined to be the length of the shortest great circle arc through $a$ and $b$, a metric is obtained called the arc metric. If $a$ and $b$ are not diametrically opposed, then there is a unique line segment with endpoints $a$ and $b$. If $a$ and $b$ are diametrically opposed, every other point of $E$ is between $a$ and $b$. $E$ is complete and satisfies the Between Axiom, but $E$ contains no lines. It almost satisfies the Extension Axiom, except for pairs of points diametrically opposed.

The same results hold in $\mathbb{R}^n$ for any $n > 1$ (in particular, for the unit circle in $\mathbb{R}^2$).

VI.3.3.5. Let $(E, \rho)$ be a metric space satisfying the Line Axiom. A subset $S$ of $E$ is collinear if there is a line in $E$ containing $S$.

(a) Prove the following theorem (cf. [Bli70, Theorem 21.3]):

**Theorem.** $(E, \rho)$ satisfies the Unique Line Axiom if and only if $(E, \rho)$ has the Two-Triple Property: whenever $a, b, c, d \in E$, $\{a, b, c\}$ is collinear, and $\{b, c, d\}$ is collinear, then $\{a, b, d\}$ is collinear and $\{a, c, d\}$ is collinear.

It is then a consequence of the theorem that the four lines necessarily coincide, and therefore $\{a, b, c, d\}$ is collinear.

(b) Show directly that if $E$ satisfies the Weak Euclidean Four-Point Axiom, then $E$ has the Two-Triple Property.

VI.3.3.6. Show that $(\mathbb{R}^2, \rho_p)$ has the Unique Line Property for $1 < p < \infty$, but not the Parallelogram Property (or other properties of VI.3.1.27.) if $p \neq 2$. More generally, any strictly convex normed real vector space $(\cdot)$ has the Unique Line Property.

VI.3.3.7. Let $(E, \rho)$ be a metric space satisfying the Unique Interpolation and Unique Extrapolation Axioms. Prove that $E$ has the Unique Line Property, as follows. Let $a, b \in E$ with $a \neq b$, and set $\lambda = \rho(a, b)$.

(a) Show the following:

(i) For each $s \geq \lambda$, there is a unique $c \in E$ with $\rho(a, c) = s$ and $\rho(b, c) = s - \lambda$.

(ii) For each $s$, $0 \leq s \leq \lambda$, there is a unique $c \in E$ with $\rho(a, c) = s$ and $\rho(c, b) = \lambda - s$.

(iii) For each $s < 0$, there is a unique $c \in E$ with $\rho(a, c) = -s$ and $\rho(b, c) = \lambda - s$.

If $s \in \mathbb{R}$, write $\phi(s)$ for the corresponding point $c$.

(b) Show that $\rho(\phi(r), \phi(s)) = |s - r|$ for all $r, s \in \mathbb{R}$; we may assume $r \leq s$. Consider six separate cases:

(i) $d \leq r \leq s$.

(ii) $0 \leq r \leq d \leq s$.

(iii) $0 \leq r \leq s \leq d$.

(iv) $r \leq 0 < d \leq s$. 

760
(v) $r \leq 0 \leq s \leq d$.

(vi) $r \leq s \leq 0$.

For case (i), consider the unique $b \in E$ with $\rho(a_1, b) = r - \lambda$ and $\rho(b, \phi(s)) = s - r$ by (a). Use the triangle inequality twice to show that $\rho(a_0, b) = r$, so $b = \phi(r)$. Give similar (or simpler) arguments in the other five cases.

VI.3.3.8. In metric geometry (), a stronger version of the Between Axiom is often used. **Midpoint Axiom:** Every pair of points in $(E, \rho)$ has a midpoint (VI.3.1.21).

No uniqueness is assumed. A metric space satisfying the Midpoint Axiom obviously satisfies the Between Axiom.

(a) Prove directly that a complete metric space satisfying the Midpoint Axiom satisfies the Line Segment Axiom, i.e. is strictly intrinsic. (Your proof should not need the AC, but will need the Axiom of Dependent Choice since midpoints are not necessarily unique.)

(b) [Blu70, Theorem 14.1] Adapt this proof to give a proof of Lemma VI.3.1.14. using only DC.

It is known that every Peano space () has a metric satisfying the Midpoint Axiom, or, equivalently, the Between Axiom or the Line Segment Axiom ([Bin49], [Moi49]; note that this result is incorrectly stated in [HY88, p. 130]).
Figure VI.5: A favorite subject in Croatia
VI.4. Length Structures and Metric Geometry

Metric spaces can be regarded as a first approximation to geometry (this is of course not the only interpretation or use for them!) True geometry has at least two other features in addition to a metric structure, i.e. a notion of distance between points:

(i) A notion of “shortest path,” curves in the space which at least locally determine distance, i.e. the distance between nearby points is measured along such a path. Such paths, generalizing lines in Euclidean space or great circles on a sphere, are called geodesics. For a given point \( p \), any other point \( q \) sufficiently close to \( p \) should be connected to \( p \) by a unique geodesic giving the metric distance between \( p \) and \( q \), and geodesics should be extendible.

(ii) A notion of “angle” between geodesics intersecting at a point. Implicit in this is the idea that each geodesic through a point \( p \) determines a well-defined “direction” (“tangent”) at \( p \). Angles should locally give well-defined notions of area and higher-dimensional volumes, which can be extended globally.

There are at least three approaches possible to defining the additional structure, of increasing generality. First, for Euclidean space there is an “elementary” interpretation of lines and angles (although a fully rigorous treatment is more complicated than it may at first appear; cf. ()), so for “nice” subsets of Euclidean space, e.g. for smooth surfaces in \( \mathbb{R}^3 \), geodesics and angles can be defined analytically. This approach is described in (). Secondly, the case of smooth surfaces can be abstracted into the notion of smooth manifolds with a Riemannian or similar structure; cf. (). Finally, the notions can be directly developed straight from the general notion of metric space. This is the approach taken in this section.

As one might expect, abstract metric spaces are too general to support geometry with reasonable properties, and additional conditions on the space must be assumed. These additional conditions will be seen as the theory is developed. Ultimately, the additional conditions force the space to essentially be the type of structure from the second approach above; it is significant that the same mathematical structures can be arrived at in these two ways, reinforcing the naturality and importance of the resulting structures.

We will only cover the basic aspects of this approach. A far more extensive and detailed treatment can be found in [BBI01] and in [Gro99] (read and study the first before tackling the second!)

VI.4.1. Arc Length in Metric Spaces

The notion of curves and arc length in Euclidean space () has a straightforward generalization to metric spaces. Throughout this section, we will fix a metric space \((X, \rho)\).

Parametrized Curves

VI.4.1.1. Definition. A parametrized curve in \( X \) is a continuous function \( \gamma : [a, b] \to X \) for some closed bounded interval \([a, b]\) in \( \mathbb{R} \). The points \( p = \gamma(a) \) and \( q = \gamma(b) \) are the initial and final endpoints of \( \gamma \) respectively, and \( \gamma \) is a parametrized curve from \( p \) to \( q \).

Note that the interval \([a, b]\) is allowed to be degenerate, i.e. we allow \( a = b \). (To be sure, parametrized curves defined on degenerate intervals are not very interesting!)

VI.4.1.2. A parametrized curve has a direction. If \( \gamma : [a, b] \to X \) is a parametrized curve from \( p \) to \( q \), its negative or reversal is \( -\gamma : [a, b] \to X \) defined by \((-\gamma)(t) = \gamma(a + b - t)\) is a parametrized curve from \( q \) to \( p \).
VI.4.1.3. We may think of the range of a parametrized curve as a “curve” in $X$ (although it need not look anything like a geometric curve), and the parametrization as giving “motion” along this curve. This motion may “retrace” parts of the curve in a complicated way.

Restriction and Concatenation

VI.4.1.4. Definition. Let $\gamma : [a, b] \to X$ be a parametrized curve, and $[c, d]$ a closed subinterval of $[a, b]$, i.e. $a \leq c \leq d \leq b$. The parametrized curve $\gamma|_{[c,d]}$ is the restriction of $\gamma$ to $[c, d]$; it is a parametrized curve from $\gamma(c)$ to $\gamma(d)$.

VI.4.1.5. Definition. If $\gamma_1 : [a, b] \to X$ is a parametrized curve from $p$ to $q$, and $\gamma_2 : [b, c] \to X$ is a parametrized curve from $q$ to $r$, the concatenation is the parametrized curve $\gamma = \gamma_1 + \gamma_2 : [a, c] \to X$ defined by

$$\gamma(t) = \begin{cases} 
\gamma_1(t) & \text{if } a \leq t \leq b \\
\gamma_2(t) & \text{if } b \leq t \leq c
\end{cases}$$

The concatenation $\gamma$ is a parametrized curve from $p$ to $r$.

We may extend the definition to $\gamma_1 + \cdots + \gamma_n$ if the curves line up properly.

VI.4.1.6. Note the conditions under which the concatenation is defined are rather severe: $\gamma_1$ and $\gamma_2$ must be parametrized on intervals in $\mathbb{R}$ which concatenate, and the final endpoint of $\gamma_1$ must be the initial endpoint of $\gamma_2$. Concatenation can be slightly generalized using reparametrizations (VI.4.1.16). Also note that although additive notation is used, concatenation is not commutative: if $\gamma_1 + \gamma_2$ is defined, then $\gamma_2 + \gamma_1$ is not even defined unless one of the intervals is degenerate.

VI.4.1.7. If $\gamma = \gamma_1 + \gamma_2$ is defined, then the restriction of $\gamma$ to $[a, b]$ (resp. to $[b, c]$) is $\gamma_1$ (resp. $\gamma_2$). Conversely, if $\gamma : [a, b]$ is a parametrized curve and $c \in [a, b]$, then $\gamma = \gamma|_{[a,c]} + \gamma|_{[c,b]}$. More generally, if $P = \{a = t_0, t_1, \ldots, t_n = b\}$ is a partition of $[a, b]$, we have

$$\gamma = \gamma|_{[a,t_1]} + \gamma|_{[t_1,t_2]} + \cdots + \gamma|_{[t_{n-1},b]}.$$

Reparametrization

VI.4.1.8. Definition. Let $\gamma : [a, b] \to X$ and $\tilde{\gamma} : [c, d] \to X$ be parametrized curves. Then $\tilde{\gamma}$ is a reparametrization of $\gamma$ if $\tilde{\gamma} = \gamma \circ \phi$, where $\phi$ is a nondecreasing continuous function from $[c, d]$ onto $[a, b]$ (hence $\phi(c) = a$ and $\phi(d) = b$). If $\phi$ is strictly increasing, $\tilde{\gamma}$ is a strict reparametrization of $\gamma$.

VI.4.1.9. A reparametrization of a parametrized curve has the same initial and final endpoints, and the same range. But two parametrized curves with the same range, even also with the same initial and final endpoints, need not be reparametrizations. A reparametrization of a parametrized curve describes “motion” along the range “curve” in the same sense, with the same retracing, but possibly over a different interval of time at a different and varying speed.
VI.4.1.10. Various special kinds of reparametrizations can be considered. The simplest is linear reparametrizations, where \( \phi \) is a linear (affine) function from \([c, d]\) onto \([a, b]\), i.e.

\[
\phi(t) = a + \frac{b - a}{d - c}(t - c) .
\]

One can also consider \( C^r \) reparametrizations, where \( \phi \) is \( C^r \), and strict \( C^r \) reparametrizations, where both \( \phi \) and \( \phi^{-1} \) are \( C^r \) (these are also called smooth reparametrizations). There are also piecewise linear and piecewise smooth reparametrizations.

VI.4.1.11. Reparametrization is not an equivalence relation: it is reflexive and transitive, but not symmetric since the function \( \phi \) need not be one-to-one. Strict reparametrization is symmetric, thus an equivalence relation on parametrized curves. Parametrization does generate an important equivalence relation, which can be described thus: two parametrized curves are equivalent if they are both reparametrizations of the same parametrized curve (VI.4.2.7.).

Nonstationary Curves

VI.4.1.12. Definition. Let \( \gamma : [a, b] \to X \) be a parametrized curve, and \([c, d]\) a closed subinterval of \([a, b]\). Then \( \gamma \) is stationary on \([c, d]\) if \( \gamma(t) = \gamma(c) \) for all \( t \in [c, d] \). The curve \( \gamma \) is nonstationary if it is not stationary on any (nondegenerate) subinterval of \([a, b]\).

VI.4.1.13. A nonstationary parametrized curve need not be one-to-one; in fact, it can be very noninjective. For example, the space-filling curve of XIV.12.14. is nonstationary (the one in XIV.12.13. is not nonstationary). For a simpler example, a nonstationary parametrized curve can wrap around a circle in \( \mathbb{R}^2 \) several times.

VI.4.1.14. The maximal intervals on which a parametrized curve \( \gamma \) is stationary form a collection of disjoint closed subintervals of \([a, b]\). Every parametrized curve is a reparametrization of a nonstationary parametrized curve, which is unique up to strict reparametrization (Exercise ()), obtained by collapsing each maximal stationary subinterval to a point (there may be infinitely many such intervals!) Two parametrized curves are equivalent in the equivalence relation generated by reparametrization (VI.4.1.11.) if and only if their nonstationary versions are strict reparametrizations of each other.

Paths

VI.4.1.15. Definition. Let \( p, q \in X \). A path from \( p \) to \( q \) is an equivalence class of parametrized curves from \( p \) to \( q \) (using the equivalence relation of VI.4.1.11. or VII.1.2.7.).

We will write \( \gamma_1 \approx \gamma_2 \) if \( \gamma_1 \) and \( \gamma_2 \) are equivalent, and write \( \langle \gamma \rangle \) for the equivalence class of \( \gamma \) (the usual notation \( [\gamma] \) for an equivalence class is normally reserved for the homotopy class of \( \gamma \), which is a quite different thing ()).

VI.4.1.16. Paths can be concatenated: if \( \langle \gamma_1 \rangle \) is a path from \( p \) to \( q \) and \( \langle \gamma_2 \rangle \) is a path from \( q \) to \( r \), then \( \gamma_1 \) can be concatenated with a suitable reparametrization \( \hat{\gamma}_2 \) of \( \gamma_2 \) (e.g. a linear reparametrization), and the equivalence class of \( \gamma_1 + \hat{\gamma}_2 \) is well defined and depends only on the classes of \( \gamma_1 \) and \( \gamma_2 \) (Exercise ()). Thus the concatenation of the paths \( \langle \gamma_1 \rangle + \langle \gamma_2 \rangle \) is well defined as \( \langle \gamma_1 + \hat{\gamma}_2 \rangle \).

Restriction of paths is a much dicier matter ().
Arc Length

So far we have not used the metric ρ (except to give the topology on X, i.e. to determine continuity of parametrized curves). We now bring ρ into the picture.

VI.4.1.17. Definition. Let γ : [a, b] → X be a parametrized curve, and 𝒫 = {a = t₀, t₁, . . . , tₙ = b} a partition of [a, b]. The polygonal approximate length of γ from 𝒫 is

$$\ell_ρ(γ, 𝒫) = \sum_{k=1}^{n} ρ(γ(t_{k-1}), γ(t_k)).$$

The arc length of γ is

$$\ell_ρ(γ) = \sup_{𝒫} \ell_ρ(γ, 𝒫).$$

We often suppress the subscript if ρ is understood and there is no possibility of confusion.

VI.4.1.18. If Q is a partition of [a, b] which refines 𝒫, we have $\ell(γ, 𝒫) ≤ \ell(γ, Q)$ by the triangle inequality. Since any two partitions have a common refinement, the polygonal approximations approach the arc length as the partitions become arbitrarily fine. The term “polygonal approximation” should not be taken too literally: there is usually not an actual “polygon” in X approximating the curve. The term is suggestive that $(p;q)$ should be the “straight-line” distance between $p$ and $q$.

VI.4.1.19. The arc length of a curve can easily be infinite (e.g. VI.4.1.20). The curve γ is rectifiable if $\ell(γ)$ is finite. Arc length and rectifiability depend crucially on $\rho (\text{VI.4.1.20}(ii)).$

VI.4.1.20. Examples. (i) Let $X = [0, 1]$ with the ordinary metric $ρ(x, y) = |x - y|$. A parametrized curve in $X$ is a continuous function $γ : [a, b] → [0, 1]$. If 𝒫 is a partition of [a, b], then $\ell(γ, 𝒫)$ is the total variation $V(γ, 𝒫)$ of $γ$ over 𝒫 (XIV.16.1.3.), and $\ell(γ)$ is the total variation $V_{[a,b]}(γ)$ of $γ$ over [a, b] (XIV.16.1.6.). The curve γ is rectifiable if and only if $γ$ has bounded variation. If $γ$ is a smooth function, then $γ$ is rectifiable and

$$\ell(γ) = \int_{a}^{b} |γ'(t)| \, dt.$$

(ii) Let $X = [0, 1]$, and let $γ : [0, 1] → X$ be the identity function $γ(t) = t$. If we give $X$ the usual metric $ρ$, we have $\ell_ρ(γ) = 1$. But if $0 < s < 1$ and we give $X$ the snowflake metric $ρ^s$, where $ρ^s(x, y) = |x - y|^s$, then for the partition $𝒫 = \{\frac{k}{n} : 0 ≤ k ≤ n\}$ of [0, 1], we have

$$\ell_{ρ^s}(γ, 𝒫) = \sum_{k=1}^{n} \frac{1}{n^s} = \frac{n}{n^s} = n^{1-s}$$

so $\ell_{ρ^s}(γ) = +∞$, i.e. γ is not rectifiable. In fact, in the metric space $(X, ρ^s)$, no nonconstant parametrized curve is rectifiable.

We now develop basic properties of arc length. First note that arc length is independent of parametrization:
VI.4.1.21. Proposition. Let \( \tilde{\gamma} : [c, d] \to X \) be a reparametrization of \( \gamma : [a, b] \to X \), i.e. \( \tilde{\gamma} = \gamma \circ \phi \), \( \phi : [c, d] \to [a, b] \). Then \( \ell(\tilde{\gamma}) = \ell(\gamma) \).

Proof: Let \( \mathcal{P} = \{ c = t_0, \ldots, t_n = d \} \) be a partition of \([c, d]\). Then \( \{ a = \phi(t_0), \ldots, \phi(t_n) = b \} \) is not quite a partition of \([a, b]\) since there may be repetitions if \( \phi \) is not injective. But repeated points contribute nothing to the sum \( \ell(\tilde{\gamma}, \mathcal{P}) \), and if \( \mathcal{Q} \) is the partition of \([a, b]\) obtained by deleting repetitions, we have \( \ell(\gamma, \mathcal{Q}) = \ell(\tilde{\gamma}, \mathcal{P}) \). Every partition of \([a, b]\) arises in this manner.

VI.4.1.22. Thus arc length of paths is well defined.

Although the reversal \(-\gamma\) of a parametrized curve is not a reparametrization of \(\gamma\), we nonetheless have:

VI.4.1.23. Proposition. If \( \gamma : [a, b] \to X \) is a parametrized curve in \( X \), then \( \ell(-\gamma) = \ell(\gamma) \).

Proof: If \( \mathcal{P} \) is a partition of \([a, b]\), let \( \tilde{\mathcal{P}} \) be the partition consisting of \( \{ a + b - t : t \in \mathcal{P} \} \). Then \( \tilde{\mathcal{P}} \) is also a partition of \([a, b]\), and every partition of \([a, b]\) arises in this manner. We have \( \ell(-\gamma, \tilde{\mathcal{P}}) = \ell(\gamma, \mathcal{P}) \).

VI.4.1.24. If \( \gamma : [a, b] \to X \) is a parametrized curve from \( p \) to \( q \) and \( \mathcal{P} = \{ a, b \} \) is the trivial partition, we have
\[
\rho(p, q) = \ell(\gamma, \mathcal{P}) \leq \ell(\gamma).
\]
More generally, we have:

VI.4.1.25. Proposition. Let \( \gamma : [a, b] \to X \) be a parametrized curve in \( X \), and \( a \leq c \leq d \leq b \), then
\[
\rho(\gamma(c), \gamma(d)) \leq \ell(\gamma|_{[c, d]}) \leq \ell(\gamma).
\]

Proof: The first inequality has already been noted. For the second, any partition \( \mathcal{P} \) of \([c, d]\) can be expanded to a partition \( \mathcal{Q} \) of \([a, b]\) by adding \( a \) and \( b \) if necessary. We have
\[
\ell(\gamma|_{[c, d]}, \mathcal{P}) \leq \ell(\gamma, \mathcal{Q}) \leq \ell(\gamma)
\]
and taking the supremum over all \( \mathcal{P} \) gives the inequality.

If \( \gamma \) is a constant path, obviously \( \ell(\gamma) = 0 \). Conversely:

VI.4.1.26. Corollary. Let \( \gamma \) be a parametrized curve in \( X \). If \( \ell(\gamma) = 0 \), then \( \gamma \) is constant.

Proof: If \( \gamma \) is not constant, there are \( c, d \in [a, b], c < d \), with \( \gamma(c) \neq \gamma(d) \). Then \( 0 < \rho(\gamma(c), \gamma(d)) \leq \ell(\gamma) \).

Here is a more precise version of VI.4.1.25:
**VI.4.1.27.** Proposition. Let $\gamma : [a, b] \to X$ be a parametrized curve, and $c \in [a, b]$. Then
\[
\ell(\gamma) = \ell(\gamma|_{[a,c]}) + \ell(\gamma|_{[c,b]}) .
\]

Proof: If $P$ is a partition of $[a, c]$ and $Q$ a partition of $[c, b]$, then $P \cup Q$ is a partition of $[a, b]$, and
\[
\ell(\gamma, P \cup Q) = \ell(\gamma|_{[a,c]}, P) + \ell(\gamma|_{[c,b]}, Q) .
\]
Every partition of $[a, b]$ containing $c$ (i.e. every sufficiently fine partition) arises in this manner. 

Iterating, we get:

**VI.4.1.28.** Corollary. Let $\gamma : [a, b] \to X$ be a parametrized curve, and $P = \{a = x_0, \ldots, x_n = b\}$ a partition of $[a, b]$. Then
\[
\ell(\gamma) = \sum_{k=1}^{n} \ell(\gamma|_{[x_{k-1}, x_k]}) .
\]

Rephrasing **VI.4.1.27.**, we get:

**VI.4.1.29.** Proposition. Let $\gamma_1 : [a, b] \to X$ and $\gamma_2 : [b, c] \to X$ with $\gamma_1(b) = \gamma_2(b)$, so that the concatenation $\gamma_1 + \gamma_2$ is defined. Then
\[
\ell(\gamma_1 + \gamma_2) = \ell(\gamma_1) + \ell(\gamma_2) .
\]

This can also be iterated to apply to arbitrary finite concatenations.

A crucial property of arc length is lower semicontinuity:

**VI.4.1.30.** Proposition. For each $n$, let $\gamma_n : [a, b] \to X$ be a parametrized curve from $p_n$ to $q_n$. Suppose $(\gamma_n)$ converges pointwise to a parametrized curve $\gamma : [a, b] \to X$ from $p$ to $q$, i.e. $\gamma_n(t) \to \gamma(t)$ for each $t \in [a, b]$ (so $p_n \to p$, $q_n \to q$). Then
\[
\ell(\gamma) \leq \liminf_{n \to \infty} \ell(\gamma_n) .
\]

We can have strict inequality, even if $\gamma_n \to \gamma$ uniformly on $[a, b]$ (**I.5.1.11.**).
Proof: First note that if \( P = \{a = t_0, \ldots, t_m = b\} \) is any partition of \([a, b]\), we have

\[
\ell(\gamma_n, P) = \sum_{k=1}^{m} \rho(\gamma_n(t_{k-1}), \gamma_n(t_k)) = \sum_{k=1}^{m} \rho(\gamma(t_{k-1}), \gamma(t_k)) = \ell(\gamma, P)
\]

by continuity of \( \rho \).

Suppose \( \ell(\gamma) = +\infty \). Fix \( M > 0 \). Then there is a partition \( P \) of \([a, b]\) with \( \ell(\gamma, P) > M \). Then

\[
M < \ell(\gamma, P) = \lim_{n \to \infty} \ell(\gamma_n, P) \leq \liminf_{n \to \infty} \ell(\gamma_n).
\]

This holds for all \( M > 0 \), so \( \liminf_{n \to \infty} \ell(\gamma_n) = +\infty \) and the inequality holds.

Now suppose \( \gamma \) is rectifiable. Let \( \epsilon > 0 \). Then there is a partition \( P \) of \([a, b]\) with \( \ell(\gamma, P) > \ell(\gamma) - \epsilon \). Then

\[
\ell(\gamma) - \epsilon < \ell(\gamma, P) = \lim_{n \to \infty} \ell(\gamma_n, P) \leq \liminf_{n \to \infty} \ell(\gamma_n).
\]

This holds for all \( \epsilon > 0 \), so \( \liminf_{n \to \infty} \ell(\gamma_n) \geq \ell(\gamma) \).

VI.4.1.31. Note for future reference that the definitions of \( \ell(\gamma, P) \) and \( \ell(\gamma) \) make perfect sense for a general function \( \gamma : [a, b] \to X \), not necessarily continuous, so “arc length” is defined even for discontinuous functions (although it is typically infinite for very discontinuous functions). None of the proofs of VI.4.1.21.–VI.4.1.30. use that \( \gamma \) is continuous, so these properties hold also for discontinuous \( \gamma \). (But VI.4.1.33. requires continuity of \( \gamma \).)

Continuity of Arc Length

VI.4.1.32. Let \( \gamma : [a, b] \to X \) be a rectifiable parametrized curve. Define a function \( \phi : [a, b] \to [0, \ell(\gamma)] \) by setting

\[
\phi(t) = \ell(\gamma|_{[a,t]}).
\]

Then \( \phi \) is nondecreasing, \( \phi(a) = 0 \), \( \phi(b) = \ell(\gamma) \). If \( \gamma \) is nonstationary, \( \phi \) is strictly increasing.

VI.4.1.33. Proposition. The function \( \phi \) is continuous.

Proof: The following lemma will provide left continuity on \([a, b]\). The simplest way to get right continuity is to apply the lemma also to \(-\gamma\) and use that \( \ell(\gamma|_{[a,t_0]}) = \ell(\gamma) - \ell(\gamma|_{[t_0,b]}) \).

VI.4.1.34. Lemma. Let \( \gamma : [a, b] \to X \) be a parametrized curve, not necessarily rectifiable. If \((t_n)\) is an increasing sequence in \([a, b]\) converging to \( t_0 \), then

\[
\ell(\gamma|_{[a,t_0]}) = \lim_{n \to \infty} \ell(\gamma|_{[a,t_n]}) = \sup_n \ell(\gamma|_{[a,t_n]})
\]

769
Proof: Define a sequence \((\gamma_n)\) of parametrized curves on \([a,t_0]\) by setting \(\gamma_n(t) = \gamma(t)\) if \(a \leq t \leq t_n\) and \(\gamma_n(t) = \gamma(t_n)\) if \(t_n \leq t \leq t_0\) (i.e. \(\gamma_n\) agrees with \(\gamma\) on \([a,t_n]\) and is stationary on \([t_n,t_0]\)). We have
\[
\ell(\gamma_n) = \ell(\gamma|_{[a,t_n]}) \leq \ell(\gamma|_{[a,t_0]})
\]
for any \(n\) by monotonicity (VI.4.1.25). On the other hand, since \(\gamma\) is continuous at \(t_0\), \(\gamma_n \to \gamma\) pointwise on \([a,t_0]\). So applying VI.4.1.30, we get
\[
\sup\limits_n \ell(\gamma|_{[a,t_n]}) \leq \ell(\gamma|_{[a,t_0]}) \leq \liminf_{n \to \infty} \ell(\gamma_n) = \liminf_{n \to \infty} \ell(\gamma|_{[a,t_n]})
\]
and the result follows.

Parametrization by Arc Length

VI.4.1.35. Let \(\gamma : [a, b] \to X\) be a nonstationary rectifiable parametrized curve, and let \(\phi\) be the above function. Then \(\phi\) is strictly increasing and continuous, so has a continuous strictly increasing inverse function \(\phi^{-1} : [0, \ell(\gamma)] \to [a, b]\). Set \(\tilde{\gamma} = \gamma \circ \phi^{-1} : [0, \ell(\gamma)] \to X\). Then \(\tilde{\gamma}\) is a strict reparametrization of \(\gamma\) with the property that \(\ell(\tilde{\gamma}|_{[0,t]}) = t\) for \(0 \leq t \leq \ell(\gamma)\), i.e. \(\tilde{\gamma}\) “traverses the path \((\gamma)\) at uniform unit speed.” The parametrized curve \(\tilde{\gamma}\) is called the reparametrization of \(\gamma\) by arc length. If \(\gamma\) is replaced by any strict reparametrization, the \(\tilde{\gamma}\) is unchanged; thus it depends only on \((\gamma)\), i.e. any rectifiable path has a unique canonical parametrization by arc length.

Length of Arcs

If \(C\) is a “curve” in \(X\), we would like to be able to say what the intrinsic “arc length” of \(C\) is. This is a tricky problem. The first question is what kind of subsets should be called “curves.” It is too broad to say that the range of any parametrized curve is a “curve” (). One reasonable possibility is:

VI.4.1.36. Definition. An arc in \(X\) is a subset of \(X\) homeomorphic to \([0,1]\).

VI.4.1.37. A subset \(C\) of \(X\) is an arc if and only if it is the range of an injective parametrized curve: a homeomorphism \(\gamma\) from \([0,1]\) to \(C\) is such a parametrized curve, and conversely an injective parametrized curve \(\gamma : [a, b] \to X\) with \(C = \gamma([a, b])\) is a homeomorphism by (). An arc thus has a unique equivalence class of oriented injective parametrizations, thus two in all; the arc length of all these parametrized curves is the same and can be taken to be the arc length of \(C\).

VI.4.1.38. Slightly more generally, if \(C\) can be written as a finite union of arcs with only endpoints in common, the arc length of \(C\) can be taken to be the sum of the arc lengths of these arcs. For more complicated subsets, there are grave difficulties in defining arc length this way.

VI.4.1.39. There is a way to unambiguously define “arc length” for general (Borel) subsets of \(X\): one-dimensional Hausdorff measure (). This “arc length” has the nice properties of a measure, generalizing VI.4.1.28. Subsets whose one-dimensional Hausdorff measure is positive and finite can be regarded as “one-dimensional” (cf. (); not every “one-dimensional” subset will have these properties).
VI.4.2. Length Metrics

VI.4.2.1. The metric distance between two points in a metric space may not have much relationship to the “traveling distance.” Here are some concrete examples, in part adapted from [BB101].

(1) What is the distance between New York and Sydney? The straight-line distance is about 11,000 km. This number is relevant if one is, say, triangulating observational data to compute the distance from Earth to Mars, but is useless for travel since it would involve tunneling through the earth. The great circle distance, which is about 16,000 km, is much more relevant.

(2) What is the distance between the top of the Eiger and the top of the Jungfrau? It is about 5 km “as the crow flies.” But a hiker/climber would have to go down into the valley and around or over the Mönch to get from one to the other, a much longer path. And the proper measure of the length of a route might be the time it takes to traverse it rather than the distance traveled.

(3) What is the distance between Boston and San Francisco? Even the great circle distance is not too relevant if one is driving; the road distance is the important consideration. So only certain paths are allowable for driving. And driving time might again be more important than distance – a longer route on interstate highways might be faster.

(4) On a more abstract level, if one lived in the Cantor set, it would not be possible to “move” or “travel” from one point to another even if these points were very nearby, if time is interpreted as a real number and motion must be continuous. Something like this could happen in the real world if people lived on a chain of small islands and did not have boats or know how to swim.

We will address (1), (2), and (4) in this section, and (3) in the next section.

Intrinsic Metrics

VI.4.2.2. We would like to describe when a metric actually represents “traveling distance” and show that every metric defines a new associated “traveling distance” metric. It will be convenient to work with extended metrics, i.e. ones allowed to take values in \([0, +\infty]\); in some of the literature on metric geometry, “metric” means “extended metric” (we will not make this convention). The next definition is reasonable:

VI.4.2.3. Definition. An extended metric \(\rho\) on a set \(X\) is strictly intrinsic, or a strict length metric, if, for every \(p, q \in X\), there is a path \(\gamma\) from \(p\) to \(q\) in \(X\) with \(\ell(\gamma) = \rho(p, q)\).

For technical reasons, it is convenient to slightly broaden the definition:

VI.4.2.4. Definition. An extended metric \(\rho\) on a set \(X\) is intrinsic, or a length metric, if, for every \(p, q \in X\), we have

\[
\rho(p, q) = \inf_{\gamma} \ell(\gamma)
\]

where the infimum is over all paths \(\gamma\) from \(p\) to \(q\) in \(X\) (with the convention that \(\inf(\emptyset) = +\infty\)).

771
VI.4.2.5. A strict length metric is a length metric (VI.4.1.24.), but not conversely. If \( \rho \) is a strict length metric, then \((X, \rho)\) is path-connected. If \( \rho \) is a length metric, then \((X, \rho)\) is not necessarily path-connected; but if \( p, q \in X \) and \( \rho(p, q) = +\infty \), then \( p \) and \( q \) are in different connected components of \((X, \rho)\) and hence there is no path in \( X \) from \( p \) to \( q \). So if \( \rho \) is an extended metric which is a length metric, the following are equivalent:

(i) \( \rho \) is a metric.

(ii) \((X, \rho)\) is path-connected.

(iii) \((X, \rho)\) is rectifiably path-connected, i.e. for any \( p, q \in X \), there is a rectifiable path from \( p \) to \( q \) in \( X \).

In particular, a strictly intrinsic metric must be an actual metric, not an extended metric. The notions of length and strict length metrics are designed for and almost exclusively used in the (rectifiably) path-connected case. In fact, see VI.4.2.8.

VI.4.2.6. The term “intrinsic” is intended to mean that the metric represents “traveling distance within the space.” For example, the arc-length metric on a circle is (strictly) intrinsic, but the Euclidean distance on a circle embedded in \( \mathbb{R}^2 \) is not intrinsic since one must travel “outside the space” to realize the Euclidean distance. Similarly, if the space is the surface of the earth (assumed to be a perfect sphere), the great-circle metric is intrinsic but not the straight-line (Euclidean) metric, which involves traveling through the earth and not within the space.

VI.4.2.7. Examples. (i) The Euclidean metric on \( \mathbb{R}^n \) is strictly intrinsic.

(ii) More generally, the norm metric on any normed vector space is strictly intrinsic, as is the restriction to any convex subset.

(iii) As noted above, the arc length metric on a circle, or the great circle metric on a sphere, is strictly intrinsic. But the restriction of the Euclidean metric to an embedded circle or sphere is not intrinsic.

(iv) Let \( X = \mathbb{R}^2 \setminus \{(0,0)\} \). Then the restriction of the usual Euclidean metric to \( X \) is intrinsic but not strictly intrinsic: \((1,0)\) and \((-1,0)\) cannot be connected by a path of minimum length in \( X \). See VI.4.5.1. for an example of a complete metric which is intrinsic but not strictly intrinsic.

(v) The discrete extended metric \( \rho \) on any set, where \( \rho(p, q) = +\infty \) if \( p \neq q \), is intrinsic.

VI.4.2.8. Proposition. Let \( \rho \) be an intrinsic metric on a set \( X \). Then \((X, \rho)\) is locally path-connected. In fact, every open ball in \((X, \rho)\) is path-connected.

Proof: Let \( p \in X \) and \( \epsilon > 0 \). Let \( q \in B_\epsilon(p) \). Since \( \rho(p, q) < \epsilon \), there is a parametrized curve \( \gamma : [a, b] \to X \) from \( p \) to \( q \) with \( \ell(\gamma) < \epsilon \). If \( c \in [a, b] \), then by VI.4.1.25.

\[
\rho(p, \gamma(c)) \leq \ell(\gamma|_{[a,c]}) \leq \ell(\gamma) < \epsilon
\]

so the range of \( \gamma \) is contained in \( B_\epsilon(p) \). Thus \( B_\epsilon(p) \) is path-connected. 

772
The Length Metric of a Metric

Now suppose \( \rho \) is a general metric (or extended metric) on a space \( X \). We want to define a new (extended) metric on \( X \) which describes “traveling distance” in \( (X, \rho) \).

VI.4.2.9. Definition. Let \((X, \rho)\) be a metric space. If \( p, q \in X \), define

\[
\rho_1(p, q) = \inf_{\gamma} \ell(\gamma)
\]

where the infimum is over all paths \( \gamma \) from \( p \) to \( q \) in \( X \) (with the convention that \( \inf(\emptyset) = +\infty \)).

The function \( \rho_1 \) is called the length metric of \( \rho \); the terminology will be justified below.

VI.4.2.10. Proposition. The function \( \rho_1 \) is an extended metric on \( X \).

Proof: We need only verify the triangle inequality. Let \( p, q, r \in X \); we show \( \rho_1(p, r) \leq \rho_1(p, q) + \rho_1(q, r) \). If \( \rho_1(p, q) \) or \( \rho_1(q, r) \) is \(+\infty\), there is nothing to prove, so assume both are finite. Let \( \epsilon > 0 \). There are paths \( \gamma_1 \) from \( p \) to \( q \) and \( \gamma_2 \) from \( q \) to \( r \) with \( \ell(\gamma_1) < \rho_1(p, q) + \epsilon \) and \( \ell(\gamma_2) < \rho_1(q, r) + \epsilon \). Reparametrizing if necessary, we can concatenate \( \gamma_1 \) and \( \gamma_2 \) (VI.4.1.16.) to get a path \( \gamma_1 + \gamma_2 \) from \( p \) to \( r \). Thus

\[
\rho_1(p, r) \leq \ell(\gamma_1 + \gamma_2) = \ell(\gamma_1) + \ell(\gamma_2) < \rho_1(p, q) + \rho_1(q, r) + 2\epsilon
\]

Since \( \epsilon > 0 \) is arbitrary, the desired inequality follows.

VI.4.2.11. Even if \( \rho \) is a metric, \( \rho_1 \) is an extended metric in general. For example, if \((X, \rho)\) is not path-connected, then \( \rho_1 \) is necessarily extended: \( \rho_1(p, q) = +\infty \) if \( p \) and \( q \) are in different path components. Even if \((X, \rho)\) is path-connected, \( \rho_1 \) can be an extended metric. In fact, \( \rho_1 \) is a metric if and only if \((X, \rho)\) is rectifiably path-connected.

VI.4.2.12. We have \( \rho(p, q) \leq \rho_1(p, q) \) for any \( p, q \) by VI.4.1.24., i.e. \( \rho_1 \) dominates \( \rho \), so the topology of \( \rho_1 \) is stronger than the topology of \( \rho \). The metrics \( \rho \) and \( \rho_1 \) are equivalent in good cases, but not in general, i.e. the \( \rho_1 \) topology can be strictly stronger than the \( \rho \)-topology. If \( \rho \) is intrinsic, then \( \rho_1 = \rho \); the converse is also true (VI.4.2.14.).

VI.4.2.13. Proposition. Let \((X, \rho)\) be a metric space, and \( \rho_1 \) the length metric of \( \rho \). Then for any parametrized curve \( \gamma : [a, b] \rightarrow X \) in \((X, \rho)\), we have \( \ell_{\rho_1}(\gamma) = \ell_\rho(\gamma) \). 

Note that there is a subtlety: a continuous function from \([a, b]\) to \((X, \rho)\) is not obviously continuous as a function from \([a, b]\) to \((X, \rho_1)\) (and is not continuous in general). But by VII.3.1.17. arc length is also defined for discontinuous \( \gamma \). In fact, we will not use continuity of \( \gamma \) in the proof.

Proof: Fix \( \gamma \). Since \( \rho \leq \rho_1 \), for any partition \( \mathcal{P} \) of \([a, b]\) we have \( \ell_\rho(\gamma, \mathcal{P}) \leq \ell_{\rho_1}(\gamma, \mathcal{P}) \), and hence \( \ell_\rho(\gamma) \leq \ell_{\rho_1}(\gamma) \). Conversely, let \( \epsilon > 0 \). If \( \mathcal{P} = \{a = t_0, \ldots, t_n = b\} \) is a partition of \([a, b]\), set \( p_k = \gamma(t_k) \) for \( 0 \leq k \leq n \). Then

\[
\ell_{\rho_1}(\gamma, \mathcal{P}) = \sum_{k=1}^{n} \rho_1(p_{k-1}, p_k) \leq \sum_{k=1}^{n} \ell_\rho(\gamma|_{[t_{k-1}, t_k]}) = \ell_\rho(\gamma)
\]
VI.4.1.28.}, and taking the supremum over all $\mathcal{P}$ we obtain $\ell_{\rho_i}(\gamma) \leq \ell_\rho(\gamma)$.

VI.4.2.14. Corollary. Let $(X, \rho)$ be a metric space, and $\rho_l$ the length metric of $\rho$. Then $\rho_l$ is intrinsic. Thus $(\rho_l)_l = \rho_l$, and $\rho = \rho_l$ if and only if $\rho$ is intrinsic.

VI.4.2.15. It can be shown using VI.4.2.13. and VI.4.1.33. that if $\gamma$ is a rectifiable parametrized curve in $(X, \rho)$, i.e. $\gamma$ is a continuous function from $[a, b]$ to $(X, \rho)$ with $\ell_\rho(\gamma) < +\infty$, then $\gamma$ is also continuous as a function from $[a, b]$ to $(X, \rho_l)$. This can be false if $\gamma$ is not rectifiable (VI.4.2.16.(iv)).

VI.4.2.16. Examples. (i) If $X$ is a circle embedded in $\mathbb{R}^2$ and $\rho$ is the restriction of the Euclidean metric, then $\rho_l$ is the arc length metric. Similarly, if $X$ is a sphere embedded in $\mathbb{R}^3$ and $\rho$ is the Euclidean metric, then $\rho_l$ is the great circle metric. In these cases $\rho_l \neq \rho$, but the metrics are equivalent.

(ii) Let $X$ be the Warsaw circle (XI.18.4.4.), and $\rho$ the restriction of the Euclidean metric in $\mathbb{R}^2$. Since $(X, \rho)$ is not locally path-connected and $(X, \rho_l)$ is (VI.4.2.8.), the metrics cannot be equivalent. In fact, $(X, \rho_l)$ is homeomorphic to a half-open interval.

(iii) Let $(X, \rho)$ be a totally disconnected metric space, e.g. the Cantor set with the usual metric. The metric $\rho_l$ is the discrete extended metric (VI.4.2.7.(v)), so the topology from $\rho_l$ is the discrete topology.

(iv) Let $X$ be $[0, 1]$ with the snowflake metric $\rho^s$ for some $s$, $0 < s < 1$ (VI.4.1.20.(ii)). Then $X$ is path-connected and locally path-connected, but has no nonconstant rectifiable paths. The metric $(\rho^s)_l$ is the discrete extended metric, so the topology from $\rho_l$ is the discrete topology. Thus the topology from $\rho_l$ can depend on the metric $\rho$ and not just on the topology from $\rho$.

Local Characterization of Intrinsic Metrics

Intrinsic metrics are characterized locally, and are in an appropriate sense the only locally determined metrics.

VI.4.2.17. Definition. Let $\rho$ and $\sigma$ be extended metrics on a set $X$. The metric $\rho$ locally dominates $\sigma$ if, for each $x \in X$, there is a $\rho$-open ball $B_x$ centered at $x$ such that $\sigma(y, z) \leq \rho(y, z)$ for all $y, z \in B_x$. The metric $\rho$ uniformly locally dominates $\sigma$ if there is an $\epsilon > 0$ such that, whenever $B$ is a ball of $\rho$-radius $\epsilon$ in $X$, $\sigma \leq \rho$ on $B$.

The extended metric $\rho$ is locally determined if, whenever $\sigma$ is an extended metric which is locally dominated by $\rho$, then $\sigma \leq \rho$.

VI.4.2.18. Examples. (i) The usual metric on $\mathbb{R}$, or any subset of $\mathbb{R}$ (e.g. $\mathbb{Q}$), is locally determined.

(ii) The arc length metric $\sigma$ on a circle in $\mathbb{R}^2$ is locally determined. But the Euclidean metric $\rho$ is not, since $\rho$ locally dominates $(1 - \epsilon)\sigma$ for every $\epsilon > 0$ but does not dominate if $\epsilon$ is small enough.

(iii) If a small open arc (less than half the circumference) is removed from a circle, the restriction of arc length to the remaining space is not locally determined.

(iv) The discrete metric $\sigma$ on any set $X$ is locally determined.

774
VI.4.2.19. **Proposition.** Let \((X, \rho)\) be a metric space. If \(\rho\) is intrinsic, it is locally determined.

**Proof:** Suppose \(\rho\) is intrinsic, and \(\sigma\) is a pseudometric which is locally dominated by \(\rho\). Let \(x, y \in X\); we show \(\sigma(x, y) \leq \rho(x, y)\). We may assume \(\rho(x, y) < +\infty\). Fix \(\epsilon > 0\). Let \(\gamma : [0, 1] \to X\) be a path from \(x\) to \(y\) with \(\ell(\gamma) < \rho(x, y) + \epsilon\). For \(z \in \gamma([0, 1])\), there is an open neighborhood \(U_z\) of \(z\) with \(\sigma(u, v) \leq \rho(u, v)\) for all \(u, v \in U_z\). Since \(\gamma([0, 1])\) is compact, there are finitely many such \(U_z\) which cover it, so there is a partition \(\{0 = t_0, \ldots, t_n = 1\}\) of \([0, 1]\) such that, if \(x_k = \gamma(t_k)\), consecutive \(x_k\) are in the same \(U_z\). Thus we have

\[
\sigma(x, y) \leq \sum_{k=1}^n \sigma(x_{k-1}, x_k) \leq \sum_{k=1}^n \rho(x_{k-1}, x_k) \leq \ell(\gamma) < \rho(x, y) + \epsilon
\]

and since \(\epsilon > 0\) is arbitrary, \(\sigma(x, y) \leq \rho(x, y)\).

VI.4.2.20. The converse is not true, even if \(\rho\) is complete (VI.4.2.18. (iv)). To obtain an appropriate converse, we make the following construction. Let \(\rho\) be an extended metric on a set \(X\) and \(\epsilon > 0\). Set

\[
\rho_{\epsilon}(x, y) = \inf \sum_{k=1}^n \rho(x_{k-1}, x_k)
\]

where the infimum is over all finite chains \(\{x = x_0, x_1, \ldots, x_n = y\}\) where \(\rho(x_{k-1}, x_k) \leq \epsilon\) for all \(k\) (set \(\rho_{\epsilon}(x, y) = +\infty\) if there is no such chain). It is easily proved by an argument almost identical to () that \(\rho_{\epsilon}\) is an extended metric, that \(\rho \leq \rho_{\epsilon} \leq \rho_{\delta}\) if \(\delta < \epsilon\). We have that \(\rho_{\epsilon}(x, y) = \rho(x, y)\) if \(\rho(x, y) \leq \epsilon\), and in particular \(\rho\) uniformly locally dominates \(\rho_{\epsilon}\) for any \(\epsilon > 0\).

VI.4.2.21. By (), \(\rho_{\text{loc}} = \sup_{\epsilon > 0} \rho_{\epsilon}\) is an extended metric, called the **local metric** of \(\rho\). Comparing definitions, we have \(\rho_{\text{loc}} \leq \rho_\epsilon\). Since \((\rho_\epsilon)_\delta = \rho_\delta\) if \(\delta \leq \epsilon\), it follows that

\[
(\rho_{\epsilon})_{\text{loc}} = (\rho_{\text{loc}})_\epsilon = (\rho_{\text{loc}})_{\text{loc}} = \rho_{\text{loc}}
\]

for any \(\epsilon > 0\).

The next proposition is an immediate corollary of VI.4.2.19., or it can be easily proved directly.

VI.4.2.22. **Proposition.** Let \((X, \rho)\) be a metric space. If \(\rho\) is intrinsic, then \(\rho = \rho_{\epsilon}\) for all \(\epsilon > 0\).

VI.4.2.23. **Definition.** Let \(\rho\) be a metric on a set \(X\). Then \(\rho\) is **uniformly locally determined** if \(\rho = \rho_{\epsilon}\) for all \(\epsilon > 0\), i.e. if \(\rho = \rho_{\text{loc}}\).

VI.4.2.24. **Examples.**

(i) The usual metric on \(\mathbb{Q}\) (or any other subset of \(\mathbb{R}\)) is uniformly locally determined.

(ii) The discrete metric on a set with more than one element is locally determined but not uniformly locally determined.

(iii) For any metric \(\rho\), \(\rho_{\text{loc}}\) is uniformly locally determined (VI.4.2.21.).

775
VI.4.2.25. Theorem. Let \((X, \rho)\) be a complete metric space. Then \(\rho_1 = \rho_{loc}\).

VI.4.2.26. Corollary. Let \((X, \rho)\) be a complete metric space. If \(\rho\) is uniformly locally determined, it is intrinsic.

For the proof of the theorem, we will use a variant of the Between Axiom (VI.3.1.11.) which is of independent interest:

VI.4.2.27. Definition. A metric space \((X, \rho)\) has the approximate midpoint property if, for every \(x, y \in X\) and \(\epsilon > 0\) there is a \(z \in X\) with

\[
\rho(x, z) - \frac{\rho(x, y)}{2} < \epsilon \quad \text{and} \quad \rho(z, y) - \frac{\rho(x, y)}{2} < \epsilon.
\]

Such a \(z\) is called an \(\epsilon\)-midpoint of \(x\) and \(y\).

VI.4.2.28. Proposition. A uniformly locally determined metric has the approximate midpoint property.

Proof: If \((X, \rho)\) is locally determined, let \(x, y \in X\) and \(\epsilon > 0\). If \(\{x = x_0, \ldots, x_n = y\}\) is a finite chain with \(\rho(x_{k-1}, x_k) < \frac{\epsilon}{2}\) for all \(k\) and \(\sum_k \rho(x_{k-1}, x_k) < \rho(x) + \frac{\epsilon}{2}\), then one of the \(x_k\) (for \(k \approx \frac{n}{2}\)) will be an \(\epsilon\)-midpoint of \(x\) and \(y\).

VI.4.2.29. Theorem. Let \((X, \rho)\) be a complete metric space with the approximate midpoint property. Then \(\rho\) is intrinsic.

Proof: This is somewhat similar to ( ), but no form of choice is needed. Let \(x, y \in X\) and \(\epsilon > 0\). Let \(x_{1/2}\) be an \(\frac{\epsilon}{4}\)-midpoint of \(x\) and \(y\). Let \(x_{1/4}\) be an \(\frac{\epsilon}{6}\)-midpoint of \(x = x_0\) and \(x_{1/2}\), and \(x_{3/4}\) an \(\frac{\epsilon}{16}\)-midpoint of \(x_{1/2}\) and \(y = x_1\). Continue inductively in this manner to define \(x_r\) for dyadic rational \(r \in [0, 1]\), using a denominator of \(4^n\) if the denominator of \(r\) is \(2^n\). It is easy to check that \(r \mapsto x_r\) is uniformly continuous and thus extends to a map \(\gamma : [0, 1] \to X\) since \(\rho\) is complete. Then \(\gamma\) is a path from \(x\) to \(y\), and \(\ell(\gamma) \leq \rho(x, y) + \epsilon\).

Theorem VI.4.2.25., and hence Corollary VI.4.2.26., follow immediately.

VI.4.2.30. The example of \(\mathbb{Q}\) (VI.4.2.24.(i)) shows that completeness is necessary in the theorem.

VI.4.3. Length Structures

We now change point of view. Instead of working with arc length defined by a metric, we assume directly that we have a notion of length for certain (“admissible”) paths in the space \(X\) and from it derive a length metric and thus a topology. We must start with a metric, or at least a topology, on \(X\), in order to have a notion of continuous path in \(X\), but the initial topology will be inconsequential at the end. In order to do this, there must be enough admissible paths, and the length function must have reasonable properties. Our exposition is largely adapted from [BBI01].
VI.4.3.1. **Definition.** Let \((X, \sigma)\) be a metric space. A length structure on \((X, \sigma)\) is a pair \(L = (A, \ell)\), where \(A\) is a set of parametrized curves in \(X\) (called admissible paths for \(L\)) such that

1. If \(\gamma : [a, b] \to X\) is in \(A\), then \(\gamma|_{[c, d]} \in L\) for every subinterval \([c, d]\) of \([a, b]\).
2. If \(\gamma_1, \gamma_2 \in A\) and \(\gamma_1 + \gamma_2\) is defined, then \(\gamma_1 + \gamma_2 \in A\).
3. Any linear reparametrization of a parametrized curve in \(A\) is also in \(A\). (Combined with (3), any piecewise-linear reparametrization of a parametrized curve in \(A\) is then also in \(A\).) Also, if \(\gamma \in A\), then its reversal \(-\gamma\) is in \(A\) too.

and \(\ell : A \to [0, +\infty]\) (called the length function of \(L\)) satisfying

1. If \(\gamma : [a, b] \to X\) is in \(A\) and \(c \in [a, b]\), then \(\ell(\gamma) = \ell(\gamma|_{[a, c]}) + \ell(\gamma|_{[c, b]})\) (i.e. \(\ell\) is additive on concatenations).
2. If \(\gamma : [a, b] \to X\) is in \(A\), then the function \(\phi(t) = \ell(\gamma|_{[a, t]}\) is continuous on \([a, b]\).
3. If \(\gamma \in A\) and \(\tilde{\gamma}\) is a linear reparametrization of \(\gamma\), then \(\ell(\tilde{\gamma}) = \ell(\gamma)\). (From (i) it then follows that \(\ell\) is invariant under piecewise-linear reparametrizations, i.e. \(\ell\) is really defined on equivalence classes of parametrized curves.) Also, \(\ell(-\gamma) = \ell(\gamma)\) for any \(\gamma \in A\).
4. If \(p \in X\) and \(U\) is an open neighborhood of \(p\) (in the \(\sigma\)-topology), then there is a \(\delta > 0\) such that any \(\gamma \in A\) from \(p\) to a point \(q \in U^\circ\) satisfies \(\ell(\gamma) \geq \delta\).

The set \(A\) of admissible paths is technically encoded in the length function \(\ell\) as its domain, and some of the literature does not distinguish between \(L\) and \(\ell\); but it seems a little clearer to make a notational distinction.

VI.4.3.2. **Condition (iv) is an additional compatibility condition of \(L\) with the \(\sigma\)-topology on \(X\) besides the requirement that the curves in \(A\) are continuous.** These two compatibility conditions are the only place the metric \(\sigma\) appears, and only depend on the \(\sigma\)-topology; the metric \(\sigma\) could be dispensed with entirely and just replaced by an initial topology on \(X\) (which should be assumed Hausdorff for a reasonable theory, although it could be dispensed with entirely by taking it to be the indiscrete topology).

VI.4.3.3. **Examples.** (i) Let \((X, \rho)\) be a metric space, \(A\) the collection of all parametrized curves in \(X\), and \(\ell(\gamma) = \ell_\rho(\gamma)\). This is the length structure induced by \(\rho\), denoted \(L_\rho\).

(ii) More generally, let \((X, \rho)\) be a metric space and \(Y \subseteq X\). Let \(A\) be the set of parametrized curves in \(X\) whose range is contained in \(Y\), and for \(\gamma \in A\) set \(\ell(\gamma) = \ell_\rho(\gamma)\). Then \((A, \ell)\) is a length structure on \((X, \rho)\), as well as on \((Y, \rho)\). This was the main motivating example for the theory of length structures, with \(X = \mathbb{R}^n\), \(\rho\) the Euclidean metric, and \(Y\) a smooth submanifold.

(iii) Let \((X, \rho)\) be \(\mathbb{R}^n\) with the Euclidean metric, and take \(A\) to be either the set of piecewise-linear curves or piecewise-smooth curves in \(\mathbb{R}^n\), with \(\ell = \ell_\rho|_A\). These length structures are not essentially different from the length structure using all parametrized curves. One can also consider the restrictions to suitable subsets as in (ii).

(iv) Let \((X, \rho)\) be \(\mathbb{R}^n\) with the Euclidean metric, and take \(A\) to be the set of all parametrized curves in \(\mathbb{R}^n\). Set \(\ell(\gamma) = \ell_\rho(\gamma)\) if \(\gamma\) is piecewise-linear and \(\ell(\gamma) = +\infty\) otherwise.

(v) Let \(X = \mathbb{R}^2\), \(\sigma\) the Euclidean metric. Let \(A\) be the collection of all parametrized curves whose image consists of a union of finitely many horizontal and vertical line segments. For \(\gamma \in A\), set \(\ell(\gamma) = \ell_\sigma(\gamma)\).
Here is a concrete example, stated somewhat imprecisely. Let $X$ be the United States, and $A$ the set of driving routes (so all points, including endpoints, are points on roads). The length $\ell(\gamma)$ of a driving route is the driving time for the route. (Driving routes are taken as paths, i.e. equivalence classes of parametrized curves, and driving time is not connected with parametrization.) This must be idealized to become precise and give a length structure: driving time must be well defined and be independent of direction, and it must be assumed that a vehicle can reverse direction instantaneously to make driving time additive on curves which retrace routes.

In this example, not all points of the space are connected by admissible paths. To rectify this, we could add to $A$ the set of all routes traversable by surface transportation, including walking (assuming that every point of the country is within walking distance of a road).

As a precise theoretical version of (vi), let $X$ be $\mathbb{R}^n$ (or a smooth submanifold) and $f : X \to (0, +\infty)$ a continuous function (continuity can be somewhat relaxed). Let $A$ be the set of piecewise-smooth parametrized curves in $X$, and for $\gamma : [a, b] \to X$ in $A$, set

$$\ell(\gamma) = \int_a^b f(\gamma(t)) \gamma'(t) \, dt$$

(this is just the integral of $f$ along the path defined by $\gamma$). In the case of (v), $X$ could be the set of all points on roads, and $f(x)$ the reciprocal of the maximum speed one can (or is allowed to) drive at the point $x$.

As a generalization, let $X$ be $\mathbb{R}^n$ (or a smooth submanifold) and $f : X \times \mathbb{R}^n \to (0, +\infty)$ a continuous function (continuity can be somewhat relaxed). Let $A$ be the set of piecewise-smooth parametrized curves in $X$, and for $\gamma : [a, b] \to X$ in $A$, set

$$\ell(\gamma) = \int_a^b f(\gamma(t), \gamma'(t)) \, dt$$

To make $\ell$ invariant under linear reparametrizations, we need $f(x, \alpha y) = |\alpha| f(x, y)$ for all $x, y, \alpha$. Such a length structure is called a Finslerian length structure. The idea is that the speed of travel may depend not only on the point, but also on the direction of travel (although the speed in opposite directions must be the same, not necessarily a realistic assumption in applications).

The Length Metric of a Length Structure

**Definition.** Let $L = (A, \ell)$ be a length structure on a metric space $(X, \sigma)$. Define an extended metric $\rho_L$ by

$$\rho_L(p, q) = \inf_{\gamma} \ell(\gamma)$$

for $p \neq q$, where the infimum is over all paths $\gamma \in A$ from $p$ to $q$ (with the convention that $\inf(\emptyset) = +\infty$).

The proof that $\rho_L$ is an extended metric is essentially identical to the proof of VI.4.2.10., using that a concatenation of admissible paths is admissible. The extended metric $\rho_L$ is a metric if and only if any two points of $X$ can be connected by an admissible path of finite length. The $\rho_L$-topology on $X$ is stronger than the initial $\sigma$-topology by condition (iv); it is often strictly stronger.
VI.4.3.5. **Proposition.** Let \( L = (A, \ell) \) be a length structure on \((X, \sigma)\), and \( \rho_L \) the corresponding extended metric. Then \( \rho_L \) is a length metric, and \( \ell_{\rho_L}(\gamma) \leq \ell(\gamma) \) for all \( \gamma \in A \).

We can have strict inequality (VI.4.3.6.(iv)).

**Proof:** For the second statement, let \( \gamma : [a, b] \to X \) be in \( A \). If \( \mathcal{P} = \{a = t_0, \ldots, t_n = b\} \) is any partition of \([a, b]\), we have

\[
\ell_{\rho_L}(\gamma, \mathcal{P}) = \sum_{k=1}^{n} \rho_L(\gamma(t_{k-1}), \gamma(t_k)) \leq \sum_{k=1}^{n} \ell(\gamma|_{[t_{k-1}, t_k]}) = \ell(\gamma)
\]

since \( \gamma|_{[t_{k-1}, t_k]} \in A \) by (1), and taking the supremum over all \( \mathcal{P} \) we obtain the inequality.

To show \( \rho_L \) is a length metric, let \( p, q \in X \). We show that

\[
\rho_L(p, q) = \lambda := \inf_{\gamma} \ell_{\rho_L}(\gamma)
\]

with the infimum over all parametrized curves from \( p \) to \( q \). We need only show \( \rho_L(p, q) \geq \lambda \), since \( \leq \) is automatic (VI.4.1.24). If \( \rho_L(p, q) = +\infty \), there is nothing to prove, so we may suppose \( \rho_L(p, q) \) is finite.

Let \( \epsilon > 0 \). There is a \( \gamma \in A \) from \( p \) to \( q \) with \( \ell(\gamma) < \rho_L(p, q) + \epsilon \). Then

\[
\lambda \leq \ell_{\rho_L}(\gamma) \leq \ell(\gamma) < \rho_L(p, q) + \epsilon .
\]

Since \( \epsilon > 0 \) is arbitrary, the inequality follows.

VI.4.3.6. **Examples.** (i) If \((X, \rho)\) is a metric space and \( L_\rho \) is the induced length structure (VI.4.3.3.(i)), then \( \rho_{L_\rho} = \rho \).

(ii) In the situation of VI.4.3.3.(ii), if \( L \) is regarded as a length structure on \((Y, \rho)\), then \( \rho_L = \rho \) as in (i). If \( L \) is regarded as a length structure on \((X, \rho)\), then \( \rho_L \) is an extended metric on \( X \), with \( \rho_L(p, q) = +\infty \) unless both \( p \) and \( q \) are in \( Y \). In the \( \rho_L \) topology on \( X \), \( Y \) is a clopen set and each point of \( X \setminus Y \) is an isolated point.

(iii) In VI.4.3.3.(iii), the induced metric \( \rho_L \) on \( \mathbb{R}^n \) is just the Euclidean metric, since the set of admissible curves includes a curve of minimal length between any two points. Thus restricting the set of admissible curves does not necessarily change the length metric, so long as the admissible curves include arbitrarily short paths (i.e. close to the minimum for all paths) between any pair of points.

(iv) In VI.4.3.3.(iv), the induced metric \( \rho_L \) on \( \mathbb{R}^n \) is again just the Euclidean metric. Thus, even if the set of admissible curves is the same, changing the length function \( \ell \) does not necessarily change the length metric, if there are short paths of (approximately) the same length under the two length functions.

(v) In VI.4.3.3.(v), the length metric is not the Euclidean metric \( \rho = \rho_2 \), but rather the 1-metric \( \rho_1 \) (\( \rho_1 \)). Thus if the set of admissible curves is changed, the length metric can change if the set of admissible curves does not contain arbitrarily short paths between points.
Recovering a Length Structure from its Metric

VI.4.3.7. If $\rho$ is a length metric, then the induced metric from the length structure $L_\rho$ is $\rho$ itself (cf. VI.4.3.6.(i)). How about the converse: if $L = (A, \ell)$ is a length structure and $\rho_L$ the induced length metric, is $L = L_{\rho_L}$? In one sense, the answer is usually no: the set of admissible paths for $L_{\rho_L}$ is often larger than $A$ (cf. Examples VI.4.3.6.(iii) and (v)). But $\ell_{\rho_L}$ may not agree with $\ell$ even on $A$ (VI.4.3.6.(iv); the problem is lower semicontinuity (VI.4.3.9)). It would be useful to know when $\ell_{\rho_L}$ agrees with $\ell$ on $A$, since $\ell$ is often given by a formula making it easier to calculate than $\ell_{\rho_L}$ (e.g. in VI.4.3.3.(vii)–(viii)).

VI.4.3.8. The length function $\ell_{\rho_L}$ is always lower semicontinuous (VI.4.1.30.), so a necessary condition that $\ell = \ell_{\rho_L}|_A$ for a length structure $L = (A, \ell)$ is that $\ell$ is lower semicontinuous on $A$. But $\ell$ is not necessarily lower semicontinuous, e.g. the $\ell$ of Example VI.4.3.3.(iv) (the $\ell$ of Example VI.4.3.3.(viii) is also not necessarily lower semicontinuous, cf. (i)). Lower semicontinuity is the only constraint:

VI.4.3.9. **Proposition.** Let $L = (A, \rho)$ be a length structure on $(X, \sigma)$, and $\rho_L$ the corresponding length metric. Then $\ell = \ell_{\rho_L}|_A$ if and only if $\ell$ is lower semicontinuous on $A$.

VI.4.4. Metric Geometry

VI.4.5. Exercises

VI.4.5.1. For each $n$ let $I_n$ be a closed interval in $\mathbb{R}$ of length $1 + \frac{1}{n}$ with endpoints $a_n$ and $b_n$. Glue the $I_n$ together by identifying all the $a_n$ to a point $a$, and all the $b_n$ to a point $b$. Let $X$ be the quotient space, and $\rho$ the length metric on $X$.

(a) Show that $(X, \rho)$ is a complete metric space.

(b) Show that $\rho(a, b) = 1$, but there is no path from $a$ to $b$ of length 1. Thus $(X, \rho)$ is not complete as a length space, i.e. $\rho$ is not strictly intrinsic.

(c) Realize $X$ concretely as a subset of $\mathbb{R}^2$ consisting of a union of circular arcs in the upper half plane through $(0, 0)$ and $(1, 0)$. Show that $\rho$ is the length metric defined by the restriction $\sigma$ of the Euclidean metric on $\mathbb{R}^2$, and that $\rho$ is equivalent (but not uniformly equivalent) to the incomplete metric $\sigma$.

VI.4.5.2. Let $(X, \rho)$ be a metric space, and $\rho_l$ the associated length metric on $X$.

(a) Show that if $\rho$ is complete, then $\rho_l$ is also complete.

(b) If $\rho_l$ is complete, then $\rho$ is not necessarily complete, even if $(X, \rho)$ is rectifiably path-connected and locally path-connected. [Let $X$ be the topologist’s sine curve (XI.18.4.3.) with the points on the $y$-axis removed, with $\rho$ the ordinary metric from $\mathbb{R}^2$. $\mathbb{Q}$ with the ordinary metric is an example if the space is not required to be path-connected.]
Chapter VII

Curves

“Everyone knows what a curve is, until he has studied enough mathematics to become confused through the countless number of possible exceptions.”

*Felix Klein*

What is a curve? Almost everyone has a good intuitive idea of what a curve should be, but it is a surprisingly delicate matter to make a precise definition which includes all the things which should be curves and excludes everything that should not.

At a minimum, a curve should be a one-dimensional subset of a Euclidean space. Most people would agree that the following are curves:

- Graphs of continuous functions, or at least graphs of differentiable functions, from $\mathbb{R}$ to $\mathbb{R}$.
- Lines, circles, and polygons.
- A figure 8, figure 6, figure $\alpha$, and the like.
- Finite separated unions of the above.

On the other hand, the following are clearly not curves:

- Anything zero-dimensional, e.g. the Cantor set $\mathcal{C}$.
- Anything more than one-dimensional, e.g. a (solid) disk or square, or a ball or sphere in $\mathbb{R}^n$, $n > 2$.
- Anything not at least locally compact.

In addition, there are many things which are in a gray area, e.g. a figure $X$, figure $Y$, figure $\otimes$, and many of the the one-dimensional subsets of $\mathbb{R}^2$ and $\mathbb{R}^3$ discussed in (), such as the Topologist’s Sine Curve, the Hawaiian Earring, the Sierpiński gasket and carpet, solenoids, the pseudo-arc, even wildly embedded arcs.

We will begin by defining curves via parametrizations, although we will distinguish between curves and parametrized curves. Parametrizations are natural since they describe “motion along the curve.” But defining a curve as just a continuous image of an interval is too broad: for example, there are “space-filling curves,” continuous functions from $[0,1]$ onto a square $[0,1]^2$. In fact, the Banach-Mazurkiewicz Theorem () says
that every compact metrizable topological space which is connected and locally connected, and in particular any connected, locally connected closed bounded subset of a Euclidean space, is a continuous image of $[0, 1]$. Allowing continuous images of non-closed intervals, e.g. $\mathbb{R}$, admits even more pathology: a continuous image of $\mathbb{R}$, even a one-to-one continuous image, need not even be locally compact (). On the other hand, requiring the parametrization to be a homeomorphism eliminates such a natural curve as a circle, and to relax the requirement to being a local homeomorphism rules out curves like a figure 8. So we will have to be more careful.

VII.1. Curves and Parametrized Curves in $\mathbb{R}^n$

VII.1.1. Parametrized Curves

**Definition.** A parametrized curve in $\mathbb{R}^n$ is a continuous function $\gamma : [a, b] \rightarrow \mathbb{R}^n$ for some closed bounded interval $[a, b]$ in $\mathbb{R}$. The points $p = \gamma(a)$ and $q = \gamma(b)$ are the initial and final endpoints of $\gamma$ respectively, and $\gamma$ is a parametrized curve from $p$ to $q$.

Note that the interval $[a, b]$ is allowed to be degenerate, i.e. we allow $a = b$. (To be sure, parametrized curves defined on degenerate intervals are not very interesting!)

**Definition.** A parametrized curve has a direction. If $\gamma : [a, b] \rightarrow \mathbb{R}^n$ is a parametrized curve from $p$ to $q$, its negative or reversal is $-\gamma : [a, b] \rightarrow \mathbb{R}^n$ defined by $(-\gamma)(t) = \gamma(a + b - t)$ is a parametrized curve from $q$ to $p$.

**Definition.** We may think of the range of a parametrized curve as a “curve” in $\mathbb{R}^n$ (although it need not look anything like a geometric curve), and the parametrization as giving “motion” along this curve. This motion may “retrace” parts of the curve in a complicated way.

**Restriction and Concatenation**

**Definition.** Let $\gamma : [a, b] \rightarrow \mathbb{R}^n$ be a parametrized curve, and $[c, d]$ a closed subinterval of $[a, b]$, i.e. $a \leq c \leq d \leq b$. The parametrized curve $\gamma|_{[c, d]}$ is the restriction of $\gamma$ to $[c, d]$; it is a parametrized curve from $\gamma(c)$ to $\gamma(d)$.

**Definition.** If $\gamma_1 : [a, b] \rightarrow \mathbb{R}^n$ is a parametrized curve from $p$ to $q$, and $\gamma_2 : [b, c] \rightarrow \mathbb{R}^n$ is a parametrized curve from $q$ to $r$, the concatenation is the parametrized curve $\gamma = \gamma_1 + \gamma_2 : [a, c] \rightarrow \mathbb{R}^n$ defined by

$$
\gamma(t) = \begin{cases} 
\gamma_1(t) & \text{if } a \leq t \leq b \\
\gamma_2(t) & \text{if } b \leq t \leq c
\end{cases}
$$

The concatenation $\gamma$ is a parametrized curve from $p$ to $r$.

We may extend the definition to $\gamma_1 + \cdots + \gamma_n$ if the curves line up properly.

782
VII.1.1.6. Note the conditions under which the concatenation is defined are rather severe: $\gamma_1$ and $\gamma_2$ must be parametrized on intervals in $\mathbb{R}$ which concatenate, and the final endpoint of $\gamma_1$ must be the initial endpoint of $\gamma_2$. Concatenation can be slightly generalized using reparametrizations (VII.4.1.16.). Also note that although additive notation is used, concatenation is not commutative: if $\gamma_1 + \gamma_2$ is defined, then $\gamma_2 + \gamma_1$ is not even defined unless one of the intervals is degenerate.

VII.1.1.7. If $\gamma = \gamma_1 + \gamma_2$ is defined, then the restriction of $\gamma$ to $[a, b]$ (resp. to $[b, c]$) is $\gamma_1$ (resp. $\gamma_2$). Conversely, if $\gamma : [a, b]$ is a parametrized curve and $c \in [a, b]$, then $\gamma = \gamma|_{[a,c]} + \gamma|_{[c,b]}$. More generally, if $P = \{a = t_0, t_1, \ldots, t_n = b\}$ is a partition of $[a, b]$, we have

$$\gamma = \gamma|_{[a,t_1]} + \gamma|_{[t_1,t_2]} + \cdots + \gamma|_{[t_{n-1},b]}.$$

VII.1.2. Reparametrization

VII.1.2.1. Definition. Let $\gamma : [a, b] \to \mathbb{R}^n$ and $\tilde{\gamma} : [c, d] \to \mathbb{R}^n$ be parametrized curves. Then $\tilde{\gamma}$ is a reparametrization of $\gamma$ if $\tilde{\gamma} = \gamma \circ \phi$, where $\phi$ is a nondecreasing continuous function from $[c, d]$ onto $[a, b]$ (hence $\phi(c) = a$ and $\phi(d) = b$). If $\phi$ is strictly increasing, $\tilde{\gamma}$ is a strict reparametrization of $\gamma$.

VII.1.2.2. A reparametrization of a parametrized curve has the same initial and final endpoints, and the same range. But two parametrized curves with the same range, even also with the same initial and final endpoints, need not be reparametrizations. A reparametrization of a parametrized curve describes “motion” along the range “curve” in the same sense, with the same retracing, but possibly over a different interval of time at a different and varying speed.

VII.1.2.3. Various special kinds of reparametrizations can be considered. The simplest is linear reparametrizations, where $\phi$ is a linear (affine) function from $[c, d]$ onto $[a, b]$, i.e.

$$\phi(t) = a + \frac{b - a}{d - c}(t - c).$$

One can also consider $C^r$ reparametrizations, where $\phi$ is $C^r$, and strict $C^r$ reparametrizations, where both $\phi$ and $\phi^{-1}$ are $C^r$ (these are also called smooth reparametrizations). There are also piecewise linear and piecewise smooth reparametrizations.

VII.1.2.4. Reparametrization is not an equivalence relation: it is reflexive and transitive, but not symmetric since the function $\phi$ need not be one-to-one. Strict reparametrization is symmetric, thus an equivalence relation on parametrized curves. Parametrization does generate an important equivalence relation, which can be described thus: two parametrized curves are equivalent if they are both reparametrizations of the same parametrized curve (VII.1.2.7.).

Nonstationary Curves

VII.1.2.5. Definition. Let $\gamma : [a, b] \to \mathbb{R}^n$ be a parametrized curve, and $[c, d]$ a closed subinterval of $[a, b]$. Then $\gamma$ is stationary on $[c, d]$ if $\gamma(t) = \gamma(c)$ for all $t \in [c, d]$. The curve $\gamma$ is nonstationary if it is not stationary on any (nondegenerate) subinterval of $[a, b]$. 

783
VII.1.2.6. A nonstationary parametrized curve need not be one-to-one; in fact, it can be very noninjective. For example, the space-filling curve of XIV.12.1.14. is nonstationary (the one in XIV.12.1.13. is not nonstationary). For a simpler example, a nonstationary parametrized curve can wrap around a circle in \( \mathbb{R}^2 \) several times.

VII.1.2.7. The maximal intervals on which a parametrized curve \( \gamma \) is stationary form a collection of disjoint closed subintervals of \([a, b]\). Every parametrized curve is a reparametrization of a nonstationary parametrized curve, which is unique up to strict reparametrization (Exercise ()), obtained by collapsing each maximal stationary subinterval to a point (there may be infinitely many such intervals!) Two parametrized curves are equivalent in the equivalence relation generated by reparametrization (VII.1.2.4.) if and only if their nonstationary versions are strict reparametrizations of each other.

VII.1.3. Paths

VII.1.3.1. Definition. Let \( p, q \in \mathbb{R}^n \). A path from \( p \) to \( q \) is an equivalence class of parametrized curves from \( p \) to \( q \) (using the equivalence relation of VI.4.1.11. or VII.1.2.7.).

We will write \( \gamma_1 \approx \gamma_2 \) if \( \gamma_1 \) and \( \gamma_2 \) are equivalent, and write \( \langle \gamma \rangle \) for the equivalence class of \( \gamma \) (the usual notation \([\gamma]\) for an equivalence class is normally reserved for the homotopy class of \( \gamma \), which is a quite different thing ()).

VII.1.3.2. Paths can be concatenated: if \( \langle \gamma_1 \rangle \) is a path from \( p \) to \( q \) and \( \langle \gamma_2 \rangle \) is a path from \( q \) to \( r \), then \( \gamma_1 \) can be concatenated with a suitable reparametrization \( \tilde{\gamma}_2 \) of \( \gamma_2 \) (e.g. a linear reparametrization), and the equivalence class of \( \gamma_1 + \tilde{\gamma}_2 \) is well defined and depends only on the classes of \( \gamma_1 \) and \( \gamma_2 \) (Exercise ()). Thus the concatenation of the paths \( \langle \gamma_1 \rangle + \langle \gamma_2 \rangle \) is well defined as \( \langle \gamma_1 + \tilde{\gamma}_2 \rangle \).

Restriction of paths is a much dicier matter ().

VII.2. Smooth and Piecewise Smooth Curves in \( \mathbb{R}^n \)

VII.3. Rectifiable Curves and Arc Length

Throughout this section, \( \rho \) will denote the Euclidean distance function on \( \mathbb{R}^d \). (We use \( d \) instead of \( n \) so that \( n \) is available as a counting parameter for partitions.)

VII.3.1. Arc Length

VII.3.1.3. Definition. Let \( \gamma : [a, b] \to \mathbb{R}^d \) be a parametrized curve, and \( \mathcal{P} = \{a = t_0, t_1, \ldots, t_n = b\} \) a partition of \([a, b]\). The polygonal approximate length of \( \gamma \) from \( \mathcal{P} \) is

\[
\ell(\gamma, \mathcal{P}) = \sum_{k=1}^{n} \rho(\gamma(t_{k-1}), \gamma(t_k)) .
\]

The arc length of \( \gamma \) is

\[
\ell(\gamma) = \sup_{\mathcal{P}} \ell(\gamma, \mathcal{P}) .
\]
VII.3.1.4. If \( Q \) is a partition of \([a, b]\) which refines \( P \), we have \( \ell(\gamma, P) \leq \ell(\gamma, Q) \) by the triangle inequality. Since any two partitions have a common refinement, the polygonal approximations approach the arc length as the partitions become arbitrarily fine. The term “polygonal approximation” should not be taken too literally: there is usually not an actual “polygon” in \( \mathbb{R}^d \) approximating the curve. The term is suggestive that \( \rho(p, q) \) should be the “straight-line” distance between \( p \) and \( q \).

The arc length of a curve can easily be infinite (e.g. VI.4.1.20.).

VII.3.1.5. Definition. The curve \( \gamma \) is rectifiable if \( \ell(\gamma) \) is finite.

VII.3.1.6. Examples. (i) A parametrized curve in \( \mathbb{R}^1 \) is a continuous function \( \gamma : [a, b] \to \mathbb{R} \). If \( P \) is a partition of \([a, b]\), then \( \ell(\gamma, P) \) is the total variation \( V(\gamma, P) \) of \( \gamma \) over \( P \) (XIV.16.1.3.), and \( \ell(\gamma) \) is the total variation \( V[a, b](\gamma) \) of \( \gamma \) over \([a, b]\) (XIV.16.1.6.). The curve \( \gamma \) is rectifiable if and only if \( \gamma \) has bounded variation. If \( \gamma \) is a smooth function, then \( \ell(\gamma) = \int_a^b |\gamma'(t)| \, dt \).

We now develop basic properties of arc length. First note that arc length is independent of parametrization:

VII.3.1.7. Proposition. Let \( \tilde{\gamma} : [c, d] \to \mathbb{R}^d \) be a reparametrization of \( \gamma : [a, b] \to \mathbb{R}^d \), i.e. \( \tilde{\gamma} = \gamma \circ \phi \), \( \phi : [c, d] \to [a, b] \). Then \( \ell(\tilde{\gamma}) = \ell(\gamma) \).

Proof: Let \( P = \{c = t_0, \ldots, t_n = d\} \) be a partition of \([c, d]\). Then \( \{a = \phi(t_0), \ldots, \phi(t_n) = b\} \) is not quite a partition of \([a, b]\) since there may be repetitions if \( \phi \) is not injective. But repeated points contribute nothing to the sum \( \ell(\tilde{\gamma}, P) \), and if \( Q \) is the partition of \([a, b]\) obtained by deleting repetitions, we have \( \ell(\gamma, Q) = \ell(\tilde{\gamma}, P) \). Every partition of \([a, b]\) arises in this manner.

VII.3.1.8. Thus arc length of paths is well defined.

Although the reversal \(-\gamma\) of a parametrized curve is not a reparametrization of \( \gamma \), we nonetheless have:

VII.3.1.9. Proposition. If \( \gamma : [a, b] \to \mathbb{R}^d \) is a parametrized curve in \( X \), then \( \ell(-\gamma) = \ell(\gamma) \).

Proof: If \( P \) is a partition of \([a, b]\), let \( \tilde{P} \) be the partition consisting of \( \{a + b - t : t \in P\} \). Then \( \tilde{P} \) is also a partition of \([a, b]\), and every partition of \([a, b]\) arises in this manner. We have \( \ell(-\gamma, \tilde{P}) = \ell(\gamma, P) \).

VII.3.1.10. If \( \gamma : [a, b] \to X \) is a parametrized curve from \( p \) to \( q \) and \( P = \{a, b\} \) is the trivial partition, we have
\[
\rho(p, q) = \ell(\gamma, P) \leq \ell(\gamma) .
\]
More generally, we have:
VII.3.1.11. PROPOSITION. Let $\gamma : [a, b] \to \mathbb{R}^d$ be a parametrized curve in $\mathbb{R}^d$, and $a \leq c \leq d \leq b$, then

$$\rho(\gamma(c), \gamma(d)) \leq \ell(\gamma|_{[c,d]}) \leq \ell(\gamma).$$

**Proof:** The first inequality has already been noted. For the second, any partition $\mathcal{P}$ of $[c, d]$ can be expanded to a partition $\mathcal{Q}$ of $[a, b]$ by adding $a$ and $b$ if necessary. We have

$$\ell(\gamma|_{[c,d]}, \mathcal{P}) \leq \ell(\gamma, \mathcal{Q}) \leq \ell(\gamma)$$

and taking the supremum over all $\mathcal{P}$ gives the inequality. $\blacksquare$

If $\gamma$ is a constant path, obviously $\ell(\gamma) = 0$. Conversely:

VII.3.1.12. COROLLARY. Let $\gamma$ be a parametrized curve in $\mathbb{R}^d$. If $\ell(\gamma) = 0$, then $\gamma$ is constant.

**Proof:** If $\gamma$ is not constant, there are $c, d \in [a, b]$, $c < d$, with $\gamma(c) \neq \gamma(d)$. Then $0 < \rho(\gamma(c), \gamma(d)) \leq \ell(\gamma)$. $\blacksquare$

Here is a more precise version of VII.3.1.11.: 

VII.3.1.13. PROPOSITION. Let $\gamma : [a, b] \to \mathbb{R}^d$ be a parametrized curve, and $c \in [a, b]$. Then

$$\ell(\gamma) = \ell(\gamma|_{[a,c]}) + \ell(\gamma|_{[c,b]}).$$

**Proof:** If $\mathcal{P}$ is a partition of $[a, c]$ and $\mathcal{Q}$ a partition of $[c, b]$, then $\mathcal{P} \cup \mathcal{Q}$ is a partition of $[a, b]$, and

$$\ell(\gamma, \mathcal{P} \cup \mathcal{Q}) = \ell(\gamma|_{[a,c]}, \mathcal{P}) + \ell(\gamma|_{[c,b]}, \mathcal{Q}).$$

Every partition of $[a, b]$ containing $c$ (i.e. every sufficiently fine partition) arises in this manner. $\blacksquare$

Iterating, we get:

VII.3.1.14. COROLLARY. Let $\gamma : [a, b] \to \mathbb{R}^d$ be a parametrized curve, and $\mathcal{P} = \{a = x_0, \ldots, x_n = b\}$ a partition of $[a, b]$. Then

$$\ell(\gamma) = \sum_{k=1}^{n} \ell(\gamma|_{[x_{k-1},x_k]}).$$

Rephrasing VII.3.1.13., we get:
VII.3.1.15. **Proposition.** Let \( \gamma_1 : [a, b] \to \mathbb{R}^d \) and \( \gamma_2 : [b, c] \to \mathbb{R}^d \) with \( \gamma_1(b) = \gamma_2(b) \), so that the concatenation \( \gamma_1 + \gamma_2 \) is defined. Then

\[
\ell(\gamma_1 + \gamma_2) = \ell(\gamma_1) + \ell(\gamma_2).
\]

This can also be iterated to apply to arbitrary finite concatenations.

A crucial property of arc length is lower semicontinuity:

VII.3.1.16. **Proposition.** For each \( n \), let \( \gamma_n : [a, b] \to \mathbb{R}^d \) be a parametrized curve from \( p_n \) to \( q_n \). Suppose \( \gamma_n \) converges pointwise to a parametrized curve \( \gamma : [a, b] \to X \) from \( p \) to \( q \), i.e. \( \gamma_n(t) \to \gamma(t) \) for each \( t \in [a, b] \) (so \( p_n \to p \), \( q_n \to q \)). Then

\[
\ell(\gamma) \leq \liminf_{n \to \infty} \ell(\gamma_n).
\]

We can have strict inequality, even if \( \gamma_n \to \gamma \) uniformly on \( [a, b] \) (I.5.1.11.).

**Proof:** First note that if \( \mathcal{P} = \{a = t_0, \ldots, t_m = b\} \) is any partition of \( [a, b] \), we have

\[
\ell(\gamma_n, \mathcal{P}) = \sum_{k=1}^{m} \rho(\gamma_n(t_{k-1}), \gamma_n(t_k)) \to \sum_{k=1}^{m} \rho(\gamma(t_{k-1}), \gamma(t_k)) = \ell(\gamma, \mathcal{P})
\]

by continuity of \( \rho \).

Suppose \( \ell(\gamma) = +\infty \). Fix \( M > 0 \). Then there is a partition \( \mathcal{P} \) of \( [a, b] \) with \( \ell(\gamma, \mathcal{P}) > M \). Then

\[
M < \ell(\gamma, \mathcal{P}) = \lim_{n \to \infty} \ell(\gamma_n, \mathcal{P}) \leq \liminf_{n \to \infty} \ell(\gamma_n).
\]

This holds for all \( M > 0 \), so \( \liminf_{n \to \infty} \ell(\gamma_n) = +\infty \) and the inequality holds.

Now suppose \( \gamma \) is rectifiable. Let \( \epsilon > 0 \). Then there is a partition \( \mathcal{P} \) of \( [a, b] \) with \( \ell(\gamma, \mathcal{P}) > \ell(\gamma) - \epsilon \). Then

\[
\ell(\gamma) - \epsilon \leq \ell(\gamma, \mathcal{P}) = \lim_{n \to \infty} \ell(\gamma_n, \mathcal{P}) \leq \liminf_{n \to \infty} \ell(\gamma_n).
\]

This holds for all \( \epsilon > 0 \), so \( \ell(\gamma) \leq \liminf_{n \to \infty} \ell(\gamma_n) \). 

VII.3.1.17. Note for future reference that the definitions of \( \ell(\gamma, \mathcal{P}) \) and \( \ell(\gamma) \) make perfect sense for a general function \( \gamma : [a, b] \to \mathbb{R}^d \), not necessarily continuous, so “arc length” is defined even for discontinuous functions (although it is typically infinite for very discontinuous functions). None of the proofs of VII.3.1.7.–VII.3.1.16. use that \( \gamma \) is continuous, so these properties hold also for discontinuous \( \gamma \). (But VII.3.2.2. requires continuity of \( \gamma \).)
VII.3.2. Rectifiable Curves

Continuity of Arc Length

VII.3.2.1. Let \( \gamma : [a, b] \to \mathbb{R}^d \) be a rectifiable parametrized curve. Define a function \( \phi : [a, b] \to [0, \ell(\gamma)] \) by setting

\[
\phi(t) = \ell(\gamma|_{[a,t]}) .
\]

Then \( \phi \) is nondecreasing, \( \phi(a) = 0 \), \( \phi(b) = \ell(\gamma) \). If \( \gamma \) is nonstationary, \( \phi \) is strictly increasing.

VII.3.2.2. Proposition. The function \( \phi \) is continuous.

Proof: The following lemma will provide left continuity on \([a, b]\). The simplest way to get right continuity is to apply the lemma also to \( \gamma(t_0) \) and use that \( \ell(\gamma|_{[a,t_0]}) = \ell(\gamma|_{[a,t_0]}) \).

VII.3.2.3. Lemma. Let \( \gamma : [a, b] \to \mathbb{R}^d \) be a parametrized curve, not necessarily rectifiable. If \( (t_n) \) is an increasing sequence in \([a, b]\) converging to \( t_0 \), then

\[
\ell(\gamma|_{[a,t_0]}) = \lim_{n \to \infty} \ell(\gamma|_{[a,t_n]}) = \sup_n \ell(\gamma|_{[a,t_n]}) .
\]

Proof: Define a sequence \( (\gamma_n) \) of parametrized curves on \([a, t_0]\) by setting \( \gamma_n(t) = \gamma(t) \) if \( a \leq t \leq t_n \) and \( \gamma_n(t) = \gamma(t_n) \) if \( t_n \leq t \leq t_0 \) (i.e. \( \gamma_n \) agrees with \( \gamma \) on \([a, t_n]\) and is stationary on \([t_n, t_0]\)). We have

\[
\ell(\gamma_n) = \ell(\gamma|_{[a,t_n]}) \leq \ell(\gamma|_{[a,t_0]})
\]

for any \( n \) by monotonicity (VII.3.1.11.). On the other hand, since \( \gamma \) is continuous at \( t_0 \), \( \gamma_n \to \gamma \) pointwise on \([a, t_0]\). So applying VII.3.1.16. we get

\[
\sup_n \ell(\gamma|_{[a,t_n]}) \leq \ell(\gamma|_{[a,t_0]}) \leq \lim_{n \to \infty} \inf \ell(\gamma_n) = \lim_{n \to \infty} \inf \ell(\gamma|_{[a,t_n]})
\]

and the result follows.

VII.3.2.4. Corollary. Let \( \gamma : [a, b] \to \mathbb{R}^d \) be a rectifiable curve. Then for any \( \epsilon > 0 \) there is a \( \delta > 0 \) such that, whenever \( a \leq c < d \leq b \) and \( d - c < \delta \), then \( \ell(\gamma|_{[c,d]}) < \epsilon \).

Proof: The function \( \phi \) is uniformly continuous on \([a, b]\).

Estimation of Arc Length

The next result is strongly reminiscent of the equivalence of Definitions 1A and 1B of the Riemann integral (XIV.2.3.1.), and proved in a similar way.
THEOREM. Let \( \gamma : [a, b] \to \mathbb{R}^d \) be a rectifiable curve. Then for any \( \epsilon > 0 \) there is a \( \delta > 0 \) such that \( \ell(\gamma, P) > \ell(\gamma) - \epsilon \) for any partition \( P \) of \([a, b] \) with \( \|P\| < \delta \).

PROOF: Let \( Q = \{a = t_0, \ldots, t_n = b\} \) be a partition of \([a, b] \) with \( \ell(\gamma, Q) > \ell(\gamma) - \frac{\epsilon}{2} \). Since \( \gamma \) is uniformly continuous (), there is a \( \delta > 0 \) such that if \( a \leq c < d \leq b \) and \( d - c < \delta \), \( \rho(\gamma(c), \gamma(d)) < \frac{\epsilon}{3n} \). We may assume \( 3\delta < \|Q\| \).

Let \( P = \{a = s_0, \ldots, s_m = b\} \) be a partition of \([a, b] \) with \( \|P\| < \delta \). For \( 1 \leq k \leq n - 1 \) let \( j_k \) be the largest \( j \) such that \( s_j \leq t_k \). We then have

\[
\ell(\gamma, P) = \sum_{j=1}^{m} \rho(\gamma(s_{j-1}), \gamma(s_j))
\]

\[
= \sum_{j=1}^{j_1} \rho(\gamma(s_{j-1}), \gamma(s_j)) + \sum_{k=1}^{n-2} \sum_{j=j_k+2}^{j_{k+1}} \rho(\gamma(s_{j-1}), \gamma(s_j)) + \sum_{j=n-1+2}^{m} \rho(\gamma(s_{j-1}), \gamma(s_j)) + \sum_{k=1}^{m-1} \rho(\gamma(s_{j_k}), \gamma(s_{j_k+1})).
\]

By the triangle inequality, we have

\[
\sum_{j=1}^{j_1} \rho(\gamma(s_{j-1}), \gamma(s_j)) \geq \rho(\gamma(a), \gamma(t_1)) - \rho(\gamma(s_{j_1}), \gamma(t_1)) > \rho(\gamma(a), \gamma(t_1)) - \frac{\epsilon}{4n}.
\]

Similarly, for \( 1 \leq k \leq n - 2 \), we have

\[
\sum_{j=j_k+2}^{j_{k+1}} \rho(\gamma(s_{j-1}), \gamma(s_j)) \geq \rho(\gamma(t_k), \gamma(t_{k+1})) - \rho(\gamma(s_{j_{k+1}}), \gamma(t_{k+1})) > \rho(\gamma(t_k), \gamma(t_{k+1})) - \frac{\epsilon}{2n}
\]

\[
\sum_{j=n-1+2}^{m} \rho(\gamma(s_{j-1}), \gamma(s_j)) > \rho(\gamma(t_{n-1}), \gamma(b)) - \frac{\epsilon}{4n}.
\]

Thus we have

\[
\ell(\gamma, P) = \sum_{j=1}^{m} \rho(\gamma(s_{j-1}), \gamma(s_j)) \geq \sum_{j=1}^{j_1} \rho(\gamma(s_{j-1}), \gamma(s_j)) + \sum_{k=1}^{n-2} \sum_{j=j_k+2}^{j_{k+1}} \rho(\gamma(s_{j-1}), \gamma(s_j)) + \sum_{j=n-1+2}^{m} \rho(\gamma(s_{j-1}), \gamma(s_j)) \geq \sum_{k=1}^{n} \rho(\gamma(t_{k-1}), \gamma(t_k)) - (n-2) \frac{\epsilon}{2n} - 2 \frac{\epsilon}{4n} = \ell(\gamma, Q) - \frac{\epsilon}{2} > \ell(\gamma) - \epsilon.
\]

\( \square \)
Parametrization by Arc Length

VII.3.2.6. Let $\gamma : [a, b] \to \mathbb{R}^d$ be a nonstationary rectifiable parametrized curve, and let $\phi$ be the above function. Then $\phi$ is strictly increasing and continuous, so has a continuous strictly increasing inverse function $\phi^{-1} : [0, \ell(\gamma)] \to [a, b]$. Set $\tilde{\gamma} = \gamma \circ \phi^{-1} : [0, \ell(\gamma)] \to X$. Then $\tilde{\gamma}$ is a strict reparametrization of $\gamma$ with the property that $\ell(\tilde{\gamma}|_{[0, t]}) = t$ for $0 \leq t \leq \ell(\gamma)$, i.e. $\tilde{\gamma}$ “traverses the path $\langle \gamma \rangle$ at uniform unit speed.” The parametrized curve $\tilde{\gamma}$ is called the reparametrization of $\gamma$ by arc length. If $\gamma$ is replaced by any strict reparametrization, the $\tilde{\gamma}$ is unchanged; thus it depends only on $\langle \gamma \rangle$, i.e. any rectifiable path has a unique canonical parametrization by arc length.

Differentiability of Rectifiable Curves

A rectifiable curve has “bounded variation” and hence should be differentiable almost everywhere, and in fact is:

VII.3.2.7. Theorem. Let $\gamma : [a, b] \to \mathbb{R}^n$ be a rectifiable curve. Then $\gamma$ is differentiable a.e.

Proof: Let $\gamma_1, \ldots, \gamma_n$ be the coordinate functions of $\gamma$. Then each $\gamma_k$ has bounded variation $V_{[a, b]}(\gamma_k) \leq \ell(\gamma)$ (VII.3.4.1.(a)). Thus $\gamma_k$ is differentiable on $[a, b]$ except on a set $A_k$ of measure 0 (XIV.16.2.4.). So $\gamma$ is differentiable on $[a, b]$ except on $A_1 \cup \cdots \cup A_n$, a set of measure 0.

A rectifiable curve can fail to be differentiable at a dense set of points, however. If $\gamma$ is rectifiable, one might expect that its arc length can be computed by integration of the length of the derivative. However, this fails in general since $\gamma$ is not necessarily absolutely continuous. For an extreme example, if $\gamma$ is parametrized on $[0, 1]$ and $g$ is the Cantor function, then $\gamma \circ g$ is a reparametrization of $\gamma$, and $(\gamma \circ g)' = 0$ a.e. But if $\gamma$ is parametrized by an absolutely continuous function, it is true. This result is surprisingly hard to prove and find in books perhaps because it falls through the crack between real analysis and differential geometry. Our proof is adapted from [Pel77], where a more general result is proved.

VII.3.2.9. Theorem. Let $\gamma : [a, b] \to \mathbb{R}^n$ be a (necessarily rectifiable) curve, with absolutely continuous coordinate functions. Then $\gamma$ is differentiable a.e., and

$$\ell(\gamma) = \int_a^b ||\gamma'(t)|| \, d\lambda(t)$$

(where the integral is a Lebesgue integral). The length function $\phi(x) = \ell(\gamma|_{[a,x]})$ is absolutely continuous, hence differentiable a.e., and $\phi'(t) = ||\gamma'(t)||$ a.e.

The proof will mostly consist of three lemmas. The first is of independent interest, that a rectifiable curve can be “unwound” to a curve with nondecreasing coordinate functions without changing the arc length or length of the derivative (a.e.):
VII.3.2.10. **Lemma.** Let $\gamma : [a, b] \to \mathbb{R}^n$ be a rectifiable curve with coordinate functions $\gamma_1, \ldots, \gamma_n$ of bounded variation. For $1 \leq k \leq n$ let $v_k = T_{\gamma_k}$ be the total variation function (XIV.16.2.1.) of $\gamma_k$ on $[a, b]$, i.e. $v_k(t) = V_{[a,t]}(\gamma_1)$ (the $v_k$ are continuous by XIV.16.2.6.). Let $\tilde{\gamma} : [a, b] \to \mathbb{R}^n$ have coordinate functions $v_1, \ldots, v_n$. Then $\ell(\tilde{\gamma}) = \ell(\gamma)$.

**Proof:** We have, for any $k$ and any $s, t \in [a, b]$,

$$|\gamma_k(t) - \gamma_k(s)| \leq |v_k(t) - v_k(s)|$$

and it follows that for any partition $P$ of $[a, b]$, $\ell(\gamma, P) \leq \ell(\tilde{\gamma}, P)$. Taking the supremum over all $P$, we obtain $\ell(\gamma) \leq \ell(\tilde{\gamma})$.

For the opposite inequality, suppose $a \leq c < d \leq b$ and $P = \{c = t_0, \ldots, t_m = d\}$ is a partition of $[c, d]$. Using the triangle inequality in $\mathbb{R}^n$ we obtain

$$\ell(\gamma|_{[c,d]}, P) = \sum_{j=1}^{m} \left( \sum_{k=1}^{n} (\gamma_k(t_j) - \gamma_k(t_{j-1})) \right)^2 \geq \sum_{k=1}^{n} \left( \sum_{j=1}^{m} |\gamma_k(t_j) - \gamma_k(t_{j-1})| \right)^2 = \sum_{k=1}^{n} [V(\gamma_k, P)]^2.$$ 

Taking the supremum over all $P$ we obtain

$$\ell(\gamma|_{[c,d]}) \geq \sqrt{\sum_{k=1}^{n} [V_{[c,d]}(\gamma_k)]^2} = \sqrt{\sum_{k=1}^{n} (v_k(d) - v_k(c))^2}.$$ 

If $Q = \{a = s_0, \ldots, s_r = b\}$ is any partition of $[a, b]$, applying this inequality over each subinterval $[s_{j-1}, s_j]$, we obtain

$$\ell(\gamma) = \sum_{j=1}^{r} \ell(\gamma|_{[s_{j-1}, s_j]}) \geq \sum_{j=1}^{r} \sqrt{\sum_{k=1}^{n} (v_k(s_j) - v_k(s_{j-1}))^2} = \ell(\tilde{\gamma}, Q)$$

and it follows by taking the supremum over all $Q$ that $\ell(\gamma) \geq \ell(\tilde{\gamma})$.

VII.3.2.11. If $\gamma_1, \ldots, \gamma_n$ are absolutely continuous, so are $v_1, \ldots, v_n$, and $v'_k = |\gamma'_k|$ a.e. for each $k$, so $\|\gamma'\| = \|\gamma'_k\|$ a.e. Thus to prove VII.3.2.9. we may work with $\tilde{\gamma}$, i.e. we may assume that $\gamma'_k \geq 0$ a.e. for each $k$.

The other two lemmas are very general:
VII.3.2.12. Lemma. Let \((X, \mathcal{A}, \mu)\) be a measure space and \(f_1, \ldots, f_n\) nonnegative measurable functions. Then, for any \(A \in \mathcal{A},\)
\[
\sqrt{\sum_{k=1}^{n} \left[ \int_A f_k \, d\mu \right]^2} \leq \int_A \sqrt{\sum_{k=1}^{n} f_k^2} \, d\mu .
\]

Proof: This is a good example of bootstrapping. First suppose the \(f_k\) are simple functions, and are all constant on sets \(E_1, \ldots, E_m,\) with \(f_k\) taking value \(\alpha_{k,j}\) on \(E_j.\) Then by the triangle inequality on \(\mathbb{R}^n,\)
\[
\sqrt{\sum_{k=1}^{n} \left[ \int_A f_k \, d\mu \right]^2} = \sqrt{\sum_{k=1}^{n} \left[ \sum_{j=1}^{m} \int_{A \cap E_j} f_k \, d\mu \right]^2} = \sqrt{\sum_{k=1}^{n} \left[ \sum_{j=1}^{m} \alpha_{k,j} \mu(A \cap E_j) \right]^2}
\]
\[
\leq \sum_{j=1}^{m} \sqrt{\sum_{k=1}^{n} \alpha_{k,j} (A \cap E_j)^2} = \sum_{j=1}^{m} \left[ \sum_{k=1}^{n} \alpha_{k,j}^2 \mu(A \cap E_j) \right] = \sum_{j=1}^{m} \left[ \int_{A \cap E_j} \sqrt{\sum_{k=1}^{n} f_k^2} \, d\mu \right] = \int_A \sqrt{\sum_{k=1}^{n} f_k^2} \, d\mu .
\]
For general \(f_k,\) take increasing sequences of nonnegative simple functions and apply the Monotone Convergence Theorem. \(\boxdot\)

VII.3.2.13. Lemma. Let \((X, \mathcal{A}, \mu)\) be a measure space, and \(f, f_1, \ldots, f_n\) nonnegative measurable functions on \(X.\) If
\[
\left[ \int_A f \, d\mu \right]^2 \geq \sum_{k=1}^{n} \left[ \int_A f_k \, d\mu \right]^2
\]
for all \(A \in \mathcal{A},\) then \(f \geq \sqrt{\sum_{k=1}^{n} f_k^2}\) a.e.

Proof: Suppose \(f_1, \ldots, f_n\) are simple and all constant on \(E_1, \ldots, E_m,\) and \(f_k\) takes the constant value \(\alpha_{k,j}\) on \(E_j.\) If \(A \subseteq E_j,\) then
\[
\int_A f \, d\mu \geq \sqrt{\sum_{k=1}^{n} \left[ \int_A f_k \, d\mu \right]^2} = \sqrt{\sum_{k=1}^{n} \left[ \sum_{j=1}^{m} \alpha_{k,j} \mu(A \cap E_j) \right]^2} = \mu(A) \sqrt{\sum_{k=1}^{n} \alpha_{k,j}^2}.
\]
This is true for all \(A \subseteq E_j,\) which implies that
\[
f \geq \sqrt{\sum_{k=1}^{n} \alpha_{k,j}^2} = \sqrt{\sum_{k=1}^{n} f_k^2}
\]
a.e. on \(E_j.\) Since \(\cup_{j=1}^{m} E_j = X,\) we have \(f \geq \sqrt{\sum_{k=1}^{n} f_k^2}\) a.e. on \(X.\)

For general \(f_k,\) take increasing sequences of nonnegative simple functions converging to the \(f_k.\) \(\boxdot\)
VII.3.2.14. We now give the proof of Theorem VII.3.2.9.

Proof: We may assume $\gamma_k'$ is nonnegative for all $k$ (VII.3.2.11.). If $\mathcal{P} = \{a = t_0, \ldots, t_m = b\}$ is a partition of $[a, b]$, we have

$$
\ell(\gamma, \mathcal{P}) = \sum_{j=1}^{m} \|\gamma(t_j) - \gamma(t_{j-1})\| = \sum_{j=1}^{m} \sqrt{\sum_{k=1}^{n} \left[ \int_{t_{j-1}}^{t_j} \gamma_k' \, d\lambda \right]^2}
$$

$$
\leq \sum_{j=1}^{m} \left[ \int_{t_{j-1}}^{t_j} \sqrt{\sum_{k=1}^{n} (\gamma_k')^2} \, d\lambda \right] = \sum_{j=1}^{m} \left[ \int_{t_{j-1}}^{t_j} \|\gamma'\| \, d\lambda \right] = \int_{a}^{b} \|\gamma'\| \, d\lambda
$$

by Lemma VII.3.2.12. Taking the supremum over all $\mathcal{P}$, we obtain

$$
\ell(\gamma) \leq \int_{a}^{b} \|\gamma'\| \, d\lambda.
$$

For the reverse inequality, note that, if $\phi(t) = \ell(\gamma|_{[a, t]})$ for $a \leq t \leq b$, then $\phi$ is absolutely continuous (VII.3.4.1.(b)). If $a \leq c < d \leq b$, we have

$$
\left[ \int_{c}^{d} \phi' \, d\lambda \right]^2 = [\phi(d) - \phi(c)]^2 = [\ell(\gamma|_{[c, d]})]^2
$$

$$
\geq \|\gamma(d) - \gamma(c)\|^2 = \sum_{k=1}^{n} \left[ \int_{c}^{d} \gamma_k' \, d\lambda \right]^2
$$

and thus $(\cdot)$, for every measurable $A$, we have

$$
\left[ \int_{A} \phi' \, d\lambda \right]^2 \geq \sum_{k=1}^{n} \left[ \int_{A} \gamma_k' \, d\lambda \right]^2.
$$

So by Lemma VII.3.2.13, we have

$$
\phi' \geq \sqrt{\sum_{k=1}^{n} (\gamma_k')^2} = \|\gamma'\| \text{ a.e.}
$$

and hence

$$
\ell(\gamma) = \int_{a}^{b} \phi' \, d\lambda \geq \int_{a}^{b} \|\gamma'\| \, d\lambda.
$$

We have, for each $x \in [a, b]$,

$$
\phi(x) = \int_{a}^{x} \phi' \, d\lambda = \int_{a}^{x} \|\gamma'\| \, d\lambda
$$

so if $f = \phi' - \|\gamma'\|$, then $f$ is an integrable function on $[a, b]$ and $\int_{a}^{x} f \, d\lambda = 0$ for all $x \in [a, b]$, so $f = 0$ a.e. (XIV.4.8.12.).

The following special case of VII.3.2.9. is especially noteworthy. The result is probably not surprising, but it is definitely nontrivial (cf. VII.3.2.16.). See $(\cdot)$ for a direct proof valid in general metric spaces.
VII.3.2.15. **Corollary.** Let \( \gamma : [0, b] \to \mathbb{R}^n \) be a rectifiable curve, parametrized by arc length. Then \( \gamma \) is absolutely continuous and hence is differentiable a.e., and \( \|\gamma'(t)\| = 1 \) for almost all \( t \).

**Proof:** Since \( \gamma \) is parametrized by arc length, it is a Lipschitz function with constant 1, so the coordinate functions are absolutely continuous and VII.3.2.9. applies; and \( \phi' \) is the constant function 1.

VII.3.2.16. **Example.** One might naïvely think that if \( \gamma \) is a rectifiable curve, parametrized by arc length, then \( \|\gamma'(t)\| = 1 \) whenever it is defined. But this is false. Here is an example, adapted from ().

Let \( c \) be the curve in \( \mathbb{R}^2 \) consisting of semicircular arcs between \( \frac{1}{n} \) and \( \frac{1}{n+1} \) for each \( n \in \mathbb{N} \), alternating above and below the \( x \)-axis to make the curve differentiable on \((0, 1)\), reflected on the interval \([1, 0)\), along with the origin. See Figure (). Then \( \gamma \) is the graph of a function on \([\frac{1}{n}, \frac{1}{n+1}]\). Parametrize \( c \) by arc length, starting at \((\frac{1}{n}, 0)\). Then \( \ell(t) = \frac{1}{n+1} \leq t \leq \frac{1}{n} \) for almost all \( t \), and thus

\[
\frac{2}{\pi} \cdot \frac{n}{n+1} = \frac{1}{\frac{n+1}{\pi}} \leq \frac{\gamma_1(t) - \gamma_1(\frac{\pi}{2})}{t - \frac{\pi}{2}} \leq \frac{1}{\frac{n}{\pi}} \leq \frac{2}{\pi} \cdot \frac{n+1}{n}
\]

and so by the squeeze theorem

\[
\lim_{t \to \frac{\pi}{2}} \frac{\gamma_1(t) - \gamma_1(\frac{\pi}{2})}{t - \frac{\pi}{2}} = \frac{2}{\pi}
\]

exists and equals \( \frac{2}{\pi} \). The limit from the left similarly equals \( \frac{2}{\pi} \). So \( \gamma_1(\frac{\pi}{2}) \) exists and equals \( \frac{2}{\pi} \).

Thus \( \gamma \) is differentiable at \( \frac{\pi}{2} \) and \( \gamma'(\frac{\pi}{2}) = (\frac{2}{\pi}, 0) \), so

\[
\left\|\gamma'(\frac{\pi}{2})\right\| = \frac{2}{\pi} < 1
\]

Replacing the semicircles by curves \( c_n \) of arc length \( \frac{2}{\sqrt{n}} \) lying in the square

\[
\left[\frac{1}{n+1}, 1\right] \times \left[\frac{1}{n^2}, \frac{1}{n^2}\right]
\]

(and similarly on the left) we can get a similar example where \( \gamma' = 0 \) at the origin. Much more pathological examples, where \( \|\gamma'(t)\| < 1 \) for many \( t \), can be constructed similarly.

VII.3.3. **Length of Arcs**

If \( C \) is a “curve” in \( \mathbb{R}^n \), we would like to be able to say what the intrinsic “arc length” of \( C \) is. This is a tricky problem. The first question is what kind of subsets should be called “curves.” It is too broad to say that the range of any parametrized curve is a “curve” (). One reasonable possibility is:
VII.3.3.17. Definition. An arc in \( \mathbb{R}^n \) is a subset of \( \mathbb{R}^n \) homeomorphic to \([0, 1]\).

VII.3.3.18. A subset \( C \) of \( \mathbb{R}^n \) is an arc if and only if it is the range of an injective parametrized curve: a homeomorphism \( \gamma \) from \([0, 1]\) to \( C \) is such a parametrized curve, and conversely an injective parametrized curve \( \gamma : [a, b] \to \mathbb{R}^n \) with \( C = \gamma([a, b]) \) is a homeomorphism by \((\). An arc thus has a unique equivalence class of oriented injective parametrizations, thus two in all; the arc length of all these parametrized curves is the same and can be taken to be the arc length of \( C \).

VII.3.3.19. Slightly more generally, if \( C \) can be written as a finite union of arcs with only endpoints in common, the arc length of \( C \) can be taken to be the sum of the arc lengths of these arcs. For more complicated subsets, there are grave difficulties in defining arc length this way.

VII.3.3.20. There is a way to unambiguously define “arc length” for general (Borel) subsets of \( \mathbb{R}^n \): one-dimensional Hausdorff measure \((\). This “arc length” has the nice properties of a measure, generalizing VII.3.1.14.. Subsets whose one-dimensional Hausdorff measure is positive and finite can be regarded as “one-dimensional” (cf. \((\); such a set need not be topologically one-dimensional, and not every “one-dimensional” subset will have these properties).

VII.4. Exercises

VII.3.4.1. (a) Let \( \gamma : [a, b] \to \mathbb{R}^n \) be a parametrized curve, with coordinate functions \( \gamma_1, \ldots, \gamma_n \). Show that the total variation \((\text{XIV.16.1.6.})\) satisfies \( V_{[a, b]}(\gamma_k) \leq \ell(\gamma) \leq \sum_{j=1}^n V_{[a, b]}(\gamma_j) \) for any \( k \), and thus \( \gamma \) is rectifiable if and only if all coordinate functions of \( \gamma \) have bounded variation. [For each \( k \) and each partition \( P \) of \([a, b]\), we have \( V(\gamma_k, P) \leq \ell(\gamma, P) \leq \ell(\gamma) \).]

(b) Let \( \gamma : [a, b] \to \mathbb{R}^n \) be a rectifiable parametrized curve, and \( \phi \) the function defined in VII.3.2.2.. Show that \( \phi \) is absolutely continuous if and only if each coordinate function of \( \gamma \) is absolutely continuous. [If each \( \gamma_k \) is absolutely continuous, and \( \epsilon > 0 \), for each \( k \) choose \( \delta_k \) which works in the definition of absolute continuity for \( \gamma_k \) for \( \xi \). Show that \( \delta = \min_k (\delta_k) \) works in the definition for \( \phi \) and \( \epsilon \).]

VII.3.4.2. Prove the following result complementary to VII.3.2.5.:

Theorem. Let \( \gamma : [a, b] \to \mathbb{R}^d \) be a parametrized curve. If \( \ell(\gamma) = \infty \), then for any \( M > 0 \) there is a \( \delta > 0 \) such that \( \ell(\gamma, P) > M \) for any partition \( P \) of \([a, b]\) with \( \|P\| < \delta \).

VII.3.4.3. Carry out the details of the last construction in VII.3.2.16..
Chapter VIII

Multivariable and Vector Calculus

In this chapter, we discuss calculus for functions from one Euclidean space $\mathbb{R}^n$ (or a subset) to another Euclidean space $\mathbb{R}^m$. The terms multivariable calculus and vector calculus used are roughly synonymous, but “vector calculus” is slightly more general: “multivariable calculus” refers to the case where $n > 1$ (and $m \geq 1$), while “vector calculus” also includes the case where $n = 1$ and $m > 1$, which is exactly the case of curves in $\mathbb{R}^m$ discussed in Chapter (). (In developing the theories, we work with general $n$ and $m$, not even excluding the case $n = m = 1$.) There is also a slight difference in point of view: multivariable calculus is generally thought of as consideration of real-valued functions, or systems of real-valued functions, of several real variables, while vector calculus is thought of as being the study of functions whose input and output are vectors in Euclidean spaces, not necessarily of the same dimension. (The two points of view are complementary and both are needed to get the full picture of the subject.)

Consideration of functions from $\mathbb{R}^n$ to $\mathbb{R}^m$ has distinct and complicating features over the case $n = m = 1$ arising from having either $n > 1$ or $m > 1$ (or both). The complications caused by considering the case $m > 1$ are quite modest, however. If $f : \mathbb{R}^n \to \mathbb{R}^m$ is a function, write

$$f(x) = (f_1(x), \ldots, f_m(x))$$

where $f_1, \ldots, f_m : \mathbb{R}^n \to \mathbb{R}$ are the coordinate functions of $f$ (technically, $f_k = \pi_k^{(m)} \circ f$, where $\pi_k^{(m)} : \mathbb{R}^m \to \mathbb{R}$ is projection onto the $k$'th coordinate, i.e. $\pi_k^{(m)}(x_1, \ldots, x_m) = x_k$), then analysis of $f$ can be largely reduced to analysis of the $f_k$. There are situations where it is undesirable to reduce to the coordinate functions, though, such as in the study of curves, and in results like the Chain Rule and the Implicit and Inverse Function Theorems, where the interplay of coordinates is crucial. Roughly speaking, the multivariable calculus approach is to reduce to coordinate functions and the vector calculus approach is to avoid doing this.

The complications arising from having $n > 1$ are essential, however, and mostly cannot be handled by considering coordinates separately. Thus multivariable calculus (and vector calculus) has a quite different nature than one-variable calculus.

VIII.1. Limits and Continuity for Vector Functions

Defining limits and continuity for functions of more than one variable can be very easy or very tricky, depending whether one takes the proper point of view.
VIII.1.1. Graphs of Functions of Several Variables

VIII.1.2. Limits of Sequences in $R^n$

VIII.1.2.1. The first observation is that there is much more “room” in $R^n$, $n \geq 2$, for sequences to behave in a complicated way than in $R = R^1$. A sequence in $R$ can approach a limit only from the left or right, or more generally jump back and forth from left or right, i.e. can be decomposed into at most two subsequences which approach from the left and right respectively. But even in $R^2$, a sequence can approach a limit in a very complicated way: it can approach from any direction or along any curve, can spiral around the limit wildly, etc., and cannot generally be decomposed into subsequences which approach in a controlled way (things can be even wilder in $R^3$). Trying to make a definition which covers all the possibilities may seem like a daunting task.

VIII.1.2.2. However, there is a very simple solution. The definition of limit of a sequence in $R$ can be used almost verbatim in $R^n$ and gives exactly the right thing. The definition only needs slight redecoration to work perfectly:

VIII.1.2.3. Definition. Let $(x_k)$ be a sequence in $R^n$, and $x \in R^n$. Then $x_k \to x$, or $\lim_{k \to \infty} x_k = x$, if for every $\epsilon > 0$ there is a $K$ such that

$$
\|x_k - x\| < \epsilon
$$

for all $k \geq K$.

This is a special case of redecorating the definition in $R$ to one valid in a general metric space $(\cdot)$.

The Coordinatewise Criterion

There is one basic fact about limits in $R^n$ which will appear in various forms, which allows a reduction to the case of limits in $R$ in some cases, including sequences:

VIII.1.2.4. Proposition. [Coordinatewise Criterion for Sequences in $R^n$] Let $(x_k)$ be a sequence in $R^n$, and $x \in R^n$. Write

$$
x_k = (x_k^{(1)}, \ldots, x_k^{(n)}), \quad x = (x^{(1)}, \ldots, x^{(n)})
$$

in coordinates. Then $x_k \to x$ in $R^n$ if and only if $x_k^{(j)} \to x^{(j)}$ in $R$ for each $j$, $1 \leq j \leq n$.

Proof: Note that for each $m$ we have

$$
|x_k^{(m)} - x^{(m)}| \leq \|x_k - x\| \leq \sum_{j=1}^{n} |x_k^{(j)} - x^{(j)}|.
$$

Suppose $x_k \to x$, and fix $j$. Let $\epsilon > 0$. There is a $K$ such that

$$
|x_k^{(j)} - x^{(j)}| \leq \|x_k - x\| < \epsilon
$$
for all $k \geq K$; thus $x_k^{(j)} \to x^{(j)}$. Conversely, suppose $x_k^{(j)} \to x^{(j)}$ for all $j$. Let $\epsilon > 0$. For each $j$ choose $K_j$ such that

$$|x_k^{(j)} - x^{(j)}| < \frac{\epsilon}{n}$$

for all $k \geq K_j$. Set $K = \max(K_1, \ldots, K_n)$. Then, if $k \geq K$,

$$|x_k - x| \leq \sum_{j=1}^{n} |x_k^{(j)} - x^{(j)}| < n \cdot \frac{\epsilon}{n} = \epsilon.$$

Since $\epsilon > 0$ is arbitrary, $x_k \to x$. 

VIII.1.3. Multivariable Limits

We now look at limits for functions from $\mathbb{R}^n$ to $\mathbb{R}^m$. We first consider the case $m = 1$.

Limits for Real-valued Functions of Several Variables

VIII.1.3.1. Suppose $f$ is a real-valued function defined on a deleted neighborhood $U$ of $a \in \mathbb{R}^n$. We want to say what $\lim_{x \to a} f(x)$ means. We first consider some examples with $n = 2$, where we change notation slightly by writing $(x,y)$ for $x$.

VIII.1.3.2. Examples. (i) Let

$$f(x,y) = \frac{xy}{x^2 + y^2}$$

for $(x,y) \neq (0,0)$. Then $f$ is defined in a deleted neighborhood of $(0,0)$ in $\mathbb{R}^2$. What should $\lim_{(x,y) \to (0,0)} f(x,y)$ be?

If $(0,0)$ is approached along either the $x$- or $y$-axis, the function is identically 0, so the limit could only reasonably be 0. On the other hand, $f(t,t) = \frac{1}{2}$ for all $t \neq 0$, so if we approach the origin along the line $x = y$ the function value approaches $\frac{1}{2}$. Since the limit should be unique and we approach different values from different directions, we should say the limit does not exist.

Geometrically, the graph is so wrinkled near the origin that no point can be added there to make the graph a reasonable unbroken surface (Figure VIII.1).
Figure VIII.1: Maple plot of $f(x, y) = \frac{xy}{x^2 + y^2}$
(ii) Here is a more striking version of the same phenomenon: Let

\[ f(x, y) = \frac{x^2y}{x^4 + y^2} \]

for \((x, y) \neq (0, 0)\). Then \(f\) is defined in a deleted neighborhood of \((0, 0)\) in \(\mathbb{R}^2\). What should \(\lim_{(x,y) \to (0,0)} f(x, y)\) be?

Again, if \((0, 0)\) is approached along either the \(x\)- or \(y\)-axis, the function is identically 0, so the limit could only reasonably be 0. And if we approach along the line \(y = mx\), we have

\[
\lim_{t \to 0} f(t, mt) = \lim_{t \to 0} \frac{mt^3}{t^4 + m^2t^2} = 0
\]

thus the function approaches 0 as \((0, 0)\) is approached radially from any direction. Does this mean that we should say the limit is 0?

Suppose we approach along the parabola \(y = x^2\). We then have

\[
\lim_{t \to 0} f(t, t^2) = \lim_{t \to 0} \frac{t^4}{2t^4} = \frac{1}{2}
\]

so the limit cannot exist. This time the crinkle in the graph is curved (Figure VIII.2).
Figure VIII.2: Maple plot of $f(x, y) = \frac{x^2 y}{x^3 + y^2}$
VIII.2. Partial and Directional Derivatives

If \( f \) is a function of several variables, one simple way to partially analyze the behavior of \( f \) is to hold all but one of the variables fixed, so that \( f \) becomes simply a function of the one remaining variable. This leads to the notion of partial derivative. Partial derivatives turn out to give considerably more information about the function than might be at first expected, at least in good cases. The notion can then be generalized to directional derivatives in any direction.

VIII.2.1. Partial Derivatives

**VIII.2.1.1. Definition.** Let \( U \) be an open set in \( \mathbb{R}^n \), and \( f : U \to \mathbb{R}^m \) a function. Let \( \mathbf{a} = (a_1, \ldots, a_n) \in U \). For \( 1 \leq k \leq n \), we define the partial derivative

\[
\frac{\partial f}{\partial x_k}(\mathbf{a}) = \lim_{h \to 0} \frac{f(a_1, \ldots, a_{k-1}, a_k + h, a_{k+1}, \ldots, a_n) - f(a_1, \ldots, a_n)}{h}
\]

where

\[
\frac{1}{h} \left[ f(a_1, \ldots, a_{k-1}, a_k + h, a_{k+1}, \ldots, a_n) - f(a_1, \ldots, a_n) \right]
\]

if the limit exists.

In other words, \( \frac{\partial f}{\partial x_k} \) is the derivative of \( f \) when it is thought of as only a function of \( x_k \) by holding the other variables fixed: if \( g(x) = f(a_1, \ldots, a_{k-1}, x, a_{k+1}, \ldots, a_n) \)

then

\[
\frac{\partial f}{\partial x_k}(\mathbf{a}) = g'(a_k)
\]

**VIII.2.1.2.** If \( \frac{\partial f}{\partial x_k}(\mathbf{a}) \) exists, it is a vector in \( \mathbb{R}^m \). Partial derivatives are most commonly discussed in the case \( m = 1 \), in which case \( \frac{\partial f}{\partial x_k}(\mathbf{a}) \in \mathbb{R} \). The relation with the general case is that if \( (f_1, \ldots, f_m) \) are the coordinate functions of \( f \), then \( \frac{\partial f}{\partial x_k}(\mathbf{a}) \) exists if and only if \( \frac{\partial f_j}{\partial x_k}(\mathbf{a}) \) exists for all \( 1 \leq j \leq m \), in which case

\[
\frac{\partial f}{\partial x_k}(\mathbf{a}) = \left( \frac{\partial f_1}{\partial x_k}(\mathbf{a}), \ldots, \frac{\partial f_m}{\partial x_k}(\mathbf{a}) \right)
\]

**VIII.2.1.3.** The partial derivative symbol \( \partial \) appears to be an italic Cyrillic \( d \). However, the origin of the notation is somewhat obscure. Alternate notations are sometimes used, especially if the variables are denoted \( x, y, z, \ldots \): if \( f \) is a function of, say, \( x, y \), and \( z \), \( \frac{\partial f}{\partial x} \) is sometimes denoted \( f_x \) or \( f_1 \), \( \frac{\partial f}{\partial y} \) is denoted \( f_y \) or \( f_2 \), etc. We will mostly stick to the \( \frac{\partial}{\partial x} \), etc., notation, except in (\).

**VIII.2.1.4.** It is easy to get caught in confusing or ambiguous notation concerning partial derivatives if one is not careful, and many references use sloppy notation in places. For example, suppose \( u = f(x, y, z) \) and \( z = g(x, y) \); then what does \( \frac{\partial u}{\partial x} \) mean? As a variation, if \( u = f(x, y) \) and \( y = g(x) \), then one can make sense of both \( \frac{\partial u}{\partial x} \) and \( \frac{du}{dx} \). To avoid such nasty ambiguities, we will sometimes seem to be overly pedantic in our notation.
VIII.2.1.5. Like ordinary derivatives, partial derivatives are defined pointwise for each fixed \( a \in U \). However, after the fact each partial derivative \( \frac{\partial f}{\partial x_k} \) may be thought of as a function from \( U \), or the subset on which it is defined, to \( \mathbb{R}^m \).

VIII.2.1.6. When a function \( f \) of two or more variables is defined by a formula, partial derivatives can be calculated by the usual rules of differentiation, treating the remaining variables as constants. For example, if
\[
f(x, y, z) = x^2y^3 + \frac{\cos yz}{z^2 + 1} - e^{xyz}
\]
we have
\[
\frac{\partial f}{\partial x}(x, y, z) = 2xy^3 - yze^{xyz}
\]
\[
\frac{\partial f}{\partial y}(x, y, z) = 3x^2y^2 - \frac{z \sin yz}{z^2 + 1} - xze^{xyz}
\]
\[
\frac{\partial f}{\partial z}(x, y, z) = \left( z^2 + 1 \right) \left( -y \sin yz - (\cos yz)(2z) \right) - yze^{xyz}.
\]

Showing that such calculations are valid takes a little (easy) work, though, a point overlooked in many references; see Exercise VIII.2.4.1.

Higher-Order Partials

VIII.2.1.7. If \( f : U \to \mathbb{R}^m \) is a function, and the partial derivatives \( \frac{\partial f}{\partial x_k} \) are defined on \( U \), then partial derivatives of these partial derivatives are also (potentially) defined. For example, if \( \frac{\partial f}{\partial x_k} \) is defined in a neighborhood of \( a \in U \), then for \( 1 \leq j \leq n \) we can define
\[
\frac{\partial^2 f}{\partial x_j \partial x_k}(a) = \lim_{h \to 0} \frac{\frac{\partial f}{\partial x_k}(a_1, \ldots, a_{j-1}, a_j + h, a_{j+1}, \ldots, a_n) - \frac{\partial f}{\partial x_k}(a_1, \ldots, a_n)}{h}
\]
if the limit exists.

Note the order of differentiation: \( \frac{\partial^2 f}{\partial x_j \partial x_k}(a) \) and \( \frac{\partial^2 f}{\partial x_k \partial x_j}(a) \) have different definitions if \( j \neq k \). It turns out (VIII.2.2.2.) that under mild continuity hypotheses these two partial derivatives are numerically equal.

VIII.2.1.8. We may keep going, defining third-order partial derivatives \( \frac{\partial^3 f}{\partial x_i \partial x_j \partial x_k} \), etc. The \( i, j, k \) need not be distinct.

VIII.2.1.9. In the definition, we may have \( j = k \) or \( j \neq k \). Thus, if \( f \) is a function \( f(x, y) \) of two variables, there are four second-order partials: \( \frac{\partial^2 f}{\partial x^2} \) (usually denoted \( \frac{\partial^2 f}{\partial x^2} \)), \( \frac{\partial^2 f}{\partial x \partial y} \), \( \frac{\partial^2 f}{\partial y \partial x} \), and \( \frac{\partial^2 f}{\partial y^2} \). The middle two, called mixed partials, are often but not always equal. The variety increases rapidly with higher derivatives and/or more variables.

VIII.2.1.10. We may also use the alternate notation \( f_{xx} \) or \( f_{11} \) for \( \frac{\partial^2 f}{\partial x^2} \), etc. When the alternate notation is used, it is conventional to take derivatives from left to right, unlike in the Leibniz notation where derivatives go from right to left: thus \( f_{xy} \) or \( f_{12} \) denotes \( \frac{\partial^2 f}{\partial y \partial x} \), i.e. the function is first differentiated with respect to \( x \) and then with respect to \( y \), not \( \frac{\partial^2 f}{\partial x \partial y} \) which is denoted \( f_{yx} \) or \( f_{21} \). (The distinction is academic in good cases.)
VIII.2.2. Equality of Mixed Partials

In general, the order in which the derivatives are taken in a higher-order partial derivative makes a difference. But under a mild continuity hypothesis, the order does not matter.

VIII.2.2.1. Example. Let

\[ f(x, y) = \begin{cases} \frac{xy(x^2 - y^2)}{x^2 + y^2} & \text{if } (x, y) \neq (0, 0) \\ 0 & \text{if } (x, y) = (0, 0) \end{cases} \]

Then \( f \) is \( C^1 \) on \( \mathbb{R}^2 \): we have

\[ \frac{\partial f}{\partial x}(x, y) = \begin{cases} \frac{y(x^4 + 4x^2y^2 - y^4)}{(x^2 + y^2)^2} & \text{if } (x, y) \neq (0, 0) \\ 0 & \text{if } (x, y) = (0, 0) \end{cases} \]

\[ \frac{\partial f}{\partial y}(x, y) = \begin{cases} \frac{-x(x^4 + 4x^2y^2 - x^4)}{(x^2 + y^2)^2} & \text{if } (x, y) \neq (0, 0) \\ 0 & \text{if } (x, y) = (0, 0) \end{cases} \]

The absolute value of the numerators are bounded by \( 6\| (x, y) \|^5 \), so the partials are continuous at \((0, 0)\).

Also, \( \frac{\partial^2 f}{\partial x \partial y} \) and \( \frac{\partial^2 f}{\partial y \partial x} \) are defined everywhere on \( \mathbb{R}^2 \), and

\[ \frac{\partial^2 f}{\partial x \partial y}(0, 0) = \lim_{h \to 0} \frac{\frac{\partial f}{\partial y}(h, 0) - \frac{\partial f}{\partial y}(0, 0)}{h} = 1 \]

\[ \frac{\partial^2 f}{\partial y \partial x}(0, 0) = \lim_{k \to 0} \frac{\frac{\partial f}{\partial x}(0, k) - \frac{\partial f}{\partial x}(0, 0)}{k} = -1 \]

so the second-order mixed partials exist at \((0, 0)\) are defined but unequal.

However, \( \frac{\partial^2 f}{\partial x \partial y} \) and \( \frac{\partial^2 f}{\partial y \partial x} \) are not continuous at \((0, 0)\).

Actually, \( f \) has continuous partials of all orders everywhere except at the origin, i.e. \( f \) is \( C^\infty \) on \( \mathbb{R}^2 \setminus \{(0, 0)\} \).

The graph has a subtle crinkle near the origin (Figure VIII.3).

VIII.2.2. Theorem. Let \( U \) be an open set in \( \mathbb{R}^n \), \( f: U \to \mathbb{R}^m \), \( a \in U \). Suppose, for some \( i \) and \( j \), \( \frac{\partial f}{\partial x_i} \) and \( \frac{\partial f}{\partial x_j} \) exist everywhere on \( U \), and \( \frac{\partial^2 f}{\partial x_i \partial x_j} \) exists everywhere on \( U \) and is continuous at \( a \). Then \( \frac{\partial^2 f}{\partial x_i \partial x_j}(a) \) is defined and

\[ \frac{\partial^2 f}{\partial x_i \partial x_j}(a) = \frac{\partial^2 f}{\partial x_j \partial x_i}(a) \]

Proof: There is no content to the statement if \( i = j \), so we assume \( i \neq j \).

We first make two reductions. By considering the coordinate functions, it suffices to assume \( m = 1 \). And, since only the coordinates \( i \) and \( j \) are varied in computing the partials, we may assume \( n = 2 \). So we suppose
Figure VIII.3: Maple plot of graph of $f(x, y) = \frac{xy(x^2 - y^2)}{x^2 + y^2}$

$U \subseteq \mathbb{R}^2$, $f : U \rightarrow \mathbb{R}$, $(a, b) \in U$, that $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$ exist on $U$, and $\frac{\partial^2 f}{\partial x \partial y}$ is defined on $U$ and continuous at $(a, b)$. We want to show that $\frac{\partial^2 f}{\partial y \partial x}(a, b)$ is defined and equal to $c := \frac{\partial^2 f}{\partial x \partial y}(a, b)$.

Let $\epsilon > 0$, and fix $\delta > 0$ such that if $|h| < \delta$ and $|k| < \delta$, then $(a + h, b + k) \in U$ and

$$\left| \frac{\partial^2 f}{\partial x \partial y}(a + h, b + k) - c \right| < \epsilon .$$

Set $V = \{(h, k) : |h| < \delta, |k| < \delta\}$. Then for $(h, k) \in V$, set

$$\Delta(h, k) = f(a + h, b + k) - f(a, b + k) - f(a + h, b) + f(a, b) .$$

If $(h, k) \in V$ is fixed, for $0 \leq t \leq 1$ set

$$\phi(t) = f(a + h, b + tk) - f(a, b + tk) .$$

Then $\phi$ is differentiable on $[0, 1]$ and by the Chain Rule

$$\phi'(t) = \frac{\partial f}{\partial y}(a + h, b + tk) \cdot k - \frac{\partial f}{\partial y}(a, b + tk) \cdot k .$$
Apply the MVT to get a \( t \in (0,1) \) such that
\[
k \frac{\partial f}{\partial y}(a + h, b + tk) - k \frac{\partial f}{\partial y}(a, b + tk) = \phi'(t)(1 - 0) = \phi(1) - \phi(0) = \Delta(h, k).
\]
Fix such a \( t \), and for \( 0 \leq s \leq 1 \) set
\[
\psi(s) = k \frac{\partial f}{\partial y}(a + sh, b + tk).
\]
Then \( \psi \) is differentiable on \([0,1]\) and
\[
\psi'(s) = k \frac{\partial^2 f}{\partial x \partial y}(a + sh, b + tk) \cdot h.
\]
Again use the MVT to obtain an \( s \in (0,1) \) such that
\[
hk \frac{\partial^2 f}{\partial x \partial y}(a + sh, b + tk) = \psi'(s)(1 - 0) = \psi(1) - \psi(0) = \Delta(h, k).
\]
For every \((h,k) \in V\) there is such a pair \((s,t) \in (0,1)^2\) (which depends on \((h,k)\)), and \((sh,tk) \in V\), so if \((h,k) \in V\), \( h \neq 0, k \neq 0 \), we have
\[
\left| \frac{\Delta(h,k)}{hk} - c \right| < \epsilon.
\]
Now fix \( k, 0 < |k| < \delta \). We have
\[
\lim_{h \to 0} \frac{\Delta(h,k)}{hk} = \frac{1}{k} \lim_{h \to 0} \left[ \frac{f(a + h, b + k) - f(a, b + k)}{h} - \frac{f(a + h, b) - f(a, b)}{h} \right] = \frac{1}{k} \left[ \frac{\partial f}{\partial x}(a, b + k) - \frac{\partial f}{\partial x}(a, b) \right]
\]
so the limit exists and we have that
\[
\left| \frac{1}{k} \left[ \frac{\partial f}{\partial x}(a, b + k) - \frac{\partial f}{\partial x}(a, b) \right] - c \right| \leq \epsilon
\]
if \( 0 < |k| < \delta \). Since \( \epsilon > 0 \) is arbitrary, we conclude that
\[
\frac{\partial^2 f}{\partial y \partial x}(a,b) = \lim_{k \to 0} \frac{\partial f}{\partial x}(a, b + k) - \frac{\partial f}{\partial x}(a, b)
\]
exists and equals \( c \).

**Remark.** (i) In **VIII.2.2.2.**, the hypothesis that \( \frac{\partial f}{\partial x} \) exists on \( U \) is implicit and automatic in the hypothesis that \( \frac{\partial^2 f}{\partial x \partial y} \) exists on \( U \).

(ii) Let \( g \) be a continuous but nowhere differentiable function from \( \mathbb{R} \) to \( \mathbb{R} \), and let \( f : \mathbb{R}^2 \to \mathbb{R} \) be defined by \( f(x,y) = g(x) \). Then \( f \) is continuous, and \( \frac{\partial f}{\partial y} \) exists everywhere and is identically zero; thus \( \frac{\partial^2 f}{\partial x \partial y} \) also exists everywhere and is identically zero, hence continuous. But \( \frac{\partial f}{\partial x} \) does not exist anywhere, so \( \frac{\partial^2 f}{\partial y \partial x} \) does not exist anywhere. So the hypothesis that \( \frac{\partial f}{\partial x} \) exists, which is necessary for the existence of \( \frac{\partial^2 f}{\partial x \partial y} \), is not automatic under the other hypotheses.
Corollary. Let $U$ be an open set in $\mathbb{R}^n$, and $f$ a $C^2$ function from $U$ to $\mathbb{R}^m$. Then, for any $i$ and $j$,
\[
\frac{\partial^2 f}{\partial x_j \partial x_i} = \frac{\partial^2 f}{\partial x_i \partial x_j}
\]
on $U$.

 VIII.2.2.5. VIII.2.2.4. is called Clairaut’s Theorem. The version in VIII.2.2.2. can be found in [Str81, p. 377]. Statements of the result in some real analysis texts have unnecessary extra hypotheses, and the “proofs” in many books have flaws. See VIII.4.1.7. for a variation, and XIV.3.11.7. for a simple alternate proof of VIII.2.2.4. based on Fubini’s Theorem.

 VIII.2.2.6. Corollary. Let $U$ be an open set in $\mathbb{R}^n$, and $f$ a $C^r$ function from $U$ to $\mathbb{R}^m$ ($r > 1$). Then any two mixed partials of $f$ of total order $\leq r$ in which each coordinate direction appears the same number of times are equal on $U$.

To show this, apply VIII.2.2.4. repeatedly to $f$ and its partial derivatives. For example, if $n \geq 5$ and $r \geq 4$, to show that
\[
\frac{\partial^4 f}{\partial x_2 \partial x_5 \partial x_3 \partial x_1} = \frac{\partial^4 f}{\partial x_2 \partial x_3 \partial x_5 \partial x_1}
\]
apply VIII.2.2.4. to $\frac{\partial f}{\partial x_1}$ to conclude that
\[
\frac{\partial^3 f}{\partial x_5 \partial x_3 \partial x_1} = \frac{\partial^3 f}{\partial x_3 \partial x_5 \partial x_1}
\]
amd then take the partial derivative of this function with respect to $x_2$. Any permutation of the order of derivatives can be built up from interchanges of successive derivatives, which can be justified in this way.

 VIII.2.2.7. This result leads to some convenient notation. A multi-index of dimension $n$ is an $n$-tuple $\alpha = (r_1, \ldots, r_n)$, where the $r_k$ are in $\mathbb{N} \cup \{0\}$. The total degree of $\alpha$ is
\[
|\alpha| = r_1 + \cdots + r_n.
\]
If $\alpha$ is a multi-index of dimension $n$ and total degree $r$, $U$ an open subset of $\mathbb{R}^n$, and $f : U \to \mathbb{R}^m$ is $C^r$, write
\[
\frac{\partial^\alpha f}{\partial x^\alpha} = \frac{\partial^r f}{\partial x_1^{r_1} \partial x_2^{r_2} \cdots \partial x_n^{r_n}}.
\]
By VIII.2.2.6., the successive partial derivatives may be taken in any order.

There is a “converse” to Clairaut’s Theorem which is important in vector field theory and in differential equations (compare with XIV.3.11.7.).
Theorem. Let $U$ be an open rectangle or open disk in $\mathbb{R}^2$, and $g$ and $h$ continuous functions from $U$ to $\mathbb{R}$ such that $\frac{\partial g}{\partial y}$ and $\frac{\partial h}{\partial x}$ are defined, continuous, and equal everywhere on $U$. Then there is a $C^1$ function $f$ on $U$, unique up to adding a constant, with $g = \frac{\partial f}{\partial x}$ and $h = \frac{\partial f}{\partial y}$.

Proof: For uniqueness, if $f$ and $F$ satisfy the conclusion, then $\phi = F - f$ is $C^1$ and $D\phi = 0$, so $\phi$ is constant.

For existence, let $(a, b)$ be the center point of $U$. For $(x, y) \in U$, define

$$f_1(x, y) = \int_b^y h(a, s) \, ds + \int_a^x g(t, y) \, dt$$
$$f_2(x, y) = \int_a^x g(t, b) \, dt + \int_b^y h(x, s) \, ds$$

(note that the paths lie in $U$). By the Fundamental Theorem of Calculus (FTC1), $\frac{\partial f_1}{\partial x} = g$ and $\frac{\partial f_2}{\partial y} = h$. So it suffices to show $f_1 = f_2$.

Fix $(x, y) \in U$. Then, by the Fundamental Theorem of Calculus (FTC2),

$$f_1(x, y) - f_2(x, y) = \int_a^x [g(t, y) - g(t, b)] \, dt - \int_b^y [h(x, s) - h(a, s)] \, ds$$

$$= \int_a^x \int_a^b \frac{\partial g}{\partial y}(t, s) \, ds \, dt - \int_b^y \int_a^x \frac{\partial h}{\partial x}(t, s) \, dt \, ds = 0$$

by Fubini’s Theorem (XIV.3.10. or XIV.3.5.2.) and the fact that $\frac{\partial g}{\partial y} = \frac{\partial h}{\partial x}$.

The equality of $f_1$ and $f_2$ is a special case of Green’s Theorem ()

VIII.2.2.9. The result can be extended to hold on a general simply connected open set (). But it fails in general on open sets which are not simply connected (). Using more advanced integration, the continuity hypotheses can be relaxed, but it is clumsy to make a precise statement. Of course, if $g$ and $h$ are $C^r$, the $f$ is $C^{r+1}$ (but the uniqueness is still among $C^1$ functions).
VIII.2.3. Directional Derivatives

VIII.2.3.1. The definition of partial derivatives can be rephrased in vector notation. We write \( \{e_1, \ldots, e_n\} \) for the standard basis vectors of \( \mathbb{R}^n \), i.e. \( e_k \) has 1 in the \( k \)'th place and 0’s elsewhere (the notation is a little ambiguous since \( n \) does not appear; we could write \( e_k^{(n)} \) if it is necessary to specify). If \( n = 3, e_1, e_2, e_3 \) are usually written \( i, j, k \) respectively.

With this notation, if \( U \subseteq \mathbb{R}^n \) and \( f : U \to \mathbb{R}^m \) is a function (we normally only consider the case \( m = 1 \)), then we have, for \( a \in U \) and \( 1 \leq k \leq n \),

\[
\frac{\partial f}{\partial x_k}(a) = \lim_{h \to 0} \frac{f(a + he_k) - f(a)}{h}
\]

(provided the limit exists).

We may generalize this definition (we only write the generalization in the case \( m = 1 \), although it can be done for general \( m \)):

VIII.2.3.2. Definition. Let \( U \subseteq \mathbb{R}^n \), and \( f : U \to \mathbb{R} \) a function. Let \( u \) be a nonzero vector in \( \mathbb{R}^n \) (which is almost always taken to be a unit vector, i.e. \( \|u\| = 1 \)). The directional derivative of \( f \) at \( a \in U \) with respect to \( u \), or in the direction \( u \) if \( u \) is a unit vector, is

\[
\frac{\partial f}{\partial u}(a) = \lim_{h \to 0} \frac{f(a + hu) - f(a)}{h}
\]

(provided the limit exists).

Partial derivatives are the special case \( u = e_k \) for some \( k \) (note that \( e_k \) is a unit vector):

\[
\frac{\partial f}{\partial x_k}(a) = \frac{\partial f}{\partial e_k}(a).
\]

VIII.2.3.3. There is a nice geometric interpretation of directional derivatives (and in particular partial derivatives). If \( f : \mathbb{R}^n \to \mathbb{R} \), the graph of \( f \) can be regarded as a hypersurface in \( \mathbb{R}^n \times \mathbb{R} \cong \mathbb{R}^{n+1} \). If \( u \) is a unit vector in \( \mathbb{R}^n \), there is a vertical plane through \((a, f(a))\) parallel to the plane spanned by \( u \) and \( e_{n+1} \). The intersection of this plane with the graph is a curve. If the plane is identified with \( \mathbb{R}^2 \) by taking \((a, f(a))\) as the origin and \( u \) and \( e_{n+1} \) as the coordinate directions, the curve becomes a plane curve in \( \mathbb{R}^2 \) through the origin, and \( \frac{\partial f}{\partial u}(a) \) is just the slope of the tangent line to this curve at the origin (Figure ()). It also has a more elementary interpretation as the rate of increase of \( f \) as one moves from \( a \) with unit speed along the line in the direction \( u \).

VIII.2.3.4. In the rarely used case where \( u \) is not a unit vector, let \( v = \frac{u}{\|u\|} \) be a unit vector in the direction of \( u \). Then we have, writing \( t = \|u\|h \),

\[
\frac{\partial f}{\partial u}(a) = \lim_{h \to 0} \frac{f(a + hu) - f(a)}{h} = \|u\| \lim_{t \to 0} \frac{f(a + tv) - f(a)}{t} = \|u\| \frac{\partial f}{\partial v}(a).
\]

809
VIII.2.4. Exercises

VIII.2.4.1. (a) Prove the following rules of partial differentiation, carefully stating each as a theorem.

For each, $U$ is an open set in $\mathbb{R}^n$, $f$ and $g$ are real-valued functions on $U$ which are differentiable at $a \in U$, $h : \mathbb{R} \to \mathbb{R}$ is differentiable at $f(a)$, $c \in \mathbb{R}$ (also denoting the constant function $c$ from $\mathbb{R}^n$ to $\mathbb{R}$), and $1 \leq j, k \leq n$. $\pi_j$ denotes the $j$'th coordinate function, i.e. $\pi_j(x_1, \ldots, x_n) = x_j$.

$$\frac{\partial (c)}{\partial x_k} (a) = 0 .$$

$$\frac{\partial (\pi_j)}{\partial x_k} (a) = \begin{cases} 1 & \text{if } j = k \\ 0 & \text{if } j \neq k \end{cases} .$$

$$\frac{\partial (f + g)}{\partial x_k} (a) = \frac{\partial f}{\partial x_k} (a) + \frac{\partial g}{\partial x_k} (a) .$$

$$\frac{\partial (cf)}{\partial x_k} (a) = c \frac{\partial f}{\partial x_k} (a) .$$

$$\frac{\partial (fg)}{\partial x_k} (a) = \frac{\partial f}{\partial x_k} (a)g(a) + f(a) \frac{\partial g}{\partial x_k} (a) .$$

$$\frac{\partial (f/g)}{\partial x_k} (a) = \frac{\frac{\partial f}{\partial x_k} (a)g(a) - f(a) \frac{\partial g}{\partial x_k} (a)}{|g(a)|^2} \quad \text{if } g(a) \neq 0 .$$

$$\frac{\partial (h \circ f)}{\partial x_k} (a) = h'(f(a)) \frac{\partial f}{\partial x_k} (a) .$$

(b) Use these rules to justify calculating partial derivatives as in VIII.2.1.6.
VIII.3. Differentiability of Multivariable Functions

VIII.3.1. Differentiability and the Derivative

VIII.3.1.1. What should it mean for a function from one Euclidean space to another to be differentiable at a point, and what kind of object should the derivative be? In the one-dimensional case, \( f \) is differentiable at \( a \) if the limit
\[
\lim_{h \to 0} \frac{f(a + h) - f(a)}{h}
\]
exists; if it does, the limit is called \( f'(a) \). But if \( f : \mathbb{R}^n \to \mathbb{R}^m \) and \( a \in \mathbb{R}^n, n > 1 \), the analogous expression
\[
\lim_{h \to 0} \frac{f(a + h) - f(a)}{h}
\]
does not even make sense since division by a vector is not defined.

VIII.3.1.2. We can change the one-dimensional definition into an equivalent one which does make sense when redecorated in this way, however. The following statements are equivalent by trivial calculation:
\[
\lim_{h \to 0} \frac{f(a + h) - f(a)}{h} = f'(a)
\]
\[
\lim_{h \to 0} \left[ \frac{f(a + h) - f(a)}{h} - f'(a) \right] = 0
\]
\[
\lim_{h \to 0} \frac{f(a + h) - f(a) - f'(a)h}{h} = 0
\]
\[
\lim_{h \to 0} \frac{f(a + h) - f(a) - f'(a)h}{|h|} = 0
\]
(for the last equivalence, consider left and right limits).

VIII.3.1.3. This last expression is almost in the form needed to make a reasonable definition in the vector case. However, it may be unclear how to modify the term \( f'(a)h \) in the numerator. A key to the proper approach comes from differential approximation: the best affine approximation to \( f \) near \( a \) is the function \( \phi(a + h) = f(a) + df(a)(h) = f(a) + f'(a)h \), so the numerator is \( f(a + h) - \phi(a + h) \), and the statement that the limit is 0 states that \( f \) can be closely approximated by this affine function.

A reasonable geometric criterion for differentiability at \( a \) in the vector case is that the function must be closely approximable near \( a \) by an affine function, i.e. there is an affine function \( \phi : \mathbb{R}^n \to \mathbb{R}^m \) (if \( f : U \subseteq \mathbb{R}^n \to \mathbb{R}^m \)) such that
\[
\lim_{h \to 0} \frac{f(a + h) - \phi(a + h)}{|h|} = 0
\]
where the fraction is interpreted as the vector
\[
\frac{1}{|h|} \left[ f(a + h) - \phi(a + h) \right] \in \mathbb{R}^m.
\]
The affine function \( \phi \) is of the form \( \phi(x) = c + T(x - a) \), where \( T : \mathbb{R}^n \to \mathbb{R}^m \) is a linear function and \( c \) is a constant. Since we must have \( \phi(a) = f(a) \), \( c = f(a) \). So we conclude that the following definition is reasonable:
VIII.3.1.4. **Definition.** Let $U \subseteq \mathbb{R}^n$ be open, and $f : U \rightarrow \mathbb{R}^m$, $a \in U$. Then $f$ is differentiable at $a$ if there is a linear transformation $T : \mathbb{R}^n \rightarrow \mathbb{R}^m$ for which

$$\lim_{h \rightarrow 0} \frac{f(a + h) - f(a) - T(h)}{\|h\|} = 0.$$ 

VIII.3.1.5. We will see that the linear transformation $T$, if it exists, is unique (this can be proved directly; cf. Exercise ()). This linear transformation will be called the **total differential** of $f$ at $a$, denoted $df(a)$, and its matrix the **total derivative matrix** of $f$ at $a$, denoted $Df(a)$. Note that $df(a)$ is a linear transformation from $\mathbb{R}^n$ to $\mathbb{R}^m$ and $Df(a)$ is an $m \times n$ matrix. $Df(a)$ has a simple formula in terms of partial derivatives of the coordinate functions of $f$ (VIII.3.1.9).

VIII.3.1.6. Since a linear transformation from $\mathbb{R}$ to $\mathbb{R}$ is of the form $T(x) = cx$ for some constant $c$, we recover the usual one-dimensional definition as modified in VIII.3.1.2., and $df(a)$ is the linear function $df(a)(x) = f'(a)x$ and $Df(a)$ is the $1 \times 1$ matrix $[f'(a)]$. So our definitions are (up to rephrasing) consistent.

VIII.3.1.7. Note that the definition of differentiability can be rephrased to require that

$$\lim_{h \rightarrow 0} \frac{\|f(a + h) - f(a) - T(h)\|}{\|h\|} = 0$$

since a limit $\lim_{x \rightarrow b} g(x) = 0$ of a vector function $g$ holds if and only if $\lim_{x \rightarrow b} \|g(x)\| = 0$. It will sometimes be more convenient to use this version.

**Uniqueness and a Formula**

VIII.3.1.8. Suppose $f : U \subseteq \mathbb{R}^n \rightarrow \mathbb{R}^m$ is differentiable at $a$, with a linear transformation $T$ which works in the definition. Fix $j$, $1 \leq j \leq n$. As a special case of the limit in the definition, we have

$$\lim_{t \rightarrow 0} \frac{f(a + te_j) - f(a) - T(te_j)}{|t|} = 0.$$ 

By considering left and right limits, we may eliminate the absolute value from the denominator:

$$\lim_{t \rightarrow 0} \frac{f(a + te_j) - f(a) - T(te_j)}{t} = 0$$

$$\lim_{t \rightarrow 0} \left[ \frac{f(a + te_j) - f(a)}{t} - T(e_j) \right] = 0$$

$$\lim_{t \rightarrow 0} \frac{f(a + te_j) - f(a)}{t} = T(e_j).$$

In particular, the limit on the left exists and equals the vector $T(e_j)$, which is the $j$'th column of the matrix of $T$. But the left side is the definition of $\frac{\partial f}{\partial x_j}(a)$. So we conclude:

812
VIII.3.1.9. PROPOSITION. Let \( f = (f_1, \ldots, f_m) : U \subseteq \mathbb{R}^n \to \mathbb{R}^m \) be differentiable at \( a \in U \). Then

(i) All partial derivatives \( \frac{\partial f_i}{\partial x_j}(a) \) exist.

(ii) The linear transformation \( T \) in the definition of differentiability at \( a \) is unique, and the \( ij \)'th entry of \( [T] \) is \( \frac{\partial f_i}{\partial x_j}(a) \) for each \( i \) and \( j \).

Thus the total differential \( df(a) \) and total derivative \( Df(a) \) are well defined, and

\[
Df(a) = \begin{bmatrix}
\frac{\partial f_1}{\partial x_1}(a) & \cdots & \frac{\partial f_1}{\partial x_n}(a) \\
\vdots & & \vdots \\
\frac{\partial f_m}{\partial x_1}(a) & \cdots & \frac{\partial f_m}{\partial x_n}(a)
\end{bmatrix}.
\]

VIII.3.1.10. The matrix

\[
\begin{bmatrix}
\frac{\partial f_1}{\partial x_1}(a) & \cdots & \frac{\partial f_1}{\partial x_n}(a) \\
\vdots & & \vdots \\
\frac{\partial f_m}{\partial x_1}(a) & \cdots & \frac{\partial f_m}{\partial x_n}(a)
\end{bmatrix}
\]

is defined whenever all partial derivatives exist at \( a \), and existence of this matrix is a necessary condition for differentiability at \( a \). But existence of this matrix is not sufficient for differentiability (cf. VIII.3.6.1–VIII.3.6.4.). We will not call this matrix the total derivative matrix or use the notation \( Df(a) \) unless \( f \) is differentiable at \( a \).

VIII.3.1.11. EXAMPLE. Let \( T : \mathbb{R}^n \to \mathbb{R}^m \) be linear. If \( a \) and \( h \) are any vectors in \( \mathbb{R}^n \), we have

\[
T(a + h) - T(a) - T(h) = 0
\]

so, fixing \( a \), we certainly have

\[
\lim_{h \to 0} \frac{T(a + h) - T(a) - T(h)}{\|h\|} = 0
\]

and thus \( T \) is differentiable at \( a \) with \( dT(a) = T \) and \( DT(a) = [T] \). So linear functions are differentiable everywhere; the differential of a linear function at any point is the function itself, and the total derivative matrix of \( T \) at any point is \( [T] \) (i.e. “the derivative of a linear function is constant”).

Coordinatewise Differentiability

We can examine differentiability coordinatewise in the range space:
VIII.3.1.12. Proposition. Let $U \subseteq \mathbb{R}^n$ be open, $f = (f_1, \ldots, f_m) : U \to \mathbb{R}^m$, $a \in U$. Then $f$ is differentiable at $a$ if and only if each $f_i$ is differentiable at $a$. In this case, the total differential $df(a)$ has coordinate functions $df_i(a)$.

Proof: This is an immediate consequence of the Coordinatewise Criterion for limits (): if $T = (T_1, \ldots, T_m)$ is linear, then
\[
\lim_{h \to 0} \frac{f(a + h) - f(a) - T(h)}{\|h\|} = 0
\]
if and only if
\[
\lim_{h \to 0} \frac{f_i(a + h) - f_i(a) - T_i(h)}{\|h\|} = 0
\]
for $1 \leq i \leq m$. 

Differentiability and Continuity

Here is a simple but important observation:

VIII.3.1.13. Proposition. Let $U \subseteq \mathbb{R}^n$ be open, $f : U \to \mathbb{R}^m$, $a \in U$. If $f$ is differentiable at $a$, then $f$ is continuous at $a$.

Proof: From the assumption
\[
\lim_{h \to 0} \frac{f(a + h) - f(a) - df(a)(h)}{\|h\|} = 0
\]

it follows that
\[
\lim_{h \to 0} [f(a + h) - f(a) - df(a)(h)] = 0
\]
and, since linear functions are continuous (), $\lim_{h \to 0} df(a)(h) = 0$, so $\lim_{h \to 0} [f(a + h) - f(a)] = 0$ also. 

VIII.3.1.14. Note that this result relies on the continuity of linear functions. This is automatic on finite-dimensional normed spaces, but not infinite-dimensional ones; so continuity is an issue if differentiability of functions between Banach spaces is considered ().

VIII.3.2. A Criterion for Differentiability

For a function of one variable, differentiability and existence of the derivative are the same thing by definition. But for a function of more than one variable, existence of all first-order partials is not sufficient to insure differentiability, or even continuity; cf. VIII.3.6.1–VIII.3.6.4. However, continuity of first-order partials is sufficient:
VIII.3.2.1. **Theorem.** Let $U$ be an open subset of $\mathbb{R}^n$, and $f = (f_1, \ldots, f_m) : U \to \mathbb{R}^m$. If all partial derivatives $\frac{\partial f}{\partial x_j}$ exist on $U$ and are continuous at $a \in U$, then $f$ is differentiable at $a$.

**Proof:** First note that by VIII.3.1.12, it suffices to assume $m = 1$, i.e. $f : U \to \mathbb{R}$ and $\frac{\partial f}{\partial x_j}$ exists on $U$ and is continuous at $a$ for each $j$.

We prove the result by induction on $n$. If $n = 1$, the statement is a tautology (and the hypotheses are even unnecessarily strong!). Now assume the statement is true for $n$, and let $U$ be an open set in $\mathbb{R}^n$ and $f : U \to \mathbb{R}$ with $\frac{\partial f}{\partial x_j}$ defined on $U$ and continuous at $c = (a, b) \in U$ for $1 \leq j \leq n + 1$. We need to show that $f$ is differentiable at $c$. Set

$$V = \{x \in \mathbb{R}^n : (x, b) \in U\}.$$

Then $V$ is an open set in $\mathbb{R}^n$ and $a \in V$. Define $g : V \to \mathbb{R}$ by $g(x) = f(x, b)$. For $1 \leq j \leq n$, we have $\frac{\partial g}{\partial x_j}(x) = \frac{\partial f}{\partial x_j}(x, b)$, so for $1 \leq j \leq n$, $\frac{\partial g}{\partial x_k}$ is defined on $V$ and continuous at $a$. Thus $g$ is differentiable at $a$ by the inductive hypothesis, i.e.

$$\lim_{h \to 0} \frac{g(a + h) - g(a) - Dg(h)}{\|h\|} = 0$$

$$\lim_{h \to 0} \frac{f(a + h, b) - f(a, b) - \sum_{j=1}^n \frac{\partial f}{\partial x_j}(a, b)h_j}{\|h\|} = 0.$$

If $h \in \mathbb{R}^n$, $k \in \mathbb{R}$, write $(h, k) \in \mathbb{R}^{n+1}$. Since $\|h\| \leq \|(h, k)\|$ for any $k$, we also have

$$\lim_{(h, k) \to (0, 0)} \frac{f(a + h, b) - f(a, b) - \sum_{j=1}^n \frac{\partial f}{\partial x_j}(a, b)h_j}{\|(h, k)\|} = 0 \quad (\text{VIII.1})$$

If $h$ and $k$ are small, by the Mean Value Theorem there is a $d_{h, k}$ between $b$ and $b + k$ such that

$$f(a + h, b + k) - f(a + h, b) = \frac{\partial f}{\partial x_{n+1}}(a + h, d_{h, k})k.$$

Now

$$\lim_{(h, k) \to (0, 0)} \frac{f(a + h, b + k) - f(a, b) - \sum_{j=1}^n \frac{\partial f}{\partial x_j}(a, b)h_j - \frac{\partial f}{\partial x_{n+1}}(a, b)k}{\|(h, k)\|}$$

$$= \lim_{(h, k) \to (0, 0)} \frac{f(a + h, b) - f(a, b) + f(a + h, b + k) - f(a + h, b) - \sum_{j=1}^n \frac{\partial f}{\partial x_j}(a, b)h_j - \frac{\partial f}{\partial x_{n+1}}(a, b)k}{\|(h, k)\|}$$

$$= \lim_{(h, k) \to (0, 0)} \left[ \frac{f(a + h, b) - f(a, b) - \sum_{j=1}^n \frac{\partial f}{\partial x_j}(a, b)h_j}{\|(h, k)\|} + \frac{f(a + h, b + k) - f(a + h, b) - \frac{\partial f}{\partial x_{n+1}}(a, b)k}{\|(h, k)\|} \right]$$

$$= \lim_{(h, k) \to (0, 0)} \left[ \frac{f(a + h, b) - f(a, b) - \sum_{j=1}^n \frac{\partial f}{\partial x_j}(a, b)h_j}{\|(h, k)\|} + \frac{\frac{\partial f}{\partial x_{n+1}}(a + h, d_{h, k}) - \frac{\partial f}{\partial x_{n+1}}(a, b)}{\|(h, k)\|} k \right].$$

The limit of the first term is 0 by VIII.1, and the limit of the second term is also 0 by continuity of $\frac{\partial f}{\partial x_{n+1}}$ at $c$ (using $|k| \leq \|(h, k)\|$). Thus $f$ is differentiable at $c$. 815
VIII.3.2.2. Remark. Examining the proof carefully, we do not need all the partial derivatives to be continuous at \( a \): the partial with respect to one variable can be discontinuous. In fact, the proof shows that if, for some \( r \), the restriction of \( f \) to an \( r \)-dimensional coordinate subspace is differentiable at \( a \), and the additional partial derivatives are continuous at \( a \), then \( f \) is differentiable at \( a \); cf. Exercise VIII.3.6.8.

VIII.3.2.3. The hypotheses of the theorem give sufficient conditions for \( f \) to be differentiable at \( a \). But these conditions are not necessary: cf. V.3.1.15., V.12., VIII.3.6.6–VIII.3.6.7. The main significance of the theorem is that the continuity conditions are often satisfied and easy to check in cases of interest, and the theorem is frequently by far the easiest way to establish differentiability.

The next special case of VIII.3.2.1. is the most important and commonly used one. We first make a definition:

VIII.3.2.4. Definition. Let \( U \) be an open set in \( \mathbb{R}^n \), and \( f : U \to \mathbb{R}^m \) a function. If \( r \in \mathbb{N} \), then \( f \) is a \( C^r \) function if \( f \) and all its partial derivatives of order \( \leq r \) exist and are continuous on \( U \).

If \( n = 1 \), this definition agrees with the definition in (); and the agreement goes deeper (VIII.4.1.5.). We extend the notation to say that \( f \) is \( C^0 \) on \( U \) if it is continuous on \( U \), and \( C^\infty \) on \( U \) if it is \( C^r \) on \( U \) for all \( r \), i.e. all partials of \( f \) of all orders exist and are continuous on \( U \).

VIII.3.2.5. Corollary. Let \( U \) be an open set in \( \mathbb{R}^n \), and \( f : U \to \mathbb{R}^m \) a \( C^1 \) function. Then \( f \) is differentiable at all points of \( U \).

VIII.3.2.6. Corollary. Let \( U \) be an open set in \( \mathbb{R}^n \), \( f : U \to \mathbb{R}^m \). If \( r \in \mathbb{N} \), suppose all partial derivatives of \( f \) of order \( r \) are continuous on \( U \). Then \( f \) itself and all partial derivatives of \( f \) of order \( < r \) are differentiable on \( U \), hence \textit{a fortiori} continuous on \( U \). In particular, \( f \) is \( C^r \) on \( U \).

\[ \text{Proof:} \] Working backwards, any partial derivative of \( f \) of order \( r - 1 \) has continuous first-order partials on \( U \), hence is differentiable (thus continuous) on \( U \). The same is then true of the partials of \( f \) of order \( r - 2 \), etc.

VIII.3.3. The Chain Rule

VIII.3.3.1. The Chain Rule concerns differentiability and the derivative of a composition of functions. Two previous results suggest that the derivative of a composition of two functions should be the product of the derivatives:

(i) If \( f, g : \mathbb{R} \to \mathbb{R} \) and \( a \in \mathbb{R} \), then \( (g \circ f)'(a) = g'(f(a))f'(a) \) (cf. V.3.4.3.).

(ii) If \( S : \mathbb{R}^n \to \mathbb{R}^m \) and \( T : \mathbb{R}^m \to \mathbb{R}^p \) are linear, then \( T \circ S : \mathbb{R}^n \to \mathbb{R}^p \) is linear and \( [T \circ S] = [T][S] \).

The Chain Rule of vector calculus generalizes these two facts. Note that, as always, the Chain Rule is a theorem, not a formula: it has hypotheses (that \( f \) and \( g \) are differentiable) and a conclusion with a theoretical part (that \( g \circ f \) is differentiable) as well as a formula for the total derivative of \( g \circ f \).

The Chain Rule is a prime example of the utility of vector calculus notation. The corresponding statement written in coordinates is unwieldy, although this form is often needed in applications.
VIII.3.3.2. **Theorem.** [Chain Rule] Let $U$ and $V$ be open sets in $\mathbb{R}^n$ and $\mathbb{R}^m$ respectively, $f : U \to \mathbb{R}^m$ and $g : V \to \mathbb{R}^p$ with $f(U) \subseteq V$, $a \in U$, $b = f(a) \in V$. If $f$ is differentiable at $a$ and $g$ is differentiable at $b$, then $g \circ f$ is differentiable at $a$ and

$$D(g \circ f)(a) = Dg(b)Df(a) = Dg(f(a))Df(a).$$

Note that under the hypotheses, $Dg(b)$ is $p \times m$, $Df(a)$ is $m \times n$, and $D(g \circ f)(a)$ is $p \times n$, so the product of the matrices on the right is defined and is the same size as the matrix on the left (this is of course not a proof of the theorem, only an indication that the statement makes sense!)

It is easily seen that the two examples in VIII.3.3.1. are special cases of this result (cf. VIII.3.3.11.).

**Proof:** The proof is largely a matter of choosing good notation, which can be a little complicated to keep straight.

For $h$ in a neighborhood of $0$ in $\mathbb{R}^n$, set

$$\phi(h) = f(a + h) - f(a) - Df(a)h$$

so we have

$$\lim_{h \to 0} \frac{\phi(h)}{\|h\|} = \lim_{h \to 0} \frac{f(a + h) - f(a) - Df(a)h}{\|h\|} = 0.$$

Similarly, for $k$ in a neighborhood of $0$ in $\mathbb{R}^m$, set

$$\psi(k) = g(b + k) - g(b) - Dg(b)k$$

so we have

$$\lim_{k \to 0} \frac{\psi(k)}{\|k\|} = \lim_{k \to 0} \frac{g(b + k) - g(b) - Dg(b)k}{\|k\|} = 0.$$

Set $\omega(k) = \frac{\psi(k)}{\|k\|}$ for $k \neq 0$ and $\omega(0) = 0$. Then $\omega$ is continuous at $0$.

If $h$ is sufficiently close to $0$, then $f(a + h)$ is defined; and if we set

$$k = f(a + h) - f(a) = Df(a)h + \phi(h)$$

we have that $k \to 0$ as $h \to 0$ since $f$ is continuous at $a$, and

$$g(f(a + h)) = g(f(a)) = g(b + k) - g(b) = Dg(b)k + \psi(k)$$

so we have

$$g(f(a + h)) - g(f(a)) - Dg(b)Df(a)h = \frac{Dg(b)\phi(h)}{\|h\|} + \frac{\psi(k)}{\|h\|}.$$

Since $\|Dg(b)\phi(h)\| \leq \|Dg(b)\|\|\phi(h)\|$ and $\lim_{h \to 0} \frac{\phi(h)}{\|h\|} = 0$, the first term has limit $0$. We show the second term also has limit $0$. We have

$$\|k\| = \|f(a + h) - f(a)\| = \|Df(a)h + \phi(h)\| \leq \|Df(a)\|\|h\| + \|\phi(h)\|.$$
∥k∥ ≤ ∥Df(a)∥ + ∥ϕ(h)∥ ∥h∥

and since the second term goes to 0 as h → 0, it is bounded in a neighborhood of 0. Thus

\[ \lim_{h \to 0} \frac{\psi(k)}{\|h\|} = \lim_{h \to 0} \frac{\|k\|}{\|h\|} \omega(k) = 0 \]

since the first factor is bounded and the second factor tends to 0. Thus

\[ \lim_{h \to 0} \frac{g(f(a + h)) - g(f(a)) - Dg(b)Df(a)h}{\|h\|} = 0. \]

VIII.3.4. The Gradient and Tangent Planes

For a real-valued differentiable function f on a region in \( \mathbb{R}^n \), there is an alternate representation or interpretation of the total derivative \( Df \) which has a nice geometric interpretation.

VIII.3.4.1. If \( U \subseteq \mathbb{R}^n \), \( a \in U \), and \( f : U \to \mathbb{R} \) is differentiable at \( a \), then \( Df(a) \) is a \( 1 \times n \) matrix:

\[ Df(a) = \left[ \frac{\partial f}{\partial x_1}(a) \quad \frac{\partial f}{\partial x_2}(a) \quad \cdots \quad \frac{\partial f}{\partial x_n}(a) \right]. \]

A \( 1 \times n \) matrix can be interpreted as a row vector in \( \mathbb{R}^n \), and thus \( Df(a) \) can be alternately interpreted as a vector in \( \mathbb{R}^n \). When it is, it is given a different name to emphasize the change of point of view:

VIII.3.4.2. Definition. Let \( U \subseteq \mathbb{R}^n \), \( a \in U \), and \( f : U \to \mathbb{R} \) a real-valued function. If \( f \) is differentiable at \( a \), the gradient of \( f \) at \( a \) is the vector \( \nabla f(a) \) in \( \mathbb{R}^n \) defined by

\[ \nabla f(a) = \left( \frac{\partial f}{\partial x_1}(a), \frac{\partial f}{\partial x_2}(a), \cdots, \frac{\partial f}{\partial x_n}(a) \right). \]

Note that, as usual, \( \nabla f \) is regarded as a single symbol. Some references use the alternate notation \( \text{Grad}(f) \).

VIII.3.4.3. Just as the total derivative matrix of a function at \( a \) is technically defined when all first-order partials exist at \( a \), even if the function is not differentiable at \( a \), the formula for the gradient makes sense if all first-order partials are just defined at \( a \). But just as we only use the notation \( Df(a) \) if \( f \) is differentiable at \( a \), we only use the notation \( \nabla f(a) \) and say the gradient exists at \( a \) if \( f \) is actually differentiable at \( a \) (e.g. if all first-order partials of \( f \) are continuous at \( a \)).
Directional Derivatives Revisited

If \( f : U \to \mathbb{R} \) is differentiable at \( a \in U \subseteq \mathbb{R}^n \), then the directional derivatives can be easily calculated using the gradient. Let \( u \) be a nonzero vector in \( \mathbb{R}^n \), and define \( \gamma : \mathbb{R} \to \mathbb{R}^n \) by

\[
\gamma(t) = a + tu .
\]

Then \( \gamma'(0) = u \), or in matrix terms \( D\gamma(0) \) is the \( n \times 1 \) matrix \( u \), regarded as a column vector. Set \( \phi(t) = f(\gamma(t)) \). If \( U \) is open, then \( \phi \) is defined in an interval around 0, and by definition we have

\[
\frac{\partial f}{\partial u}(a) = \phi'(0)
\]

and by the Chain Rule we have

\[
\phi'(0) = D\phi(0) = Df(\gamma(0))\gamma'(0) = Df(a)u
\]

where \( u \) is regarded as an \( n \times 1 \) matrix (column vector). However, observe that the scalar \( Df(a)u \) is exactly the dot product \( \nabla f(a) \cdot u \). Thus we conclude:

VIII.3.4.4. Proposition. Let \( U \) be an open set in \( \mathbb{R}^n \), \( a \in U \), and \( f : U \to \mathbb{R} \) a real-valued function. If \( f \) is differentiable at \( a \) and \( \nabla f(a) \neq 0 \), then for any nonzero vector \( u \in \mathbb{R}^n \), the directional derivative of \( f \) at \( a \) with respect to \( u \) is defined and

\[
\frac{\partial f}{\partial u}(a) = \nabla f(a) \cdot u .
\]

VIII.3.4.5. This simple relationship does not necessarily hold if \( f \) is not differentiable at \( a \), even if all directional derivatives (and in particular all first-order partials) of \( f \) exist at \( a \). For example, if \( f : \mathbb{R}^2 \to \mathbb{R} \) is the function of VIII.3.6.5., then \( \frac{\partial f}{\partial x}(0) \) exists for all \( u \). But \( \frac{\partial f}{\partial x}(0) = \frac{\partial f}{\partial y}(0) = 0 \), so “\( \nabla f(0) \)” is \( 0 \), although \( \frac{\partial f}{\partial u}(0) \neq 0 \) for some \( u \)’s. This shows again that \( f \) cannot be differentiable at \( 0 \) (and, in particular, \( \nabla f(0) \) is actually undefined).

Geometric Interpretation of the Gradient

Returning to the case where \( f \) is differentiable at \( a \), we can interpret VIII.3.4.4. geometrically:

VIII.3.4.6. Corollary. Let \( U \) be an open set in \( \mathbb{R}^n \), \( a \in U \), and \( f : U \to \mathbb{R} \) a real-valued function. If \( f \) is differentiable at \( a \) and \( \nabla f(a) \neq 0 \), then for any unit vector \( u \in \mathbb{R}^n \), the directional derivative of \( f \) at \( a \) in the direction \( u \) is defined and

\[
\frac{\partial f}{\partial u}(a) = \|\nabla f(a)\| \cos \theta
\]

where \( \theta \) is the angle between \( \nabla f(a) \) and \( u \).

The conclusion also holds if \( \nabla f(a) = 0 \) (although \( \theta \) is not defined): then \( \frac{\partial f}{\partial u}(a) = 0 \) for any \( u \).
VIII.3.4.7. Thus $\frac{\partial f}{\partial u}(a)$ is maximum when $\theta = 0$, i.e. if and only if $u$ is a unit vector in the direction of $\nabla f(a)$ (in the case $\nabla f(a) \neq 0$). So if $\nabla f(a) \neq 0$, it points in the direction of greatest increase of $f$ at $a$, and the length of the gradient gives the maximum rate of increase. In the case $n = 2$, the graph of $f$ can be regarded as a surface in $\mathbb{R}^3$, and at any point of the surface where the function is differentiable with nonzero gradient the gradient points “straight uphill” (see Figure ()).

The Tangent Hyperplane

VIII.3.4.8. If $\nabla f(a) \neq 0$, then for a unit vector $u \in \mathbb{R}^n$ we have $\frac{\partial f}{\partial u}(a) = 0$ if and only if $u \perp \nabla f(a)$. The set of all such vectors spans an $(n - 1)$-dimensional subspace of $\mathbb{R}^n$.  

820
VIII.3.5. Functional Independence

VIII.3.5.1. Let $U$ be an open set in $\mathbb{R}^n$, and $f = (f_1, \ldots, f_m) : U \to \mathbb{R}^m$ a $C^1$ function. We say \{f_1, \ldots, f_m\} is functionally dependent on $U$ if there is a $C^1$ function $g$ on an open set $V$ in $\mathbb{R}^{n-1}$ such that, for some $k$, $1 \leq k \leq m$, we have

$$(f_1(x), \ldots, f_{k-1}(x), f_{k+1}(x), \ldots, f_m(x)) \in V$$

$$f_k(x) = g(f_1(x), \ldots, f_{k-1}(x), f_{k+1}(x), \ldots, f_m(x))$$

for all $x \in U$. Otherwise \{f_1, \ldots, f_m\} is functionally independent on $U$. (The $C^1$ requirement can be relaxed in various ways, but this is the most useful form of the definition.)

Geometrically, functional dependence says that $f(x)$ lies on the graph of $g$ in $\mathbb{R}^m = \mathbb{R}^m \setminus \mathbb{R}$ for all $x \in U$. Note that functional independence implies, but is much stronger than, linear independence (Exercise ()).

VIII.3.5.2. An apparently more general functional dependence is to just require that there is a function $F$, $C^1$ on an open set in $\mathbb{R}^m$ containing $f(U)$ with nonvanishing derivative, such that $F(f(x)) = 0$ for all $x \in U$. But this is actually not really more general, at least locally, by the Implicit Function Theorem.

VIII.3.5.3. In general, it is a difficult problem to determine whether a set of functions is functionally dependent. We will obtain from the Chain Rule a simple necessary condition in the case $n \geq m$, although this condition is by no means sufficient.

VIII.3.5.4. Proposition. Let $U$ be an open set in $\mathbb{R}^n$, and $f = (f_1, \ldots, f_m) : U \to \mathbb{R}^m$ a $C^1$ function, with $n \geq m$. If \{f_1, \ldots, f_m\} is functionally dependent, then for every $\{j_1, \ldots, j_m\} \subseteq \{1, \ldots, n\}$ and every $x \in U$ we have

$$\det \begin{bmatrix} \frac{\partial f_1}{\partial x_{j_1}}(x) & \cdots & \frac{\partial f_1}{\partial x_m}(x) \\ \vdots & \ddots & \vdots \\ \frac{\partial f_m}{\partial x_{j_1}}(x) & \cdots & \frac{\partial f_m}{\partial x_m}(x) \end{bmatrix} = 0.$$ 

Proof: By reordering $f_1, \ldots, f_m$, we may assume the $k$ in the definition of functional dependence is $m$, i.e. there is a $C^1$ function $g$ such that $f_m(x) = g(f_1(x), \ldots, f_{m-1}(x))$ for all $x \in U$, to simplify notation. Fix $x \in U$, and write $y = (f_1(x), \ldots, f_{m-1}(x)) \in \mathbb{R}^{m-1}$. Then by the Chain Rule, for each $j$ we have

$$\frac{\partial f_m}{\partial x_j} = \sum_{k=1}^{m-1} \frac{\partial g}{\partial y_k}(y) \frac{\partial f_k}{\partial x_j}(x)$$

so the last row in the matrix is a linear combination of the first $m - 1$ rows (the $k$'th row is multiplied by $\frac{\partial g}{\partial y_k}(y)$), hence the matrix has zero determinant. $\blacksquare$
VIII.3.5.5. **Corollary.** Let $U$ be an open set in $\mathbb{R}^n$, and $f = (f_1, \ldots, f_m) : U \to \mathbb{R}^m$ a $C^1$ function, with $n \geq m$. If there is an $a \in U$ and $\{j_1, \ldots, j_m\} \subseteq \{1, \ldots, n\}$ such that

$$
\begin{vmatrix}
\frac{\partial f_1}{\partial x_{j_1}}(a) & \cdots & \frac{\partial f_1}{\partial x_{j_m}}(a) \\
\vdots & \ddots & \vdots \\
\frac{\partial f_m}{\partial x_{j_1}}(a) & \cdots & \frac{\partial f_m}{\partial x_{j_m}}(a)
\end{vmatrix} \neq 0
$$

then $\{f_1, \ldots, f_m\}$ is functionally independent.

VIII.3.5.6. In fact, under the hypotheses of VIII.3.5.5., a stronger consequence holds: the Inverse Function Theorem (applied to a suitable $m$-dimensional affine subspace of $\mathbb{R}^n$) implies that the range of $f$ has nonempty interior (which clearly implies functional independence).

VIII.3.5.7. The converse of VIII.3.5.4. does not hold, and there are no reasonable sufficient conditions for functional dependence along these lines. If the conclusion of VIII.3.5.4. holds, or if $n < m$, then the Straightening Theorem says that generically $\{f_1, \ldots, f_m\}$ is *locally* functionally dependent.
VIII.3.6. Exercises

VIII.3.6.1. Define \( f : \mathbb{R}^2 \rightarrow \mathbb{R} \) by
\[
f(x, y) = \begin{cases} 
\frac{xy}{x^2+y^2} & \text{if } (x, y) \neq (0, 0) \\
0 & \text{if } (x, y) = (0, 0)
\end{cases}
\]
(a) Show that \( f \) is not continuous at \( 0 \).
(b) Show that \( \frac{\partial f}{\partial x} \) and \( \frac{\partial f}{\partial y} \) exist everywhere.
(c) Show that \( D_u f(0, 0) \) does not exist unless \( u = e_1 \) or \( u = e_2 \).

VIII.3.6.2. Define \( f : \mathbb{R}^2 \rightarrow \mathbb{R} \) by
\[
f(x, y) = \begin{cases} 
\sqrt{x^2+y^2} & \text{if } (x, y) \neq (0, 0) \\
0 & \text{if } (x, y) = (0, 0)
\end{cases}
\]
(a) Show that \( f \) is continuous at \( 0 \).
(b) Show that \( \frac{\partial f}{\partial x} \) and \( \frac{\partial f}{\partial y} \) exist everywhere.
(c) Show that \( D_u f(0, 0) \) does not exist unless \( u = e_1 \) or \( u = e_2 \).
(d) Show that \( f \) is not differentiable at \( 0 \). [Use ().]

VIII.3.6.3. Define \( f : \mathbb{R}^2 \rightarrow \mathbb{R} \) by
\[
f(x, y) = \begin{cases} 
\frac{x^2y}{x^2+y^2} & \text{if } (x, y) \neq (0, 0) \\
0 & \text{if } (x, y) = (0, 0)
\end{cases}
\]
(a) Show that \( f \) is not continuous at \( 0 \). [Consider \( \lim_{t \to 0} f(t, t^2) \).] Then \( f \) is a fortiori not differentiable at \( 0 \).
(b) Show that \( \frac{\partial f}{\partial x} \) and \( \frac{\partial f}{\partial y} \) exist everywhere.
(c) Show that \( D_u f(x, y) \) exists for all \( u \) and for all \( (x, y) \) (and in particular for \( (x, y) = (0, 0) \)).

VIII.3.6.4. Define \( f : \mathbb{R}^2 \rightarrow \mathbb{R} \) by
\[
f(x, y) = (x^{1/3} + y^{1/3})^3.
\]
(a) Show that \( f \) is continuous everywhere, and in particular at \( 0 \).
(b) Show that \( \frac{\partial f}{\partial x} \) and \( \frac{\partial f}{\partial y} \) exist everywhere.
(c) Show that \( D_u f(0, 0) \) exists and equals \( f(u) \) for all \( u \).
(d) Show that \( f \) is not differentiable at \( 0 \). [Use ().]
VIII.3.6.5. Define \( f : \mathbb{R}^2 \to \mathbb{R} \) by

\[
f(x, y) = \begin{cases} 
  \frac{x^2 y}{x^2 + y^2} & \text{if } (x, y) \neq (0, 0) \\
  0 & \text{if } (x, y) = (0, 0)
\end{cases}
\]

(a) Show that \( f \) is continuous everywhere, and in particular at \( 0 \).

(b) Show that \( \frac{\partial f}{\partial x} \) and \( \frac{\partial f}{\partial y} \) exist everywhere.

(c) Show that \( \frac{\partial f}{\partial u}(0, 0) \) exists for all \( u \).

(d) Show that \( f \) is not differentiable at \( 0 \).

VIII.3.6.6. Define \( f : \mathbb{R}^2 \to \mathbb{R} \) by

\[
f(x, y) = \begin{cases} 
  x^2 + y^2 & \text{if } x^2 + y^2 \text{ is rational} \\
  0 & \text{if } x^2 + y^2 \text{ is irrational}
\end{cases}
\]

(a) Show that \( f \) is continuous only at \( 0 \).

(b) Show that \( \frac{\partial f}{\partial x} \) and \( \frac{\partial f}{\partial y} \) only exist at \( 0 \).

(c) Show that \( f \) is differentiable at \( 0 \).

VIII.3.6.7. Define \( f : \mathbb{R}^2 \to \mathbb{R} \) by

\[
f(x, y) = \begin{cases} 
  (x^2 + y^2) \sin \frac{1}{x^2 + y^2} & \text{if } (x, y) \neq (0, 0) \\
  0 & \text{if } (x, y) = (0, 0)
\end{cases}
\]

(a) Show that \( f \) is differentiable everywhere, and in particular at \( 0 \).

(b) Show that \( \frac{\partial f}{\partial x} \) and \( \frac{\partial f}{\partial y} \) are not continuous at \( 0 \).

VIII.3.6.8. Modify the proof of Theorem VIII.3.2.1. to give the following precise version of Remark VIII.3.2.2.:

**Theorem.** Let \( U \) be an open subset of \( \mathbb{R}^n \), and \( f = (f_1, \ldots, f_m) : U \to \mathbb{R}^m \). Suppose that, for some \( r \), \( 1 \leq r < n \), and \( c = (a, b) \in U \), where \( a \in \mathbb{R}^r \) and \( b \in \mathbb{R}^{n-r} \), we have that

(1) The function \( g(x) = f(x, b) \) is differentiable at \( a \).

(2) All partial derivatives \( \frac{\partial f_i}{\partial x_j} \), \( 1 \leq i \leq n, r+1 \leq j \leq n \), exist on \( U \) and are continuous at \( c \).

Then \( f \) is differentiable at \( c \).
VIII.4. Higher-Order Derivatives and Critical Point Analysis

VIII.4.1. Higher-Order Differentiability

VIII.4.1.1. If $U$ is an open set in $\mathbb{R}^n$ and $f : U \to \mathbb{R}^m$ is differentiable on $U$ (i.e. at every point of $U$), the total derivative $df$ is a function from $U$ to the set $\mathcal{L}(\mathbb{R}^n, \mathbb{R}^m)$ of linear transformations from $\mathbb{R}^n$ to $\mathbb{R}^m$. $\mathcal{L}(\mathbb{R}^n, \mathbb{R}^m)$ is a vector space over $\mathbb{R}$ of dimension $nm$ and can thus be identified with $\mathbb{R}^{nm}$ in a natural way (Exercise VIII.4.1.1). Alternatively, $Df$ is a function from $U$ to the $m \times n$ matrices $M_{m \times n}$, which can evidently be identified with $\mathbb{R}^{nm}$. Thus $df$ or, equivalently, $Df$, may be regarded as a function from $U$ to $\mathbb{R}^{nm}$.

VIII.4.1.2. Definition. If $U$ is an open set in $\mathbb{R}^n$ and $f : U \to \mathbb{R}^m$ is differentiable on $U$, then $f$ is second-order differentiable at $a \in U$ if $df$ (or, equivalently, $Df$) is differentiable at $a$. Write $d^2f(a)$ for $d(df)(a)$ and $D^2f(a)$ for $D(Df)(a)$.

VIII.4.1.3. We can go on. If $df$ ($Df$) is differentiable at $a$, then $D^2f(a)$ is an $nm \times n$ matrix, identifiable with $\mathbb{R}^{nm}$. Thus if $f$ is second-order differentiable on $U$ and $D^2f$ is differentiable at $a \in U$, then $f$ is third-order differentiable at $a$. Continuing, we can define what it means for $f$ to be $r$th order differentiable at a point or on the set $U$, for any $r \in \mathbb{N}$. We also say $f$ is $r$th order differentiable on $U$ if it is $r$th order differentiable on $U$ for every $r$. We can also write $d^rf(a)$ and $D^rf(a)$ if $f$ is differentiable to order $r$ at $a$; $D^rf(a)$ is an $n^{r-1} m \times n$ matrix, which can be identified with a point in $\mathbb{R}^{nm}$.

The coordinate functions of $D^rf$ are just the $r$th order partials of the coordinate functions of $f$ (Exercise VIII.4.4.1.). By VIII.3.1.2., we have:

VIII.4.1.4. Proposition. If $U$ is an open set in $\mathbb{R}^n$ and $f : U \to \mathbb{R}^m$, then $f$ is $r$th order differentiable at $a \in U$ if and only if each partial derivative of $f$ of order $r-1$ is defined in a neighborhood of $a$ and is differentiable at $a$.

We thus have the following immediate corollary of VIII.3.1.13. and VIII.3.2.1.:

VIII.4.1.5. Corollary. Let $U$ be an open set in $\mathbb{R}^n$, and $f : U \to \mathbb{R}^m$, and $r \in \mathbb{N}$. If $f$ is $r$th order differentiable on $U$, then $f$ is $C^{r-1}$ on $U$. If $f$ is $C^r$ on $U$, then it is $r$th order differentiable on $U$. The function $f$ is $C^\infty$ on $U$ if and only if it is infinitely differentiable on $U$.

Note that an $r$th order differentiable function does not have to be $C^r$ (VIII.3.2.3.).

VIII.4.1.6. There is a little more structure to higher derivatives: $\mathcal{L}(\mathbb{R}^n, \mathbb{R}^m)$ has more structure than $\mathbb{R}^{nm}$. If $f$ is second-order differentiable at $a$, then $d^2f(a)$ is actually a linear transformation from $\mathbb{R}^n$ to $\mathcal{L}(\mathbb{R}^n, \mathbb{R}^m)$, which can be thought of as a bilinear () function from $\mathbb{R}^n \times \mathbb{R}^n$ to $\mathbb{R}^m$. Similarly, for any $r$, $d^rf(a)$ can be regarded as an $r$-multilinear function from $\mathbb{R}^n \times \cdots \times \mathbb{R}^n$ to $\mathbb{R}^m$. This point of view is important in formulating the multivariable version of Taylor’s Theorem (), for example. (The two points of view are actually equivalent, since bilinear functions from $\mathbb{R}^n \times \mathbb{R}^n$ to $\mathbb{R}^m$ correspond naturally to linear functions from $\mathbb{R}^n \otimes \mathbb{R}^n \cong \mathbb{R}^{n^2}$ to $\mathbb{R}^m$, etc.)
Equality of Mixed Partial Again

There is a variation of Theorem VIII.2.2. involving differentiability:

VIII.4.1.7. \textbf{Theorem.} Let $U$ be an open set in $\mathbb{R}^n$, $f: U \to \mathbb{R}^m$, $a \in U$. If $f$ is second-order differentiable at $a$, then, for $1 \leq i, j \leq n$,

$$\frac{\partial^2 f}{\partial x_j \partial x_i}(a) = \frac{\partial^2 f}{\partial x_i \partial x_j}(a).$$

For the proof, which is similar to the proof of VIII.2.2. and of comparable difficulty, see [Pug15].

VIII.4.1.8. \textbf{Theorems VIII.2.2.2. and VIII.4.1.7.} are complementary: neither directly implies the other. (Clairaut’s Theorem VIII.2.2.4., the version of the equality of mixed partials used most frequently, is a special case of both VIII.2.2.2. and VIII.4.1.7., so the distinction between these results is mostly academic.) In VIII.4.1.7. there is no assumption of continuity for any second-order partial, so it might seem to be more general than VIII.2.2.2. However, the hypotheses of VIII.4.1.7. imply that \textit{all} second-order partials of $f$ exist at $a$ (and even more), which is not necessary for VIII.2.2.2., as the next example shows.

VIII.4.1.9. \textbf{Example.} Let $g: \mathbb{R} \to \mathbb{R}$ be a function which is differentiable everywhere, but does not have a second derivative anywhere; $g'$ may be continuous, i.e. $g$ is an antiderivative of a continuous but non-differentiable function, or it may be quite discontinuous. Define $f: \mathbb{R}^2 \to \mathbb{R}$ by $f(x, y) = g(x)$. Then $\frac{\partial f}{\partial x}$, $\frac{\partial^2 f}{\partial x \partial y}$, $\frac{\partial^2 f}{\partial y \partial x}$, and $\frac{\partial^2 f}{\partial y^2}$ all exist everywhere, and the last four are identically 0, hence continuous, so the hypotheses (and conclusion!) of VIII.2.2.2. are satisfied everywhere. But $f$ is not second-order differentiable anywhere: in fact, $\frac{\partial^2 f}{\partial x \partial y}$ does not exist anywhere.

Theorem VIII.4.1.7. has an extension which is a true generalization of VIII.2.2.6.:

VIII.4.1.10. \textbf{Corollary.} Let $U$ be an open set in $\mathbb{R}^n$, and $f$ an $r$'th order differentiable function from $U$ to $\mathbb{R}^m$ ($r > 1$). Then any two mixed partials of $f$ of total order $\leq r$ in which each coordinate direction appears the same number of times are equal on $U$.

VIII.4.1.11. \textbf{From the point of view of VIII.4.1.6.} (cf. VIII.4.4.1.), VIII.4.1.7. has a nice rephrasing: the bilinear form $d^2 f(a)$, when defined, is \textit{symmetric}: $d f(a)(x, y) = d f(a)(y, x)$ for all $x, y \in \mathbb{R}^n$. Similarly, the $r$-multilinear map $d^r f(a)$, when defined, is symmetric in the sense that it is invariant under any permutation of the arguments.

VIII.4.2. \textbf{Taylor’s Theorem}

VIII.4.3. \textbf{Critical Point Analysis}

VIII.4.4. \textbf{Exercises}
(a) Let \( f : U \subseteq \mathbb{R}^n \rightarrow \mathbb{R}^m \) be second-order differentiable at \( a \in U \). Show that

\[
d^2 f(a)(e_j)(e_k) = \frac{\partial^2 f}{\partial x_j \partial x_k}(a)
\]

for any \( j,k \). Thus the second-order partials of \( f \) are the natural coordinates for the identification of \( d^2 f \) regarded as a function from \( U \) to \( \mathbb{R}^{nm} \).

(b) More generally, if \( f \) is \( r \)'th order differentiable at \( a \), and \( d^r f(a) \) is regarded as an \( r \)-multilinear map from \( \mathbb{R}^n \times \cdots \times \mathbb{R}^n \) to \( \mathbb{R}^m \), then for any \( i_1, \ldots, i_r \) we have

\[
d^r f(a)(e_{i_1}, \ldots, e_{i_r}) = \frac{\partial^r f}{\partial x_{i_1} \cdots \partial x_{i_r}}(a) .
\]

(c) Give a similar description of \( D^r f(a) \).

VIII.5. Vector Analysis

VIII.5.1. Surfaces in \( \mathbb{R}^3 \)

VIII.5.2. Divergence and Curl
VIII.6. The Implicit and Inverse Function Theorems

The Implicit and Inverse Function Theorems are the deepest results from differential calculus, and among the most important; they are the primary means of passing from the *infinitesimal* to the *local* in analysis and geometry. Although they are distinct results, each is a relatively easy corollary of the other, so one only needs to carry out the (rather difficult) proof of one of them to obtain both (and in fact the two theorems have a common generalization, cf. VIII.6.2.1.). They can both be regarded as aspects of the general problem of solving systems of functional equations; existence and uniqueness theorems for solutions to differential equations fall into the same class of results (see IX.1.9.10.).

These results are stated in less generality than they have to be in many references, with proofs more difficult than they have to be (and at that not even always entirely complete or correct). There are several standard proofs, and some of these proofs arguably give better insight into why the theorems are true than the simplest ones. We will give proofs of each theorem which illustrate two common approaches; each approach gives versions not obtainable from the others.

These theorems have a long and complicated history, going back at least to DESCARTES (although for a long time it was not always appreciated that they had to be proved), and there are many versions. We will give only a few. The Smooth (C¹) Implicit Function Theorem (VIII.6.1.7.) was first proved by Dini in the 1870’s, although Dini’s contributions were not properly recognized for a long time since he published them only in his lecture notes, which had a limited circulation. For continuous and higher-order smooth versions, see [Gou03] and [You09]. The book [KP02a] contains the most thorough treatment available of the various forms of the Implicit and Inverse Function Theorems.

VIII.6.1. Statements of the Theorems

VIII.6.1.1. The idea of the theorems is that if one has n equations in m unknowns, then there is “usually” a unique solution if n = m, many solutions if n < m, and no solutions if n > m; if n < m, it should be possible to solve for n of the variables as functions of the others (specifying values for m−n of the variables yields a system of n equations in the remaining n variables). These statements are literally true if the equations are linear (cf. ()) unless there is degeneracy in the system. Since smooth functions are “approximately linear”, it might also be possible (and in fact is) to do the same locally in the smooth case.

VIII.6.1.2. Vector notation is a convenient way to rephrase systems of equations. An equation in unknowns x₁, . . . , xₘ can, by moving everything to one side of the equation, be written as $F(x₁, . . . , xₘ) = 0$, where $F : \mathbb{R}^m \to \mathbb{R}$ is a function. A set of n equations

$$F_1(x₁, . . . , xₘ) = 0$$
$$F_2(x₁, . . . , xₘ) = 0$$
$$\ldots$$
$$F_n(x₁, . . . , xₘ) = 0$$

can be written as $F(x₁, . . . , xₘ) = 0$, or $F(x) = 0$, where $F$ is the function from $\mathbb{R}^m$ (or a subset) to $\mathbb{R}^n$ with coordinate functions $(F₁, . . . , Fₙ)$, and $x = (x₁, . . . , xₘ)$.  

828
In the case \( m > n \), it is convenient to change notation slightly by setting \( p = m - n \). We would like to be able to solve the system \( \mathbf{F}(\mathbf{x}) = \mathbf{0} \) for \( n \) of the variables in terms of the other \( p \) variables. (Here the relative sizes of \( n \) and \( p \) do not matter; we could have \( n < p \), \( n = p \), or \( n > p \).) We can in general choose any \( n \) of the variables to solve for in terms of the other ones; we will notationally choose the last \( n \) and rename them \( y_1, \ldots, y_n \), i.e. our equation to solve is of the form

\[
\mathbf{F}(x_1, \ldots, x_p, y_1, \ldots, y_n) = \mathbf{0}
\]

or \( \mathbf{F}(\mathbf{x}, \mathbf{y}) = \mathbf{0} \), where \( \mathbf{x} = (x_1, \ldots, x_p) \in \mathbb{R}^p \) and \( \mathbf{y} = (y_1, \ldots, y_n) \in \mathbb{R}^n \). A solution on a subset \( W \) of \( \mathbb{R}^p \) is a function \( f : W \to \mathbb{R}^n \) such that the pair \( (\mathbf{x}, \mathbf{y}) \) for \( \mathbf{y} = f(\mathbf{x}) \) satisfies the equation for all \( \mathbf{x} \in W \), i.e. \( \mathbf{F}(\mathbf{x}, f(\mathbf{x})) = \mathbf{0} \) for all \( \mathbf{x} \in W \). We say the function \( f \) is implicitly defined by the equation \( \mathbf{F}(\mathbf{x}, \mathbf{y}) = \mathbf{0} \). It is rarely possible to find an explicit formula for an implicitly defined function in the nonlinear case.

Examples with \( n = p = 1 \) from elementary calculus (e.g. the one in VIII.6.1.10.) show that one can only expect the equation \( \mathbf{F}(\mathbf{x}, \mathbf{y}) = \mathbf{0} \) to define \( \mathbf{y} \) as a continuous function of \( \mathbf{x} \) locally, i.e. in some neighborhood of a point \( \mathbf{a} \) where \((\mathbf{a}, \mathbf{b})\) satisfies the equation, and then only around points where there is some nondegeneracy condition on \( \mathbf{F} \). If \( n = p = 1 \) and \( \mathbf{F} \) is smooth, the graph of the equation \( \mathbf{F}(\mathbf{x}, \mathbf{y}) = \mathbf{0} \) is a curve in \( \mathbb{R}^2 \), and this curve is in general only locally the graph of a smooth function, and not even necessarily around every point of the curve; points where the curve crosses itself or has a vertical tangent must be excluded (see Exercise VIII.6.9.2.).

In the statements of the theorems, we will use the following notation. Let \( \mathbf{F} \) be a function from an open set \( U \) in \( \mathbb{R}^{p+n} \) to \( \mathbb{R}^n \). Write the coordinates of \( \mathbb{R}^{p+n} \) as \( (x_1, \ldots, x_p, y_1, \ldots, y_n) \), or \( (\mathbf{x}, \mathbf{y}) \) with \( \mathbf{x} = (x_1, \ldots, x_p) \in \mathbb{R}^p \) and \( \mathbf{y} = (y_1, \ldots, y_n) \in \mathbb{R}^n \) as above, and let \( F_1, \ldots, F_n \) be the coordinate functions of \( \mathbf{F} \). So, in coordinates,

\[
\mathbf{F}(\mathbf{x}, \mathbf{y}) = (F_1(\mathbf{x}, \mathbf{y}), \ldots, F_n(\mathbf{x}, \mathbf{y})) = (F_1(x_1, \ldots, x_p, y_1, \ldots, y_n), \ldots, F_n(x_1, \ldots, x_p, y_1, \ldots, y_n))
\]

Let \( (\mathbf{x}, \mathbf{y}) \in U \), and suppose all partial derivatives of the form \( \frac{\partial F_i}{\partial y_j}(\mathbf{x}, \mathbf{y}) \) exist. Write

\[
D_y \mathbf{F}(\mathbf{x}, \mathbf{y}) = \begin{bmatrix}
\frac{\partial F_1}{\partial y_1}(\mathbf{x}, \mathbf{y}) & \cdots & \frac{\partial F_1}{\partial y_n}(\mathbf{x}, \mathbf{y}) \\
\vdots & \ddots & \vdots \\
\frac{\partial F_n}{\partial y_1}(\mathbf{x}, \mathbf{y}) & \cdots & \frac{\partial F_n}{\partial y_n}(\mathbf{x}, \mathbf{y})
\end{bmatrix}
\]

and, if all partial derivatives of the form \( \frac{\partial F_i}{\partial x_j}(\mathbf{x}, \mathbf{y}) \) exist, write

\[
D_x \mathbf{F}(\mathbf{x}, \mathbf{y}) = \begin{bmatrix}
\frac{\partial F_1}{\partial x_1}(\mathbf{x}, \mathbf{y}) & \cdots & \frac{\partial F_1}{\partial x_p}(\mathbf{x}, \mathbf{y}) \\
\vdots & \ddots & \vdots \\
\frac{\partial F_n}{\partial x_1}(\mathbf{x}, \mathbf{y}) & \cdots & \frac{\partial F_n}{\partial x_p}(\mathbf{x}, \mathbf{y})
\end{bmatrix}
\]

(note that \( D_y \mathbf{F}(\mathbf{x}, \mathbf{y}) \) is \( n \times n \) and \( D_x \mathbf{F}(\mathbf{x}, \mathbf{y}) \) is \( n \times p \) if they are defined). Then if \( \mathbf{F} \) is differentiable at \( (\mathbf{x}, \mathbf{y}) \), we have that the \( n \times (p + n) \) matrix \( D \mathbf{F}(\mathbf{x}, \mathbf{y}) \) partitions as

\[
D \mathbf{F}(\mathbf{x}, \mathbf{y}) = \begin{bmatrix}
\vdots & D_y \mathbf{F}(\mathbf{x}, \mathbf{y}) & \vdots \\
D_x \mathbf{F}(\mathbf{x}, \mathbf{y}) & \vdots & \vdots
\end{bmatrix}
\]

829
VIII.6.1.6. Theorem. [Implicit Function Theorem, Continuous Version] Let $U$ be an open set in $\mathbb{R}^{p+n}$ and $(a, b) \in U$. Let $F : U \to \mathbb{R}^n$ with $F(a, b) = 0$. Suppose $F$ is continuous on $U$ and that $D_y F$ exists and is continuous on $U$, i.e. that $\frac{\partial F}{\partial y}$ exists and is continuous on $U$ for $1 \leq j \leq n$. If $D_y F(a, b)$ is invertible, i.e. $\det(D_y F(a, b)) \neq 0$, then there are:

(i) An open set $V$ in $\mathbb{R}^{p+n}$ containing $(a, b)$, with $V \subseteq U$, such that $D_y F(x, y)$ is invertible for all $(x, y) \in V$;

(ii) An open set $W$ in $\mathbb{R}^{p}$ containing $a$;

(iii) A unique function $f : W \to \mathbb{R}^n$ such that $f(a) = b$ and, for all $x \in W$, $(x, f(x)) \in V$ and

$$F(x, f(x)) = 0.$$ 

Additionally, $f$ is continuous on $W$.

VIII.6.1.7. Theorem. [Implicit Function Theorem, Smooth Version] Let $U$ be an open set in $\mathbb{R}^{p+n}$ and $(a, b) \in U$. Let $F : U \to \mathbb{R}^n$ with $F(a, b) = 0$. Suppose $F$ is $C^r$ on $U$ for some $r$, $1 \leq r \leq \infty$. If $D_y F(a, b)$ is invertible, i.e. $\det(D_y F(a, b)) \neq 0$, then there are:

(i) An open set $V$ in $\mathbb{R}^{p+n}$ containing $(a, b)$, with $V \subseteq U$, such that $D_y F(x, y)$ is invertible for all $(x, y) \in V$;

(ii) An open set $W$ in $\mathbb{R}^{p}$ containing $a$;

(iii) A unique function $f : W \to \mathbb{R}^n$ such that $f(a) = b$ and, for all $x \in W$, $(x, f(x)) \in V$ and

$$F(x, f(x)) = 0.$$ 

Additionally, $f$ is $C^r$ on $W$, and for any $x \in W$, we have

$$Df(x) = -D_y F(x, f(x))^{-1}D_x F(x, f(x))$$

(in particular, $D_y F(x, f(x))$ is invertible for all $x \in W$).

VIII.6.1.8. Note that the difference between the continuous version and the $C^1$ version (smooth version with $r = 1$) is merely in the differentiability of $F$ in the $x$-coordinates; continuity of $F$ and continuous differentiability in the $y$-coordinates are necessary in both cases (there is a version with this weakened: see VIII.6.3.9. and VIII.6.6.7.). To obtain continuous differentiability of higher order for the implicitly defined function, higher-order continuous differentiability of $F$ in both $x$- and $y$-coordinates is needed.

VIII.6.1.9. The uniqueness of the implicitly defined function $f$ precisely means that there is an open neighborhood $V'$ of $(a, b)$ (specifically, $V' = \{(x, y) \in V : x \in W\}$) such that the part of the level set $S = \{(x, y) \in U : F(x, y) = 0\}$ in $V'$ is exactly the graph of $f$, i.e. $S$ is locally the graph of a (continuous or smooth) function.

The use of $0$ in the statements is arbitrary: it could be replaced by any constant $c \in \mathbb{R}^n$ by applying the theorems to $F = F - c$. 830
VIII.6.1.10. In the statement of the theorems, one would expect the neighborhood $V$ to be contained in $U$ (this of course does not preclude the possibility that the conclusion could hold on a larger $V$). To show the necessity in general of passing to a smaller neighborhood $V$ of $(a, b)$ as well as the (expected) passage to a small neighborhood $W$ of $a$, consider the basic example of implicit differentiation every calculus class begins with: the case $p = n = 1$ and

$$F(x, y) = x^2 + y^2 - 25.$$ 

The set \{(x, y) : F(x, y) = 0\} is, of course, the circle of radius 5 around the origin in $\mathbb{R}^2$. Let $(a, b) = (3, 4)$. In this case the set $U$ could be taken to be all of $\mathbb{R}^2$, but no matter how small an open interval $W$ around $a = 3$ in $\mathbb{R}$ is taken, there is not a unique function $f$ on $W$ giving a solution, since we could have $f(x) = \pm \sqrt{25 - x^2}$ with the sign chosen arbitrarily for each $x$ (so long as $f(3) = 4$). There is a unique \textit{continuous solution} for $W$ small, but to obtain a unique \textit{solution}, one must cut down to a smaller neighborhood $V$ of $(3, 4)$. Actually $V$ does not have to be all that small in this case: it only needs not to contain any points on the lower half-circle with $x$-coordinate close to 3.

In this case, if $f$ is the unique solution on an interval $W$ (which must be contained in the interval $(-5, 5)$), then by the theorem

$$f'(x) = -\frac{\partial F}{\partial x}(x, f(x)) = -\frac{2x}{2f(x)} = -\frac{x}{f(x)},$$

for any $x \in W$. Here we can find an explicit formula for $f$: $f(x) = \sqrt{25 - x^2}$, and verify the formula for $f'$ directly. In most examples it is impossible to find an explicit formula for the implicitly defined function.

VIII.6.1.11. To obtain a reasonable Implicit Function Theorem, the function $F$ must be continuous. This in itself is not enough to guarantee an implicitly defined function, even a nonunique one, even if $p = n = 1$ (Exercise VIII.6.9.4.). But if there is a (unique) implicitly defined function, it is automatically continuous.

VIII.6.1.12. \textbf{Proposition.} Let $F$ be a continuous function on a subset $U$ of $\mathbb{R}^{p+n}$, with values in $\mathbb{R}^n$, and $K$ a compact subset of $U$. Suppose there is an open set $W$ in $\mathbb{R}^p$ on which there is a unique function $f : W \to \mathbb{R}^n$ implicitly defined by the equation $F(x, y) = 0$ with respect to $K$, i.e. for each $x \in W$ there is a unique $y \in \mathbb{R}^n$ such that $(x, y) \in K$ and $F(x, y) = 0$. Then $f$ is continuous.

\textbf{Proof:} Let $(x_k)$ be a sequence in $W$ with $x_k \to a \in W$. Suppose $f(x_k) \not= f(a)$. Then by compactness of $K$ there is a subsequence $(x_{k_j})$ such that $(f(x_{k_j}))$ converges to a point $y \in \mathbb{R}^n$, $y \not= f(a)$, with $(a, y) \in K$. But then $0 = F(x_{k_j}, f(x_{k_j})) \to F(a, y)$ by continuity of $F$, so $F(a, y) = F(a, f(a)) = 0$, contradicting the uniqueness assumption on $F$ and $K$.

VIII.6.1.13. The Implicit Function Theorem is strictly a local result, i.e. the conclusion just holds on some neighborhood $W$ of $a$. In some situations it is possible to determine an explicit $W$ on which the conclusion holds (cf. IX.1.9.10.).

\textbf{The Inverse Function Theorem}

VIII.6.1.14. If $f$ is a function defined on an open subset $U$ of $\mathbb{R}^n$, with values in $\mathbb{R}^m$, we would like to know when $f$ has an inverse function with the same continuity or differentiability properties as $f$. An
obvious necessary condition is that \( f \) be one-to-one (injective) on \( U \), and to discuss differentiability we also need that \( f(U) \) is open in \( \mathbb{R}^m \).

The Invariance of Domain Theorem \( (\ref{VIII.6.1.16}) \) gives a complete answer to the continuous version of the question: if \( f \) is continuous and one-to-one, then \( f(U) \) is open if and only if \( n = m \), and in this case \( f^{-1} \) is automatically continuous on \( f(U) \).

The answer to the differentiability question is more elementary. The next result does not depend on the Invariance of Domain Theorem:

\textbf{VIII.6.1.15. Proposition.} Let \( U \) be an open set in \( \mathbb{R}^n \), \( a \in U \), \( V \) an open set in \( \mathbb{R}^m \), and \( f \) a one-to-one function from \( U \) onto \( V \). Set \( b = f(a) \). Suppose \( f \) is differentiable at \( a \). Then \( f^{-1} : V \to U \) is differentiable at \( b \) if and only if \( m = n \) and \( Df(a) \) is invertible. If these conditions hold, then \( D(f^{-1})(b) = [Df(a)]^{-1} \).

\textbf{Proof:} One direction is almost immediate. If \( f^{-1} \) is differentiable at \( b \), then by the Chain Rule we have
\[
I_n = D(f^{-1} \circ f)(a) = D(f^{-1})(b)Df(a) \\
I_m = D(f \circ f^{-1})(b) = Df(a)D(f^{-1})(b)
\]
and so \( m = n \), \( Df(a) \) is invertible, and \( D(f^{-1})(b) = Df(a)^{-1} \) by \( (\ref{VIII.6.1.16}) \).

For the converse direction, we need a lemma:

\textbf{VIII.6.1.16. Lemma.} Let \( U \) be an open set in \( \mathbb{R}^n \), \( a \in U \), and \( f \) a one-to-one function from \( U \) to \( \mathbb{R}^n \). Suppose \( f \) is differentiable at \( a \) and \( Df(a) \) is invertible. Then there are strictly positive constants \( c, d \) and a neighborhood \( W \) of \( a \) contained in \( U \), such that
\[
c\|x - a\| < \|f(x) - f(a)\| < d\|x - a\|
\]
for all \( x \in W \setminus \{a\} \). In fact, we may choose \( c \) to be any positive number less than \( \|Df(a)^{-1}\|^{-1} \) and \( d \) any number greater than \( \|Df(a)\| \).

\textbf{Proof:} Fix \( c, d \) with \( 0 < c < \|Df(a)^{-1}\|^{-1} \) and \( d > \|Df(a)\| \), and set
\[
\epsilon = \min \left( \|Df(a)^{-1}\|^{-1} - c, d - \|Df(a)\| \right) > 0.
\]
Since \( f \) is differentiable at \( a \), there is a \( \delta > 0 \) such that, whenever \( 0 < \|x - a\| < \delta \), \( x \in U \) and
\[
\left| \frac{\|f(x) - f(a)\|}{\|x - a\|} - \frac{\|Df(a)(x - a)\|}{\|x - a\|} \right| \leq \frac{\|f(x) - f(a) - Df(a)(x - a)\|}{\|x - a\|} < \epsilon
\]
\[
-\epsilon < \frac{\|f(x) - f(a)\|}{\|x - a\|} - \frac{\|Df(a)(x - a)\|}{\|x - a\|} < \epsilon.
\]
But we have \( \|Df(a)(x - a)\| \leq \|Df(a)\|\|x - a\| \) by definition of the operator norm, so
\[
\frac{\|f(x) - f(a)\|}{\|x - a\|} < \frac{\|Df(a)(x - a)\|}{\|x - a\|} + \epsilon \leq \|Df(a)\| + \epsilon \leq d
\]
and similarly
\[ \|x - a\| = \|Df(a)^{-1}(Df(a)(x - a))\| \leq \|Df(a)^{-1}\| \|Df(a)(x - a)\| \]
\[ c \leq \|Df(a)^{-1}\|^{-1} - \epsilon \leq \frac{\|Df(a)(x - a)\|}{\|x - a\|} - \epsilon < \frac{\|f(x) - f(a)\|}{\|x - a\|} \]
so we may take \( W \) to be the open ball of radius \( \delta \) around \( a \).

**VIII.6.1.17.** We now prove the other direction of VIII.6.1.15. Suppose \( m = n \) and \( Df(a) \) is invertible. Since \( f \) is a bijection between \( U \) and \( V \), for each \( x \in U \) there is a unique \( y \in V \) with \( y = f(x) \), and conversely for each \( y \in V \) there is a unique \( x \in U \) with \( x = f^{-1}(y) \). We will suppress the function names and just use \( x \) and \( y \) with the understanding that they are related in this manner.

We must show that for any \( \epsilon > 0 \), there is a \( \delta > 0 \) such that, whenever \( 0 < \|y - b\| < \delta \), \( y \in V \) and
\[ \frac{\|x - a - Df(a)^{-1}(y - b)\|}{\|y - b\|} < \epsilon . \]
By VIII.6.1.16., reducing \( U \) if necessary we may assume there are positive constants \( c \) and \( d \) such that
\[ c\|x - a\| < \|f(x) - f(a)\| < d\|x - a\| \]
\[ \frac{1}{d} < \frac{\|x - a\|}{\|y - b\|} < \frac{1}{c} \]
for all \( x \in U, x \neq a \). Since \( f \) is differentiable at \( a \), there is an \( \eta > 0 \) such that, whenever \( 0 < \|x - a\| < \eta \), \( x \in U \) and
\[ \frac{\|y - b - Df(a)(x - a)\|}{\|x - a\|} < \frac{\epsilon c}{\|Df(a)^{-1}\|} . \]
Since
\[ x - a - Df(a)^{-1}(y - b) = Df(a)^{-1}[Df(a)(x - a) - (y - b)] \]
we have, for \( \|y - b\| < c\eta, \|x - a\| < \eta \) and
\[ \frac{\|x - a - Df(a)^{-1}(y - b)\|}{\|y - b\|} \leq \frac{\|Df(a)^{-1}\| \|Df(a)(x - a) - (y - b)\|}{\|y - b\|} \]
\[ = \frac{\|x - a\| \|Df(a)^{-1}\| \|y - b - Df(a)(x - a)\|}{\|x - a\| \|y - b\|} \leq \frac{1}{c} \|Df(a)^{-1}\| \frac{\epsilon c}{\|Df(a)^{-1}\|} = \epsilon \]
so we may take \( \delta = c\eta \). \( \diamondsuit \)

**VIII.6.1.18.** Corollary. Let \( U \) be an open set in \( \mathbb{R}^n \), \( V \) an open set in \( \mathbb{R}^m \), and \( f \) a one-to-one function from \( U \) onto \( V \). If \( f \) is differentiable at every point of \( U \), then \( f^{-1} : V \to U \) is differentiable at every point of \( V \) if and only if \( m = n \) and, for every \( x \in U \), \( Df(x) \) is invertible. If these conditions hold, then \( D(f^{-1})(y) \) is invertible for every \( y \in V \) and \( D(f^{-1})(y) = Df(f^{-1}(y))^{-1} \).

Actually, if \( f : U \to V \) is one-to-one, onto, and differentiable, then \( m \) must equal \( n \) even without the assumption that \( Df(x) \) is invertible for every \( x \in U \), by Invariance of Domain; but we do not need to use this fact for the Corollary.
VIII.6.1.19. There are two principal drawbacks to these results, however. First, the Invariance of Domain is a deep theorem requiring a considerable excursion into topology to prove. And second, even for the differentiable result which is more elementary, it must be verified that the function is locally one-to-one, with open range, which is often not easy to do directly. The most useful result would be one in which (local) injectivity can be deduced simply from nondegeneracy of the derivative. This is the principal content of the Inverse Function Theorem:

VIII.6.1.20. \textbf{Theorem. [Inverse Function Theorem]} Let $U$ be an open set in $\mathbb{R}^n$, $a \in U$, and $f : U \to \mathbb{R}^n$ a $C^r$ function for some $r, 1 \leq r \leq \infty$. If $Df(a)$ is invertible, then there is a neighborhood $V$ of $a$, $V \subseteq U$, such that

(i) $f$ is one-to-one on $V$.

(ii) $f(V)$ is open in $\mathbb{R}^n$.

(iii) $Df(x)$ is invertible for all $x \in V$.

(iv) $f^{-1}$ is $C^r$ on $f(V)$ and, for all $y \in f(V)$,

$$D(f^{-1})(y) = [Df(f^{-1}(y))]^{-1}.$$ 

VIII.6.1.21. If $Df(x)$ is not invertible everywhere on $U$, it will obviously be necessary to restrict to a smaller neighborhood $V$ of $a$ to get (iii) and (iv). But this may be necessary even if $Df(x)$ is invertible for all $x \in U$ to make $f$ injective.

If $n = 1$ and $I$ is an interval in $\mathbb{R}$, and $f : I \to \mathbb{R}$ is differentiable on $I$ with $f'(x) \neq 0$ for all $x \in I$, then $f$ is strictly monotone on $I$ (and thus one-to-one; so if $U = I$ we may take $V = U$). But if $n > 1$ invertibility of $Df$ on $U$ does not guarantee that $f$ is one-to-one on $U$, even if $U$ is connected. A simple and important example is the following function, which is the transformation from rectangular coordinates to polar coordinates in $\mathbb{R}^2$ (hence we use $(r, \theta)$ for the coordinates). Set $U = \{(r, \theta) : r > 0\}$, and define $f : U \to \mathbb{R}^2$ by

$$f(r, \theta) = (r \cos \theta, r \sin \theta).$$

Then $Df(r, \theta)$ is invertible everywhere on $U$; but $f$ is not one-to-one on all of $U$, only locally one-to-one.

VIII.6.2. \textbf{Twin Theorems and a Generalization}

The Inverse Function Theorem and Implicit Function Theorem (smooth version) are twin theorems in the sense that each is easily derivable from the other; the arguments are much easier than proving either theorem from scratch. In fact, either argument can be used to prove a common generalization:

VIII.6.2.1. \textbf{Theorem. [General Implicit/Inverse Function Theorem]} Let $n \in \mathbb{N}$, $p \in \mathbb{N} \cup \{0\}$, $a \in \mathbb{R}^p$, $b, c \in \mathbb{R}^n$, $U$ an open neighborhood of $(a, b)$ in $\mathbb{R}^{p+n}$, $F : U \to \mathbb{R}^n$ a $C^r$ function $(1 \leq r \leq \infty)$ with $F(a, b) = c$ and $D_y F(a, b)$ invertible. Then there are:

(i) An open neighborhood $V$ of $(a, b)$ in $\mathbb{R}^{p+n}$, contained in $U$, such that $D_y F(x, y)$ is invertible for all $(x, y) \in V$;
(ii) An open neighborhood $W$ of $(a, c)$ in $\mathbb{R}^{p+n}$;

(iii) A unique function $G : W \to \mathbb{R}^n$ satisfying $G(a, c) = b$ and, for all $(x, z) \in W$, $(x, G(x, z)) \in V$ and

$$F(x, G(x, z)) = z.$$  

Additionally, $G$ is $C^r$ on $W$, and for all $(x, z) \in W$,

$$DG(x, z) = \begin{bmatrix} -D_y F(x, G(x, z))^{-1} D_x F(x, G(x, z)) & D_y F(x, G(x, z))^{-1} \\ \vdots & \vdots \\ \vdots & \vdots \end{bmatrix}.$$  

Note that the Inverse Function Theorem is the case $p = 0$ (so the $a$ is absent). The Smooth Implicit Function Theorem is a corollary by taking $c = 0$ and setting $f(x) = G(x, 0)$. In fact, the Smooth Implicit Function Theorem says that for certain fixed $z$ near $c$, there is a function $f_z$ implicitly defined near $a$ by $F(x, y) = z$, which is $C^r$ in $x$; we have $G(x, z) = f_z(x)$, and the additional content of the above theorem is that the $f_z$ are defined for all $z$ near $c$ and “vary smoothly” in $z$. Thus Theorem VIII.6.2.1. is a “parametrized version” of both the Implicit and Inverse Function Theorems: holding $x$ fixed gives the Inverse Function Theorem and holding $z$ fixed gives the (Smooth) Implicit Function Theorem.

The situation is symmetric in $F$ and $G$. $G$ satisfies the hypotheses of the theorem, so there is a $C^r$ function $H$ defined near $(a, b)$ for which $H(a, b) = c$ and $G(x, H(x, y)) = y$ for $(x, y)$ near $(a, b)$. By the formula, $DH(x, y) = DF(x, y)$ for all $(x, y)$ near $(a, b)$, and since $H(a, b) = F(a, b)$, we have $H = F$ on a neighborhood of $(a, b)$, i.e. $H = F$ (perhaps restricted to a smaller neighborhood of $(a, b)$). In particular, we have $G(x, F(x, y)) = y$ for $(x, y)$ near $(a, b)$ (this can be verified directly).

We will give simple proofs of VIII.6.2.1. from both the Inverse Function Theorem and the Smooth Implicit Function Theorem.

**Proof From Inverse Function Theorem**

**VIII.6.2.2.** Assume the Inverse Function Theorem VIII.6.1.20. We will deduce VIII.6.2.1.

Suppose $U \subseteq \mathbb{R}^{p+n}$ is open, $(a, b) \in U$, and $F : U \to \mathbb{R}^n$ is a $C^r$ function with $F(a, b) = c$ and $D_y F(a, b)$ invertible. Define

$$\tilde{F}(x, y) = (x, F(x, y))$$

for $(x, y) \in U$. Then $\tilde{F}$ is a $C^r$ function from $U$ to $\mathbb{R}^{p+n}$. We have

$$D \tilde{F}(x, y) = \begin{bmatrix} I_p & 0 \\ D_x F(x, y) & D_y F(x, y) \end{bmatrix}$$

for $(x, y) \in U$; thus $D \tilde{F}(a, b)$ is invertible ($\tilde{F}(a, b) = (a, c)$). We have $(a, c) \in W$ and $\Phi(a, c) = (a, b)$. 

835
Write $\Phi(x, z) = (H(x, z), G(x, z))$, where $H: W \to \mathbb{R}^p$ and $G: W \to \mathbb{R}^n$. Then $H$ and $G$ are $C^r$, and $G(a, c) = b$. Since for $(x, z) \in W$ we have
\[(x, z) = \tilde{F}(\Phi(x, z)) = \tilde{F}(H(x, z), G(x, z)) = (H(x, z), F(H(x, z), G(x, z)))\]
we obtain that $H(x, z) = x$ and
\[F(H(x, z), G(x, z)) = F(x, G(x, z)) = z\]
for $(x, z) \in W$.

Uniqueness of $G$ follows from the fact that $\tilde{F}$ is one-to-one: if $\tilde{G}$ is a function from $W$ to $\mathbb{R}^n$ with $(x, \tilde{G}(x, z)) \in V$ and $F(x, \tilde{G}(x, z)) = z$ for all $(x, z) \in W$, then for $(x, z) \in W$ we have
\[\tilde{F}(x, \tilde{G}(x, z)) = (x, z) = \tilde{F}(x, G(x, z))\]
so $\tilde{G}(x, z) = G(x, z)$.

Thus VIII.6.2.1. is proved (see Exercise VIII.6.9.5. for the derivative formula). \(\square\)

**Proof From Implicit Function Theorem**

**VIII.6.2.3.** Now assume the Smooth Implicit Function Theorem VIII.6.1.7. holds. We will deduce VIII.6.2.1.

Suppose $U \subseteq \mathbb{R}^{p+n}$ is open, $(a, b) \in U$, and $F: U \to \mathbb{R}^n$ is as in the statement of VIII.6.2.1.. Set $c = F(a, b)$. Write $\mathbb{R}^{p+2n} \cong \mathbb{R}^p \times \mathbb{R}^n \times \mathbb{R}^n$, and set
\[U' = \{(x, z, y) \in \mathbb{R}^{p+2n} : (x, y) \in U\}.

Then $U'$ is open in $\mathbb{R}^{p+2n}$, and $(a, c, b) \in U'$. Define $\tilde{F}: U' \to \mathbb{R}^n$ by
\[\tilde{F}(x, z, y) = F(x, y) - z.\]

Then $\tilde{F}$ is $C^r$ on $U'$, $\tilde{F}(a, c, b) = 0$, and
\[D\tilde{F}(x, z, y) = [D_x F(x, y) - I_n \quad D_y F(x, y)]\]
for $(x, z, y) \in U'$, and in particular $D_y \tilde{F}(a, c, b) = D_y F(a, b)$ is invertible.

We can thus solve the equation $\tilde{F}(x, z, y) = 0$ implicitly for $y$ as a function of $(x, z)$, i.e. there are open neighborhoods $W$ of $(a, c)$ and $V$ of $(a, b)$ and a unique function $G : W \to \mathbb{R}^n$ such that $G(x, z) \in V$ and $F(x, z, G(x, z)) = 0$ for all $(x, z) \in W$, and $G$ is $C^r$. But $\tilde{F}(x, z, G(x, z)) = 0$ is equivalent to $F(x, G(x, z)) = z$.

Thus VIII.6.2.1. is proved (cf. Exercise VIII.6.9.5.). \(\square\)

**VIII.6.2.4.** There are versions of the Continuous and Mixed Implicit Function Theorems similar to VIII.6.2.1. (Exercise VIII.6.9.15.).

836
VIII.6.3. Proof of the Implicit Function Theorem, Case $n = 1$

It is much easier to prove the Implicit Function Theorem in the case where we are only solving for one variable in terms of the others. We also obtain the desired results under somewhat weaker hypotheses. It does not make any difference in the proof how many other variables there are, i.e. we will prove the case where $n = 1$ and $p$ is arbitrary.

VIII.6.3.1. The general setup for this case is a function $F : U \to \mathbb{R}$, where $U \subseteq \mathbb{R}^{p+1}$ is open, and $(a, b) = (a_1, \ldots, a_p, b) \in U$ with $F(a, b) = 0$. Write $(x, y) = (x_1, \ldots, x_p, y)$ for the coordinates of a general point of $U$. We will need to assume at a minimum that $F$ is continuous on $U$ and that $\frac{\partial F}{\partial y}(a, b)$ exists and is nonzero. To obtain most of the conclusions we will need a little more. Of course, the conditions need only hold on some neighborhood of $(a, b)$, since for the conclusion we will have to restrict to a smaller neighborhood of $(a, b)$ anyway in general, i.e. the conclusion will be only a local one.

The Continuous Version

VIII.6.3.2. Theorem. [One-Dimensional Weak Implicit Function Theorem, Continuous Version] Let $F(x_1, \ldots, x_p, y) : U \to \mathbb{R}$, where $U \subseteq \mathbb{R}^{p+1}$ is open, and $(a, b) = (a_1, \ldots, a_p, b) \in U$ with $F(a, b) = 0$. Suppose $F$ is continuous on $U$ and $\frac{\partial F}{\partial y}$ exists and is nonzero at $(a, b)$. Then there are:

(i) An open set $V$ in $\mathbb{R}^{p+1}$ containing $(a, b)$, with $V \subseteq U$;

(ii) An open set $W$ in $\mathbb{R}^p$ containing $a$;

(iii) Functions $\overline{f}, \underline{f} : W \to \mathbb{R}$ such that $\overline{f}(a) = \underline{f}(a) = b$, $(x, \overline{f}(x))$ and $(x, \underline{f}(x))$ are in $V$ and $F(x, \overline{f}(x)) = F(x, \underline{f}(x)) = 0$

for all $x \in W$, and such that if $f$ is any function from $W$ to $\mathbb{R}$ with $(x, f(x)) \in V$ and $F(x, f(x)) = 0$ for all $x \in W$, then $\underline{f} \leq f \leq \overline{f}$.

Additionally, $\overline{f}$ is upper semicontinuous and $\underline{f}$ is lower semicontinuous on $W$, and $\overline{f}$ and $\underline{f}$ are continuous at $a$.

Proof: By passing to a smaller neighborhood, we may assume $U$ is convex. Suppose $\frac{\partial F}{\partial y}(a, b) > 0$. Then there are $y_1 > b$ and $y_2 < b$ such that $(a, y_1)$ and $(a, y_2)$ are in $U$ and $\frac{F(a, z) - F(a, b)}{z - b} > 0$ for $y_2 \leq z \leq y_1$ and $z \neq b$ (in fact, this will be true for all such $y_1, y_2$ sufficiently close to $b$). It follows that $F(a, y_1) > 0$ and $F(a, y_2) < 0$ (and in fact, $F(a, z) > 0$ for $b < z \leq y_1$ and $F(a, z) < 0$ for $y_2 \leq z < b$). Then there is an open neighborhood $W$ of $a$ in $\mathbb{R}^p$ such that, for all $x \in W$, $(x, y_1)$ and $(x, y_2)$ are in $U$, $F(x, y_1) > 0$, and $F(x, y_2) < 0$. So for each fixed $x \in W$, there is at least one $y$ between $y_2$ and $y_1$ for which $F(x, y) = 0$ by the Intermediate Value Theorem, since $F$ is continuous on $U$. Among these, there is a largest $\overline{f}$ and a smallest $\underline{f}$. Set $\overline{f}(x) = y_1$ and $\underline{f}(x) = y_2$. This defines $\overline{f}$ and $\underline{f}$ on $W$. We obviously have $\overline{f}(a) = \underline{f}(a) = b$.

Set $V = W \times (y_2, y_1) \subseteq U$. If $f$ is any real-valued function on $W$ such that $(x, f(x)) \in V$ and $F(x, f(x)) = 0$ for all $x \in W$, we obviously have $\underline{f}(x) \leq f(x) \leq \overline{f}(x)$ for all $x \in W$.

It remains to show that $\overline{f}$ and $\underline{f}$ are semicontinuous on $W$. We give the argument for $\overline{f}$; the one for $\underline{f}$ is essentially identical. Let $x_n \in \overline{W}$, $x_n \to x_0$. Passing to a subsequence we may assume $\overline{f}(x_n) \to z$ for some $z$ between $y_2$ and $y_1$. But then $0 = F(x_n, \overline{f}(x_n)) \to F(x_0, z)$ by continuity of $F$, so $F(x_0, z) = 0$ and
and \( F \) (contradicting the assumption that By continuity of Proof: Corollary VIII.6.3.5.

\[
\begin{align*}
\text{Proof: Let } F \text{ function Under the hypotheses of VIII.6.3.4. we have that An open set } V \text{ except the uniqueness of An open set } V = \text{A unique function } V \text{ with } z \text{ are continuous at } \text{An open set } V \text{ and } F. \text{Fix } x \in W. \text{Then there are:}
\end{align*}
\]

(i) An open set \( V \) in \( \mathbb{R}^{p+1} \) containing \((a, b)\), with \( V \subset U \);

(ii) An open set \( W \) in \( \mathbb{R}^p \) containing \( a \);

(iii) A unique function \( f : W \to \mathbb{R} \) such that \( f(a) = b \), and \((x, f(x)) \in V \) and \( F(x, f(x)) = 0 \) for all \( x \in W \).

Additionally, \( f \) is continuous on \( W \).

**Proof:** Everything follows immediately from VIII.6.3.2, except the uniqueness of \( f \), i.e. that \( \overline{F} = f \). Define \( V \) and \( W \) as in the proof of VIII.6.3.2. Fix \( x \in W \). If there were \( y \) and \( z \), \( y \neq z \), with \((x, y)\) and \((x, z)\) in \( V \) and \( F(x, y) = F(x, z) = 0 \), then by Rolle’s Theorem there would be a \( c \) between \( y \) and \( z \) with \( \frac{\partial F}{\partial y}(x, c) = 0 \), contradicting the assumption that \( \frac{\partial F}{\partial y} \) is never zero on \( U \). Thus there is a unique \( y \) such that \((x, y) \in V \) and \( F(x, y) = 0 \), and we may set \( f(x) = y \). This \( f \) is the unique real-valued function defined on \( W \) with \((x, f(x)) \in V \) and \( F(x, f(x)) = 0 \) for all \( x \in W \).

**VIII.6.3.5. Corollary.** Let \( F(x_1, \ldots, x_p, y) : U \to \mathbb{R}, \) where \( U \subset \mathbb{R}^{p+1} \) is open, and \((a, b) = (a_1, \ldots, a_p, b) \in U \) with \( F(a, b) = 0 \). Suppose \( F \) is continuous on \( U \) and \( \frac{\partial F}{\partial y} \) exists at all points of \( U \), and is continuous at \((a, b)\), with \( \frac{\partial F}{\partial y}(a, b) \neq 0 \). Then there are:

(i) An open set \( V \) in \( \mathbb{R}^{p+1} \) containing \((a, b)\), with \( V \subset U \);

(ii) An open set \( W \) in \( \mathbb{R}^p \) containing \( a \);

(iii) A unique function \( f : W \to \mathbb{R} \) such that \( f(a) = b \), and \((x, f(x)) \in V \) and \( F(x, f(x)) = 0 \) for all \( x \in W \).

Additionally, \( f \) is continuous on \( W \).

**Proof:** By continuity of \( \frac{\partial F}{\partial y} \) at \((a, b)\), there is a neighborhood \( U' \) of \((a, b)\) contained in \( U \) such that \( \frac{\partial F}{\partial y}(x, y) \neq 0 \) for all \((x, y) \in U' \). Apply VIII.6.3.4, with \( U' \) in place of \( U \).
A Pictorial Version

VIII.6.3.6. We illustrate the argument in the case \( p = n = 1 \) (the picture represents the case of general \( p \) if the horizontal axis is regarded as multidimensional). Suppose \( U \) is an open set in \( \mathbb{R}^2 \) large enough to include the region pictured in the diagrams (which may actually be very small, and the proportions may vary), and \( F \) is a continuous function from \( U \) to \( \mathbb{R} \) such that \( \frac{\partial F}{\partial y} \) exists and is nonzero on \( U \), and let \( (a, b) \in U \) with \( F(a, b) = 0 \). We assume that \( \frac{\partial F}{\partial y}(a, b) > 0 \); the proof in the case \( \frac{\partial F}{\partial y}(a, b) < 0 \) is identical with red and blue reversed. Because of the shapes in the diagrams, this proof can be called the “T proof.”

Since \( F(a, b) = 0 \) and \( \frac{\partial F}{\partial y}(a, b) > 0 \), \( g(y) = F(a, y) \) is increasing at \( b \) (V.3.6.8.), i.e. there are \( y_1 < b \) and \( y_2 > b \) such that \( F(a, y) > F(a, b) = 0 \) for \( b < y \leq y_2 \), and \( F(a, y) < 0 \) for \( y_1 \leq y < b \), i.e. \( F(x, y) > 0 \) for all points \((x, y)\) in red in Figure VIII.4 and \( F(x, y) < 0 \) for all \((x, y)\) in blue:

![Figure VIII.4: Implicit Function Theorem I](image)

We may assume \( y_2 - b = b - y_1 \) if desired by taking a minimum; although this is not necessary for the proof, it will be convenient later since this can be called \( \epsilon \).
Since $F(a, y_2) > 0$ and $F$ is continuous, there are $x_1 < a$ and $x_2 > a$ such that $F(x, y_2) > 0$ for $x_1 \leq x \leq x_2$. Similarly, since $F(a, y_1) < 0$, there are $x_3 < a$ and $x_4 > a$ with $F(x, y_1) < 0$ for $x_3 \leq x \leq x_4$. As before, we may assume $x_3 = x_1$ and $x_4 = x_2$ and that $x_2 - a = a - x_1$ by taking a minimum; this can be called $\delta$. Thus all red points $(x, y)$ in Figure VIII.5 have $F(x, y) > 0$, and all blue points have $F(x, y) < 0$:

![Diagram of red and blue points with $F(x, y)$ values]

Figure VIII.5: Implicit Function Theorem II

In the case of general $p$, the top and bottom horizontal segments become balls in $\mathbb{R}^p$ centered at $a$, which can be taken to have the same radius which we can call $\delta$. 
Now fix $x_0$, $x_1 \leq x_0 \leq x_2$. We have that $F(x_0, y_1) < 0$ and $F(x_0, y_2) > 0$. Since $F(x_0, y)$ is a continuous function of $y$, there must be a $y$, $y_1 < y < y_2$, with $F(x_0, y) = 0$. If there were more than one such $y$, by Rolle’s Theorem there would be a $y$ in between with $\frac{\partial F}{\partial y}(x_0, y) = 0$, contradicting that $\frac{\partial F}{\partial y}$ is nonzero on $U$. Thus there is a unique $y$ between $y_1$ and $y_2$ with $F(x_0, y) = 0$, and we call this $y \ f(x_0)$. This procedure uniquely defines a function $f$ on the interval $[x_1, x_2]$ with values in $(y_1, y_2)$, which satisfies $F(x, f(x)) = 0$ for $x_1 \leq x \leq x_2$. We also have $F(x, y) > 0$ for $f(x) < y \leq y_2$ and $F(x, y) < 0$ if $y_1 \leq y < f(x)$, for any $x \in [x_1, x_2]$. See Figure VIII.6.

Figure VIII.6: Implicit Function Theorem III
To show $f$ is continuous, fix $x_0$, $x_1 < x_0 < x_2$. Let $\epsilon > 0$. We may assume $\epsilon \leq \min(y_2 - f(x_0), f(x_0) - y_1)$ without loss of generality. We repeat the first part of the proof replacing $a$ and $b$ by $x_0$ and $f(x_0)$, and $y_1$ and $y_2$ by $f(x_0) \pm \epsilon$: $F(x_0, y) > 0$ for $f(x_0) < y \leq f(x_0) + \epsilon$ and $F(x_0, y) < 0$ for $f(x_0) - \epsilon \leq y < f(x_0)$, so there is a $\delta, 0 < \delta \leq \min(x_2 - x_0, x_0 - x_1)$, such that $F(x, y) > 0$ for all red points in Figure VIII.7 and $F(x, y) < 0$ for all blue points.

![Figure VIII.7: Implicit Function Theorem IV](image)

If $|x - x_0| < \delta$, there is thus a unique $y$, $f(x_0) - \epsilon < y < f(x_0) + \epsilon$, with $F(x, y) = 0$; this $y$ must be $f(x)$, i.e. $|f(x) - f(x_0)| < \epsilon$. Thus $f$ is continuous at $x_0$. 

842
The Differentiable Version

The next lemma contains the most delicate part of the entire proof of the Implicit Function Theorem. It is needed for the differentiable and smooth versions of the theorem if $n = 1$, and even for the continuous version for general $n$. If the first-order partials of $F$ are continuous at $(a, b)$, the proof can be simplified (Exercise VIII.6.9.8).

VIII.6.3.7. Lemma. Let $F(x_1, \ldots, x_p, y) : U \to \mathbb{R}$, where $U \subseteq \mathbb{R}^{p+1}$ is open, and $(a, b) = (a_1, \ldots, a_p, b) \in U$ with $F(a, b) = 0$. Suppose $F$ is continuous on $U$ and differentiable at $(a, b)$, and that $\frac{\partial F}{\partial y}(a, b) \neq 0$. Then there are:

(i) An open set $V$ in $\mathbb{R}^{p+1}$ containing $(a, b)$, with $V \subseteq U$;

(ii) An open set $W$ in $\mathbb{R}^p$ containing $a$;

such that whenever $f$ is a real-valued function on $W$ with $f(a) = b$ and $(x, f(x)) \in V$ and $F(x, f(x)) = 0$ for all $x \in W$ (there exist such functions by VIII.6.3.2.), then $f$ is differentiable at $a$ and, for $1 \leq j \leq p$,

$$\frac{\partial f}{\partial x_j}(a) = -\frac{\frac{\partial F}{\partial x_j}(a, b)}{\frac{\partial F}{\partial y}(a, b)}.$$

Proof: The little-o notation $()$ is very helpful in this proof. As $h = (\Delta x, \Delta y) = (\Delta x_1, \ldots, \Delta x_p, \Delta y) \to 0$, we have

$$\Delta F = F(a + \Delta x, b + \Delta y) - F(a, b) = \frac{\partial F}{\partial x_1}(a, b)\Delta x_1 + \cdots + \frac{\partial F}{\partial x_p}(a, b)\Delta x_p + o(1)\|\Delta x\| + \frac{\partial F}{\partial y}(a, b)\Delta y + o(1)\Delta y$$

and if we set $y = f(x)$, so $\Delta y = f(a + \Delta x) - f(a)$, we have $\Delta F = 0$ since $F(a + \Delta x, b + \Delta y) = F(a, b) = 0$, i.e.

$$\Delta y \left[\frac{\partial F}{\partial y}(a, b) + o(1)\right] = -\frac{\partial F}{\partial x_1}(a, b)\Delta x_1 - \cdots - \frac{\partial F}{\partial x_p}(a, b)\Delta x_p + o(1)\|\Delta x\|.$$

By VIII.6.3.2., we have $f \leq f \leq \overline{f}$, and hence by the Squeeze Theorem $f$ is continuous at $a$; thus $\Delta y = o(1)$ as $\Delta x \to 0$, and hence $\overline{h} = o(1)$ as $\Delta x \to 0$. Thus we have that the $o(1)$’s in the last expression are still $o(1)$ as $\Delta x \to 0$. Also, if $\Delta x$ is sufficiently small, we can divide by the expression in brackets on the left (using that $\frac{\partial F}{\partial y}(a, b) \neq 0$ by assumption) to obtain

$$\Delta y = \frac{-\frac{\partial F}{\partial x_1}(a, b)\Delta x_1 - \cdots - \frac{\partial F}{\partial x_p}(a, b)\Delta x_p + o(1)\|\Delta x\|}{\frac{\partial F}{\partial y}(a, b) + o(1)}$$

as $\Delta x \to 0$. By $()$, the last expression is

$$\Delta y = \|\Delta x\|\left[\frac{-\frac{\partial F}{\partial x_1}(a, b)\Delta x_1 - \cdots - \frac{\partial F}{\partial x_p}(a, b)\Delta x_p + o(1)}{\frac{\partial F}{\partial y}(a, b) + o(1)}\right]$$

$$= \|\Delta x\|\left[\frac{-\frac{\partial F}{\partial x_1}(a, b)\Delta x_1}{\frac{\partial F}{\partial y}(a, b)\|\Delta x\|} - \cdots - \frac{\partial F}{\partial x_p}(a, b)\Delta x_p}{\frac{\partial F}{\partial y}(a, b)\|\Delta x\|} + o(1)\right]$$

843
\[
= - \frac{\partial F}{\partial x_1}(a, b) \Delta x_1 - \cdots - \frac{\partial F}{\partial x_p}(a, b) \Delta x_p + o(1)\|\Delta x\|
\]
as \(\Delta x \to 0\); thus \(f\) is differentiable at \(a\) and

\[
\frac{\partial f}{\partial x_j}(a) = - \frac{\partial F}{\partial x_j}(a, b) \cdot \frac{\partial F}{\partial y}(a, b).
\]

The following technical strengthening will be used in the inductive proof of the general Implicit Function Theorem. It can be proved in the same way, or it follows immediately from VIII.6.3.7.

VIII.6.3.8. **Lemma.** Let \(F(x_1, \ldots, x_p, y) : U \to \mathbb{R}\), where \(U \subseteq \mathbb{R}^{p+1}\) is open, and \((a, b) = (a_1, \ldots, a_p, b) \in U\) with \(F(a, b) = 0\). Let \(S = \{x_{k_1}, \ldots, x_{k_m}\}\) be a subset of \(\{x_1, \ldots, x_p\}\). Suppose \(F\) is continuous on \(U\) and differentiable with respect to \(S \cup \{y\}\) at \((a, b)\), and that \(\frac{\partial F}{\partial y}(a, b) \neq 0\). Then there are:

(i) An open set \(V\) in \(\mathbb{R}^{p+1}\) containing \((a, b)\), with \(V \subseteq U\);

(ii) An open set \(W\) in \(\mathbb{R}^p\) containing \(a\);

such that whenever \(f\) is a real-valued function on \(W\) with \(f(a) = b\) and \((x, f(x)) \in V\) and \(F(x, f(x)) = 0\) for all \(x \in W\) (there exist such functions by VIII.6.3.2.), then \(f\) is differentiable with respect to \(S\) at \(a\) and, for \(x_j \in S\),

\[
\frac{\partial f}{\partial x_j}(a) = - \frac{\partial F}{\partial x_j}(a, b) \cdot \frac{\partial F}{\partial y}(a, b).
\]

VIII.6.3.9. **Theorem.** [One-Dimensional Implicit Function Theorem, Differentiable Version] Let \(F(x_1, \ldots, x_p, y) : U \to \mathbb{R}\), where \(U \subseteq \mathbb{R}^{p+1}\) is open, and \((a, b) = (a_1, \ldots, a_p, b) \in U\) with \(F(a, b) = 0\). Suppose \(F\) is differentiable at all points of \(U\) and \(\frac{\partial F}{\partial y}\) is nonzero at all points of \(U\). Then there are:

(i) An open set \(V\) in \(\mathbb{R}^{p+1}\) containing \((a, b)\), with \(V \subseteq U\);

(ii) An open set \(W\) in \(\mathbb{R}^p\) containing \(a\);

(iii) A unique function \(f : W \to \mathbb{R}\) such that \(f(a) = b\), and \((x, f(x)) \in V\) and \(F(x, f(x)) = 0\) for all \(x \in W\).

Additionally, \(f\) is differentiable at every point of \(W\) and, for all \(x \in W\) and \(1 \leq j \leq p\),

\[
\frac{\partial f}{\partial x_j}(x) = - \frac{\partial F}{\partial x_j}(x, f(x)) \cdot \frac{\partial F}{\partial y}(x, f(x)).
\]
Proof: The existence of $V, W, \text{and } f$, and the uniqueness (and continuity) of $f$, follow immediately from VIII.6.3.4., and if $x_0 \in V$, differentiability of $f$ at $x_0$ follows from VIII.6.3.7. applied at the point $(x_0, f(x_0))$. 

In the case $p = 1$, we get the version of the Implicit Function Theorem which justifies implicit differentiation in first-semester calculus (note that there is no truly “one-dimensional” version of the Implicit Function Theorem – one-variable implicit differentiation must be justified by the “two-dimensional” version):

**VIII.6.3.10. Corollary. [One-Variable Implicit Function Theorem, Differentiable Version]**

Let $F(x, y) : U \to \mathbb{R}$, where $U \subseteq \mathbb{R}^2$ is open, and $(a, b) \in U$ with $F(a, b) = 0$. Suppose $F$ is differentiable at all points of $U$ and $\frac{\partial F}{\partial y}$ is nonzero at all points of $U$. Then there are:

(i) An open set $V$ in $\mathbb{R}^2$ containing $(a, b)$, with $V \subseteq U$;

(ii) An open set $W$ in $\mathbb{R}$ containing $a$;

(iii) A unique function $f : W \to \mathbb{R}$ such that $f(a) = b$, and $(x, f(x)) \in V$ and $F(x, f(x)) = 0$ for all $x \in W$.

Additionally, $f$ is differentiable at every point of $W$ and, for all $x \in W$,

$$f'(x) = -\frac{\frac{\partial F}{\partial x}(x, f(x))}{\frac{\partial F}{\partial y}(x, f(x))}.$$ 

**VIII.6.3.11.** The fact that the slope of the tangent line to the level curve at $(x, y)$ is $-\frac{\frac{\partial F}{\partial x}(x, y)}{\frac{\partial F}{\partial y}(x, y)}$ should come as no surprise, since this level curve should be perpendicular to $\nabla F(x, y) = \left(\frac{\partial F}{\partial x}(x, y), \frac{\partial F}{\partial y}(x, y)\right)$.

But what is not obvious is that the level curve through $(x, y)$ is a smooth curve with a tangent line, or indeed that the level set is a “curve” at all; this is the theoretical conclusion of the theorem (cf. VIII.6.1.9.).

The formula for $f'(x)$ given in the theorem is equivalent to but more efficient than the one obtained by first-semester calculus methods before partial derivatives are introduced (VIII.6.9.7.); indeed, the partial derivative version is the “right” way to do one-variable implicit differentiation.

We also get a mixed version in which differentiability with respect to only some of the variables is assumed and concluded:

**VIII.6.3.12. Theorem. [One-Dimensional Implicit Function Theorem, Mixed Version]**

Let $F(x_1, \ldots, x_p, y) : U \to \mathbb{R}$, where $U \subseteq \mathbb{R}^{p+1}$ is open, and $(a, b) = (a_1, \ldots, a_p, b) \in U$ with $F(a, b) = 0$. Let $S = \{x_{k_1}, \ldots, x_{k_p}\}$ be a subset of $\{x_1, \ldots, x_p\}$. Suppose $F$ is differentiable with respect to $S \cup \{y\}$ at all points of $U$ and $\frac{\partial F}{\partial y}$ is nonzero at all points of $U$. Then there are:

(i) An open set $V$ in $\mathbb{R}^{p+1}$ containing $(a, b)$, with $V \subseteq U$;

(ii) An open set $W$ in $\mathbb{R}^p$ containing $a$;
(iii) A unique function $f : W \to \mathbb{R}$ such that $f(a) = b$, and $(x, f(x)) \in V$ and $F(x, f(x)) = 0$ for all $x \in W$.

Additionally, $f$ is continuous on $W$ and differentiable with respect to $S$ at every point of $W$ and, for all $x \in W$ and $x_j \in S$,

$$\frac{\partial f}{\partial x_j}(x) = -\frac{\frac{\partial F}{\partial x_j}(x, f(x))}{\frac{\partial F}{\partial y}(x, f(x))}.$$

The continuous version (VIII.6.5.) and the differentiable version (VIII.6.9.) are the special cases $S = \emptyset$ and $S = \{x_1, \ldots, x_p\}$ respectively.

**The Smooth Version**

**Theorem.** [One-Dimensional Implicit Function Theorem, Smooth Version] Let $F(x_1, \ldots, x_p, y) : U \to \mathbb{R}$, where $U \subseteq \mathbb{R}^{p+1}$ is open, and $(a, b) = (a_1, \ldots, a_p, b) \in U$ with $F(a, b) = 0$. Suppose $F$ is $C^r$ on $U$ ($1 \leq r \leq \infty$) and $\frac{\partial F}{\partial y}(a, b) \neq 0$. Then there are:

(i) An open set $V$ in $\mathbb{R}^{p+1}$ containing $(a, b)$, with $V \subseteq U$, such that $\frac{\partial F}{\partial y}(x, y) \neq 0$ for all $(x, y) \in V$;

(ii) An open set $W$ in $\mathbb{R}^p$ containing $a$;

(iii) A unique function $f : W \to \mathbb{R}$ such that $f(a) = b$, and $(x, f(x)) \in V$ and $F(x, f(x)) = 0$ for all $x \in W$.

Additionally, $f$ is $C^r$ on $W$ and, for all $x \in W$ and $1 \leq j \leq p$,

$$\frac{\partial f}{\partial x_j}(x) = -\frac{\frac{\partial F}{\partial x_j}(x, f(x))}{\frac{\partial F}{\partial y}(x, f(x))}.$$

**Proof:** By continuity, there is an open neighborhood $U'$ of $(a, b)$ contained in $U$ such that $\frac{\partial F}{\partial y}$ is nonzero everywhere on $U'$. Everything then follows immediately from VIII.6.9. (applied with $U'$ in place of $U$) except the fact that $f$ is $C^r$. We prove this by induction on $r$.

First suppose $F$ is $C^1$. Then, for $1 \leq j \leq p$, $\frac{\partial F}{\partial x_j}$ is continuous on $V$, and $f$ is continuous on $W$, so $g_j(x) = \frac{\partial F}{\partial x_j}(x, f(x))$ is continuous on $W$. Similarly, $g(x) = \frac{\partial F}{\partial y}(x, f(x))$ is continuous and nonzero on $W$, so

$$\frac{\partial f}{\partial x_j}(x) = -\frac{g_j(x)}{g(x)}$$

is also continuous on $W$ for each $j$. Thus $f$ is $C^1$ on $W$.

Now assume the result for $r$, and suppose $F$ is $C^{r+1}$. Then by the inductive hypothesis $f$ is $C^r$, so $g$ and each $g_j$ are $C^r$ by the higher-order Chain Rule (1). We then obtain that $\frac{\partial F}{\partial x_j}$ is $C^r$ for each $j$ since it is a quotient of $C^r$ functions with nonvanishing denominator. Thus $f$ is $C^{r+1}$.
**VIII.6.3.14.** Corollary. [One-Variable Implicit Function Theorem, Smooth Version] Let $F(x, y) : U \to \mathbb{R}$, where $U \subseteq \mathbb{R}^2$ is open, and $(a, b) \in U$ with $F(a, b) = 0$. Suppose $F$ is $C^r$ on $U$ ($1 \leq r \leq \infty$) and $\frac{\partial F}{\partial y}(a, b) \neq 0$. Then there are:

(i) An open set $V$ in $\mathbb{R}^2$ containing $(a, b)$, with $V \subseteq U$, such that $\frac{\partial F}{\partial y}(x, y) \neq 0$ for all $(x, y) \in V$;

(ii) An open set $W$ in $\mathbb{R}$ containing $a$;

(iii) A unique function $f : W \to \mathbb{R}$ such that $f(a) = b$, and $(x, f(x)) \in V$ and $F(x, f(x)) = 0$ for all $x \in W$.

Additionally, $f$ is $C^r$ on $W$ and, for all $x \in W$,

$$f'(x) = -\frac{\frac{\partial F}{\partial x}(x, f(x))}{\frac{\partial F}{\partial y}(x, f(x))}.$$

We also get a mixed version which will be used in the inductive proof of the general theorem:

**VIII.6.3.15.** Theorem. [One-Dimensional Implicit Function Theorem, Mixed Smooth Version] Let $F(x_1, \ldots, x_p, y) : U \to \mathbb{R}$, where $U \subseteq \mathbb{R}^{p+1}$ is open, and $(a, b) = (a_1, \ldots, a_p, b) \in U$ with $F(a, b) = 0$. Let $S = \{x_{k_1}, \ldots, x_{k_m}\}$ be a subset of $\{x_1, \ldots, x_p\}$. Suppose $F$, $\frac{\partial F}{\partial y}$, and $\frac{\partial F}{\partial x_j}$ are continuous on $U$ ($1 \leq r \leq \infty$) for all $x_j \in S$, and $\frac{\partial F}{\partial y}(a, b) \neq 0$. Then there are:

(i) An open set $V$ in $\mathbb{R}^{p+1}$ containing $(a, b)$, with $V \subseteq U$, such that $\frac{\partial F}{\partial y}(x, y) \neq 0$ for all $(x, y) \in V$;

(ii) An open set $W$ in $\mathbb{R}^p$ containing $a$;

(iii) A unique function $f : W \to \mathbb{R}$ such that $f(a) = b$, and $(x, f(x)) \in V$ and $F(x, f(x)) = 0$ for all $x \in W$.

Additionally, $f$ and $\frac{\partial f}{\partial x_j}$ are continuous on $W$ for all $x_j \in S$ and, for all $x \in W$, $x_j \in S$, and $1 \leq j \leq p$,

$$\frac{\partial f}{\partial x_j}(x) = \frac{\frac{\partial F}{\partial y}(x, f(x))}{\frac{\partial F}{\partial y}(x, f(x))}.$$

**Proof:** The conclusion follows from VIII.6.3.12. just as VIII.6.3.13. follows from VIII.6.3.9.. 

**VIII.6.4.** Proof of the General Implicit Function Theorem

**VIII.6.4.1.** The most straightforward proof of the general Implicit Function Theorem is by induction on the number $n$ of variables being solved for (this was also the first proof). The inductive proof requires a stronger continuity hypothesis on the partial derivatives of $F$ than the one-dimensional version, as explained in VIII.6.4.3.

We will prove the following mixed version of the Implicit Function Theorem, which includes both the continuous version (VIII.6.1.6.) and the smooth ($C^1$) version (VIII.6.1.7.):
Theorem. [Implicit Function Theorem, Mixed Version] Let $U$ be an open set in $\mathbb{R}^{p+n}$ and $(a, b) \in U$. Let $F : U \to \mathbb{R}^n$ with $F(a, b) = 0$. Suppose $F$ is continuous on $U$ and that $D_y F$ exists and is continuous on $U$ for $1 \leq j \leq n$. If $D_y F(a, b)$ is invertible, i.e. $\det(D_y F(a, b)) \neq 0$, then there are:

(i) An open set $V$ in $\mathbb{R}^{p+n}$ containing $(a, b)$, with $V \subseteq U$, such that $D_y F(x, y)$ is invertible for all $(x, y) \in V$;

(ii) An open set $W$ in $\mathbb{R}^p$ containing $a$;

(iii) A unique function $f : W \to \mathbb{R}^n$ such that $f(a) = b$ and, for all $x \in W$, $(x, f(x)) \in V$ and $F(x, f(x)) = 0$.

Additionally, $f$ is continuous on $W$. If additionally $S = \{x_k_1, \ldots, x_{k_m}\}$ is a subset of $\{x_1, \ldots, x_p\}$ and $\frac{\partial F}{\partial x_{k_i}}$ exists and is continuous on $U$ for each $x_{k_i} \in S$, then $\frac{\partial F}{\partial x_{k_i}}$ exists and is continuous on $W$ for each $x_{k_i} \in S$ and these partials satisfy

$$D_S f(x) = -D_y F(x, f(x))^{-1}D_S F(x, f(x))$$

for all $x \in W$, where $D_S F(x, y)$ is the $n \times m$ matrix

$$D_S F(x, y) = \begin{bmatrix}
\frac{\partial F_1}{\partial x_{k_1}}(x, y) & \cdots & \frac{\partial F_n}{\partial x_{k_1}}(x, y) \\
\vdots & \ddots & \vdots \\
\frac{\partial F_1}{\partial x_{k_m}}(x, y) & \cdots & \frac{\partial F_n}{\partial x_{k_m}}(x, y)
\end{bmatrix}.$$

Proof: The case $n = 1$ is VIII.6.3.15. We now assume the theorem is true for $n$, and show it is true for $n+1$. So suppose $F(x, y) = F(x_1, \ldots, x_p, y_1, \ldots, y_{n+1})$ is a continuous function from an open set $U \subseteq \mathbb{R}^{p+n+1}$ to $\mathbb{R}^{n+1}$, $(a, b) = (a_1, \ldots, a_p, b_1, \ldots, b_{n+1}) \in U$, that $D_y F$ and $D_S F$ are continuous on $U$ for some subset $S$ of $\{x_1, \ldots, x_p\}$, and $D_y F(a, b)$ is invertible. The strategy for finding the implicit function $f : \mathbb{R}^p \to \mathbb{R}^{n+1}$ will be to show that for some $i$, $1 \leq i \leq n+1$, the $y_k$ for $2 \leq k \leq n+1$ can be written as implicit functions $g_k$ of $(x_1, \ldots, x_p, y_1)$ satisfying

$$F_j(x_1, \ldots, x_p, y_1, g_2(x_1, \ldots, x_p, y_1), \ldots, g_{n+1}(x_1, \ldots, x_p, y_1)) = 0$$

for $j \neq i$ and $(x_1, \ldots, x_p, y_1)$ close to $(a_1, \ldots, a_p, b_1)$ by the inductive hypothesis, and that $y_1$ can then be written as an implicit function $h$ of $(x_1, \ldots, x_p)$ satisfying

$$F_i(x_1, \ldots, x_p, h(x), g_2(x, h(x)), \ldots, g_{n+1}(x, h(x))) = 0$$

for $x$ near $a$ by an application of VIII.6.3.15. Then $f$ can be defined by

$$f(x) = (h(x), g_2(x, h(x)), \ldots, g_{n+1}(x, h(x))).$$

For the details, we will use the following notation. Write $J(x, y)$ for the determinant of the $(n+1) \times (n+1)$ matrix $D_y F(x, y)$. For each $i$, let $J_i(x, y)$ be the determinant of the $i$’th minor in the first column, i.e.

$$J_i(x, y) = (-1)^{i+1} \det \begin{bmatrix}
\frac{\partial F_1}{\partial y_2}(x, y) & \cdots & \frac{\partial F_1}{\partial y_{n+1}}(x, y) \\
\vdots & \ddots & \vdots \\
\frac{\partial F_{n+1}}{\partial y_2}(x, y) & \cdots & \frac{\partial F_{n+1}}{\partial y_{n+1}}(x, y)
\end{bmatrix}.$$
with the $i$'th row (partials of $F_i$) deleted. Then

$$J(x, y) = J_1(x, y) \frac{\partial F_1}{\partial y_1}(x, y) + J_2(x, y) \frac{\partial F_2}{\partial y_1}(x, y) + \cdots + J_{n+1}(x, y) \frac{\partial F_{n+1}}{\partial y_1}(x, y)$$

and so, since $J(a, b) \neq 0$, there is an $i$, $1 \leq i \leq n+1$, such that $J_i(a, b) \neq 0$ and $\frac{\partial F_i}{\partial y_1}(a, b) \neq 0$. Then there is an open neighborhood $U'$ of $(a, b)$ such that $J_i(x, y) \neq 0$ and $\frac{\partial F_i}{\partial y_1}(x, y) \neq 0$ for all $(x, y) \in U'$. Apply the inductive hypothesis with $S' = S \cup \{y_1\}$ to obtain an open neighborhood $V_1$ of $(a, b)$ in $\mathbb{R}^{p+n+1}$, an open neighborhood $W_1$ of $(a_1, \ldots, a_p, b_1)$ in $\mathbb{R}^{p+1}$, and unique functions $g_k : W_1 \to \mathbb{R} \ (2 \leq k \leq n+1)$ which satisfy, for $(x_1, \ldots, x_p, y_1) \in W_1$,

$$(x_1, \ldots, x_p, y_1, g_1(x_1, \ldots, x_p, y_1), \ldots, g_{n+1}(x_1, \ldots, x_p, y_1)) \in V_1$$

$$F_j(x_1, \ldots, x_p, y_1, g_1(x_1, \ldots, x_p, y_1), \ldots, g_{n+1}(x_1, \ldots, x_p, y_1)) = 0$$

for $j \neq i$, and $g_k, \frac{\partial g_k}{\partial y_1}$, and $\frac{\partial g_j}{\partial x_j}$ for $x_j \in S$ continuous on $W_1$ for each $k$.

Now, for $(x_1, \ldots, x_p, y_1) \in W_1$, set

$$G(x_1, \ldots, x_p, y_1) = F_i(x_1, \ldots, x_p, y_1, g_1(x_1, \ldots, x_p, y_1), \ldots, g_{n+1}(x_1, \ldots, x_p, y_1)).$$

Then $G$ is continuous on $W_1$ and $G(a_1, \ldots, a_p, b_1) = 0$. We show that $G$ satisfies the hypotheses of VIII.6.3.15. on $W_1$. By the Chain Rule, $\frac{\partial G}{\partial y_1}$ exists on $W_1$ and

$$\frac{\partial G}{\partial y_1}(x, y_1) = \frac{\partial F}{\partial y_1}(x, y_1, g_1(x, y_1), \ldots, g_{n+1}(x, y_1)) + \frac{\partial F_i}{\partial y_1}(x, y_1, g_2(x, y_1), \ldots, g_{n+1}(x, y_1)) \frac{\partial g_2}{\partial y_1}(x, y_1) + \cdots + \frac{\partial F_i}{\partial y_1}(x, y_1, g_2(x, y_1), \ldots, g_{n+1}(x, y_1)) \frac{\partial g_{n+1}}{\partial y_1}(x, y_1).$$

Thus $\frac{\partial G}{\partial y_1}$ is continuous on $W_1$. It remains to show that $\frac{\partial G}{\partial y_1}(a_1, b_1) \neq 0$. If we set $G_i = G$ and define, for $j \neq i$,

$$G_j(x_1, \ldots, x_p, y_1) = F_j(x_1, \ldots, x_p, y_1, g_1(x_1, \ldots, x_p, y_1), \ldots, g_{n+1}(x_1, \ldots, x_p, y_1))$$

we similarly have

$$\frac{\partial G_j}{\partial y_1}(x, y_1) = \frac{\partial F}{\partial y_1}(x, y_1, g_1(x, y_1), \ldots, g_{n+1}(x, y_1)) + \frac{\partial F_i}{\partial y_1}(x, y_1, g_2(x, y_1), \ldots, g_{n+1}(x, y_1)) \frac{\partial g_2}{\partial y_1}(x, y_1) + \cdots + \frac{\partial F_i}{\partial y_1}(x, y_1, g_2(x, y_1), \ldots, g_{n+1}(x, y_1)) \frac{\partial g_{n+1}}{\partial y_1}(x, y_1).$$

But $G_j$ is identically 0, so abbreviating notation we have

$$\frac{\partial G_i}{\partial y_1} = \frac{\partial F_i}{\partial y_1} + \frac{\partial F_i}{\partial y_2} \frac{\partial g_2}{\partial y_1} + \cdots + \frac{\partial F_i}{\partial y_{n+1}} \frac{\partial g_{n+1}}{\partial y_1} = 0$$

849
for \( j \neq i \). Multiplying the \( j \)’th equation by \( J_j \) and adding the equations together, we get

\[
J_i \frac{\partial G_i}{\partial y_1} = \sum_{j=1}^{n+1} J_j \frac{\partial F_j}{\partial y_1} + \frac{\partial g_2}{\partial y_2} \sum_{j=1}^{n+1} J_j \frac{\partial F_j}{\partial y_2} + \cdots + \frac{\partial g_{n+1}}{\partial y_{n+1}} \sum_{j=1}^{n+1} J_j \frac{\partial F_j}{\partial y_{n+1}}.
\]

The first sum is \( J \), and the second sum is the determinant of the matrix

\[
\begin{bmatrix}
\frac{\partial F_1}{\partial y_2} & \frac{\partial F_1}{\partial y_2} & \cdots & \frac{\partial F_1}{\partial y_{n+1}} \\
\frac{\partial F_2}{\partial y_2} & \frac{\partial F_2}{\partial y_2} & \cdots & \frac{\partial F_2}{\partial y_{n+1}} \\
\vdots & \vdots & \ddots & \vdots \\
\frac{\partial F_{n+1}}{\partial y_2} & \frac{\partial F_{n+1}}{\partial y_2} & \cdots & \frac{\partial F_{n+1}}{\partial y_{n+1}}
\end{bmatrix}
\]

expanded by minors on the first column. This matrix has two identical columns, hence has determinant 0 ()), so the second sum is 0. Similarly, the other sums are 0. Thus

\[
J_i(x, y) \frac{\partial G}{\partial y_1}(x, y_1) = J(x, y)
\]

for all \((x, y)\); so \( \frac{\partial G}{\partial y_1}(a, b_1) \neq 0 \) since \( J(a, b) \neq 0 \).

Then by VIII.6.3.15, there is an open set \( W \) in \( \mathbb{R}^p \) containing \( a \) and an open set \( V \) in \( \mathbb{R}^{p+1} \) containing \((a, b_1), V_2 \subseteq W_1, \) and a unique function \( h : W \to \mathbb{R} \), such that \((x, h(x)) \in V_2 \) and \( G(x, h(x)) = 0 \) for all \( x \in W \). Set

\[
V = \{(x_1, \ldots, x_p, y_1, \ldots, y_n) \in V_1 : (x_1, \ldots, x_p, y_1) \in V_2\}
\]

and define

\[
f(x) = (h(x), g_2(x, h(x)), \ldots, g_{n+1}(x, h(x)))
\]

for \( x \in W \). Then, for \( x \in W \), we have \((x, f(x)) \in V \), and \( F_i(x, f(x)) = G(x, h(x)) = 0 \). And if \( j \neq i \),

\[
F_j(x, f(x)) = F_j(x, h(x), g_2(x, h(x)), \ldots, g_{n+1}(x, h(x))) = 0.
\]

Thus \( F(x, f(x)) = 0 \).

The uniqueness of \( f \) follows immediately from the uniqueness of the \( g_k \) and of \( h \), and continuity of \( f \) follows from continuity of the \( g_k \) and \( h \). Continuity of \( \frac{\partial f}{\partial x_j} \) on \( W \) for \( x_j \in S \) then follows from continuity of the partials of the \( g_k \) and \( h \) for \( x_j \in S \).

The formula for \( D_S f \) now follows easily from the Chain Rule. We write the case \( S = \{x_1, \ldots, x_p\} \); the case of general \( S \) is identical with notational complications (or can be obtained immediately by restricting coordinates). Define \( H : W \to \mathbb{R}^{p+n} \) by \( H(x) = (x, f(x)) \). Then \( H \) is \( C^1 \) on \( W \), and

\[
DH(x) = \begin{bmatrix} I_p \\ Df(x) \end{bmatrix}
\]

for \( x \in W \), where \( I_p \) is the \( p \times p \) identity matrix and \( Df(x) \) is \( n \times p \). Then by the Chain Rule we have

\[
D(F \circ H)(x) = D(F(H(x)))DH(x) = \begin{bmatrix} D_x F(x, f(x)) & D_y F(x, f(x)) \end{bmatrix} \begin{bmatrix} I_p \\ Df(x) \end{bmatrix} = D_x F(x, f(x)) + D_y F(x, f(x))Df(x)
\]

850
for \( x \in W \). But \( F \circ H \) is identically zero on \( W \), so \( D(F \circ H)(x) = 0 \) for all \( x \in W \). Since \( D_y F(x, f(x)) \) is invertible for \( x \in W \), we have, for \( x \in W \),
\[
D_y F(x, f(x))^{-1} D_x F(x, f(x)) + Df(x) = 0.
\]

This completes the proof of VIII.6.4.2., and hence of the continuous version VIII.6.1.6. (the case \( S = \emptyset \)) and the \( C^1 \) smooth version VIII.6.1.7. (the case \( S = \{x_1, \ldots, x_p\} \)).

** VIII.6.4.3. ** The reason this proof requires continuity of the partials, and not just that the partials exist and \( J(x, y) \neq 0 \) in a neighborhood of \( (a, b) \), is that not only must \( J \) be nonzero, but at least one of the minors \( J_i \) must also be nonzero in a neighborhood of \( (a, b) \) to apply the inductive assumption. The continuity can be replaced by an assumption that not only is the \( J \) nonzero in a neighborhood of \( (a, b) \), but also a decreasing chain of minors of smaller and smaller size are nonzero in a neighborhood of \( (a, b) \). This version was explicitly stated in [You09], but is quite clumsy so we have stuck to the cleaner statement of VIII.6.4.2., which is adequate for almost all applications. For a full extension of VIII.6.3.10. to the \( n \)-dimensional case, see VIII.6.6.7.. It does not appear to be known whether the assumption of the decreasing sequence of nonzero minors is automatic (cf. Exercise VIII.6.9.13.(b)).

** VIII.6.4.4. ** To finish the proof of the smooth version, it remains only to show that if \( F \) is \( C^r \), then \( f \) is also \( C^r \). The entries of \( D_x F(x, f(x)) \) and \( D_y F(x, f(x)) \) are \( C^{r-1} \) by assumption. Since the determinant of \( D_y F(x, f(x)) \) is a polynomial in the entries, it is also \( C^{r-1} \) on \( W \), and since the determinant is never 0 on \( W \), it follows that the reciprocal of the determinant is also \( C^{r-1} \) on \( W \). Thus the entries of \( D_y F(x, f(x))^{-1} \) are also \( C^{r-1} \) on \( W \) by the formula in III.11.7.45., and therefore so are the entries of
\[
Df(x) = -D_y F(x, f(x))^{-1} D_x F(x, f(x))
\]
which is equivalent to \( f \) being \( C^r \) on \( W \).

This completes the full proof of the smooth version VIII.6.1.7..

** VIII.6.5. ** **Proof of the Inverse Function Theorem**

The Inverse Function Theorem can now be proved from the Implicit Function Theorem as in ( ). In this section we give an alternate direct proof, which “explains” better why the theorem is true and which generalizes to other settings, such as Banach spaces ( ). This proof uses the Contraction Mapping Principle ( ). This argument first appeared, in somewhat disguised form, in [Gou03]; cf. Exercise VIII.6.9.10. .

To prove the Inverse Function Theorem, it suffices the prove the following theorem. Differentiability of the inverse function then follows from VIII.6.1.15., and the formula there shows that the inverse function is \( C^1 \); and if \( f \) is \( C^r \), the inverse function is also \( C^r \) by the argument in VIII.6.4.4..
VIII.6.5.1.  **Theorem.** Let $U$ be an open set in $\mathbb{R}^n$, $a \in \mathbb{R}^n$, and $f : U \to \mathbb{R}^n$ a $C^1$ function. If $Df(a)$ is invertible, then there is a neighborhood $V$ of $a$, $V \subseteq U$, such that

(i) $f$ is one-to-one on $V$.

(ii) $W = f(V)$ is open in $\mathbb{R}^n$.

(iii) $Df(x)$ is invertible for all $x \in V$.

VIII.6.5.2.  The first reduction is to make an affine change of variables to make $a = 0$, $f(0) = 0$, and $Df(0) = I_n$, which greatly simplifies the notation of the rest of the proof. We define

$$T(x) = Df(a)^{-1}(x).$$

Then $T$ is an invertible linear function from $\mathbb{R}^n$ to $\mathbb{R}^n$; $T$ is $C^1$ and $DT(x) = Df(a)^{-1}$ for all $x$. Define

$$g(x) = T(f(x + a)) - c$$

for $x \in U - a$, where $c = T(f(a))$; then by the Chain Rule $g$ is $C^1$ on $U - a$ and

$$Dg(x) = DT(f(x + a))Df(x + a) = Df(a)^{-1}Df(x + a)$$

for $x \in U - a$. In particular, $Dg(0) = I_n$.

It suffices to prove VIII.6.5.1. for $g$ on $U - a$, since we would then have

$$f^{-1}(y) = g^{-1}(T(y) - c) + a$$

on $T^{-1}(W + c)$ with values in $V + a$.

So, changing notation, in VIII.6.5.1. we will assume $a = 0$, $f(0) = 0$, and $Df(0) = I_n$.

VIII.6.5.3.  Now define $g(x) = x - f(x)$. Then $g$ is $C^r$. Since $Dg(0) = 0$, there is an $\epsilon > 0$ such that $\|Dg_k(x)\| < \frac{1}{2\epsilon}$ for all $k$ whenever $\|x\| < \epsilon$. Set $W_1 = B_\epsilon(0)$. If $x, z \in W_1$, then by the MVT (1) for each $k$ there is a $c_k$ between $x$ and $z$ with $g_k(x) - g_k(z) = Dg_k(c_k)(x - z)$; $c_k \in W_1$ since $W_1$ is convex. Thus

$$\|g(x) - g(z)\| \leq \sum_{k=1}^n |g_k(x) - g_k(z)| = \sum_{k=1}^n |Dg_k(c_k)(x - z)| \leq \sum_{k=1}^n \|Dg_k(c_k)\| \|x - z\| < \frac{1}{2} \|x - z\|$$

for $x, z \in W_1$. In particular, $\|g(x)\| < \frac{1}{2}\|x\|$ for all $x \in W_1$.

VIII.6.5.4.  Now fix $\eta, 0 < \eta < \epsilon$, and fix $y \in \mathbb{R}^n$ with $\|y\| \leq \frac{\eta}{\epsilon}$. Define $g_y : \mathbb{R}^n \to \mathbb{R}^n$ by

$$g_y(x) = y + x - f(x) = y + g(x).$$

If $\|x\| \leq \eta$, then $\|g(x)\| < \frac{\eta}{\epsilon}$, so $\|g_y(x)\| < \eta$; thus $g_y$ maps $B_\eta(0)$ into itself. If $x, z \in B_\eta(0)$, then

$$\|g_y(x) - g_y(z)\| = \|g(x) - g(z)\| < \frac{1}{2} \|x - z\|$$

852
and so $g_y$ is a contractive mapping of the complete metric space $\tilde{B}_\eta(0)$ to itself. By the Contractive Mapping Principle (), $g_y$ has a unique fixed point $x \in \bar{B}_\eta(0)$, i.e. there is a unique $x$ with $\|x\| \leq \eta$ and $f(x) = y$. Thus, if $W = B_{\epsilon/2}(0)$, for any $y \in W$ there is a unique $x \in B_\epsilon(0)$ with $f(x) = y$ (such a $y$ is in $\tilde{B}_{\eta/2}(0)$ for $2\|y\| \leq \eta < \epsilon$). Set $V = B_\epsilon(0) \cap f^{-1}(W)$; then $V$ is an open set in $\mathbb{R}^n$ containing 0 and $f$ maps $V$ bijectively to $W$.

This completes the proof of VIII.6.5.1.

VIII.6.5.5. Of course, this argument is not a full proof of the Inverse Function Theorem; the arguments of VIII.6.1.15. and VIII.6.4.4. are also needed to finish the proof.

VIII.6.6. How Much Can the Theorems be Generalized?

VIII.6.6.1. One might hope that the hypotheses of the Inverse Function Theorem can be relaxed to only require differentiability at $a$, or at least nondegeneracy of the derivative at $a$. But this is not enough to force the function to be locally injective around $a$, even in one dimension:

VIII.6.6.2. Example. Let

$$f(x) = \begin{cases} x + x^2 \sin \frac{1}{x^2} & \text{if } x \neq 0 \\ 0 & \text{if } x = 0 \end{cases}$$

for $x \in \mathbb{R}$. Then $f$ is differentiable on $\mathbb{R}$ and $f'(0) = 1$, but $f$ is not injective (strictly increasing) on any neighborhood of 0. In fact, $f'$ takes all real number values (in particular, both positive and negative values) in any neighborhood of 0.

VIII.6.6.3. Suppose we assume $f$ is injective in an open neighborhood $V$ of $a$, with $f(V)$ open, and that $f$ is differentiable at $a$ and $Df(a)$ is invertible. Then there is an inverse function $g$ defined on $f(V)$. By VIII.6.1.15., $g$ is differentiable at $f(a)$.

VIII.6.6.4. However, one of the main points of the Inverse Function Theorem is that nondegeneracy of the derivative of $f$ at $a$ forces $f$ to be injective in a neighborhood $V$ of $a$, with $f(V)$ open. Continuity of the partial derivatives is seemingly used mainly to insure that the derivative is nondegenerate in an entire neighborhood of $a$ (this can fail if the derivative is discontinuous; cf. VIII.6.6.2.). So what if this is just assumed? In the one-dimensional case, if the derivative of a function is nonzero in an open interval around $a$, then $f$ must be strictly monotone in that interval by () and hence locally injective. Remarkably, this remains true in higher dimensions:

VIII.6.6.5. Theorem. Let $U$ be an open set in $\mathbb{R}^n$, $a \in U$, and $f : U \rightarrow \mathbb{R}^n$. Suppose $f$ is differentiable at every point of $U$ and that $Df(x)$ is invertible for all $x \in U$. Then there is a neighborhood $V$ of $a$ such that $f$ is one-to-one on $V$, $f(V)$ is open in $\mathbb{R}^n$, and the inverse function $g : f(V) \rightarrow V$ is differentiable at every point of $f(V)$ with

$$Dg(f(x)) = (Df(x))^{-1}$$

for all $x \in V$. 

853
VIII.6.6.6. Curiously, this theorem appears to have been first stated and proved by J. Saint Raymond in 2002 [Ray02], although it is implicit in an earlier result of Chernavskii in 1964 [Čer64]; see also [Hal74], [Cri92], and http://terrytao.wordpress.com/2011/09/12/the-inverse-function-theorem-for-everywhere-differentiable-maps/. It should be pointed out, however, that as a practical matter this result is of limited use beyond the case covered in the usual Inverse Function Theorem if \( n > 1 \), since in most cases the only reasonable way to verify that a function is differentiable is to show that the partial derivatives are continuous (cf. ()), although there are cases where the partial derivatives are continuous except at one point \( a \) and it can be shown by brute force that the function is differentiable at \( a \) (cf. ()), and this version but not the usual version can be applied in such a situation (provided, of course, that the nondegeneracy condition is satisfied).

There is a corresponding version of the Implicit Function Theorem, proved from VIII.6.6.5. the same way VIII.6.1.7. is deduced from VIII.6.1.20. () The one-dimensional version of this result is VIII.6.3.10.. I am not aware of any analogous version of the Continuous or Mixed Implicit Function Theorems; cf. Exercises VIII.6.9.12. and VIII.6.9.13.(b). There is also a corresponding version of VIII.6.2.1.

VIII.6.6.7. **Theorem.** Let \( U \) be an open set in \( \mathbb{R}^{p+n} \) and \((a, b) \in U \). Let \( F : U \to \mathbb{R}^n \) with \( F(a, b) = 0 \). Suppose \( F \) is differentiable at every point of \( U \). If \( D_y F(x, y) \) is invertible, i.e. \( \det(D_y F(x, y)) \neq 0 \), for all \((x, y) \in U \), then there is an open set \( V \) in \( \mathbb{R}^{p+n} \) containing \((a, b) \), an open set \( W \) in \( \mathbb{R}^p \) containing \( a \), and a unique function \( f : W \to \mathbb{R}^n \) such that \( f(a) = b \) and, for all \( x \in W \), \((x, f(x)) \in V \) and \( F(x, f(x)) = 0 \). Additionally, \( f \) is differentiable at every point of \( W \), and for any \( x \in W \), we have

\[
Df(x) = -D_y F(x, f(x))^{-1} D_x F(x, f(x)).
\]

VIII.6.6.8. It should be noted that the results of this section are technically not “generalizations” of the usual Implicit and Inverse Function Theorems – they are distinct results (but obviously closely related) since both the hypotheses and conclusions are weaker. A true generalization of a theorem is a new result for which the original theorem is a special case, generally consisting of obtaining the same, or stronger, conclusions under weaker hypotheses (here “weaker” means hypotheses which hold in actually or potentially more situations); obtaining stronger conclusions under the same hypotheses could also be considered a type of generalization, although such a result is usually just called a stronger theorem and not a generalization. Thus VIII.6.3.12. is a true generalization of both VIII.6.3.4. and VIII.6.3.9., and VIII.6.4.2. a generalization of VIII.6.1.6. and VIII.6.1.7. (\( C^1 \) version). The only other true generalizations I know of the Implicit and Inverse Function Theorems are extensions to maps between more general spaces like Banach spaces (cf. ()), or results like VIII.6.2.1.

VIII.6.7. **The Domain and Range Straightening Theorems**

From the Implicit and Inverse Function Theorems we can get a simple general local picture of a differentiable function, especially one of constant rank: up to a smooth change of coordinates, such a function of constant rank \( k \) from \( \mathbb{R}^n \) to \( \mathbb{R}^m \) locally consists simply of projection onto a \( k \)-dimensional subspace of \( \mathbb{R}^n \) followed by a linear embedding of this subspace into \( \mathbb{R}^m \).

The first result, a variation of VIII.6.2.1., is called the **Domain-Straightening Theorem** in some references, e.g. [?]. If \( f \) is a smooth function from \( U \subseteq \mathbb{R}^n \) to \( \mathbb{R}^m \) and \( a \in U \), then \( a \) is called a **regular point** of \( f \) if the
rank of $Df(a)$ is $m$. (If $f$ has a regular point, then necessarily $n \geq m$.) The set of regular points of $f$ is an open set.

**VIII.6.7.1. Theorem.** [Domain-Straightening Theorem] Let $f$ be a $C^r$ function ($1 \leq r \leq \infty$) from an open subset of $\mathbb{R}^n$ to $\mathbb{R}^m$, $n \geq m$, and $a$ a regular point of $f$. Then there is an open neighborhood $U$ of $a$ and a $C^r$ diffeomorphism $g$ from a neighborhood $U'$ of $(b, 0)$ in $\mathbb{R}^n \cong \mathbb{R}^m \times \mathbb{R}^{n-m}$ to $U$ with $g(b, 0) = a$ and $f \circ g(x, y) = x$ for all $(x, y) \in U'$, i.e.

$$f \circ g(x_1, \ldots, x_n) = (x_1, \ldots, x_m)$$

for all $(x_1, \ldots, x_n) \in U'$.

The name “Domain-Straightening Theorem” is appropriate since the theorem says that local coordinates can be chosen around $a$ so that $f$ just picks out the first $m$ coordinates of a point, and thus the preimage of any point in $\mathbb{R}^n$ in a neighborhood of $b$ is a piece of a vertical $(n-m)$-dimensional hyperplane. The case $n = m$ is just the Inverse Function Theorem.

**Proof:** By precomposing $f$ with a translation, there is no loss of generality in assuming $a = 0$. By assumption, the column rank of $Df(0)$ is $m$, so the columns of $Df(0)$ can be permuted so that the first $m$ columns are linearly independent. Thus $f$ can be precomposed with a linear transformation $T$ (permutation of coordinates) so that, if we write $\mathbb{R}^n$ as $\mathbb{R}^m \times \mathbb{R}^{n-m}$ and points in $\mathbb{R}^n$ as $(x, y)$, with $x \in \mathbb{R}^m$ and $y \in \mathbb{R}^{n-m}$, we have $D_x(f \circ T)(0, 0)$ invertible. Thus applying VIII.6.2.1. with the roles of $x$ and $y$ interchanged, there is an open neighborhood $V$ of $(b, 0)$ in $\mathbb{R}^n$ and a $C^r$ function $h : V \to \mathbb{R}^m$ such that $h(b, 0) = (0, 0)$ and $(f \circ T)(h(x, y), y) = x$ for all $(x, y) \in V$. The function $\phi : V \to \mathbb{R}^n$ defined by $\phi(x, y) = (h(x, y), y)$ has $D\phi(0, 0)$ invertible, so by the Inverse Function Theorem there is an open neighborhood $U'$ of $(b, 0)$ for which $\phi(U') \subseteq V$ and $\phi|_{U'}$ is a $C^r$ diffeomorphism from $U'$ to $\phi(U')$. Set $U = T(\phi(U'))$ and $g = T \circ \phi$.

**VIII.6.7.2. Corollary.** Let $f$ be a $C^r$ function ($r \geq 1$) from an open set in $\mathbb{R}^n$ to $\mathbb{R}^m$ ($n \geq m$), $a$ a regular point of $f$, and $b = f(a)$. Then $a$ has an open neighborhood $U$ such that every open neighborhood of $a$ contained in $U$ maps onto an open neighborhood of $b$, and $f^{-1}(b) \cap U$ is an $(n-m)$-dimensional $C^r$ hypersurface in $U$. In particular, the range of $f$ contains an open set around $f(a)$.

**Proof:** Let $U$ and $g$ be as in VIII.6.7.1. Then

$$f^{-1}(b) \cap U = g((f \circ g)^{-1}(b)) = g \left(\{(b_1, \ldots, b_m, x_{m+1}, \ldots, x_n) : x_{m+1}, \ldots, x_n \in \mathbb{R}\} \cap U'\right)$$

where $b = (b_1, \ldots, b_m)$.

**VIII.6.7.3.** Conversely, it is a remarkable fact (??, a consequence of Sard’s Theorem) that if the range of $f$ contains a nonempty open set in $\mathbb{R}^m$, and $f$ is sufficiently smooth, then $f$ has “many” regular points.

By straightening only some of the coordinates in the domain, we obtain: 855
VIII.6.7.4. **Theorem.** Let \( f \) be a \( C^r \) function \((1 \leq r < \infty)\) from an open subset \( \Omega \) of \( \mathbb{R}^n \) to \( \mathbb{R}^m \), and \( a \) a point of the domain of \( f \). Suppose \( Df(a) \) has rank \( \geq k \), \( k < m \). Then there is an open neighborhood \( U \) of \( a \), a point \( b \in \mathbb{R}^k \), and a \( C^r \) diffeomorphism \( g \) from a neighborhood \( U' \) of \((b,0)\) in \( \mathbb{R}^n \cong \mathbb{R}^k \times \mathbb{R}^{n-k}\) to \( U \) with \( g(b,0) = a \), an invertible linear transformation \( T : \mathbb{R}^m \rightarrow \mathbb{R}^m \) (permutation of coordinates) with \( T \circ f(a) = (b,c) \) for some \( c \in \mathbb{R}^{m-k} \), and a \( C^r \) function \( f_0 : \mathbb{R}^n \rightarrow \mathbb{R}^{m-k} \) defined on a neighborhood of \((b,0)\) such that
\[
T \circ f \circ g(x,y) = (x,f_0(x,y))
\]
for all \((x,y) \in U' \subseteq \mathbb{R}^k \times \mathbb{R}^{n-k} \), i.e.
\[
T \circ f \circ g(x_1, \ldots, x_k, x_{k+1}, \ldots, x_n) = (x_1, \ldots, x_k, f_0(x_1, \ldots, x_n))
\]
for all \((x_1, \ldots, x_n) \in U' \). We have \( f_0(b,0) = c \).

**Proof:** The matrix \( Df(a) \) has rank at least \( k \), so by permuting rows we may make the first \( k \) rows linearly independent. Let \( T \) be such a coordinate permutation, and let \( \phi \) be the function from \( \Omega \) to \( \mathbb{R}^k \) whose coordinate functions are the first \( k \) coordinate functions of \( T \circ f \). Set \( b = \phi(a) \). Then \( \phi \) is \( C^r \) and satisfies the hypotheses of VIII.6.7.1., so there is a \( C^r \) diffeomorphism \( g \) from a neighborhood \( U' \) of \((b,0)\) in \( \mathbb{R}^n \cong \mathbb{R}^k \times \mathbb{R}^{n-k} \) to a neighborhood \( U \) of \( a \) with \( \phi \circ g(x,y) = x \) for all \((x,y) \in U' \). Then \( T \circ f \circ g(x,y) \) is of the form
\[
(\phi \circ g(x,y), f_0(x,y)) = (x,f_0(x,y))
\]
for \((x,y) \in U' \), for some \( C^r \) function \( f_0 : U' \rightarrow \mathbb{R}^{m-k} \).

VIII.6.7.5. Suppose \( f \) is as in the statement of the theorem. If the rank of \( Df(z) \) is exactly \( k \) for all \( z \) in a neighborhood of \( a \), we can say more. Set \( h = T \circ f \circ g \). Then \( h \) has rank exactly \( k \) in a neighborhood of \((b,0)\). The derivative of \( h \) at \((x,y)\) is of the form
\[
\begin{bmatrix}
I_k & 0 \\
B & A
\end{bmatrix}
\]
where \( Df_0(x,y) = [B \; A] \), \( B \) is \((m-k) \times k \), and \( A \) is \((m-k) \times (n-k) \). For such a matrix to have rank \( k \), \( A \) must be 0: the first \( k \) columns are linearly independent, and if \( A \) has a nonzero entry the column it appears in will be linearly independent from the first \( k \) columns, a contradiction. Thus the partial derivatives of \( f_0 \) in the \( y \) variables are identically zero near \((b,0)\), i.e. \( f_0(x,y) \) depends only on the \( x \) variables in a neighborhood of \((b,0)\). Thus we obtain:

VIII.6.7.6. **Theorem.** [Rank Theorem] Let \( f \) be a \( C^r \) function \((1 \leq r < \infty)\) from an open subset of \( \mathbb{R}^n \) to \( \mathbb{R}^m \), and \( a \) a point of the domain of \( f \). Suppose \( Df \) has constant rank \( k \) in a neighborhood of \( a \). Then there is an open neighborhood \( U \) of \( a \), a point \( b \in \mathbb{R}^k \), a \( C^r \) diffeomorphism \( g \) from an open neighborhood \( U' \) of \((b,0)\) in \( \mathbb{R}^n \cong \mathbb{R}^k \times \mathbb{R}^{n-k} \) to \( U \), an open neighborhood \( W \) of \( b \) in \( \mathbb{R}^k \) such that \( x \in W \) whenever \((x,y) \in U' \), and a \( C^r \) function \( \tilde{f} : W \rightarrow \mathbb{R}^m \) such that
\[
f \circ g(x,y) = \tilde{f}(x)
\]
for all \((x,y) \in U' \).
In fact, since $f_0(x, y) = f_0(x, 0)$ for any $y$, we can take
\[ \tilde{f}(x) = T^{-1}(x, f_0(x, 0)) \]

In the case $k = n < m$ in VIII.6.7.4., the $T$ is unnecessary and can be eliminated, and the Rank Theorem applies (the case $k = n = m$ is just the Inverse Function Theorem). In this case a better result holds, called the Range-Straightening Theorem in [?]:

\[ \text{VIII.6.7. Theorem. [Range-Straightening Theorem]} \]

Let $f$ be a $C^r$ function $(1 \leq r \leq \infty)$ from an open subset $\Omega$ of $\mathbb{R}^n$ to $\mathbb{R}^m$, and $a$ a point of the domain of $f$. Suppose $Df(a)$ has rank $n$ (then necessarily $n \leq m$). Set $b = f(a)$. Then there are open neighborhoods $U$ of $a$ in $\mathbb{R}^n$ and $V$ of $b$ in $\mathbb{R}^m$, and a $C^r$ diffeomorphism $h$ from $V$ to a neighborhood $V'$ of $(a, 0)$ in $\mathbb{R}^m$ with $h(b) = (a, 0)$, such that

\[ h \circ f(x) = (x, 0) \]

for all $x \in U$, i.e.

\[ h \circ f(x_1, \ldots, x_n) = (x_1, \ldots, x_n, 0, \ldots, 0) \]

for all $(x_1, \ldots, x_n) \in U$.

The name “Range-Straightening Theorem” means that a smooth function from $\mathbb{R}^n$ to $\mathbb{R}^m$ $(n < m)$ which has rank $n$ at a point $a$ has local range which up to a smooth change of coordinates is a piece of a horizontal $n$-dimensional hyperplane in $\mathbb{R}^m$. See VIII.6.7.10. for a precise and more general result.

**Proof:** Since $Df(a)$ has row rank $n$, there is an invertible linear transformation $T : \mathbb{R}^m \to \mathbb{R}^m$ (permutation of coordinates) so that the first $n$ rows of $D(T \circ f)(a)$ are linearly independent. Define $F : \Omega \times \mathbb{R}^{m-n} \subseteq \mathbb{R}^m \to \mathbb{R}^m$ by

\[ F(x, z) = T(f(x)) + (0, z) \]

where $x \in \mathbb{R}^n$, $z \in \mathbb{R}^{m-n}$, and the last expression uses $\mathbb{R}^m \cong \mathbb{R}^n \times \mathbb{R}^{m-n}$. Then $DF(a, 0)$ is of the form

\[
\begin{bmatrix}
A & 0 \\
B & I_{m-n}
\end{bmatrix}
\]

where the first column is $D(T \circ f)(a)$; since $A$ is invertible, $DF(a, 0)$ is invertible. Thus by the Inverse Function Theorem there is an inverse function $G$ defined on a neighborhood $V''$ of $F(a, 0) = T(f(a))$ to a neighborhood $V'$ of $(a, 0)$. Set $V = T^{-1}(V'')$ and $h = G \circ T$. If $U = \{ x \in \Omega : (x, 0) \in V' \}$, then

\[ h \circ f(x) = G \circ T \circ f(x) = G(T(f(x))) + (0, 0) = G(F(x, 0)) = (x, 0) \]

for all $x \in U$. \hfill \Box

Putting together the Range-Straightening Theorem with the Rank Theorem (which depends on the Domain-Straightening Theorem), we obtain the ultimate result (this result is called the Rank Theorem or the Constant Rank Theorem in some references):

\[ \text{VIII.6.7.8. Theorem. [Straightening Theorem]} \]

Let $f$ be a $C^r$ function $(1 \leq r \leq \infty)$ from an open subset of $\mathbb{R}^n$ to $\mathbb{R}^m$, and $a$ a point of the domain of $f$. Suppose $Df$ has constant rank $k$ in a neighborhood of $a$. Then there is an open neighborhood $U$ of $a$ and an open neighborhood $V$ of $b = f(a)$ with $f(U) \subseteq V$, and $C^r$ diffeomorphisms $g$ from a neighborhood $U'$ of $(0, 0)$ in $\mathbb{R}^n \cong \mathbb{R}^k \times \mathbb{R}^{n-k}$ to $U$ and $h$ from $V$ to a neighborhood $V'$ of $(0, 0)$ in $\mathbb{R}^m \cong \mathbb{R}^k \times \mathbb{R}^{m-k}$ with $g(0, 0) = a$, $h(b) = (0, 0)$, and

\[ h \circ f \circ g(x_1, \ldots, x_k, x_{k+1}, \ldots, x_n) = (x_1, \ldots, x_k, 0, \ldots, 0) \]
Proof: By pre- and post-composing \( f \) with translations, there is no loss of generality in assuming that \( a = 0 \) and that \( b = f(0) = 0 \). By the Rank Theorem, there is a \( C^r \) diffeomorphism \( g \), defined on an open neighborhood \( U'' \) of \( 0 \) in \( \mathbb{R}^n \), an open neighborhood \( W \) of \( 0 \) in \( \mathbb{R}^k \), and a \( C^r \) function \( \tilde{f} : W \to \mathbb{R}^m \), such that \( f \circ g(x, y) = \tilde{f}(x) \) for all \( (x, y) \in U'' \). Then \( \tilde{f} \) satisfies the hypotheses of the Range-Straightening Theorem, so there is a neighborhood \( W' \) of \( 0 \) in \( \mathbb{R}^k \), contained in \( W \), an open neighborhood \( V \) of \( 0 \) in \( \mathbb{R}^m \), and a \( C^r \) diffeomorphism \( h \) from \( V \) to an open neighborhood \( V' \) of \( 0 \) such that

\[
\tilde{f} \circ h(x) = (x, 0)
\]

for all \( x \in W' \). Set

\[
U' = \{(x, y) \in U'' : x \in W'\}
\]

Then \( U' \) is an open neighborhood of \( 0 \) in \( \mathbb{R}^n \), and

\[
h \circ f \circ g(x, y) = (x, 0)
\]

for all \( (x, y) \in U' \). Set \( U = g(U') \).

VIII.6.7.9. Note that this theorem automatically applies if the rank of \( Df(a) \) is \( m \) (i.e. \( a \) is a regular point of \( f \)), since it is rank \( \leq m \) everywhere and at least \( m \) in some neighborhood of \( a \). In this case the \( h \) can be simply be taken to be a translation. Thus the Straightening Theorem is a generalization of the Domain-Straightening Theorem VIII.6.7.1. A similar observation holds if \( Df(a) \) has rank \( n \), so the Range-Straightening Theorem VIII.6.7.7. is also a special case of the Straightening Theorem. (And the Inverse Function Theorem is the case \( k = n = m \).)

VIII.6.7.10. Corollary. Let \( f \) be a \( C^r \) function \((1 \leq r \leq \infty)\) from an open subset of \( \mathbb{R}^n \) to \( \mathbb{R}^m \), and \( a \) a point of the domain of \( f \). Suppose \( Df \) has constant rank \( k \) in a neighborhood of \( a \). Then there is an open neighborhood \( U \) of \( a \) such that \( f(U) \) is a \( k \)-dimensional \( C^r \) hypersurface in \( \mathbb{R}^m \) passing through \( b = f(a) \).

Although the Straightening Theorem only applies at points where the function is locally of constant rank (i.e. has constant rank in a neighborhood of the point), this set of points is “generic”:

VIII.6.7.11. Proposition. Let \( f \) be a \( C^r \) function \((1 \leq r \leq \infty)\) from an open subset \( U \) of \( \mathbb{R}^n \) to \( \mathbb{R}^m \). Then the set of points where \( f \) is locally of constant rank is a dense open subset of \( U \).

Proof: For \( 0 \leq k \leq n \) let \( V_k \) be the set of points of \( U \) where \( f \) has rank \( \geq k \). Then each \( V_k \) is open, and the set \( W \) of points where \( f \) is locally of constant rank is

\[
W = \bigcup_{k=0}^{n} (V_k \setminus \bar{V}_{k+1})
\]

858
Thus $W$ is open, and $U \setminus W$ is

$$U \setminus W = U \cap \left[ \bigcup_{k=0}^{n} (\tilde{V}_k \setminus V_k) \right].$$

Each $\tilde{V}_k \setminus V_k = \partial V_k$ is closed and nowhere dense, hence its complement is dense and open; and a finite intersection of dense open sets is dense and open (XI.2.3.10.).

VIII.6.7.12. Remarks. (i) The only result in this section which applies to an $f$ which is not necessarily of locally constant rank around $a$ is VIII.6.7.4. But the Straightening Theorem applies at “almost every” point by VIII.6.7.11.

(ii) The Domain-Straightening Theorem and Range-Straightening Theorem are stated in such a way that only composition of $f$ on one side with a diffeomorphism is necessary. For the ultimate Straightening Theorem, composition on both sides is necessary in general.

(iii) Much of the notational complication of the results and proofs in this section comes from the need to carefully specify and name exact neighborhoods on which functions are defined and formulas are valid. It is probably a good idea for a reader to at first ignore these precise neighborhoods, replacing each instance simply by “on some neighborhood of $a$ (etc.)” or just “near $a$” (as is done in the text in a few places where precise specification of the neighborhood is unnecessary) to follow the essence of the argument without distraction; at the end of the day, the exact neighborhoods are unimportant, since the real conclusion is merely that there are some neighborhoods on which the results hold.

VIII.6.8. Analytic Versions

There are analytic versions of most of the results of this section:

VIII.6.8.1. Theorem. [Implicit Function Theorem, Real Analytic Version] Let $U$ be an open set in $\mathbb{R}^{p+n}$ and $(a, b) \in U$. Let $F : U \to \mathbb{R}^n$ with $F(a, b) = 0$. Suppose $F$ is analytic on $U$. If $D_y F(a, b)$ is invertible, i.e. $\det(D_y F(a, b)) \neq 0$, then there are:

(i) An open set $V$ in $\mathbb{R}^{p+n}$ containing $(a, b)$, with $V \subseteq U$, such that $D_y F(x, y)$ is invertible for all $(x, y) \in V$;

(ii) An open set $W$ in $\mathbb{R}^p$ containing $a$;

(iii) A unique function $f : W \to \mathbb{R}^n$ such that $f(a) = b$ and, for all $x \in W$, $(x, f(x)) \in V$ and

$$F(x, f(x)) = 0.$$

Additionally, $f$ is analytic on $W$, and for any $x \in W$, we have

$$Df(x) = -D_y F(x, f(x))^{-1} D_x F(x, f(x))$$

(in particular, $D_y F(x, f(x))$ is invertible for all $x \in W$).
VIII.6.8.2. **Theorem.** [Real Analytic Inverse Function Theorem] Let $U$ be an open set in $\mathbb{R}^n$, $a \in U$, and $f : U \to \mathbb{R}^n$ an analytic function. If $Df(a)$ is invertible, then there is a neighborhood $V$ of $a$, $V \subseteq U$, such that

(i) $f$ is one-to-one on $V$.

(ii) $f(V)$ is open in $\mathbb{R}^n$.

(iii) $Df(x)$ is invertible for all $x \in V$.

(iv) $f^{-1}$ is analytic on $f(V)$ and, for all $y \in f(V)$,

$$D(f^{-1})(y) = [Df(f^{-1}(y))]^{-1}.$$ 

VIII.6.8.3. **Theorem.** [General Real Analytic Implicit/Inverse Function Theorem] Let $n \in \mathbb{N}$, $p \in \mathbb{N} \cup \{0\}$, $a \in \mathbb{R}^p$, $b, c \in \mathbb{R}^n$, $U$ an open neighborhood of $(a, b)$ in $\mathbb{R}^{p+n}$, $F : U \to \mathbb{R}^n$ an analytic function with $F(a, b) = c$ and $D_y F(a, b)$ invertible. Then there are:

(i) An open neighborhood $V$ of $(a, b)$ in $\mathbb{R}^{p+n}$, contained in $U$, such that $D_y F(x, y)$ is invertible for all $(x, y) \in V$;

(ii) An open neighborhood $W$ of $(a, c)$ in $\mathbb{R}^{p+n}$;

(iii) A unique function $G : W \to \mathbb{R}^n$ satisfying $G(a, c) = b$ and, for all $(x, z) \in W$, $(x, G(x, z)) \in V$ and

$$F(x, G(x, z)) = z.$$ 

Additionally, $G$ is analytic on $W$, and for all $(x, z) \in V$,

$$DG(x, z) = \begin{bmatrix} \vdots \\ -D_y F(x, G(x, z))^{-1}D_x F(x, G(x, z)) & D_y F(x, G(x, z))^{-1} \\ \vdots \end{bmatrix}.$$ 

VIII.6.8.4. **Theorem.** [Implicit Function Theorem, Complex Analytic Version] Let $U$ be an open set in $\mathbb{C}^{p+n}$ and $(a, b) \in U$. Let $F : U \to \mathbb{C}^n$ with $F(a, b) = 0$. Suppose $F$ is analytic on $U$. If $D_y F(a, b)$ is invertible, i.e. $det(D_y F(a, b)) \neq 0$, then there are:

(i) An open set $V$ in $\mathbb{C}^{p+n}$ containing $(a, b)$, with $V \subseteq U$, such that $D_y F(x, y)$ is invertible for all $(x, y) \in V$;

(ii) An open set $W$ in $\mathbb{C}^p$ containing $a$;
(iii) A unique function \( f : W \to \mathbb{C}^n \) such that \( f(a) = b \) and, for all \( x \in W \), \((x, f(x)) \in V \) and
\[
F(x, f(x)) = 0.
\]
Additionally, \( f \) is analytic on \( W \), and for any \( x \in W \), we have
\[
Df(x) = -DyF(x, f(x))^{-1}DxF(x, f(x))
\]
(in particular, \( D_yF(x, f(x)) \) is invertible for all \( x \in W \)).

VIII.6.8.5. Theorem. [Complex Analytic Inverse Function Theorem] Let \( U \) be an open set in \( \mathbb{C}^n \), \( a \in U \), and \( f : U \to \mathbb{C}^n \) an analytic function. If \( Df(a) \) is invertible, then there is a neighborhood \( V \)
of \( a \), \( V \subseteq U \), such that
(i) \( f \) is one-to-one on \( V \).
(ii) \( f(V) \) is open in \( \mathbb{C}^n \).
(iii) \( Df(x) \) is invertible for all \( x \in V \).
(iv) \( f^{-1} \) is analytic on \( f(V) \) and, for all \( y \in f(V) \),
\[
D(f^{-1})(y) = [Df(f^{-1}(y))]^{-1}.
\]

VIII.6.8.6. Theorem. [General Complex Analytic Implicit/Inverse Function Theorem] Let \( n \in \mathbb{N} \), \( p \in \mathbb{N} \cup \{0\} \), \( a \in \mathbb{C}^p \), \( b, c \in \mathbb{C}^n \), \( U \) an open neighborhood of \((a, b)\) in \( \mathbb{C}^{p+n} \), \( F : U \to \mathbb{C}^n \) an analytic function with \( F(a, b) = c \) and \( D_yF(a, b) \) invertible. Then there are:
(i) An open neighborhood \( V \) of \((a, b)\) in \( \mathbb{C}^{p+n} \), contained in \( U \), such that \( D_yF(x, y) \) is invertible for all \((x, y) \in V \);
(ii) An open neighborhood \( W \) of \((a, c)\) in \( \mathbb{C}^{p+n} \);
(iii) A unique function \( G : W \to \mathbb{C}^n \) satisfying \( G(a, c) = b \) and, for all \((x, z) \in W \), \((x, G(x, z)) \in V \) and
\[
F(x, G(x, z)) = z.
\]
Additionally, \( G \) is analytic on \( W \), and for all \((x, z) \in V \),
\[
DG(x, z) = \begin{bmatrix}
-D_yF(x, G(x, z))^{-1}D_xF(x, G(x, z)) & \cdots & D_yF(x, G(x, z))^{-1} \\
\vdots & \ddots & \vdots \\
\vdots & \cdots & \end{bmatrix}.
\]
The complex analytic versions can be efficiently proved as follows. We outline the proof of VIII.6.8.6., of which VIII.6.8.4. and VIII.6.8.5. are corollaries. So begin with an analytic function $F : U \to \mathbb{C}^n$ satisfying the hypotheses.

1. Regard $F$ as a $C^\infty$ function from $\mathbb{R}^{2p+2n}$ to $\mathbb{R}^{2n}$.

2. Apply VIII.6.2.1. to obtain the unique $G : \mathbb{R}^{2p+2n} \to \mathbb{R}^{2n}$ with the right properties. Then $G$ is $C^\infty$.

3. Check from the derivative formula of VIII.6.2.1. (cf. III.11.11.2.) that the partial derivatives of $G$ with respect to any consecutive odd/even pair of coordinates satisfy the Cauchy-Riemann equations (X.8.1.7.).

4. Conclude from X.8.1.6. that $G$, regarded as a function from $\mathbb{C}^{p+n}$ to $\mathbb{C}^n$, is complex analytic.

The Taylor series of $G$ around $(a, c)$ can be computed by brute force algebraic manipulation of power series (there is a unique multivariable power series which formally satisfies the identity $F(x, G(x, z)) = z$ for all $x, z$; cf. VIII.6.9.9.), although the calculation becomes rather ghastly. This calculation can be used to give an alternate proof of most of VIII.6.8.6.. But the calculation is not sufficient by itself: it must also be shown that the resulting series converges in a neighborhood of $(a, c)$. Then the function it converges to must satisfy the identity in the conclusion, and is the only analytic solution. Thus there is a unique analytic function satisfying the conclusion. But to conclude there is a unique function satisfying the identity, additional argument is needed (such as an application of VIII.6.2.1.).

There is an alternate approach which avoids all use of VIII.6.2.1. (or the other smooth results). Begin by proving the Complex Analytic Inverse Function Theorem VIII.6.8.5., where uniqueness comes along essentially for free, using the method of VIII.6.8.8. Then conclude VIII.6.8.6. as in VIII.6.2.2.

For the real analytic versions, the following procedure seems to suffice (we again outline the proof of VIII.6.8.3.). Let $F : U \to \mathbb{R}^n$ satisfy the hypotheses.

1. Complexify $F$ to a complex analytic function $F_C$ from a neighborhood of $(a, b)$ in $\mathbb{C}^{p+n}$ to $\mathbb{C}^n$, using the same power series centered at $(a, b)$.

2. Apply VIII.6.8.6. to $F_C$ to obtain a complex analytic function $G_C : \mathbb{C}^{p+n} \to \mathbb{C}^n$.

3. Restrict $G_C$ to $\mathbb{R}^{p+n}$ to get $G$.

There is, however, a technical subtlety: it must be shown that $G$ takes values in $\mathbb{R}^n$, not just in $\mathbb{C}^n$. This can be done by computing the Taylor series for $G_C$ around $(a, c)$ as in VIII.6.8.8. and verifying that all coefficients (partial derivatives) are real.

There is a better approach: as in VIII.6.8.9., first prove the Real Analytic Inverse Function Theorem VIII.6.8.2.. This can be done as follows. Suppose $f$ satisfies the hypotheses of VIII.6.8.2..

1. Apply the Inverse Function Theorem to show that $f$ is one-to-one on a neighborhood $V_r$ of $a$ with $C^\infty$ inverse function $f^{-1}$ on the neighborhood $W_r = f(V_r)$ of $b = f(a)$ in $\mathbb{R}^n$. 

862
(2) Complexify \( f \) to \( f_C \) on a neighborhood of \( a \) in \( \mathbb{C}^n \) with the same Taylor series. Verify that \( f_C \) satisfies the hypotheses of the Complex Analytic Inverse Function Theorem, hence is one-to-one on a neighborhood \( V_\epsilon \) of \( a \) in \( \mathbb{C}^n \) with complex analytic inverse function \( f_C^{-1} \) on the neighborhood \( W_\epsilon = f_C(V_\epsilon) \) of \( b \) in \( \mathbb{C}^n \).

(3) Use that \( f_C \) is one-to-one and extends \( f \) to conclude that the restriction of \( f_C^{-1} \) to the neighborhood \( W = W_\epsilon \cap W_\epsilon' \) of \( b \) in \( \mathbb{R}^n \) agrees with the restriction of \( f^{-1} \) to \( W \). Thus \( f^{-1} \) is real analytic on \( W \).

Theorem VIII.6.8.2. can also be proved by the method of VIII.6.8.8. without any use of the usual Inverse Function Theorem.

Thus the real and complex analytic theorems are all proved (see Exercise VIII.6.9.19. for details). \( \square \)

VIII.6.8.12. There are then real and complex analytic versions of the Straightening Theorems and the Rank Theorem; see Exercise VIII.6.9.19.

VIII.6.9. Exercises

VIII.6.9.1. Show that the hypothesis that \( D_yF(a, b) \) is invertible is not necessary for the conclusion of the Smooth Implicit Function Theorem, i.e. that the converse of the theorem does not hold. [Consider \( F(x, y) = x^3 - y^3 \).]

VIII.6.9.2. (a) If \( F \) is a function from \( \mathbb{R}^2 \) to \( \mathbb{R} \), and the graph of the equation \( F(x, y) = 0 \) is a curve that crosses itself at \( a \) with different tangent lines, and \( F \) is differentiable at \( a \), show that \( DF(a) = 0 \). [Consider directional derivatives.] This “explains” why the Implicit Function Theorem cannot apply at \( a \).

(b) If \( F \) is a \( C^1 \)-function from \( \mathbb{R}^2 \) to \( \mathbb{R} \), and the graph of the equation \( F(x, y) = 0 \) is a curve with two segments passing through \( a \) with the same tangent line, not identically equal in any neighborhood of \( a \), show that \( DF(a) = 0 \). [By making a linear change of variables, it may be assumed the tangent line at \( a \) is horizontal. Show that the Implicit Function Theorem cannot apply at \( a \).]

VIII.6.9.3. Let \( W \) be an open set in \( \mathbb{R}^p \), and \( f \) a continuous function from \( U \) to \( \mathbb{R}^n \). Define \( F : W \times \mathbb{R}^n \to \mathbb{R}^n \) by \( F(x, y) = y - f(x) \). Let \( a \in W \), and set \( b = f(a) \).

(a) Show that \( F, a, b \) satisfy the hypotheses of VIII.6.1.6..

(b) Show that the implicitly defined function is \( f \) (possibly restricted to a smaller neighborhood of \( a \)).

Thus every continuous function is defined implicitly by a function as in VIII.6.1.6. Since \( f \) need not be differentiable anywhere, no stronger conclusion can be obtained in VIII.6.1.6. without additional hypotheses, even in the case \( p = n = 1 \).

VIII.6.9.4. Show that under the hypotheses of VIII.6.3.2., even if \( p = 1 \), there is not necessarily a continuous function \( f \) on a neighborhood \( W \) of \( a \) with \( f(a) = b \) and \( F(x, f(x)) = 0 \) for all \( x \in W \). [Construct a pseudo-arc \( P \) in \( \{0, 1\} \times (0, 1) \subseteq \mathbb{R}^2 \) containing only one point \((0, c)\) on the left edge and one point on the right edge, whose complement in \([0, 1]^2\) has exactly two components, and let \( F \) be a continuous function from \([0, 1]^2\) to \( \mathbb{R} \) with \( F(0, y) = y - c \), \( F(x, 1) = 1 - c \), \( F(x, 0) = -c \), and which is zero precisely on \( P \). Note that \( \frac{\partial f}{\partial y}(0, c) \) exists and equals 1.]
VIII.6.9.5. (a) Assuming the Implicit Function Theorem, use the formula for $DF$ in VIII.6.2.3. to deduce the formula for the total derivative of the inverse function to $f$.

(b) Assuming the Inverse Function Theorem, use the formula for $D\tilde{F}$ in VIII.6.2.2. and () to deduce the formula for the total derivative $Df = -(D_yF)^{-1}D_xF$ of the implicitly defined function $f$.

VIII.6.9.6. Use VIII.6.3.9. and the argument of VIII.6.2.3. to obtain the version of the one-dimensional Inverse Function Theorem described in VIII.6.6.4.

VIII.6.9.7. Recall the way the formula for $f'(x)$ is found by implicit differentiation in first-semester calculus from an equation $F(x,y) = 0$: differentiate $G(x) = F(x,f(x))$ by the Chain Rule and other differentiation rules, set it equal to 0, and solve for $f'(x)$ (streamlined notation is usually used which amounts to this). Show that the same formula as the one in VIII.6.3.10. is always obtained.

VIII.6.9.8. In VIII.6.3.7., assume that the first-order partials of $F$ are defined on $U$ and continuous at $(a,b)$ (which implies that $F$ is differentiable at $(a,b)$), and that $\partial F/\partial y$ is nonzero on $U$ (which can be automatically arranged in the continuous partial case if $\partial F/\partial y(a,b) \neq 0$ by replacing $U$ by a smaller neighborhood of $(a,b)$). Give a simplified proof as follows (note that the $f$ is unique and continuous in this case by VIII.6.3.4.):

(a) For notational simplicity, assume $p = 1$. If $\Delta x$ is sufficiently small, write $\Delta y = f(a+\Delta x) - f(a) = f(a+\Delta x) - b$. Then

\[ 0 = F(a+\Delta x, b+\Delta y) = F(a, b) = F(a+\Delta x, b+\Delta y) - F(a, b) \]

\[ = [F(a+\Delta x, b + \Delta y) - F(a, b + \Delta y)] + [F(a, b + \Delta y) - F(a, b)] . \]

(b) By two applications of the MVT, there are $0 < \alpha, \beta < 1$ (depending on $\Delta x$) such that

\[ F(a + \Delta x, b + \Delta y) - F(a, b + \Delta y) = \partial F/\partial x(a + \alpha \Delta x, b + \Delta y) \Delta x \]

\[ F(a, b + \Delta y) - F(a, b) = \partial F/\partial y(a, b + \beta \Delta y) \Delta y . \]

(c) From (a) and (b),

\[ \partial F/\partial x(a + \alpha \Delta x, b + \Delta y) \Delta x + \partial F/\partial y(a, b + \beta \Delta y) \Delta y = 0 \]

so

\[ \frac{\Delta y}{\Delta x} = -\frac{\partial F/\partial x(a + \alpha \Delta x, b + \Delta y)}{\partial F/\partial y(a, b + \beta \Delta y)} . \]

(d) By continuity,

\[ \lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x} = \lim_{\Delta x \to 0} -\frac{\partial F/\partial x(a + \alpha \Delta x, b + \Delta y)}{\partial F/\partial y(a, b + \beta \Delta y)} \]

exists and equals $\partial F/\partial y(a,b)$.

(e) Adapt the argument notationally to the case $p > 1$. 

864
VIII.6.9.9. Use the Chain Rule to find formulas for the higher-order derivatives of implicitly defined functions.

VIII.6.9.10. Give a direct argument proving the Continuous Implicit Function Theorem along the lines of the proof of VIII.6.5.1. by proving the following version first proved in [Gou03]:

THEOREM. Let $U$ be an open set in $\mathbb{R}^{p+n}$ containing $(0, 0)$, and $G : U \to \mathbb{R}^n$ a continuous function with $G(0, 0) = 0$, such that $D_yG$ is continuous on $U$ and $D_yG(0, 0) = 0$. Then there are open sets $V$ in $\mathbb{R}^{p+n}$, $V \subseteq U$, $(0, 0) \in V$, and $W$ in $\mathbb{R}^p$, $0 \in W$, and $Y$ in $\mathbb{R}^n$, $0 \in Y$, such that for every $y \in Y$ there is a unique $x \in W$ with $(x, y) \in V$ and $G(x, y) = y$.

(a) Prove this theorem by using the Contraction Mapping Principle.
(b) If $U \subseteq \mathbb{R}^{p+n}$, $(0, 0) \in U$, and $F : U \to \mathbb{R}^n$ is a continuous with $F(0, 0) = 0$, such that $D_yF$ is continuous on $U$ and $D_yF(0, 0) = I$, show that there is a unique implicitly defined function $f$ on a neighborhood $W$ of $0$ in $\mathbb{R}^p$, taking values in a neighborhood $Y$ of $0$ in $\mathbb{R}^n$, such that $F(x, f(x)) = 0$ for all $x \in W$. [Set $G(x, y) = y - F(x, y)$]
(c) Use an affine change of variables to deduce the existence of an implicit function under the hypotheses of VIII.6.1.6. Conclude continuity of the implicit function from VIII.6.1.12.

See [?] for a nice geometric interpretation of this argument.

VIII.6.9.11. Define $F : \mathbb{R}^2 \to \mathbb{R}$ by

$$ F(x, y) = \begin{cases} y + x^2 \cos \left( \frac{y}{x^2} \right) & \text{if } x \neq 0 \\ y & \text{if } x = 0 \end{cases} $$

(a) Show that $F$ is differentiable everywhere. In particular, $F$ is continuous, and $\frac{\partial F}{\partial x}$ and $\frac{\partial F}{\partial y}$ exist everywhere.
(b) Show that $\frac{\partial F}{\partial y}$ is continuous in $y$ for fixed $x$, and that $\frac{\partial F}{\partial y}(0, 0) = 1$.
(c) Show that the equation $F(x, y) = 0$ cannot be uniquely solved for $y$ as a differentiable function of $x$ in any small neighborhood of $(0, 0)$ (the smaller the neighborhood, the more differentiable solutions there are).

VIII.6.9.12. (a) Write a statement which is a common generalization of VIII.6.3.12. and VIII.6.6.7., along the lines of VIII.6.4.2.

***(b) Is this statement true? [cf. VIII.6.9.13.(b).]

VIII.6.9.13. (a) Show that under the hypotheses of VIII.6.6.5., if $U$ is connected, then $\text{det}(Df(x))$ does not change sign on $U$, i.e. $f$ either preserves or reverses orientation on all of $U$.

***(b) Is the assumption of a decreasing chain of minors as in VIII.6.4.3. automatic? (If so, an inductive proof of VIII.6.6.5. and the statement in VIII.6.9.12. can be given.)

VIII.6.9.14. Let $U$ and $V$ be open sets in $\mathbb{R}^n$, and $f : U \to V$ a bijection which is $C^r$ ($1 \leq r \leq \infty$). If $f^{-1}$ is differentiable everywhere on $V$, show that $f^{-1}$ is necessarily $C^r$ on $V$.

VIII.6.9.15. Formulate and prove generalizations of the Continuous and Mixed Implicit Function Theorem similar to VIII.6.2.1.
VIII.6.9.16. Let $f : \mathbb{R} \rightarrow \mathbb{R}$ be given by $f(x) = x^2$. Around which points can $f$ be straightened?

VIII.6.9.17. Let $f : \mathbb{R} \rightarrow \mathbb{R}^2$ be given by $f(x) = (x^3, x^2)$. Then $f$ is $C^\infty$. Show that the range of $f$ can be topologically straightened but not smoothly straightened around 0.

VIII.6.9.18. Define $f : \mathbb{R} \rightarrow \mathbb{R}^2$ by

$$f(x) = \left( e^{-1/x^2} \left[ 1 - \cos \frac{2\pi}{x} \right], e^{-1/x^2} \sin \frac{2\pi}{x} \right)$$

for $x \neq 0$, and $f(0) = (0, 0)$.

(a) Show that $f$ is a $C^\infty$ function.

(b) Show that the image of $\left( -\frac{1}{n}, \frac{1}{n} \right)$ is topologically a Hawaiian earring (XI.18.4.6.) for any $n \in \mathbb{N}$. Thus the range cannot even be topologically straightened around 0.

(c) Discuss straightening of the function $g : \mathbb{R}^2 \rightarrow \mathbb{R}^2$ given by

$$g(x, y) = \left( e^{-1/x^2} \left[ 1 - \cos \frac{2\pi}{x} \right], y + e^{-1/x^2} \sin \frac{2\pi}{x} \right)$$

for $x \neq 0$ and $g(0, y) = (0, y)$.

VIII.6.9.19. (a) Write out the details of the proofs of the real and complex analytic versions of the Implicit and Inverse Function Theorems.

(b) Compute enough terms of the Taylor series of the implicitly defined function to indicate the general procedure and the proof of uniqueness.

(c) Verify by calculation the derivative formulas for the complex analytic versions (for the real analytic versions, these formulas are trivial from the smooth versions).

(d) Formulate and prove real and complex analytic versions of the Straightening Theorems and the Rank Theorem.

VIII.6.9.20. Formulate and prove precise versions, both real and complex, of the statement that the roots of an $n$'th degree polynomial are continuous, and in fact analytic, functions of the coefficients, except at multiple roots. [Fix $n$, and consider the function

$$F(a_0, \ldots, a_n, x) = a_0 + a_1 x + \cdots + a_n x^n$$

and solve $F(a_0, \ldots, a_n, x) = 0$ for $x$.]

This suggests there are analytic formulas for the roots of a general $n$'th degree polynomial, although explicit expressions for the formulas may not be possible in general. There cannot be explicit formulas just involving finitely many algebraic operations, including roots, if $n \geq 5$. 

866
VIII.6.9.21. Let $U$ be an open set in $\mathbb{R}^3$, and $F : U \to \mathbb{R}$ be a $C^1$ function with $\frac{\partial F}{\partial x}$, $\frac{\partial F}{\partial y}$, and $\frac{\partial F}{\partial z}$ nonzero on $U$. Then the equation $F(x, y, z) = 0$ can be locally solved for each of $x, y, z$ as functions of the other two. Show that

$$\frac{\partial x}{\partial y} \frac{\partial y}{\partial z} \frac{\partial z}{\partial x} = -1.$$ 

(Give a careful explanation of what this equation means.) Thus algebraic manipulations of Leibniz notation must be done carefully.

VIII.7. Power Series and Analytic Functions of Several Variables

The theory of power series and analytic functions in several variables is similar to the theory in one variable with some technical complications. In this section, we will take the path of least resistance to the most important aspects of the theory, avoiding some of the (sometimes interesting) technicalities that arise. As in the one-variable case, we can do the real and complex theories in parallel; we let \( \mathbb{F} \) stand for either \( \mathbb{R} \) or \( \mathbb{C} \).

VIII.7.1. Multivariable Power Series

VIII.7.1.1. In general, we want to consider power series of the form

\[
\sum_{k_1=0}^{\infty} \sum_{k_2=0}^{\infty} \cdots \sum_{k_n=0}^{\infty} a_{k_1 \ldots k_n} x_1^{k_1} x_2^{k_2} \cdots x_n^{k_n}
\]

where the \( a_{k_1 \ldots k_n} \) are scalars (real or complex) and \( x_1, \ldots, x_n \) are independent variables. The notation can become oppressive working with a general \( n \), although multiindex notation (VIII.7.1.5.) can help, so sometimes we will notationally stick to the case \( n = 2 \), writing \( x \) and \( y \) (or \( z \) and \( w \) in the complex case) for the independent variables. Just as in multivariable calculus, the case \( n = 2 \) exhibits all the essential features of the theory for general \( n \) in contrast with the case \( n = 1 \). Thus a power series in two variables will be written

\[
\sum_{j=0}^{\infty} \sum_{k=0}^{\infty} a_{jk} x^j y^k
\]

or more generally

\[
\sum_{j=0}^{\infty} \sum_{k=0}^{\infty} a_{jk} (x-x_0)^j (y-y_0)^k.
\]

VIII.7.1.2. Even in the two-variable case, there is no natural ordering on the terms, so we will regard the infinite series as an unordered sum

\[
\sum_{(j,k)} a_{jk} (x-x_0)^j (y-y_0)^k
\]

where the sum is over \( \mathbb{N}_0^3 \) (recall the notation \( \mathbb{N}_0 = \mathbb{N} \cup \{0\} \)). In general, we will have an unordered sum over \( \mathbb{N}_0^n \). Regarding multivariable power series as unordered sums means that we will only consider absolute convergence, and leads to technical simplifications in the theory without essential loss of generality.

VIII.7.1.3. Since we are considering multivariable power series as unordered sums, there is no harm in allowing more than one term with the same powers \( (x-x_0)^j (y-y_0)^k \); we may even have infinitely many terms with the same pair \( (j,k) \) of powers, and it is convenient to allow this. Any such sum can be converted to standard form by first summing together all terms with powers a fixed \( (j,k) \), and then summing over \( (j,k) \); the standard form is a drastic revision of the original power series. As long as the original power series converges (as an unordered sum, i.e. converges absolutely), the standard form conversion and series will also converge (IV.2.10.20.). So we can make a formal definition:
VIII.7.1.4. Definition. Let $\Omega$ be an index set, and $\phi = (\phi_1, \ldots, \phi_n) : \Omega \to \mathbb{N}_0^n$ a function. A multivariable power series in variables $X_1, \ldots, X_n$ indexed by $\Omega$ is an unordered sum

$$
\sum_{\omega \in \Omega} a_{\omega} X_1^{\phi_1(\omega)} X_2^{\phi_2(\omega)} \cdots X_n^{\phi_n(\omega)}
$$

where the $a_{\omega}$ are scalars. If $(c_1, \ldots, c_n)$ is an $n$-tuple of scalars, a multivariable power series in $x_1, \ldots, x_n$ centered at $(c_1, \ldots, c_n)$, indexed by $\Omega$, is an unordered sum

$$
\sum_{\omega \in \Omega} a_{\omega} (x_1 - c_1)^{\phi_1(\omega)} (x_2 - c_2)^{\phi_2(\omega)} \cdots (x_n - c_n)^{\phi_n(\omega)} .
$$

If $n = 2$, a multivariable power series in $x$ and $y$ centered at $(x_0, y_0)$, indexed by $\Omega$, is an unordered sum

$$
\sum_{\omega \in \Omega} a_{\omega} (x - x_0)^{\phi_1(\omega)} (y - y_0)^{\phi_2(\omega)} .
$$

The multivariable power series is in standard form if $\phi$ is one-to-one; in this case, we may take $\Omega = \mathbb{N}_0^n$ and write the power series as

$$
\sum_{(k_1, \ldots, k_n) \in \mathbb{N}_0^n} a_{k_1, \ldots, k_n} (x_1 - c_1)^{k_1} \cdots (x_n - c_n)^{k_n} .
$$

Any multivariable power series has a unique drastic revision which is in standard form.

VIII.7.1.5. It is convenient to use multi-index notation: if $\alpha = (m_1, \ldots, m_n) \in \mathbb{N}_0^n$, and $x = (x_1, \ldots, x_n)$, write $x^\alpha = x_1^{m_1} x_2^{m_2} \cdots x_n^{m_n}$. We can then write the series

$$
\sum_{\omega \in \Omega} a_{\omega} (x_1 - c_1)^{\phi_1(\omega)} (x_2 - c_2)^{\phi_2(\omega)} \cdots (x_n - c_n)^{\phi_n(\omega)}
$$

centered at $c = (c_1, \ldots, c_n)$ as

$$
\sum_{\omega \in \Omega} a_{\omega} (x - c)^{\phi(\omega)}
$$

and a standard form multivariable power series as

$$
\sum_{\alpha \in \mathbb{N}_0^n} a_{\alpha} (x - c)^\alpha .
$$

VIII.7.1.6. If $c = (c_1, \ldots, c_n) \in \mathbb{R}^n$, the power series

$$
\sum_{\omega \in \Omega} a_{\omega} (x - c)^{\phi(\omega)}
$$

converges at $b = (b_1, \ldots, b_n) \in \mathbb{R}^n$ if the unordered sum

$$
\sum_{\omega \in \Omega} a_{\omega} (b - c)^{\phi(\omega)}
$$

converges (i.e. converges absolutely). We then have by comparison:
VIII.7.1.7. **Proposition.** Let
\[ \sum_{\omega \in \Omega} a_{\omega}(x - c)^{\phi(\omega)} \]
be a multivariable power series. If the series converges at \( b = (b_1, \ldots, b_n) \), then it converges at \( x = (x_1, \ldots, x_n) \) for any \( (x_1, \ldots, x_n) \in \mathbb{F}^n \) with \( |x_1 - c_1| \leq |b_1 - c_1|, \ldots, |x_n - c_n| \leq |b_n - c_n| \).

VIII.7.1.8. Thus, if the series converges for some \( b \) with \( b_k \neq c_k \) for all \( k \), then it converges at all points of the rectangle (or polydisk if \( \mathbb{F} = \mathbb{C} \))
\[ R = \{ x : |x_k - c_k| \leq |b_k - c_k| \text{ for all } 1 \leq k \leq n \} \]
centered at \( c \), and thus defines a function from \( R \) to \( \mathbb{F} \).

VIII.7.1.9. **Example.** A one-variable power series converges precisely on an interval (or disk in the complex case). But the situation is more complicated with multivariable power series: the set of convergence need not be a rectangle (or polydisk). For example, consider the real 2-variable power series
\[ \sum_{k=0}^{\infty} x^k y^k. \]
This series converges (to \( \frac{1}{1-xy} \)) if and only if \( |xy| < 1 \), i.e. on the open subset of \( \mathbb{R}^2 \) containing \( (0,0) \) bounded by the hyperbolas \( y = \pm \frac{1}{x} \).

The best simple general statement we can make is that for any fixed \( y \), a 2-variable power series converges at \( (x,y) \) exactly for all \( x \) in a (possibly degenerate or empty) interval (disk) centered at \( x_0 \), and similarly for fixed \( x \). Thus if \( S \) is the set of convergence, every horizontal cross section is an interval (disk) centered at \( x_0 \), and every vertical cross section is an interval (disk) centered at \( y_0 \). These statements are true since if one variable is fixed, the series is an ordinary power series in the other variable. A similar statement holds in higher dimensions (fixing all but one variable). Thus, in general, the set of convergence is a union of rectangles (polydisks) centered at \( c \).

VIII.7.1.10. **Proposition.** Let
\[ \sum_{\omega \in \Omega} a_{\omega}(x - c)^{\phi(\omega)} \]
be a multivariable power series which converges on a rectangle (polydisk)
\[ R = \{ x : |x_k - c_k| \leq r_k \text{ for all } 1 \leq k \leq n \} \]
centered at \( c \), where \( r_1, \ldots, r_n > 0 \). Let \( f \) be the function on \( R \) defined by the power series. For each finite \( E \subseteq \Omega \), define
\[ f_E(x) = \sum_{\omega \in E} a_{\omega}(x - c)^{\phi(\omega)} \]

for $\mathbf{x} \in \mathbb{R}$. Then $f_E \to f$ uniformly on $\mathbb{R}$, i.e. for every $\epsilon > 0$ there is a finite subset $F$ of $\Omega$ such that, whenever $E$ is a finite subset of $\Omega$ containing $F$,

$$|f(\mathbf{x}) - f_E(\mathbf{x})| < \epsilon$$

for all $\mathbf{x} \in \mathbb{R}$.

**Proof:** This is essentially the Weierstrass $M$-test (). Set $\mathbf{r} = (r_1, \ldots, r_n)$. The unordered sum

$$\sum_{\omega \in \Omega} a_{\omega} \mathbf{r}^{\phi(\omega)}$$

converges; hence for $\epsilon > 0$ there is a finite subset $F \subseteq \Omega$ such that

$$\sum_{\omega \in \Omega \setminus F} |a_{\omega}| r^{\phi(\omega)} < \epsilon .$$

Thus, if $E$ is a finite subset of $\Omega$ containing $F$, we have

$$|f(\mathbf{x}) - f_E(\mathbf{x})| = \left| \sum_{\omega \in \Omega \setminus E} a_{\omega} (\mathbf{x} - \mathbf{c})^{\phi(\omega)} \right|$$

$$\leq \sum_{\omega \in \Omega \setminus E} |a_{\omega}| |x_1 - c_1|^{\phi_1(\omega)} |x_2 - c_2|^{\phi_2(\omega)} \cdots |x_n - c_n|^{\phi_n(\omega)} \leq \sum_{\omega \in \Omega \setminus F} |a_{\omega}| r^{\phi(\omega)} < \epsilon .$$

\[ \blacksquare \]

**VIII.7.1.11. Corollary.** If a multivariable power series converges on a rectangle (polydisk) $\mathbb{R}$, it defines a continuous function on $\mathbb{R}$.

We now show that a multivariable power series can be differentiated term-by-term.

**VIII.7.1.12. Theorem.** Let

$$\sum_{\omega \in \Omega} a_{\omega} (\mathbf{x} - \mathbf{c})^{\phi(\omega)}$$

be a multivariable power series which converges on a rectangle (polydisk)

$$\mathbb{R} = \{ \mathbf{x} : |x_k - c_k| \leq r_k \text{ for all } 1 \leq k \leq n \}$$

centered at $\mathbf{c}$, where $r_1, \ldots, r_n > 0$. Let $f$ be the function on $\mathbb{R}$ defined by the power series. Then, for each $k, 1 \leq k \leq n$, the unordered sum

$$\sum_{\omega \in \Omega} a_{\omega} \frac{\partial}{\partial x_k} ((\mathbf{x} - \mathbf{c})^{\phi(\omega)}) = \sum_{\omega \in \Omega} \phi_k(\omega) a_{\omega} (x_1 - c_1)^{\phi_1(\omega)} (x_2 - c_2)^{\phi_2(\omega)} \cdots (x_k - c_k)^{\phi_k(\omega)-1} \cdots (x_n - c_n)^{\phi_n(\omega)}$$

(VIII.2)
converges u.c. to \( \frac{\partial f}{\partial x_k} \) on the open rectangle (polydisk) \( R^0 = \{ x : |x_k - c_k| < r_k \text{ for all } 1 \leq k \leq n \} \).

**Proof:** This can be quickly reduced to the one-variable case. Fix \( k \). For each \( j \neq k \), fix \( x_j \) with \( |x_j - c_j| \leq r \). For any \( x_k, |x_k - c_k| \leq r_k \), the unordered sum
\[
\sum_{\omega \in \Omega} a_\omega (x - c)^{\phi(\omega)}
\]
converges; hence it can be computed by summing in any manner. Form the drastic revision
\[
\sum_{m \in \mathbb{N}_0} b_m (x_k - c_k)^m
\]
obtained by first summing all terms with factor \( (x_k - c_k)^m \) for fixed \( m \). This is an unordered power series in one variable \( x_k - c_k \) which converges for \( |x_k - c_k| \leq r_k \); thus the associated ordinary power series
\[
\sum_{m=0}^{\infty} b_m (x_k - c_k)^m \tag{VIII.3}
\]
has radius of convergence at least \( r_k \), and converges to \( f(x_1, \ldots, x_{k-1}, x, x_{k+1}, \ldots, x_n) \) for \( |x - c_k| \leq r_k \). Thus, by V.15.3.23., the series of term-by-term derivatives converges absolutely to
\[
\frac{d}{dx} \left( f(x_1, \ldots, x_{k-1}, x, x_{k+1}, \ldots, x_n) \right) = \frac{\partial f}{\partial x_k} (x_1, \ldots, x_{k-1}, x, x_{k+1}, \ldots, x_n)
\]
for \( |x - c_k| < r_k \), i.e. VIII.3 converges to \( \frac{\partial f}{\partial x_k} \) on \( R^0 \).

We have not yet shown that the original multivariable series VIII.2 converges. But this can be shown by a majorization argument. The above argument can be used starting with the series of absolute values
\[
\sum_{\omega \in \Omega} |a_\omega| (|x - c|)^{\phi(\omega)}
\]
which converges on \( R \) to a function \( F \). If we choose the \( x_j \) so that \( x_j - c_j \geq 0 \) for all \( j \), then the unordered sum
\[
\sum_{\omega \in \Omega} \phi_k(\omega)|a_\omega| (x_1 - c_1)^{\phi_1(\omega)}(x_2 - c_2)^{\phi_2(\omega)} \cdots (x_k - c_k)^{\phi_k(\omega)-1} \cdots (x_n - c_n)^{\phi_n(\omega)} \tag{VIII.4}
\]
has a drastic revision which converges (to \( \frac{\partial F}{\partial x_k} \)); thus the series VIII.4 also converges since all the terms are nonnegative. This implies that VIII.2 converges on \( R^0 \) by comparison. Since it has a drastic revision which converges to \( \frac{\partial f}{\partial x_k} \) on \( R^0 \), VIII.2 also converges to \( \frac{\partial F}{\partial x_k} \) on \( R^0 \).

This argument shows pointwise convergence of VIII.2 on \( R^0 \); u.c. convergence is then automatic by VIII.7.1.10. \( \blacklozenge \).
VIII.7.1.13. **Corollary.** Let
\[ \sum_{\omega \in \Omega} a_\omega (x - c)^{\phi(\omega)} \]
be a multivariable power series which converges on an open rectangle (polydisk)
\[ R^o = \{ x : |x_k - c_k| < r_k \text{ for all } 1 \leq k \leq n \} \]
centered at \( c \), where \( r_1, \ldots, r_n > 0 \). Let \( f \) be the function on \( R^o \) defined by the power series. Then \( f \) is \( C^\infty \) on \( R^o \), and the partial derivatives of all orders of \( f \) are obtained by term-by-term partial differentiation, i.e.
for any \( m_1, \ldots, m_n \geq 0 \) the unordered sum
\[ \sum_{\omega \in \Omega} a_\omega \frac{\partial^{m_1 + \cdots + m_n}}{\partial x_1^{m_1} \cdots \partial x_n^{m_n}} ( (x - c)^{\phi(\omega)} ) \]
converges u.c. to \( \frac{\partial^{m_1 + \cdots + m_n} f}{\partial x_1^{m_1} \cdots \partial x_n^{m_n}} \) on \( R^o \).

**Proof:** Every point of \( R^o \) is contained in the interior of a closed polydisc centered at \((c_1, \ldots, c_n)\) contained in \( R^o \). Apply VIII.7.1.12. repeatedly, shrinking the polydisk slightly each time.

VIII.7.1.14. We extend the multi-index notation: if \( \alpha = (m_1, \ldots, m_n) \in \mathbb{N}^n_0 \), write
\[ |\alpha| = m_1 + \cdots + m_n \]
\[ \alpha! = m_1! m_2! \cdots m_n! \]
\[ \frac{\partial^\alpha}{\partial x_\alpha} = \frac{\partial^{|\alpha|}}{\partial x_\alpha} = \frac{\partial^{m_1 + \cdots + m_n}}{\partial x_1^{m_1} \cdots \partial x_n^{m_n}}. \]
We can then rephrase VIII.7.1.13.: under the hypotheses, for every \( \alpha \) the series
\[ \sum_{\omega \in \Omega} a_\omega \frac{\partial^\alpha}{\partial x_\alpha} ( (x - c)^{\phi(\omega)} ) \]
converges u.c. on \( R^o \) to \( \frac{\partial^\alpha f}{\partial x_\alpha} \).

VIII.7.1.15. Equality of mixed partials (VIII.2.2.2.) for functions defined by convergent power series is an immediate corollary of VIII.7.1.13., giving a simpler alternate proof in this case.

VIII.7.1.16. Note that when \( F = \mathbb{C} \), these partial derivatives are interpreted in the complex sense: fix the remaining variables and take the derivative as in X.1.1.2.. Thus a complex-valued function defined on a polydisk by a multivariable power series has partial derivatives of all orders in the complex sense, which are also given by multivariable power series obtained by term-by-term differentiation.
VIII.7.2. Analytic Functions of Several Variables

In this section, we describe some of the basics of the theory of real and complex analytic functions of several variables. Some aspects of the theory are virtually identical to the one-variable case, but there are also significant differences.

VIII.7.2.1. Definition. Let $U$ be an open set in $\mathbb{F}^n$. A function $f : U \rightarrow \mathbb{F}$ is analytic if, for every $c \in U$, $f$ is represented in a neighborhood of $c$ by a multivariable power series centered at $c$. A function $f = (f_1, \ldots, f_m) : U \rightarrow \mathbb{F}^m$ is analytic if each $f_k$ is analytic.

VIII.7.2.2. As in the one-variable case, this definition is a local one: a function $f$ on an open set $U$ is analytic on $U$ if and only if it is analytic on a neighborhood of $c$ for each $c \in U$. In particular, if $U = \cup_j U_j$ is a union of open sets, then $f$ is analytic on $U$ if and only if it is analytic on each $U_j$.

An immediate corollary of VIII.7.1.13. is:

VIII.7.2.3. Corollary. Let $U$ be an open set in $\mathbb{F}^n$, and $f$ analytic on $U$. Then $f$ is $C^\infty$ on $U$, and for any multi-index $\alpha$, $\frac{\partial^\alpha f}{\partial x^\alpha}$ is analytic on $U$.

VIII.7.2.4. An analytic function $f$ is “jointly analytic” in its variables. If all but one variable is fixed, it is analytic in the remaining variable in the usual sense of $(\cdot)$, since the multivariable power series for $f$ around any point has a drastic revision obtained by collecting together all terms of like power in the remaining variable, which will converge in a neighborhood of the point in $\mathbb{F}$. (More generally, if some of the variables are fixed, the function is analytic in the remaining variables.) Thus an analytic function is “separately analytic” in its variables. But a separately real analytic function is not (jointly) analytic in general. For example,

$$f(x, y) = \begin{cases} \frac{xy}{x^2+y^2} & \text{if } (x, y) \neq (0, 0) \\ 0 & \text{if } (x, y) = (0, 0) \end{cases}$$

is separately analytic, but not even continuous at $(0, 0)$ $(\cdot)$. This function is analytic on $\mathbb{R}^2 \setminus \{(0,0)\}$. The function

$$g(x, y) = \begin{cases} xye^{-1/(x^2+y^2)} & \text{if } (x, y) \neq (0, 0) \\ 0 & \text{if } (x, y) = (0, 0) \end{cases}$$

is separately analytic, $C^\infty$ on $\mathbb{R}^2$, and analytic on $\mathbb{R}^2 \setminus \{(0,0)\}$, but not analytic on any neighborhood of $(0,0)$.

The situation is completely different in the complex case: a complex-valued function on an open subset of $\mathbb{C}^n$ which is separately analytic is in fact analytic (X.8.1.5.).

As in the one-variable case, the definition of analytic function is hard to check, since the condition of the definition must be verified for every $c \in U$. Thus the next result is crucial in obtaining a useful theory:
VIII.7.2.5. **Theorem.** Let $U$ be an open set in $\mathbb{F}^n$. Then any multivariable power series which converges on $U$ defines an analytic function on $U$.

**Proof:** Let

$$\sum_{\omega \in \Omega} a_\omega (x - c)^{\phi(\omega)}$$

be a multivariable power series which converges on $U$. We may assume that $U$ is the interior of the set on which the series converges, which is a union of polydisks centered at $c$ (since this is an open set containing $U$), and in particular that $c \in U$. $\Diamond$
Chapter IX

Differential Equations

“The most widely and successfully used concept in mathematical descriptions of scientific problems has been the differential equation, even though success has often been impeded by the fact that differential equations can be extremely difficult to analyze. These difficulties, rather than thwarting progress, have instead stimulated more research and better understanding. As a result, the subject of differential equations contains a wealth of deep theories and subtle methods of analysis.”

E. A. Herman

The subject of Differential Equations consists of the study of differential equations, how to solve them, and the properties the solutions must have. A differential equation is an equation involving an unknown function and its derivatives. A solution to a differential equation is a sufficiently differentiable function satisfying the equation, usually also satisfying some specified initial or boundary conditions. The unknown function may be a function of one independent variable or more than one. A differential equation involving a function of one independent variable is an ordinary differential equation or ODE; a differential equation involving a function of more than one independent variable is a partial differential equation or PDE. One can also consider systems of ODEs or PDEs involving several unknown functions. In general, as might be easily predicted, the theory of PDEs is much more difficult than the theory of ODEs, and most active research in Differential Equations today involves PDEs.

Differential equations are of fundamental importance in both pure and applied mathematics. For example, the basic laws of physics, beginning with $F = ma$, are really differential equations [if $y(t)$ is position at time $t$, and $F(y)$ is the force at position $y$, then the equation is

$$my''(t) = F(y(t)).$$

The force could also be a function of both $y$ and $t$. There are variations possible such as taking both $y$ and $F$ to be vector-valued.]

The subject of Differential Equations is one of the largest areas of mathematics, bridging pure and applied mathematics. Entire books are written on the solutions to important specific differential equations. A considerable part of Numerical Analysis involves computing numerical approximations to solutions of

1[? p. 161].

876
differential equations. We will only treat the most basic aspects of the theory, with an emphasis on the analysis tools needed to obtain them, and we will concentrate on establishing general theorems about existence, uniqueness, and properties of solutions rather than the elaborate techniques used to actually find them explicitly.

“Newton’s *Principia* was impressive, with its revelation of deep mathematical laws underlying natural phenomena. But what happened next was even more impressive. Mathematicians tackled the entire panoply of physics – sound, light, heat, fluid flow, gravitation, electricity, magnetism. In every case, they came up with differential equations that described the physics, often very accurately.

The long-term implications have been remarkable. Many of the most important technological advances, such as radio, television, and commercial jet aircraft depend, in numerous ways, on the mathematics of differential equations. The topic is still the subject of intense research activity, with new applications emerging almost daily. It is fair to say that Newton’s invention of differential equations, fleshed out by his successors in the 18th and 19th centuries, is in many ways responsible for the society in which we now live. This only goes to show what is lurking just behind the scenes, if you care to look.”

*Ian Stewart*²

IX.1. Existence and Uniqueness of Solutions to Ordinary Differential Equations

IX.1.1. Elementary Considerations and Terminology

IX.1.1.1. It is customary (although by no means universal) in the theory of ODEs to denote the independent variable by $t$, since in many applications the independent variable represents time. The unknown function is typically denoted $x$ or $y$; we will standardize on using $y$ as being less confusing to those of us used to using $x$ as an independent variable. While $t$ is always assumed to be a real variable, usually ranging over an interval, $y$ can be real-valued or vector-valued (we will use $x$’s to denote elements of the range space and $y$’s to denote functions from $\mathbb{R}$ to the range space).

IX.1.1.2. An ODE is thus an equation involving $t, y, y', \ldots, y^{(n)}$. Such an equation is called an ordinary differential equation of order $n$ (most differential equations arising in physics and other applications have order 1 or 2). For the most part, we consider only differential equations of the form

$$y^{(n)}(t) = f(t, y(t), y'(t), \ldots, y^{(n-1)}(t))$$

which is an abbreviation for

$$y^{(n)} = f(t, y, y', \ldots, y^{(n-1)})$$

where $f$ is a specified real-valued (or, more generally, vector-valued) function with reasonable properties (usually at least continuous) and the equation is to hold for all $t$ in a suitable subset of $\mathbb{R}$. Most reasonable ODEs can in principle be put into this form using the Implicit Function Theorem (Exercise IX.1.9.2.), and most ODE’s arising in applications are already of this form or can easily be put into it explicitly (with the exception of certain linear ODEs; cf. ()).

If $f$ is a function of only $y, y', \ldots, y^{(n-1)}$ (i.e. not explicitly of $t$), the differential equation is called autonomous; when $t$ is interpreted as time, an autonomous differential equation is “time-independent.”

Many, but by no means all, differential equations in applications are autonomous.

A solution $y$ to an $n$’th order ODE is necessarily a function which is $n$-times differentiable; if $f$ is continuous, $y$ must be $C^n$ since the right side will be a continuous function of $t$. If $f$ is $C^1$, then $y^{(n)}$ is $C^1$ by the Chain Rule, so $y$ is $C^{(n+1)}$.

IX.1.1.3. We almost always want to consider only solutions to differential equations on intervals, generally open intervals; sometimes solutions given by formulas have domains consisting of a disjoint union of open intervals, in which case the restriction to each of the subintervals is considered a separate solution. Most commonly we want a solution $y(t)$ on an interval $I$ taking a specified value $x_0$ at a specified number $t_0 \in I$ (our use of $x_0$ for the initial value instead of $y_0$ is nonstandard, but the reasons for using this notation will be apparent later, and it is consistent with our convention described in IX.1.1.1.). A differential equation with a specified value at an “initial” point $t_0$ is called an initial value problem or IVP (for a higher-order differential equation, initial values for lower-order derivatives are also needed, or values at more than one point, called a boundary value problem or BVP). While differential equations typically have many solutions, with various intervals of definition, in reasonable cases initial value problems have unique solutions.

IX.1.1.4. In fact, the general principle of the theory of differential equations is that, subject to some mild technical restrictions, the general solution to an $n$’th order differential equation is a family of functions
determined by \( n \) more or less independent constants (parameters), which can be expressed in various ways. (Conversely, a smooth family of functions determined by \( n \) independent parameters is the general solution set to an \( n' \)th order differential equation, again subject to mild technical restrictions, cf. Exercise IX.1.9..)

However, it is usually impossible to find an explicit or closed formula for the general solution to even simple differential equations. Implicit relations can be found in somewhat greater generality, but even these can be difficult or impossible to come by in many cases. Power-series solutions can often be found if the differential equation is sufficiently regular. But in many cases the best one can do is generate approximate numerical solutions, and there are now powerful and efficient techniques for doing this.

**IX.1.1.5. Examples.** Here are some simple examples of first- and second-order differential equations that illustrate the general nature of the subject.

(i) Let \( f \) be a real-valued continuous function on an interval \( I \). A solution to the first-order differential equation

\[
y' = f(t)
\]

is simply an antiderivative for \( f \) on \( I \). There is thus a solution by V.8.5.9., in fact infinitely many, all differing by constants. If \( t_0 \in I \) is fixed and \( x_0 \) is a fixed real number, then there is a unique solution \( y \) on \( I \) satisfying the differential equation (i.e. an antiderivative for \( f \) on \( I \)) and also the initial condition \( y(t_0) = x_0 \).

(ii) Consider the autonomous first-order differential equation

\[
y' = ky
\]
on \( \mathbb{R} \), where \( k \in \mathbb{R} \) is a constant. A solution is \( y(t) = Ae^{kt} \), where \( A \) is an arbitrary real constant. To see that these are all the solutions, suppose \( y \) is a solution which is not identically 0, and fix \( t_0 \) with \( y(t_0) \neq 0 \). Then \( y \) is nonzero in an interval around \( t_0 \), and we have, for \( t \) in this interval,

\[
\frac{d}{dt}(\log |y(t)|) = \frac{y'(t)}{y(t)} = k
\]

so \( |y(t)| = kt + C \) for some constant \( C \). Thus \( |y(t)| = e^{C}e^{kt} \) for some \( C \), at least for \( t \) near enough to \( t_0 \). But it follows easily that \( y(t) = \pm e^{C}e^{kt} \) for \( t \) near \( t_0 \) (with constant sign depending on the sign of \( y(t_0) \)), and this solution extends uniquely to a solution on all of \( \mathbb{R} \). If we specify the initial condition \( y(t_0) = x_0 \), we have a unique solution with \( A = x_0e^{-kt_0} \), valid on all of \( \mathbb{R} \).

(iii) Let \( k > 0 \) be a constant, and consider the autonomous second-order differential equation

\[
y'' = k^2y
\]
The function

\[
y(t) = Ae^{kt} + Be^{-kt}
\]
is a solution on all of \( \mathbb{R} \) for arbitrary real constants \( A \) and \( B \). The differential equation

\[
y'' = -k^2y
\]
has as solution

\[
y(t) = A \cos kt + B \sin kt
\]
for constants $A$, $B$. It can be shown that in both cases, every solution is of this form ($\cdot$). Simple calculations show that if we fix $t_0 \in \mathbb{R}$ and real constants $x_0$ and $x'_0$, then in either case there is a unique solution (i.e. unique choice of $A$ and $B$) with $y(t_0) = x_0$ and $y'(t_0) = x'_0$.

Here are some more examples which illustrate other characteristics of solutions to differential equations:

**IX.1.1.6. Examples.** (i) Consider the autonomous first-order differential equation

$$y' = |y|.$$ 

The constant function $f_0(t) = 0$ is a solution, as is $f_A(t) = Ae^t$ for $A > 0$ and $f_A(t) = Ae^{-t}$ for $A < 0$. It can be shown (Exercise ($\cdot$)) that every solution on an interval $I$ is the restriction of one of these solutions to $I$. These solutions are $C^\infty$ on all of $\mathbb{R}$ despite the fact that $|y|$ is not a differentiable function of $y$. It is easily checked that for every $t_0$ and $x_0$ there is a unique choice of $A \in \mathbb{R}$ for which $f_A$ is a solution to the IVP

$$y' = |y|, \quad y(t_0) = x_0.$$ 

The function $f(t, y) = |y|$ is continuous on $\mathbb{R}^2$; although it is not differentiable in $y$ for $y = 0$, it satisfies a uniform Lipschitz condition in $y$: $|f(t, y_2) - f(t, y_1)| \leq |y_2 - y_1|$ for all $t, y_1, y_2 \in \mathbb{R}$.

(ii) Consider the autonomous first-order differential equation

$$y' = y^2.$$ 

The constant function 0 is a solution, as is

$$f_c(t) = \frac{1}{c-t}$$

for $c \in \mathbb{R}$. It can be shown (Exercise ($\cdot$)) that every solution on an interval $I$ is the restriction of one of these solutions to $I$. For any $t_0$ and $x_0$, the initial-value problem

$$y' = y^2, \quad y(t_0) = x_0$$

has a unique solution in an interval around $t_0$: if $x_0 = 0$, the solution is the constant function 0, and if $x_0 \neq 0$, the solution is the restriction of $f_c$, where $c = t_0 + \frac{1}{x_0}$. This solution is only defined on the interval ($-\infty, c$) or ($c, +\infty$) around $t_0$, not on all of $\mathbb{R}$. The (maximum) domain of the solution depends on $t_0$ and $x_0$.

(iii) Consider the autonomous first-order differential equation

$$y' = \frac{3}{2}y^{1/3}$$

(the constant $\frac{3}{2}$ just makes subsequent calculations easy). The constant function 0 is a solution, as are

$$\phi_c^+(t) = \begin{cases} 0 & \text{if } t < c \\ (t - c)^{3/2} & \text{if } t \geq c \end{cases}$$

$$\phi_c^-(t) = \begin{cases} 0 & \text{if } t < c \\ -(t - c)^{3/2} & \text{if } t \geq c \end{cases}$$
for any \( c \in \mathbb{R} \). Note that these solutions are defined and \( C^1 \) (but not \( C^2 \)) on all of \( \mathbb{R} \). It can be shown (Exercise ()) that every solution on an interval \( I \) is the restriction of one of these solutions to \( I \). Note that \( f(t, y) = \frac{3}{2} y^{1/3} \) is continuous on \( \mathbb{R}^2 \), but does not satisfy a Lipschitz condition in \( y \) around \( y = 0 \).

If \( t_0, x_0 \in \mathbb{R} \), the initial-value problem

\[
y' = \frac{3}{2} y^{1/3}, \quad y(t_0) = x_0
\]

always has a solution. If \( x_0 \neq 0 \), the unique solution is \( \phi_c^\pm \), where \( c = t_0 - x_0^{2/3} \) and the sign is the sign of \( x_0 \). If \( x_0 = 0 \), there are many solutions: the constant function 0 is a solution, as are \( \phi_c^+ \) and \( \phi_c^- \) for any \( c \geq t_0 \). The solutions 0, \( \phi_{t_0}^+ \), and \( \phi_{t_0}^- \) do not agree on any interval around \( t_0 \), so the solutions are not locally unique.

(iv) Consider the autonomous first-order differential equation

\[
y' = 3y^{2/3}.
\]

The constant function 0 is a solution, as are

\[
\phi_c(t) = (t - c)^3
\]

\[
\psi_c^+(t) = \begin{cases} 0 & \text{if } t < c \\ (t - c)^3 & \text{if } t \geq c \end{cases}
\]

\[
\psi_c^-(t) = \begin{cases} (t - c)^3 & \text{if } t < c \\ 0 & \text{if } t \geq c \end{cases}
\]

for any \( c \in \mathbb{R} \), and

\[
\psi_{c,d}(t) = \begin{cases} (t - c)^3 & \text{if } t < c \\ 0 & \text{if } c \leq t \leq d \\ (t - d)^3 & \text{if } t > d \end{cases}
\]

for any \( c, d \in \mathbb{R} \), \( c < d \) (we could write \( \psi_{c,c} = \phi_c \)). Note that these solutions are defined on all of \( \mathbb{R} \); \( \phi_c \) is \( C^\infty \) (even analytic) on \( \mathbb{R} \), and \( \psi_c^+ \) and \( \psi_{c,d} \) for \( c < d \) are \( C^2 \) but not \( C^3 \) on \( \mathbb{R} \). It can be shown (Exercise ()) that every solution on an interval \( I \) is the restriction of one of these solutions to \( I \). Note that \( f(t, y) = 3y^{2/3} \) is continuous on \( \mathbb{R}^2 \), but does not satisfy a Lipschitz condition in \( y \) around \( y = 0 \).

If \( t_0, x_0 \in \mathbb{R} \), the initial-value problem

\[
y' = 3y^{2/3}, \quad y(t_0) = x_0
\]

always has a solution. If \( x_0 \neq 0 \), there is locally a unique solution \( \phi_c \), where \( c = t_0 - x_0^{1/3} \). However, this solution is not globally unique: \( \psi_c^\pm \) (where the sign is the sign of \( x_0 \)) is also a solution, as is \( \psi_{c,d} \) for any \( d > c \) if \( x_0 < 0 \) and \( \psi_{d,c} \) for any \( d < c \) if \( x_0 > 0 \). If \( x_0 = 0 \), there are many solutions: the constant function 0 is a solution, as are \( \phi_{t_0}^+ \), \( \psi_{t_0}^+ \) for any \( c \geq t_0 \), \( \psi_{t_0}^- \) for any \( c \leq t_0 \), and \( \psi_{c,d} \) for \( c \leq t_0 \leq d \). The solutions 0, \( \phi_{t_0}^+ \), \( \psi_{t_0}^+ \), and \( \psi_{t_0}^- \) do not agree on any interval around \( t_0 \), so the solutions are not locally unique.
IX.1.2. Existence and Uniqueness Theorem for First-Order ODEs

In this subsection, we prove a general theorem about existence and uniqueness of local solutions to a first-order initial-value problem

\[ y' = f(t, y), \quad y(t_0) = x_0 \]

where \( y \) is an unknown function from an interval \( I \) in \( \mathbb{R} \) to a (real) Banach space \( \mathcal{X} \). In most elementary applications \( \mathcal{X} \) will be \( \mathbb{R} \), or \( \mathbb{R}^n \) for some \( n \). This fundamental theorem is closely related to the Implicit and Inverse Function Theorems, at least in spirit (cf. IX.1.9.10.). In particular, it is a local result, but we have control over the size of the interval on which the solution is valid, which in some key special cases gives global solutions. This result was first obtained by E. Picard in 1890; our exposition is adapted from [?]. The result is called the Picard Existence Theorem, Picard-Lindelöf Theorem, or Cauchy-Lipschitz Theorem in various references (the Cauchy-Lipschitz Theorem is properly the crucial special case IX.1.2.7., obtained before Picard’s general result).

IX.1.2.1. The setup of this theorem is as follows. Let \( \mathcal{X} \) be a Banach space and \( x_0 \in \mathcal{X} \). Let \( \tilde{B}_r(x_0) \) be the closed ball in \( \mathcal{X} \) centered at \( x_0 \) with radius \( r > 0 \). Let \( t_0 \in \mathbb{R} \), and \( I \) an interval in \( \mathbb{R} \) with \( t_0 \in I \). Let \( f \) be a continuous function from \( I \times \tilde{B}_r(x_0) \) to \( \mathcal{X} \). We suppose in addition there is a constant \( M \) such that \( \|f(t, x)\| \leq M \) for all \((t, x) \in I \times \tilde{B}_r(x_0)\), and that \( f \) satisfies a uniform Lipschitz condition in \( x \) (or, as we usually write, in \( y \)) on \( I \times \tilde{B}_r(x_0) \), i.e. there is a constant \( K \) such that for every \( t \in I \) and \( x_1, x_2 \in \tilde{B}_r(x_0) \) we have

\[ \|f(t, x_2) - f(t, x_1)\| \leq K \|x_2 - x_1\| . \]

We seek an interval \( I_0 \subseteq I \), \( t_0 \in I_0 \), and a differentiable function \( y : I_0 \rightarrow \mathcal{X} \) such that \( y'(t) = f(t, y(t)) \) for \( t \in I_0 \) and \( y(t_0) = x_0 \), and to show that any two such functions agree on \( I_0 \).

IX.1.2.2. Theorem. [Existence and Uniqueness Theorem for First-Order ODEs] Using the above notation, set

\[ I_0 = I \cap \left[ t_0 - \frac{r}{M}, t_0 + \frac{r}{M} \right] . \]

Then there is a unique differentiable function \( y : I_0 \rightarrow \mathcal{X} \) such that \( y'(t) = f(t, y(t)) \) for \( t \in I_0 \) and \( y(t_0) = x_0 \). Additionally, \( y \) is \( C^1 \) on \( I_0 \). If \( \bar{I} \) is any subinterval of \( I_0 \) containing \( t_0 \), the restriction of \( y \) to \( \bar{I} \) is the unique solution to the IVP on \( \bar{I} \).

Proof: It suffices to show there is a unique solution on any closed subinterval \( J \) of \( I_0 \) containing \( t_0 \). The strategy of the proof is to use the (Extended) Banach Fixed-Point Theorem (VI.2.9.10.) to obtain the solution on \( J \) as the unique fixed point of a suitable strict power contraction on a complete metric space. To this end, set \( \epsilon = \frac{r}{4M} \) and let \( Y \) be the set of continuous functions from \( J \) to the closed ball \( \tilde{B}_r(x_0) \) in \( \mathcal{X} \) of radius \( r \) centered at \( x_0 \). Define a metric \( \rho \) on \( Y \) by

\[ \rho(\phi, \psi) = \max_{t \in J} \|\phi(t) - \psi(t)\| . \]

Then \( Y \) is a complete metric space under \( \rho \) (it is a closed subset of \( C(J, \mathcal{X}) \)). Define a map \( T : Y \rightarrow Y \) by

\[ [T(\phi)](t) = x_0 + \int_{t_0}^t f(u, \phi(u)) \, du . \]
It is obvious from (i) that $T(\phi)$ is a continuous function from $J$ to $\mathcal{X}$. We must show that $T(\phi) \in Y$ if $\phi \in Y$, and that there is an $n$ and a constant $\alpha < 1$ such that $\rho(T^n(\phi), T^n(\psi)) \leq \alpha \rho(\phi, \psi)$ for all $\phi, \psi \in Y$.

We have, for $t \in J$ and $\phi \in Y$,

$$\|T(\phi)(t) - x_0\| = \left\| \int_{t_0}^{t} f(u, \phi(u)) \, du \right\| \leq \int_{t_0}^{t} \|f(u, \phi(u))\| \, du \leq M|t - t_0| \leq M \epsilon = r$$

so $T(\phi) \in Y$. And we have, for $\phi, \psi \in Y$ and $t \in J$,

$$\|T(\phi)(t) - T(\psi)(t)\| = \left\| \int_{t_0}^{t} [f(u, \phi(u)) - f(u, \psi(u))] \, du \right\|$$

$$\leq \int_{t_0}^{t} \|f(u, \phi(u)) - f(u, \psi(u))\| \, du \leq K \int_{t_0}^{t} \|\phi(u) - \psi(u)\| \, du$$

$$\leq K \epsilon \max_{u \in J} \|\phi(u) - \psi(u)\| = K \epsilon \rho(\phi, \psi).$$

Similarly, for each $n$ we have

$$\|T^n(\phi) - T^n(\psi)\| \leq K \left| \int_{t_0}^{t} \|T^{n-1}(\phi)(u_1) - T^{n-1}(\psi)(u_1)\| \, du_1 \right|$$

$$\leq K^2 \left| \int_{t_0}^{t} \int_{t_0}^{u_1} \|T^{n-2}(\phi)(u_2) - T^{n-2}(\psi)(u_2)\| \, du_2 \, du_1 \right|$$

$$\leq \cdots \leq K^n \left| \int_{t_0}^{t} \int_{t_0}^{u_1} \cdots \int_{t_0}^{u_{n-1}} \|\phi(u_n) - \psi(u_n)\| \, du_n \cdots du_1 \right|$$

$$\leq K^n \rho(\phi, \psi) \left| \int_{t_0}^{t} \int_{t_0}^{u_1} \cdots \int_{t_0}^{u_{n-1}} \, du_n \cdots du_1 \right| = \frac{K^n |t - t_0|^n}{n!} \rho(\phi, \psi) \leq \frac{(K \epsilon)^n}{n!} \rho(\phi, \psi).$$

Since $t$ is arbitrary, we have

$$\rho(T^n(\phi), T^n(\psi)) \leq \frac{(K \epsilon)^n}{n!} \rho(\phi, \psi).$$

If $n$ is sufficiently large, then

$$\frac{(K \epsilon)^n}{n!} < 1$$

and thus $T^n$ is a strict contraction from $Y$ to $Y$.

Thus, by VI.2.9.10., $T$ has a unique fixed point $y$. We thus have

$$y(t) = t_0 + \int_{t_0}^{t} f(u, y(u)) \, du$$

for $t \in J$, and since $g(u) = f(u, y(u))$ is continuous, by (i) we have that $y'(t) = f(t, y(t))$ for $t \in J$. Also obviously $y(t_0) = x_0$. Conversely, any solution on $J$ must be a fixed point of $T$, and thus $y$ is the unique solution on $J$.

If $J'$ is a closed subinterval of $I_0$ containing $t_0$ different from $J$, say $J \subseteq J'$, the unique solution on $J'$ restricted to $J$ must be the unique solution on $J$.

Since $g(t) = f(t, y(t))$ is continuous, $y'$ is continuous, i.e. $y$ is $C^1$. \nonumber
IX.1.2.3.  The restriction of the domain of the solution to \([t_0 - \frac{r}{M}, t_0 + \frac{r}{M}]\) simply insures that the unique solution near \(t_0\), when continued to the endpoints of the interval, does not leave the range of \(y\)-values for which \(f\) is defined (the restriction is a real one even if \(r\) can be chosen arbitrarily large; cf. Example IX.1.1.6.(ii)); the constant \(\frac{r}{M}\) is conservative in general (cf. Exercise IX.1.9.6.). Note that the size of the Lipschitz constant \(K\) does not affect the length of the interval on which the existence of a unique solution is guaranteed by the theorem. Note also that if \(t_0\) is in the interior of \(I\) (the usual situation in which the theorem is applied), it is also in the interior of \(I_0\).

IX.1.2.4.  The proof of Theorem IX.1.2.2. is constructive: it not only shows the existence of a unique solution, but actually gives an iterative algorithm for finding it. In fact, if \(\phi\) is any continuous function from \(I_0\) to \(X\) with \(\phi(t_0) = x_0\) (e.g. the constant function \(x_0\)), then the sequence \((T^n(\phi))\) converges uniformly on \(I_0\) to the solution. This “method of successive approximations,” called Picard iteration, is a practical computational method for finding approximations to the solution in many cases, although there are usually better numerical techniques.

IX.1.2.5.  In fact, we have the following error estimate for the successive approximation: if \(\phi_0\) is the constant function \(x_0\) and \(\phi_n = T^n(\phi_0)\) for \(n \in \mathbb{N}\), then, for \(t \in I_0\),

\[
\|\phi_0(t) - \phi_1(t)\| = \left\| \int_{t_0}^{t} f(u, y_0) \, du \right\| \leq \left\| \int_{t_0}^{t} \|f(t, y_0)\| \, du \right\| \leq M|t - t_0|
\]

and by induction

\[
\|\phi_n(t) - \phi_{n+1}(t)\| \leq \frac{MK^n}{(n+1)!}|t - t_0|^{n+1} \leq \frac{M (Kr/M)^{n+1}}{K (n+1)!}
\]

\[
\|\phi_n(t) - y(t)\| \leq \frac{M}{K} \sum_{k=n+1}^{\infty} \frac{(Kr/M)^k}{k!}
\]

The sum is the error in the \(n\)’th Taylor approximation to \(e^{Kr/M}\), hence by ()

\[
\rho(\phi_n, y) \leq \frac{Me^{Kr/M}}{K(n+1)!} .
\]

Thus the \(\phi_n\) converge uniformly quite rapidly to \(y\).

We then get a local version with a cleaner statement but less precise conclusion:

IX.1.2.6.  Corollary.  [Existence and Uniqueness Theorem for First-Order ODEs, Local Version] Let \(\mathcal{X}\) be a Banach space, \(x_0 \in \mathcal{X}, t_0 \in \mathbb{R}\), and \(f(t, y)\) a continuous function from a neighborhood \(U\) of \((t_0, x_0)\) in \(\mathbb{R} \times \mathcal{X}\) to \(\mathcal{X}\). Suppose \(f\) satisfies a uniform Lipschitz condition in \(y\) on \(U\). Then there is a \(\delta > 0\) such that the first-order initial value problem

\[
y' = f(t, y), \quad y(t_0) = x_0
\]

has a unique solution on \([t_0 - \delta, t_0 + \delta]\). Additionally, \(y\) is \(C^1\) on \([t_0 - \delta, t_0 + \delta]\).
Proof: An $r$ and a closed bounded interval $I$ containing $t_0$ in its interior can be chosen such that $I \times \bar{B}_r(x_0)$ is contained in $U$. By compactness, $f(t,x_0)$ is bounded, say by $N$, on $I$. If $K$ is the Lipschitz constant, then for $y \in \bar{B}_r(x_0)$ we have
\[
\|f(t,y)\| \leq \|f(t,x_0)\| + \|f(t,y) - f(t,x_0)\| \leq N + Kr
\]
so $f$ is bounded on $I \times \bar{B}_r(y_0)$. Apply the theorem with this $I$ and $r$.

As a special case, we get the following version which covers most standard applications. This is the version commonly stated and (sometimes) proved in Differential Equations texts.

**IX.1.2.7. Corollary. [Existence and Uniqueness Theorem for First-Order ODEs, Standard Version]** Let $R$ be a rectangle in $\mathbb{R}^2$, and $(t_0,x_0)$ an interior point of $R$. Let $f(t,y)$ be a function from $R$ to $\mathbb{R}$ with $f$ and $\frac{\partial f}{\partial y}$ continuous on $R$. Then there is a $\delta > 0$ such that the initial-value problem
\[
y' = f(t,y), \quad y(t_0) = x_0
\]
has a unique solution on $(t_0 - \delta, t_0 + \delta)$. Additionally, $y$ is $C^1$ on $(t_0 - \delta, t_0 + \delta)$.

Proof: Since $\frac{\partial f}{\partial y}$ is continuous, it is bounded in a neighborhood of $(t_0,x_0)$, and thus by the MVT (V.8.2.11.) $f$ satisfies a uniform Lipschitz condition in $y$ on this neighborhood.

Using the theorem, one can get an explicit estimate for the size $\delta$ can be. Actually $R$ can be any neighborhood of $(t_0,x_0)$.

**Global Solutions**

**IX.1.2.8.** The above results only give a solution in a (usually small) interval around $t_0$. Even if $f$ is defined on all of $I \times \mathcal{X}$, i.e. the hypotheses of IX.1.2.2. are satisfied for all $r$ (with the Lipschitz constant $K$ depending on $r$), Example IX.1.1.6.(ii) shows that the solution may not be defined on all of $I$. The maximum interval on which the solution is defined can even depend on the choice of $x_0$ (this might be predicted since the constant $M$ can depend on $x_0$ as well as on $r$).

But if $f$ satisfies a uniform Lipschitz condition in $y$ on all of $I \times \mathcal{X}$, the control on the domain in IX.1.2.2. allows us to cobble together local solutions into a solution defined on all of $I$.

**IX.1.2.9. Theorem. [Existence and Uniqueness Theorem for First-Order ODEs, Global Version]** Let $\mathcal{X}$ be a Banach space, $I$ an interval in $\mathbb{R}$, and $t_0 \in I$. Let $f(t,y)$ be a continuous function from $I \times \mathcal{X}$ to $\mathcal{X}$ satisfying a uniform Lipschitz condition in $y$ on $I$. Then, for any $x_0 \in \mathcal{X}$, the initial-value problem
\[
y' = f(t,y), \quad y(t_0) = x_0
\]
has a unique solution defined on all of $I$. Additionally, the solution is $C^1$ on $I$.

Proof: It suffices to show that if $J = [a,b]$ is any closed bounded subinterval of $I$ containing $t_0$ in its interior, then there is a unique solution to the IVP $y' = f(t,y)$, $y(t_0) = x_0$ on $J$. Fix such a $J$. If $K$ is the Lipschitz constant, also fix $L$ with $0 < L < \frac{1}{K}$. 885
First let $t_1 \in J$ and $x_1 \in \mathcal{X}$, and consider the IVP $y' = f(t, y)$, $y(t_1) = x_1$. The function $g(t) = f(t, x_1)$ is bounded on $J$ by compactness, say by $N$. Then for any $r$, $f$ is bounded on $J \times B_r(x_1)$ by $N + Kr$ (cf. the proof of IX.1.2.6.). Thus one bound on the length of the interval on which a unique solution is guaranteed by Theorem IX.1.2.2. is $\frac{r}{N + Kr}$. If $r$ is taken large enough, this is greater than $L$. Thus Theorem IX.1.2.2. gives a unique solution to this IVP on $J \cap [t_1 - L, t_1 + L]$.

Now return to the original IVP $y' = f(t, y)$, $y(t_0) = x_0$. Theorem IX.1.2.2. gives a unique solution $y = \phi_0(t)$ on $J_0 = J \cap [t_0 - L, t_0 + L]$. We now successively extend this unique solution to the right until it extends to $b$. If $t_0 + L \geq b$, we are done. Otherwise, fix $t_1$ with $t_0 + \frac{L}{2} < t_1 < t_0 + L$. Set $x_1 = \phi_0(t_1)$. Theorem IX.1.2.2. gives a unique solution $y = \phi_1(t)$ to the IVP $y' = f(t, y)$, $y(t_1) = x_1$ on $J_1 = J \cap [t_1 - L, t_1 + L]$. We must have $\phi_1 = \phi_0$ on $J_0 \cap J_1$ since both are solutions to the IVP $y' = f(t, y)$, $y(t_1) = x_1$ on $J_0 \cap J_1$, and thus we have extended $\phi_0$ to a solution on $J_0 \cup J_1$.

If $t_1 + L \geq b$, we are done extending to the right. If not, we have $t_1 + L \geq (t_0 + L) + \frac{L}{2}$, i.e. we have extended to the right by at least $\frac{L}{2}$. Repeat the process, choosing $t_2$ with $t_1 + \frac{L}{2} < t_2 < t_1 + L$, $x_2$, $J_2$, $\phi_2$, etc. Since at each stage we extend to the right by at least $\frac{L}{2}$, we reach $b$ in a finite number of steps.

Extend $\phi_0$ to the left of $t_0$ to $a$ in the same manner. We obtain a solution $\phi$ on $J$ in this manner. Any solution to the original IVP must agree with $\phi$ on a subset of $J$ which is both relatively open and closed, hence must agree with $\phi$ everywhere on $J$.

### IX.1.3. Systems of First-Order Differential Equations

The result IX.1.2.2. is general enough to immediately give solutions not only to a single differential equation, but also to systems of differential equations: we want differentiable functions $y_1, \ldots, y_n$ on an interval $I$ satisfying the $n$ equations

$$ y_k' = f_k(t, y_1, \ldots, y_n) \quad (1 \leq k \leq n). $$

We also want the $y_k$ to have specified values at some $t_0 \in I$.

#### IX.1.3.1. The setup is similar to the one for single equations, but we change notation slightly. We have a Banach space $\mathcal{X}$, an interval $I \subseteq \mathbb{R}$, a point $t_0 \in I$, $n$ points $x_0(1), \ldots, x_0(n)$ in $\mathcal{X}$, $r > 0$, $M > 0$, $K > 0$, and $n$ continuous functions

$$ f_1, \ldots, f_n : I \times B_r(x_0(1)) \times \cdots \times B_r(x_0(n)) \to \mathcal{X} $$

with the property that $\|f_k(t, x_1, \ldots, x_n)\| \leq M$ for $t \in I$ and $\|x_j - x_j(0)\| \leq r$ (1 \leq j, k \leq n), and

$$ \|f_k(t, x_1^{(2)}, \ldots, x_n^{(2)}) - f_k(t, x_1^{(1)}, \ldots, x_n^{(1)})\| \leq K \max_{1 \leq j \leq n} \|x_j^{(2)} - x_j^{(1)}\| $$

for $1 \leq k \leq n$ whenever $t \in I$ and $x_j^{(1)}$, $x_j^{(2)} \in B_r(x_j(0))$ for all $j$ (the $f_k$ satisfy a uniform Lipschitz condition in $x_1, \ldots, x_n$ on $I$).

#### IX.1.3.2. Theorem. [Existence and Uniqueness Theorem for Systems of First-Order ODEs] Using the above notation, set

$$ I_0 = I \cap \left[ t_0 - \frac{r}{M}, t_0 + \frac{r}{M} \right]. $$

886
Then there are unique differentiable functions \( y_1, \ldots, y_n : I_0 \to \mathcal{X} \) such that
\[
y'_k(t) = f_k(t, y_1(t), \ldots, y_n(t))
\]
(\( 1 \leq k \leq n \)) for \( t \in I_0 \) and \( y_k(t_0) = x_k^{(0)} \). Additionally, the \( y_k \) are \( C^1 \) on \( I_0 \). If \( \tilde{I} \) is any subinterval of \( I_0 \) containing \( t_0 \), the restriction of the \( y_k \) to \( \tilde{I} \) is the unique solution to the IVP on \( \tilde{I} \).

**Proof:** This is an almost immediate corollary of IX.1.2.2. Set \( \tilde{X} = X^n \) with the \( \infty \)-norm \( (\cdot) \), and \( x_0 = (x_1^{(0)}, \ldots, x_n^{(0)}) \). Define \( f : I \times \tilde{B}_r(x_0) \to \tilde{X} \) by
\[
f(t, (x_1, \ldots, x_n)) = (f_1(t, x_1, \ldots, x_n), \ldots, f_n(t, x_1, \ldots, x_n))
\]
Then the hypotheses of IX.1.2.2. are satisfied, and the coordinate functions of the solution \( y \) give the \( y_k \).

As in the single equation case, we get a local version with a cleaner statement but less precise conclusion:

**IX.1.3.3. Corollary.** [Existence and Uniqueness Theorem for Systems of First-Order ODEs, Local Version] Let \( \mathcal{X} \) be a Banach space, \( x_1^{(0)}, \ldots, x_n^{(0)} \in \mathcal{X}, t_0 \in \mathbb{R} \), and \( f_1, \ldots, f_n \) continuous functions from a neighborhood \( U \) of \( (t_0, x_1^{(0)}, \ldots, x_n^{(0)}) \) in \( \mathbb{R} \times \mathcal{X}^n \) to \( \mathcal{X} \). Suppose each \( f_k \) satisfies a uniform Lipschitz condition in \( x_1, \ldots, x_n \) on \( U \). Then there is a \( \delta > 0 \) such that the first-order initial value problem
\[
y'_k = f_k(t, y_1, \ldots, y_n), \quad y_k(t_0) = x_k^{(0)} \quad (1 \leq k \leq n)
\]
has a unique solution on \( (t_0 - \delta, t_0 + \delta) \). Additionally, the \( y_k \) are \( C^1 \) on \( (t_0 - \delta, t_0 + \delta) \).

We also get a global version from IX.1.2.9.:

**IX.1.3.4. Theorem.** [Existence and Uniqueness Theorem for Systems of First-Order ODEs, Global Version] Let \( \mathcal{X} \) be a Banach space, \( I \) an interval in \( \mathbb{R} \), and \( t_0 \in I \). Let \( f_1, \ldots, f_n \) be continuous functions from \( I \times \mathcal{X}^n \) to \( \mathcal{X} \) satisfying a uniform Lipschitz condition in \( x_1, \ldots, x_n \) on \( I \). Then, for any \( x_1^{(0)}, \ldots, x_n^{(0)} \in \mathcal{X} \), the initial-value problem
\[
y'_k = f_k(t, y_1, \ldots, y_n), \quad y_k(t_0) = x_k^{(0)} \quad (1 \leq k \leq n)
\]
has a unique solution defined on all of \( I \). Additionally, the solutions are \( C^1 \) on \( I \).
IX.1.4. Higher-Order Differential Equations and Systems

We can use the results for systems of first-order equations to obtain similar existence and uniqueness theorems for higher-order differential equations, by a simple but clever trick. We want to solve the initial-value problem

\[ y^{(n)} = f(t, y, y', \ldots, y^{(n-1)}), \quad y(t_0) = x_0, y'(t_0) = x'_0, \ldots, y^{(n-1)}(t_0) = x^{(n-1)}_0 \]

where \( y \) is an \( n \)-times differentiable function from an interval in \( \mathbb{R} \) to a Banach space \( \mathcal{Y} \) and \( f \) is a suitably nice function from a neighborhood of \( (t_0, x_0, x'_0, \ldots, x^{(n-1)}_0) \) in \( \mathbb{R} \times \mathcal{X}^n \) to \( \mathcal{X} \).

The trick is to define new unknown functions \( y_1, \ldots, y_{n-1} \) which satisfy the system of equations

\[ y' = y_1, y'_1 = y_2, \ldots, y'_{n-2} = y_{n-1}, y'_{n-1} = f(t, y_1, \ldots, y_{n-1}) \]

so \( y_k = y^{(k)} \). Then we have a system of \( n \) first-order equations in \( n \) unknown functions \( y, y_1, \ldots, y_{n-1} \), and we can apply the various existence and uniqueness theorems for such systems. The statements are:

IX.1.4.1. Theorem. [Existence and Uniqueness Theorem for Higher-Order ODE’s] Let \( \mathcal{X} \) be a Banach space, \( I \) an interval in \( \mathbb{R} \), \( t_0 \in I \), \( x_0, x'_0, \ldots, x^{(n-1)}_0 \in \mathcal{X} \), \( r > 0 \), and

\[ f : I \times \bar{B}_r(x_0) \times \bar{B}_r(x'_0) \times \cdots \times \bar{B}_r(x^{(n-1)}_0) \to \mathcal{X}. \]

Suppose \( f \) is continuous and bounded by \( N \) on \( I \times \bar{B}_r(x_0) \times \bar{B}_r(x'_0) \times \cdots \times \bar{B}_r(x^{(n-1)}_0) \) and satisfies a uniform Lipschitz condition in the \( y \)-variables. Set

\[ M = \max\{N, \|y_0\| + r, \ldots, \|y^{(n-1)}_0\| + r\} \]

\[ I_0 = I \cap \left[ t_0 - \frac{r}{M}, t_0 + \frac{r}{M} \right]. \]

Then there is a unique \( n \)-times differentiable function \( y : I_0 \to \mathcal{X} \) with \( y(t_0) = x_0, y'(t_0) = x'_0, \ldots, y^{(n-1)}(t_0) = x^{(n-1)}_0 \), and \( y^{(n)}(t) = f(t, y(t), y'(t), \ldots, y^{(n-1)}(t)) \) for all \( t \in I_0 \). Additionally, \( y \) is \( C^n \) on \( I_0 \).

Proof: Define \( f_k(t, x_0, x_1, \ldots, x_{n-1}) = x_{k+1} \) for \( 0 \leq k < n - 1 \) and \( f_{n-1} = f \), and apply IX.1.3.2. \( \diamond \)

The interval on which the existence of a unique solution is guaranteed can sometimes be shown to be larger than \( I_0 \); see Exercise IX.1.9.8.

IX.1.4.2. Corollary. [Existence and Uniqueness Theorem for Higher-Order ODEs, Local Version] Let \( \mathcal{X} \) be a Banach space, \( x_0, x'_0, \ldots, x^{(n-1)}_0 \in \mathcal{X} \), \( t_0 \in \mathbb{R} \), and \( f \) a continuous function from a neighborhood \( U \) of \( (t_0, x_0, x'_0, \ldots, x^{(n-1)}_0) \) in \( \mathbb{R} \times \mathcal{X}^n \) to \( \mathcal{X} \). Suppose \( f \) satisfies a uniform Lipschitz condition in the \( y \)-variables on \( U \). Then there is a \( \delta > 0 \) such that the first-order initial value problem

\[ y^{(n)} = f(t, y, y', \ldots, y^{(n-1)}), \quad y(t_0) = x_0, y'(t_0) = x'_0, \ldots, y^{(n-1)}(t_0) = x^{(n-1)}_0 \]

has a unique solution on \( (t_0 - \delta, t_0 + \delta) \). Additionally, \( y \) is \( C^n \) on \( (t_0 - \delta, t_0 + \delta) \).
IX.1.4.3. Theorem. [Existence and Uniqueness Theorem for Higher-Order ODEs, Global Version] Let $\mathcal{X}$ be a Banach space, $I$ an interval in $\mathbb{R}$, and $t_0 \in I$. Let $f$ be a continuous function from $I \times \mathcal{X}^n$ to $\mathcal{X}$ satisfying a uniform Lipschitz condition in the $y$-variables on $I$. Then, for any $x_0, x'_0, \ldots, x_0^{(n-1)} \in \mathcal{X}$, the initial-value problem

$$y^{(n)} = f(t, y, y', \ldots, y^{(n-1)}), \quad y(t_0) = x_0, y'(t_0) = x'_0, \ldots, y^{(n-1)}(t_0) = x_0^{(n-1)}$$

has a unique solution defined on all of $I$. Additionally, the solution is $C^n$ on $I$.

IX.1.4.4. There are similar extensions to systems of higher-order differential equations. The equations in the system do not all need to be of the same order. The extensions are straightforward, but the notation is oppressive, and it is left to the reader to formulate and prove the results.

IX.1.5. Continuous Dependence on Initial Conditions

IX.1.5.1. We now examine what happens when the initial conditions are varied. To do this we will treat the initial value as a parameter. Thus, if $f(t, y)$ is a suitably nice function (e.g. continuous and satisfying a uniform Lipschitz condition in $y$) defined near $(t_0, x_0)$, the IVP

$$y' = f(t, y), \quad y(t_0) = x_0$$

has a unique solution, and the IVP

$$y' = f(t, y), \quad y(t_0) = x_1$$

even has a unique solution for any $x_1$ sufficiently close to $x_0$.

IX.1.5.2. What we would hope is that if $x_1$ is close to $x_0$, the solution with initial value $x_1$ should be uniformly close to the solution for initial value $x_0$ for $t$ close to $t_0$, i.e. that the solution for initial value $x$ should “vary continuously” (or even “smoothly”) in $x$.

To be precise, what we might hope for is that there is a continuous (or even smooth) function $u(t, x)$ of two variables, defined near $(t_0, x_0)$, such that if $x_1$ is close to $x_0$, the function $y(t) = u(t, x_1)$ is the unique solution to the IVP with initial value $x_1$. We get continuity:

IX.1.5.3. Theorem. Let $\mathcal{X}, f, r, K, M$ be as in IX.1.2.2. Fix $\epsilon$, $0 < \epsilon < \min \left( \frac{1}{rM}, \frac{1}{K} \right)$. Let $y_0$ be the unique solution to the IVP

$$y' = f(t, y), \quad y(t_0) = x_0$$

in the interval $J = [t_0 - \epsilon, t_0 + \epsilon]$. Fix $x_1$, $\|x_1 - x_0\| \leq \frac{\epsilon}{2}$, and let $y_1$ be the unique solution to the IVP

$$y' = f(t, y), \quad y(t_0) = x_1$$
on $J$. Then, for any $t \in J$, we have

$$\|y_1(t) - y_0(t)\| \leq \frac{\|x_1 - x_0\|}{1 - K \epsilon}.$$
IX.1.5.4. Some initial observations:

(i) The $\epsilon$ is not the same as the one in the proof of IX.1.2.2. (it is smaller).

(ii) The interval $J$ is shorter than the maximum length interval on which $y_0$ is guaranteed to exist by IX.1.2.2. and is not the same as the $J$ in that proof, but $t_0$ is still in the interior of $J$.

(iii) It is easily checked that IX.1.2.2. guarantees the existence of the solution $y_1$ as well as $y_0$ on $J$.

The reason $J$ is taken shorter in this theorem than in IX.1.2.2. is that we need the $T$ defined in the proof to be an actual strict contraction, not just a strict power contraction, in order to apply VI.2.9.7.

IX.1.5.5. Corollary. Under the hypotheses and notation of IX.1.5.3., if $u(t, x)$ is the function from $I \times \bar{B}_{r/2}(x_0)$ to $Y$ such that, for fixed $x$, $u(t, x)$ is the unique solution to the initial-value problem

$$y' = f(t, y), \quad y(t_0) = x$$

then $u$ is uniformly continuous on $I \times \bar{B}_{r/2}(x_0)$.

We now give the proof of IX.1.5.3.

Proof: We proceed exactly as in the proof of IX.1.2.2. Let $Y$ be the set of continuous functions from $J$ to the closed ball $\bar{B}_r(x_0)$ in $\mathcal{X}$ of radius $r$ centered at $x_0$. Define a metric $\rho$ on $Y$ by

$$\rho(\phi, \psi) = \max_{t \in J} \|\phi(t) - \psi(t)\|.$$ 

Then $Y$ is a complete metric space under $\rho$ (it is a closed subset of $C(J, \mathcal{X})$). Define maps $T, S : Y \to Y$ by

$$[T(\phi)](t) = x_0 + \int_{t_0}^{t} f(u, \phi(u)) \, du$$

$$[S(\phi)](t) = x_1 + \int_{t_0}^{t} f(u, \phi(u)) \, du.$$ 

It is obvious from () that $T(\phi)$ and $S(\phi)$ are continuous functions from $J$ to $\mathcal{X}$. We have, for $t \in J$ and $\phi \in Y$,

$$\|T(\phi)(t) - x_0\| = \int_{t_0}^{t} f(u, \phi(u)) \, du \leq \int_{t_0}^{t} \|f(u, \phi(u))\| \, du \leq M|t - t_0| \leq M\epsilon = \frac{r}{2}$$ 

so $T(\phi) \in Y$. Also,

$$\|S(\phi)(t) - x_0\| \leq \|[S(\phi)](t) - x_1\| + \|x_1 - x_0\| = \int_{t_0}^{t} f(u, \phi(u)) \, du + \|x_1 - x_0\|$$

$$\leq \int_{t_0}^{t} \|f(u, \phi(u))\| \, du + \|x_1 - x_0\| \leq M|t - t_0| + \|x_1 - x_0\| \leq M\epsilon + \frac{r}{2} = \frac{r}{2} + \frac{r}{2} = r$$ 

so $S(\phi) \in Y$. And we have, for $\phi, \psi \in Y$ and $t \in J$,

$$\|T(\phi)(t) - T(\psi)(t)\| = \int_{t_0}^{t} [f(u, \phi(u)) - f(u, \psi(u))] \, du$$
\[
\leq \int_{t_0}^{t} \| f(u, \phi(u)) - f(u, \psi(u)) \| du \leq K \int_{t_0}^{t} \| \phi(u) - \psi(u) \| du
\]

and similarly \( \| S(\phi)(t) - S(\psi)(t) \| \leq K \epsilon \rho(\phi, \psi) \). Thus \( T \) and \( S \) are strict contractions on \( Y \) with constant \( K \epsilon < 1 \). Since \( T(\phi) - S(\phi) = x_0 - x_1 \) for all \( \phi \), we have \( \| T(\phi) - S(\phi) \| = \| x_1 - x_0 \| \) for all \( \phi \). The fixed points for \( T \) and \( S \) are \( y_0 \) and \( y_1 \) respectively. The result now follows from an application of VI.2.9.7.

**IX.1.5.6.** The technicalities of the proof only yield that uniform continuity holds on a small neighborhood of each point, but it follows that continuity holds throughout the region in which unique local solutions exist. Uniform continuity can be cobbled together to hold on somewhat larger regions; details are left to the interested reader.

**IX.1.5.7.** The problem in IX.1.5.2. can be converted to a first-order quasilinear PDE problem (Cauchy problem): we seek a smooth function \( u(t, x) \) in a neighborhood of \( (t_0, x_0) \) satisfying (writing \( u_t \) for \( \frac{\partial u}{\partial t} \))

\[
u_t = f(t, u)
\]

with boundary condition \( u(t_0, x) = x \). () then shows the solution \( u(t, x) \) of IX.1.5.5. is not only continuous, but even smooth.

**IX.1.5.8.** We might even want to allow the function \( f \) to depend on the \( x \), i.e. to allow the differential equation itself to vary as the initial condition is varied, or in other words to consider the PDE

\[
u_t = f(t, x, u)
\]

with boundary condition \( u(t_0, x) = x \), where \( f \) is a suitable function defined in a neighborhood of \( (t_0, x_0, x_0) \). Under reasonable hypotheses () shows that there is also a smooth solution in this case.

**IX.1.6. Peano’s Existence Theorem for First-Order ODEs**

If \( f \) does not satisfy a uniform Lipschitz condition in \( y \), we cannot expect a locally unique solution to the IVP \( y' = f(t, y), y(t_0) = x_0 \) in general (Examples IX.1.1.6.(iii)–(iv)). But we can still show existence of a local solution. The first step is to uniformly approximate \( f \) by functions which do satisfy a uniform Lipschitz condition in \( y \); this can only done in general if the target Banach space is finite-dimensional. An application of the Arzela-Ascoli Theorem (which also needs finite-dimensionality of the target space) then gives a solution. In fact, the conclusion can fail if the Banach space \( \mathcal{X} \) is infinite-dimensional, even if \( \mathcal{X} \) is a separable Hilbert space [Yor70]. See [?] for other proofs of the theorem and some generalizations.

**IX.1.6.1. Theorem.** [Peano’s Existence Theorem for First-Order ODEs] Let \( \mathcal{X} \) be a finite-dimensional Banach space, \( I \) a closed bounded interval in \( \mathbb{R} \), \( t_0 \in I \), \( x_0 \in \mathcal{X} \). Let \( f : I \times \bar{B}_r(x_0) \to \mathcal{X} \) be a continuous function, and

\[
M = \max \{ \| f(t, y) \| : (t, y) \in I \times \bar{B}_r(x_0) \}.
\]
Set
\[ I_0 = I \cap \left[ t_0 - \frac{r}{M}, t_0 + \frac{r}{M} \right]. \]
Then there is a \( C^1 \) function \( y : I_0 \to B_r(y_0) \subseteq \mathcal{X} \) satisfying \( y(t_0) = x_0 \) and \( y'(t) = f(t, y(t)) \) for all \( t \in I_0 \).

**Proof:** We may assume \( \mathcal{X} = \mathbb{R}^n \) with a norm equivalent to the Euclidean norm. By the Weierstrass Approximation Theorem, we may approximate \( f \) uniformly on \( I \times B_r(y_0) \) by functions \( f_n \) whose coordinate functions are polynomials. Thus each \( f_n \) satisfies a uniform Lipschitz condition in \( y \) on \( I \times B_r(x_0) \).

Thus by Theorem IX.1.2.2., there is a (unique) solution \( \phi_n \) to the IVP \( y' = f_n(t, y) \), \( y(t_0) = x_0 \) on the closed bounded interval \( I_0 \). We have, for all \( n \) and all \( t \in I_0 \),
\[ \phi_n(t) = x_0 + \int_{t_0}^{t} f_n(u, \phi_n(u)) \, du \]
and thus
\[ \|\phi_n(t)\| \leq \|x_0\| + \left| \int_{t_0}^{t} \|f_n(u, \phi_n(u))\| \, du \right| \leq \|x_0\| + M|t - t_0| \leq \|x_0\| + r \]
so the \( \phi_n \) are uniformly bounded on \( I_0 \). Also, \( \|\phi'_n(t)\| = \|f_n(t, \phi_n(t))\| \leq M \) for all \( t \in I_0 \), so the set \( \{ \phi_n : n \in \mathbb{N} \} \) is equicontinuous on \( I_0 \) ( ). Thus there is a uniformly convergent subsequence by the Arzela-Ascoli Theorem ( ). Passing to a subsequence, we may assume \( (\phi_n) \) converges uniformly on \( I_0 \) to a (necessarily continuous) function \( \phi \). Then, for each \( t \in \mathbb{R} \),
\[ x_0 + \int_{t_0}^{t} f_n(u, \phi_n(u)) \, du \to x_0 + \int_{t_0}^{t} f(u, \phi(u)) \, du \]
by ( ). Since the left side is \( \phi_n(t) \), we obtain
\[ \phi(t) = x_0 + \int_{t_0}^{t} f(u, \phi(u)) \, du \]
for all \( t \in I_0 \), and thus \( \phi \) is a solution to the original IVP on \( I_0 \). The equation \( \phi'(t) = f(t, \phi(t)) \) shows that \( \phi \) is \( C^1 \), since the right side is a continuous function of \( t \).

IX.1.7. Power Series and Analytic Solutions

IX.1.8. Linear ODEs

IX.1.9. Exercises

IX.1.9.1. Let \( I \) be an interval, \( t_0 \in I \), and \( f : I \times \mathbb{R} \to \mathbb{R} \) a continuous function. Consider the differential equation
\[ y' = f(t, y) \]
and the integral equation
\[ y(t) = y(t_0) + \int_{t_0}^{t} f(u, y(u)) \, du . \]
The aim of this problem is to show that a function on \( I \) satisfies the differential equation if and only if it satisfies the integral equation.

(a) Suppose \( y \) is a differentiable function on \( I \) satisfying the differential equation. Show that \( y \) is necessarily \( C^1 \) on \( I \). [Use continuity of \( f \).]

(b) Suppose \( y \) is a differentiable function on \( I \) satisfying the differential equation. Integrate both sides of the differential equation to show that \( y \) also satisfies the integral equation. [Use the Fundamental Theorem of Calculus II.]

(c) Conversely, suppose \( y \) is a function on \( I \) such that the integral in the integral equation exists as a Riemann, Lebesgue, or H-K integral for each \( t \in I \), and that \( y \) satisfies the integral equation. Show that \( y \) is necessarily continuous on \( I \), and hence the integral in the integral equation exists as a Riemann integral for each \( t \in I \). [Use (.).]

(d) Under the assumptions of (c), show that \( y \) is differentiable on \( I \) and satisfies the differential equation. [Use the Fundamental Theorem of Calculus I.]

(e) Extend the results to the case where the range space \( \mathbb{R} \) is replaced by a Banach space.

**IX.1.9.2. Implicit Differential Equations.** (a) Prove the following theorem about existence and uniqueness of solutions to a differential equation of the form \( F(t,y,y') = 0 \).

**Theorem.** Let \( U \) be an open set in \( \mathbb{R}^3 \), and \((t_0,x_0,z_0) \in U \). Let \( F : U \to \mathbb{R} \) be a continuous function with \( F(t_0,x_0,z_0) = 0 \). Suppose \( \frac{\partial F}{\partial z} \) exists and is continuous on \( U \) and that \( \frac{\partial F}{\partial z}(t_0,x_0,z_0) \neq 0 \). Then

(i) There is an open interval \( I \) around \( t_0 \) and a \( C^1 \) function \( y : I \to \mathbb{R} \) such that \( y(t_0) = x_0 \), \( y'(t_0) = z_0 \), and \( F(t,y(t),y'(t)) = 0 \) for all \( t \in I \).

(ii) If \( \frac{\partial F}{\partial y} \) also exists and is continuous on \( U \), then there is an open interval \( I \) around \( t_0 \) and a unique differentiable function \( y : I \to \mathbb{R} \) such that \( y(t_0) = x_0 \), \( y'(t_0) = z_0 \), and \( F(t,y(t),y'(t)) = 0 \) for all \( t \in I \), and additionally \( y \) is \( C^1 \) on \( I \).

(iii) If \( F \) is analytic on \( U \), then there is an open interval \( I \) around \( t_0 \) and a unique differentiable function \( y : I \to \mathbb{R} \) such that \( y(t_0) = x_0 \), \( y'(t_0) = z_0 \), and \( F(t,y(t),y'(t)) = 0 \) for all \( t \in I \), and additionally \( y \) is analytic on \( I \).

[First use the Implicit Function Theorem to rewrite the equation \( F(t,y,z) = 0 \) as \( z = f(t,y) \). Apply VIII.6.3.4. and IX.1.6.1. in case (i), VIII.6.3.12. and IX.1.2.7. in case (ii), and (i) and (ii) in case (iii).]

However, such an implicit differential equation need not have any solutions, i.e. there may be no \((t_0,x_0,z_0)\) satisfying the hypotheses: see Exercise IX.1.9.3.

(b) Generalize to systems and to higher-order implicit equations.

**IX.1.9.3.** Show that the (autonomous) implicit differential equation

\[(y' - 1)^2 + y^2 = 0\]

has no (real) solutions.
IX.1.9.4. Implicit Solutions. (a) Carefully define what it means for a relation \( G(t, y) = 0 \) to be a “solution” to the differential equation \( F(t, y, y') = 0 \) (or a higher-order equation).

(b) [p. 3] Show that \( t^2 = 2y^2 \log y \) is an implicit solution to the differential equation
\[
y' = \frac{ty}{t^2 + y^2}.
\]

Implicit solutions are particularly easily obtained for exact differential equations (ones which can be put in the form \( g(t, y)y' + h(t, y) = 0 \) with \( \frac{\partial g}{\partial t} = \frac{\partial h}{\partial y} \)), cf. VIII.2.2.8., and in particular for separable differential equations (ones which can be put in the form \( g(y)y' = h(t) \)).

IX.1.9.5. This is a sort of converse to IX.1.9.4. Let \( G(t, y, c_1, \ldots, c_n) \) be a \( C^n \) function with \( \frac{\partial G}{\partial y} \neq 0 \). Regard \( t \) as the independent variable, \( y \) the dependent variable, and \( c_1, \ldots, c_n \) as “constants” (parameters). By the Implicit Function Theorem, the equation
\[
G(t, y, c_1, \ldots, c_n) = 0
\]
nimplicitly defines \( y \) as a function of \( t \) and the parameters \( c_1, \ldots, c_n \), i.e. \( y = g(t, c_1, \ldots, c_n) \).

(a) Successively differentiate \( y \) with respect to \( t \) to obtain \( n \) additional equations
\[
\frac{\partial G}{\partial t} + \frac{\partial G}{\partial y} y' = 0
\]
\[
\frac{\partial^2 G}{\partial t^2} + \frac{\partial^2 G}{\partial t \partial y} y' + \frac{\partial^2 G}{\partial y^2} (y')^2 + \frac{\partial G}{\partial y} y'' = 0
\]
\[
\ldots
\]
\[
\frac{\partial^n G}{\partial t^n} + \ldots + \frac{\partial G}{\partial y} y^{(n)} = 0
\]
(where we really mean \( y^{(k)} = \frac{\partial^k y}{\partial t^k} \), but we symbolically regard the \( y^{(k)} \) as new variables).

(b) Show that if \( c = (c_1, \ldots, c_n) \) is independent in \( G \) in a suitable sense, then by the Implicit Function Theorem the first \( n \) equations can (in principle) be solved for \( c_1, \ldots, c_n \) as functions of \( t, y, y', \ldots, y^{(n-1)} \) and substituted into the last equation to obtain a differential equation
\[
F(t, y, y', \ldots, y^{(n-1)}, y^{(n)}) = 0
\]
for which \( G(t, y, c_1, \ldots, c_n) = 0 \) is a solution (in the sense of IX.1.9.4.) for any suitable \( c \) (references such as [Gou59, V. 2 Part 2] and [Inc44] state that \( c_1, \ldots, c_n \) “can be eliminated” from the \( n + 1 \) equations without elaboration; in [?] it is at least acknowledged there is a nontrivial issue, but that “a precise statement of the conditions under which this is true is too complicated to be stated here.”) Use the existence and uniqueness theorem to show that, under appropriate conditions, every solution is of this form.

(c) Generalize to the case where there is more than one \( G, y, \) and/or \( t \) (the same number of \( G \)'s and \( y \)'s) to obtain a system of ordinary or partial differential equations from an equation or set of equations with an arbitrary (finite) set of constants.
Consider the IVP \( y' = y^2, y(t_0) = x_0 \) (IX.1.1.6.iii). Theorem IX.1.2.2. guarantees a unique solution on
\[
\left[ t_0 - \frac{r}{(|x_0| + r)^2}, t_0 + \frac{r}{(|x_0| + r)^2} \right]
\]
for any \( r > 0 \). If \( x_0 = 0 \), the supremum of the lengths of these intervals for all \( r \) is \( +\infty \), and the solution to the IVP \( (y = 0) \) is defined on all of \( \mathbb{R} \). If \( x_0 \neq 0 \), show that the maximum of \( \frac{r}{(|x_0| + r)^2} \) is \( \frac{1}{4|x_0|} \). In this case, the unique solution \( y = \frac{1}{c-t}, c = t_0 + \frac{1}{x_0} \), has domain \((-\infty, c)\) if \( x_0 > 0 \) and \((c, +\infty)\) if \( x_0 < 0 \), so the maximum symmetric interval around \( t_0 \) on which the solution exists is \( \left( t_0 - \frac{1}{|x_0|}, t_0 + \frac{1}{|x_0|} \right) \).

**IX.1.9.7.** Show that Theorem IX.1.3.2. can be generalized as follows to give a unique solution on a generally larger interval. Suppose we have a Banach space \( \mathcal{X} \), an interval \( I \subseteq \mathbb{R} \), a point \( t_0 \in I \), \( n \) points \( x_1^{(0)}, \ldots, x_n^{(0)} \) in \( \mathcal{X} \), \( r_1, \ldots, r_n > 0 \), \( M > 0 \), \( K > 0 \), and \( n \) continuous functions
\[
f_1, \ldots, f_n : I \times \bar{B}_{r_1}(x_1^{(0)}) \times \cdots \times \bar{B}_{r_n}(x_n^{(0)}) \to \mathcal{X}
\]
with the property that \( \|f_k(t, x_1, \ldots, x_n)\| \leq M_k \) for \( t \in I \) and \( \|x_j - x_j^{(0)}\| \leq r_j (1 \leq j, k \leq n) \), and
\[
\|f_k(t, x_1^{(2)}, \ldots, x_n^{(2)}) - f_k(t, x_1^{(1)}, \ldots, x_n^{(1)})\| \leq K \max_{1 \leq j \leq n} (\|x_j^{(2)} - x_j^{(1)}\|)
\]
for \( 1 \leq k \leq n \) whenever \( t \in I \) and \( x_j^{(1)}, x_j^{(2)} \in \bar{B}_{r_j}(x_j^{(0)}) \) for all \( j \) (the \( f_k \) satisfy a uniform Lipschitz condition in \( x_1, \ldots, x_n \) on \( I \)). Slightly adapt the proof of Theorem IX.1.2.2. to show the following:

**Theorem. [Existence and Uniqueness Theorem for Systems of First-Order ODEs]** Using the above notation, set
\[
L = \min \left\{ \frac{r_1}{M_1}, \ldots, \frac{r_n}{M_n} \right\}
\]
\[
I_0 = I \cap [t_0 - L, t_0 + L] .
\]
Then there are unique differentiable functions \( y_1, \ldots, y_n : I_0 \to \mathcal{X} \) such that
\[
y_k(t) = f_k(t, y_1(t), \ldots, y_n(t))
\]
\( (1 \leq k \leq n) \) for \( t \in I_0 \) and \( y_k(t_0) = x_k^{(0)} \). Additionally, the \( y_k \) are \( C^1 \) on \( I_0 \). If \( \tilde{I} \) is any subinterval of \( I_0 \) containing \( t_0 \), the restriction of the \( y_k \) to \( \tilde{I} \) is the unique solution to the IVP on \( \tilde{I} \).

**IX.1.9.8.** Use the theorem in IX.1.9.7. to obtain the following generalization of Theorem IX.1.4.1. which guarantees a unique solution on a larger interval in general:

**Theorem. [Existence and Uniqueness Theorem for Higher-Order ODE’s]** Let \( \mathcal{X} \) be a Banach space, \( I \) an interval in \( \mathbb{R} \), \( t_0 \in I \), \( x_0, x_0', \ldots, x_0^{(n-1)} \in \mathcal{X} \), \( r_0, \ldots, r_{n-1} > 0 \), and
\[
f : I \times \bar{B}_{r_0}(x_0) \times \bar{B}_{r_1}(x_0') \times \cdots \times \bar{B}_{r_{n-1}}(x_0^{(n-1)}) \to \mathcal{X} .
\]
Suppose $f$ is continuous and bounded by $N$ on $I \times \bar{B}_r(x_0) \times \bar{B}_r(x_0') \times \cdots \times \bar{B}_r(x_0^{(n-1)})$ and satisfies a uniform Lipschitz condition in the $y$-variables. Set

$$L = \max \left\{ \frac{r_0}{\|x_0\| + r_1}, \ldots, \frac{r_{n-2}}{\|x_0^{(n-1)}\| + r_{n-1}}, \frac{r_{n-1}}{N} \right\}$$

$$I_0 = I \cap [t_0 - L, t_0 + L] .$$

Then there is a unique $n$-times differentiable function $y : I_0 \to Y$ with $y(t_0) = x_0$, $y'(t_0) = x_0'$, $\ldots$, $y^{(n-1)}(t_0) = x_0^{(n-1)}$, and $y^{(n)}(t) = f(t, y(t), y'(t), \ldots, y^{(n-1)}(t))$ for all $t \in I_0$. Additionally, $y$ is $C^n$ on $I_0$.

**IX.1.9.9.** Let $I$ be an interval in $\mathbb{R}$, $\mathcal{X}$ a Banach space, and $f : I \to \mathcal{X}$ a continuous function. Then $f$ may be regarded as a continuous function from $I \times \mathcal{X}$ to $\mathcal{X}$ satisfying a uniform Lipschitz condition in $\mathcal{X}$ with Lipschitz constant 0. Show that one step of Picard iteration gives the exact (unique) solution to the IVP $y' = f(t)$, $y(t_0) = x_0$ for any $t_0 \in I$, $x_0 \in \mathcal{X}$.

**IX.1.9.10.** (a) Use the Existence and Uniqueness Theorem IX.1.2.7. to give an alternate proof of the one-variable $C^r$ Implicit Function Theorem VIII.6.3.14. for $r \geq 2$ by considering the IVP (with $x$ the independent variable)

$$y' = -\frac{\partial F(x, y)}{\partial x}, \quad y(a) = b.$$ Use the Chain Rule to show that the unique solution $y = f(x)$ satisfies $F(x, f(x)) = 0$ for all $x$ near $a$. (One does not obtain uniqueness of the implicitly defined function this way, only uniqueness of a differentiable implicitly defined function.) What can one conclude from this argument if $F$ is only $C^1$? (cf. IX.1.6.1.)

(b) Generalize to the case of VIII.6.1.7. for $p = 1$ and $r \geq 2$, for general $n$, by considering a system of differential equations.

(c) Give a similar proof of the general $C^r$ Implicit Function Theorem VIII.6.1.7. ($r \geq 2$) by considering a system of partial differential equations

$$Dy = -D_y F(x, y)^{-1} D_x F(x, y), \quad y(a) = b.$$ Use these results to give explicit descriptions of sets on which the implicitly defined functions exist.
IX.2. Partial Differential Equations

"PDEs constitute one of the most dynamic and varied domains of the mathematical sciences, defying all attempts at unification. They are found in every phenomenon studied by the physics of continuous systems, involving all states of matter (gases, fluids, solids, plasmas) and all physical theories (classical, relativistic, quantum, and so on).

But partial differential equations also lurk behind many geometric problems. Geometric PDEs, as they are called, make it possible to deform geometric objects in accordance with well-established laws. The application of methods of analysis to problems in other fields of mathematics is an example of the sort of cross-fertilization that became increasingly common in the course of the twentieth century."

C. Villani

IX.2.1. Elementary Theory

It is common to denote the unknown function in a partial differential equation by \( u \) (or \( v, w \)), and the independent variables by \( x, y, z \), and/or \( t \). Of course, a PDE can have any number of independent variables, but PDE’s arising in physics often describe an unknown function of three (or fewer) spatial coordinates \((x, y, z)\) and/or one time coordinate \( t \). It is also notationally economical to use the subscript notation for partial derivatives, e.g. \( u_x \) for \( \frac{\partial u}{\partial x} \) or \( u_{xy} \) for \( \frac{\partial^2 u}{\partial y \partial x} \) (note the order of differentiation, which is often but not always irrelevant; cf. VIII.2.2.2).

IX.2.1.1. Example. Consider the apparently extremely simple PDE which can be variously written

\[
\frac{\partial u}{\partial x} = \frac{\partial u}{\partial t} \\
\frac{\partial u}{\partial x} - \frac{\partial u}{\partial t} = 0 \\
u_x - u_t = 0
\]

where \( u \) is an unknown function of \( x \) and \( t \). It is easy to check using the Chain Rule that

\[
u(x, t) = f(x + t)\]

is a solution on \( \Omega = \{(x, t) : x + t \in I\} \), for any real-valued function \( f \) which is differentiable on an open interval \( I \) in \( \mathbb{R} \) (it turns out that these are all the solutions (i)). There are several observations to take away from this example:

(i) There is not a clean standard form for PDEs such as in IX.1.1.2..

(ii) Even a homogeneous linear first-order PDE with constant coefficients can have solutions which are not even \( C^1 \), much less analytic (cf. (i)).

\[^3[Vil16, \text{p. } 107].\]
(iii) The general solution to such a PDE does not just contain an arbitrary constant, but an arbitrary (differentiable) function which must be determined by initial or boundary conditions (the fact that there is one equation and two independent variables suggests that there is an arbitrary function of $2 - 1 = 1$ variables which comes into the general solution, which is correct when properly formulated).

IX.2.2. Quasilinear Partial Differential Equations

IX.2.3. The Cauchy-Kovalevskaya Theorem
Chapter X

Fundamentals of Complex Analysis

Complex Analysis is calculus done on the complex numbers. Although at first it bears superficial resemblance to ordinary calculus, it quickly assumes a much different character.

Complex Analysis is one of the most beautiful parts of mathematics. Many of the theorems seem almost too good to be true, especially in comparison with the situation in Real Analysis. Complex Analysis is also extraordinarily important throughout mathematics, with applications ranging from number theory to geometry to mathematical physics (and almost everything else).

It is beyond the scope of this book to give a full treatment of this vast subject. We will only describe some of the most fundamental aspects and their connections with real analysis. There is an overabundant supply of texts on Complex Analysis, which are of varying quality but mostly adequate or better. Four of the best are the classic [Ahl78], [GK06], [Gam01], and [SS03].

Throughout this chapter, we will always use the standard model of the complex numbers $\mathbb{C}$, the complex plane (III.6.2.). Thus we will freely regard $\mathbb{C}$ as $\mathbb{R}^2$ with the additional operation of complex multiplication. Thus any function from $\mathbb{C}$ (or a subset) to $\mathbb{C}$ can be equally well thought of as a function from $\mathbb{R}^2$ to $\mathbb{R}^2$. In discussing limits and continuity in $\mathbb{C}$, we always use the topology on $\mathbb{C}$ obtained by the identification with $\mathbb{R}^2$. This topology is induced by the metric $\rho(z, w) = |z - w|$.

X.1. Elementary Theory

X.1.1. Complex Differentiation and Holomorphic Functions

We first discuss the complex analog of ordinary differentiation. Many basic definitions and results bear a close formal resemblance to corresponding notions in usual calculus of one variable.

X.1.1.1. We will use the following standard notation. The independent variable in complex analysis is usually denoted $z = x + iy$, where $z \in \mathbb{C}$ and $x$ and $y$ are the real and imaginary parts of $z$. Then $z$ corresponds to the point $(x, y) \in \mathbb{R}^2$. If $\Omega$ is a (usually open) subset of $\mathbb{C}$, and $f : \Omega \to \mathbb{C}$ is a function, write

$$f(z) = f(x + iy) = u(x, y) + iv(x, y)$$

where $u, v : \Omega \to \mathbb{R}$ are the real and imaginary parts of $f$ (the coordinate functions of $f$ when $f$ is regarded as a function from $\Omega$ to $\mathbb{R}^2$).
X.1.1.2. Definition. Let $\Omega$ be an open subset of $\mathbb{C}$, $f : \Omega \to \mathbb{C}$ a function, and $z_0 = x_0 + iy_0 \in \Omega$. Then $f$ is differentiable in the complex sense (or just complex differentiable) at $z_0$ if

$$
\lim_{z \to z_0} \frac{f(z) - f(z_0)}{z - z_0}
$$

exists. If the limit exists, it is called the complex derivative of $f$ at $z_0$, denoted $f'(z_0)$.

The function $f$ is complex differentiable on $\Omega$, or holomorphic on $\Omega$, if it is complex differentiable at every $z_0 \in \Omega$.

X.1.1.3. In Complex Analysis, the term analytic is often used as a synonym for holomorphic. We will not initially use analytic in this way since it has a different official definition (V.16.1.1.). One of the major fundamental theorems of Complex Analysis is that the notions of being analytic and holomorphic on an open set $\Omega$ coincide (X.4.4.7.).

Here is the relation between complex differentiation and ordinary differentiation on $\mathbb{R}^2$:

X.1.1.4. Proposition. Let $\Omega$ be an open subset of $\mathbb{C}$, $f : \Omega \to \mathbb{C}$ a function, and $z_0 = x_0 + iy_0 \in \Omega$, $c = a + ib \in \mathbb{C}$. The following are equivalent:

(i) $f$ is complex differentiable at $z_0$ with $f'(z_0) = c$.

(ii) For $z \in \Omega$, $f(z) = f(z_0) + c(z - z_0) + o(|z - z_0|)$.

(iii) $f$ (regarded as a function from $\Omega$ to $\mathbb{R}^2$) is differentiable at $z_0 = (x_0, y_0)$ in the vector calculus sense () and $Df(x_0, y_0) = \begin{bmatrix} a & -b \\ b & a \end{bmatrix}$.

This result gives motivation and “explanation” for the model of $\mathbb{C}$ in Exercise III.6.3.1..

Proof: The argument is very similar to the calculation motivating the definition of vector calculus differentiation (). The following statements are equivalent:

$$
\lim_{z \to z_0} \frac{f(z) - f(z_0)}{z - z_0} = c
$$

$$
\lim_{z \to z_0} \frac{f(z) - f(z_0) - c(z - z_0)}{z - z_0} = 0
$$

$$
\lim_{z \to z_0} \frac{|f(z) - f(z_0) - c(z - z_0)|}{|z - z_0|} = 0
$$

$$
\lim_{(x,y) \to (x_0,y_0)} \frac{||f(x,y) - f(x_0,y_0) - T(h)||}{||h||} = 0
$$

where $h = (x, y) - (x_0, y_0)$ and $T$ is the linear transformation of $\mathbb{R}^2$ given by multiplication by $c$. The argument is completed by noting that the matrix of $T$ is $\begin{bmatrix} a & -b \\ b & a \end{bmatrix}$.

$\square$
X.1.1.5. **Corollary.** Let $\Omega$ be an open subset of $\mathbb{C}$, $f = u + iv : \Omega \to \mathbb{C}$ a function, and $z_0 = x_0 + iy_0 \in \Omega$. Then $f$ is complex differentiable at $z_0$ if and only if $u$ and $v$ are differentiable in the vector calculus sense at $(x_0, y_0)$ and satisfy the Cauchy-Riemann equations:

$$\frac{\partial u}{\partial x}(x_0, y_0) = \frac{\partial v}{\partial y}(x_0, y_0), \quad \frac{\partial u}{\partial y}(x_0, y_0) = -\frac{\partial v}{\partial x}(x_0, y_0).$$

The complex derivative, when it exists, is given by

$$f'(x_0 + iy_0) = \frac{\partial u}{\partial x}(x_0, y_0) + i \frac{\partial v}{\partial x}(x_0, y_0) = \frac{\partial v}{\partial y}(x_0, y_0) - i \frac{\partial u}{\partial y}(x_0, y_0).$$

So $f$ is holomorphic on $\Omega$ if and only if $f$ is differentiable in the vector calculus sense on $\Omega$ and the Cauchy-Riemann equations hold everywhere on $\Omega$. In particular, if $\frac{\partial u}{\partial x}$, $\frac{\partial u}{\partial y}$, $\frac{\partial v}{\partial x}$, $\frac{\partial v}{\partial y}$ are continuous on $\Omega$ and satisfy the Cauchy-Riemann equations, then $f$ is holomorphic on $\Omega$.

X.1.1.6. It turns out that in X.1.1.5., the assumption that $f$ be differentiable in the vector calculus sense on $\Omega$ can be relaxed. If the first-order partials of $u$ and $v$ exist everywhere on $\Omega$ and satisfy the Cauchy-Riemann equations, and if $f$ is continuous on $\Omega$ (Looman-Menchoff Theorem) or just locally bounded (Montel-Tolstoff Theorem), then $f$ is automatically holomorphic on $\Omega$. Some additional condition on $f$ besides the Cauchy-Riemann equations is necessary: cf. Exercise X.8.2.1. The question of when a function satisfying the Cauchy-Riemann equations is holomorphic is a subtle one, which is discussed thoroughly in [GM78]. (And a strong version of the converse of the last statement of X.1.1.5. also holds (X.3.3.6.).)

X.1.1.7. X.1.1.4. suggests that it is qualitatively harder for a function from $\mathbb{C}$ to $\mathbb{C}$ to be complex differentiable than it is for a function from $\mathbb{R}$ to $\mathbb{R}$ to be differentiable in the usual sense. This turns out to be correct, and complex differentiability implies all sorts of remarkable properties that do not necessarily hold for usual differentiable functions on $\mathbb{R}$.

There are nonetheless many examples of holomorphic functions, enough to make a rich theory. Here are some basic ones:

X.1.1.8. **Examples.** (i) If $f$ is a polynomial in $z$ with complex coefficients, then by a calculation using the product formula in $\mathbb{C}$ the real and imaginary parts of $f$ are polynomials in $x$ and $y$ with real coefficients. Thus $f$ is differentiable (in fact, $C^\infty$) on $\mathbb{C}$. A rather ugly calculation shows that the Cauchy-Riemann equations are satisfied, so $f$ is holomorphic on $\mathbb{C}$. A simpler argument which shows this, and that $f'$ is given by the usual formula, is in X.1.2.5.

(ii) Similarly, any rational function in $z$ is holomorphic on its domain (X.1.2.8).

(iii) **[Complex Exponential Function]** For $z = x + iy \in \mathbb{C}$, set

$$e^z = e^{x+iy} = e^x \cos y + ie^x \sin y = e^x (\cos y + i \sin y).$$

Then $f(z) = e^z$ is differentiable (in fact, $C^\infty$) on $\mathbb{C}$, and it is easily checked that the Cauchy-Riemann equations hold; hence $f$ is holomorphic on $\mathbb{C}$. By X.1.1.4.,

$$f'(x + iy) = \frac{\partial u}{\partial x}(x, y) + i \frac{\partial v}{\partial x}(x, y) = f(x + iy).$$
i.e. $f' = f$. The complex exponential function also satisfies $e^{z+w} = e^z e^w$, $e^{-z} = \frac{1}{e^z}$, and $e^{z-w} = \frac{e^z}{e^w}$ for all $z, w \in \mathbb{C}$, and agrees with the usual exponential function for $z$ real (and is the only holomorphic function extending the real exponential function, cf. X.5.1.4. and Exercise X.8.2.6.).

(iv) **[Complex Trigonometric Functions]** For $z = x + iy \in \mathbb{C}$, set

$$
sin z = \sin x \cosh y + i \cos x \sinh y
$$

$$
cos z = \cos x \cosh y - i \sin x \sinh y
$$

Then $f(z) = \sin z$ and $g(z) = \cos z$ are differentiable (in fact, $\mathcal{C}^\infty$) on $\mathbb{C}$, and the Cauchy-Riemann equations hold, so $f$ and $g$ are holomorphic on $\mathbb{C}$. By a calculation as in (iii), $f' = g$ and $g' = -f$. These functions satisfy the usual trigonometric identities, and reduce to the usual $\sin$ and $\cos$ when $z$ is real. The other trigonometric functions can be defined from these in the usual way, and give holomorphic functions on their domains extending the usual ones and satisfying the same identities and differentiation rules.

(v) **[Complex Hyperbolic Functions]** For $z = x + iy \in \mathbb{C}$, set

$$
\sinh z = \sinh x \cosh y + i \cosh x \sinh y = \frac{e^z - e^{-z}}{2}
$$

$$
cosh z = \cosh x \cosh y + i \sinh x \sinh y = \frac{e^z + e^{-z}}{2}
$$

Then similarly $f(z) = \sinh z$ and $g(z) = \cosh z$ are holomorphic on $\mathbb{C}$, and $f' = g$, $g' = f$. These functions satisfy the usual identities, and reduce to the usual $\sinh$ and $\cosh$ when $z$ is real. The other hyperbolic functions can be defined from these in the usual way, and give holomorphic functions on their domains extending the usual ones and satisfying the same identities and differentiation rules. We have

$$
cos z = \cosh iz = \frac{e^{iz} + e^{-iz}}{2}
$$

$$
sin z = -i \sinh iz = \frac{e^{iz} - e^{-iz}}{2i}
$$

for all $z \in \mathbb{C}$.

These examples show the intimate connections between the exponential, trigonometric, and hyperbolic functions which become clear only when the extensions to the complex numbers are considered.

Defining inverse functions (log, arcsin, etc., even $\sqrt{z}$) is a trickier matter, primarily due to complications of domain.

**X.1.1.9.** In this case, all these functions are $\mathcal{C}^\infty$ on their domains (as functions from $\mathbb{R}^2$ to $\mathbb{R}^2$), and their derivatives of all orders are also holomorphic. This in fact is true for any holomorphic function on an open set in $\mathbb{C}$ (X.3.3.6.), one of the remarkable properties of holomorphic functions.

**X.1.2. Rules of Differentiation**

There are complex analogs of the usual rules of differentiation. These can be proved by an easy adaptation of the arguments in the real case, or by rather tediously using the real results, the formulas for complex multiplication and division, and X.1.1.4.
X.1.2.1. **Proposition.** Let \( f \) be a function from an open set \( \Omega \subseteq \mathbb{C} \) to \( \mathbb{C} \). If \( f \) is complex differentiable at \( z_0 \in \Omega \), then \( f \) is continuous at \( z_0 \).

X.1.2.2. **Theorem.** [Power Rule] Let \( n \in \mathbb{N} \), and \( f : \mathbb{C} \to \mathbb{C} \) be defined by \( f(z) = z^n \). Then \( f \) is complex differentiable at any \( z_0 \in \mathbb{C} \), and

\[
f'(z_0) = nz_0^{n-1}.
\]

X.1.2.3. **Proposition.** [Sum Rule] Let \( f \) and \( g \) be functions from an open set \( \Omega \subseteq \mathbb{C} \) to \( \mathbb{C} \), and \( h = f + g : \Omega \to \mathbb{C} \). If \( f \) and \( g \) are complex differentiable at \( z_0 \in \Omega \), then \( h \) is complex differentiable at \( z_0 \) and

\[
h'(z_0) = f'(z_0) + g'(z_0).
\]

X.1.2.4. **Proposition.** [Constant Multiple Rule] Let \( f \) be a function from an open set \( \Omega \subseteq \mathbb{C} \) to \( \mathbb{C} \), \( c \in \mathbb{C} \), and \( h = cf : \Omega \to \mathbb{C} \). If \( f \) is complex differentiable at \( z_0 \in \Omega \), then \( h \) is complex differentiable at \( z_0 \) and

\[
h'(z_0) = cf'(z_0).
\]

X.1.2.5. **Corollary.** Any sum or constant multiple of functions holomorphic on \( \Omega \) is holomorphic on \( \Omega \). In particular, a polynomial with complex coefficients is holomorphic on \( \mathbb{C} \).

X.1.2.6. **Theorem.** [Product Rule] Let \( f \) and \( g \) be functions from an open set \( \Omega \subseteq \mathbb{C} \) to \( \mathbb{C} \), and \( h = fg : \Omega \to \mathbb{C} \). If \( f \) and \( g \) are complex differentiable at \( z_0 \in \Omega \), then \( h \) is complex differentiable at \( z_0 \) and

\[
h'(z_0) = f'(z_0)g(z_0) + f(z_0)g'(z_0).
\]

X.1.2.7. **Theorem.** [Quotient Rule] Let \( f \) and \( g \) be functions from an open set \( \Omega \subseteq \mathbb{C} \) to \( \mathbb{C} \). If \( f \) and \( g \) are complex differentiable at \( z_0 \in \Omega \) and \( g(z_0) \neq 0 \), then \( h = \frac{f}{g} \) is defined in an open neighborhood of \( z_0 \) and differentiable at \( z_0 \), and

\[
h'(z_0) = \frac{g(z_0)f'(z_0) - f(z_0)g'(z_0)}{|g(z_0)|^2}.
\]
X.1.2.8. Corollary. If \( f \) and \( g \) are holomorphic on \( \Omega \), then \( fg \) is holomorphic on \( \Omega \), and if \( g \) is nonzero on \( \Omega \), then \( \frac{1}{g} \) is also holomorphic on \( \Omega \). In particular, every rational function with complex coefficients is holomorphic on its domain.

X.1.2.9. Theorem. [Chain Rule] Let \( f \) be defined on a neighborhood \( U \) of \( z_0 \) in \( \mathbb{C} \) and complex differentiable at \( z_0 \), with \( f(z_0) = w_0 \), and let \( g \) be defined on a neighborhood \( V \) of \( w_0 \) in \( \mathbb{C} \) and complex differentiable at \( w_0 \), with \( f(U) \subseteq V \). Set \( h = g \circ f \) on \( U \). Then \( h \) is complex differentiable at \( z_0 \), and
\[
h'(z_0) = (g \circ f)'(z_0) = g'(w_0)f'(z_0) = g'(f(z_0))f'(z_0).
\]

X.1.2.10. Theorem. [Inverse Function Theorem] Let \( \Omega \subseteq \mathbb{C} \) be open, \( f \) holomorphic on \( \Omega \), and \( z_0 \in \Omega \). If \( f'(z_0) \neq 0 \), then there is an open neighborhood \( V \) of \( z_0 \) contained in \( \Omega \) for which \( f \) maps bijectively to an open neighborhood \( W \) of \( f(z_0) \), and the inverse function \( f^{-1} \) is holomorphic on \( W \). If \( z \in V \), then
\[
(f^{-1})'(f(z)) = \frac{1}{f'(z)}.
\]

Proof: There is one aspect of this theorem not yet established: it follows automatically that \( f' \) is continuous (in fact, holomorphic) on \( \Omega \) (X.3.3.6.). The result now follows from the Inverse Function Theorem, since if \( f \) is regarded as a function from \( \Omega \) to \( \mathbb{R}^2 \), we have \( J_f(z) = det(Df(z)) = |f'(z)|^2 \). The inverse function is holomorphic, since if \( z \in V \) and \( f'(z) = a + ib \), then
\[
D(f^{-1})(f(z)) = \begin{bmatrix} a & -b \\ b & a \end{bmatrix}^{-1} = \frac{1}{a^2 + b^2} \begin{bmatrix} a & b \\ -b & a \end{bmatrix}
\]
and thus \( f^{-1} \) satisfies the Cauchy-Riemann equations; then
\[
(f^{-1})'(f(z)) = \frac{a}{a^2 + b^2} - i \frac{b}{a^2 + b^2} = \frac{1}{f'(z)}.
\]

Although we have stated this result in maximum generality, we have so far only given a complete proof of the following slightly weaker version:

X.1.2.11. Corollary. Let \( \Omega \subseteq \mathbb{C} \) be open, \( f \) holomorphic on \( \Omega \), and \( z_0 \in \Omega \). If \( f' \) is continuous on \( \Omega \) and \( f'(z_0) \neq 0 \), then there is an open neighborhood \( V \) of \( z_0 \) contained in \( \Omega \) which \( f \) maps bijectively to an open neighborhood \( W \) of \( f(z_0) \), and the inverse function \( f^{-1} \) is holomorphic on \( W \). If \( z \in V \), then
\[
(f^{-1})'(f(z)) = \frac{1}{f'(z)}.
\]
X.1.2.12. In particular, if $f$ is holomorphic on $\Omega$ and $f'$ never vanishes, then $f$ is an open mapping. If $\Omega$ is connected, this result extends to the case where $f$ is just assumed to be not constant (). In fact, $f$ is locally an open mapping around any point where it is not locally constant ()

X.1.3. Branch Cuts and Branches

X.1.3.1. A holomorphic function which is locally one-to-one (i.e. whose derivative does not vanish) is not globally one-to-one in general. The fundamental example is the complex exponential function: $e^{z+2\pi i} = e^z$ for any $z$. If we want to define an inverse function for such a function, we must restrict to regions where the function gives a bijection.

X.1.3.2. The prototype problem is how to define a complex logarithm. Since we have $e^{x+iy} = e^x e^{iy}$, we have

$$|e^{x+iy}| = e^x, \quad \text{arg}(e^{x+iy}) = y$$

so we may try to define the complex logarithm using polar coordinates by

$$\log(re^{i\theta}) = \log r + i\theta.$$ 

The real part is well defined as long as $r \neq 0$ (obviously $\log 0$ cannot make sense since $e^z$ is never zero); but the problem is that the argument $\theta$ is only defined up to adding a multiple of $2\pi$.

X.1.3.3. The standard solution is to restrict the exponential function to an open horizontal strip of width $2\pi$, say the strip $S_\alpha = \{x + iy : \alpha < y < \alpha + 2\pi\}$ for a fixed real number $\alpha$. The exponential function maps this open strip one-one onto the plane with a ray out from 0 at angle $\alpha$ (measured in the usual way from the positive real axis counterclockwise) removed. An inverse function can then be defined on this open set $\Omega_\alpha$ taking values in the strip, which is a reasonable definition of a complex logarithm function. This function is called a branch of the complex logarithm function with the ray as branch cut. There is thus one branch of the complex logarithm for each real number $\alpha$. Note that for a given branch cut, there are infinitely many branches: the branch cuts for the branches corresponding to $\alpha$ and $\beta$ are the same if (and only if) $\alpha$ and $\beta$ differ by a multiple of $2\pi$.

A branch of the complex logarithm cannot be continuously extended to any point on the branch cut, since the limits as the point is approached from opposite sides of the cut differ by $2\pi i$.

X.1.3.4. The branch corresponding to $\alpha = -\pi$ is called the principal branch of the complex logarithm. The branch cut for the principal branch is the negative real axis, and the values are in $S_{-\pi} = \{x + iy : -\pi < y < \pi\}$.

The principal branch of the complex logarithm agrees with the usual (real) logarithm function on the positive real axis.

X.1.3.5. Although branch cuts are usually taken to be straight rays, any curve beginning at 0 and going to $\infty$ without crossing itself can be used as a branch cut, and a branch of the complex logarithm (actually infinitely many) can be defined on the complement. (The inverse image of such a curve under the exponential function gives a sequence of parallel curves in the plane a vertical distance $2\pi$ apart, and the exponential function is bijective on the region between consecutive curves.)
X.1.4. The Fundamental Theorem of Algebra

The Fundamental Theorem of Algebra, that every complex polynomial has a root in $\mathbb{C}$, has many essentially different proofs. There is a nice one due to J. Milnor [Mil97], based on the results of X.1.1., which we describe here. See X.8.2.3. and X.8.2.4. for two more proofs using Complex Analysis.

X.1.4.1. Lemma. Let $p$ be a nonconstant polynomial with complex coefficients,

$$p(z) = a_0 + a_1 z + a_2 z^2 + \cdots + a_n z^n$$

with $n \geq 1$ and $a_n \neq 0$. Then for any $M > 0$ there is a $K > 0$ such that $|p(z)| > M$ for all $z$ with $|z| > K$.

Proof: For all $z$ with $|z| \geq 1$, we have

$$|p(z)| = |z^n|(|a_0 z^{-n} + \cdots + a_n|z|^{-1} + a_n|) \geq |z|^n \left( |a_n| - |z|^{-1} \sum_{k=0}^{n-1} |a_k| \right)$$

If $|z|$ is sufficiently large, the second factor is greater than $\left| \frac{a_n}{z} \right|$, and $|z|^n > \frac{2M}{|a_n|}$. So

$$K = \max \left( 1, \frac{2 \sum_{k=0}^{n-1} |a_k|}{|a_n|}, \left[ \frac{2M}{|a_n|} \right]^{1/n} \right)$$

will do.

X.1.4.2. Theorem. [Fundamental Theorem of Algebra] Let $p$ be a nonconstant polynomial with coefficients in $\mathbb{C}$. Then there is at least one $c \in \mathbb{C}$ with $p(c) = 0$.

Proof: Let $R \subseteq \mathbb{C}$ be the range of $p$, i.e.

$$R = \{p(z) : z \in \mathbb{C}\}$$

and set

$$F = \{p(z) : z \in \mathbb{C}, p'(z) = 0\}$$

and $S = R \setminus F$. Then $F$ is a finite subset of $R$ since $p'$ is not identically zero. We will show that $R$ is closed and $S$ is open in $\mathbb{C}$. This will prove the theorem since if $\mathbb{C} \setminus R$ is nonempty, then $S$ and $\mathbb{C} \setminus R$ would be disjoint nonempty open sets whose union is the connected open set $\mathbb{C} \setminus F$, a contradiction. (Note that $S$ is nonempty since otherwise $R = F$, and $F$ would have to be a singleton by continuity, so $p$ would be constant.) Thus $R = \mathbb{C}$, and in particular $0 \in R$.

To show that $R$ is closed, it suffices to show that $R \cap \bar{B}_M(0)$ is closed for all $M > 0$. Fix $M$. There is a $K$ such that $|p(z)| > M$ for all $z$ with $|z| > K$ (Lemma X.1.4.1.). Thus

$$R \cap \bar{B}_M(0) = p(\bar{B}_K(0)) \cap \bar{B}_M(0)$$

which is compact since $p$ is continuous (\).

We now show $S$ is open. Let $w_0 \in S$. Fix $z_0 \in \mathbb{C}$ with $p(z_0) = w_0$, $p'(z_0) \neq 0$. So by X.1.2.11. there is a neighborhood $V$ of $z_0$ which $p$ maps homeomorphically onto a neighborhood $W$ of $w_0$; thus $W \subseteq R$. Since $F$ is finite and $w_0 \notin F$, $W \setminus F$ is a neighborhood of $w_0$ contained in $S$. \(\blacksquare\)
X.2. Contour Integration

Contour integration is one of the most fundamental tools of Complex Analysis. Cauchy’s Theorem, which roughly says that the contour integral of a holomorphic function around a closed contour is zero, is the key to all the deeper properties of holomorphic functions.

X.2.1. Integration along a Contour

X.2.1.1. Definition. Let $p, q \in \mathbb{C}$. A contour from $p$ to $q$ is a continuous rectifiable curve ($\gamma$) in $\mathbb{C} \cong \mathbb{R}^2$ from $p$ to $q$.

X.2.1.2. A contour from $p$ to $q$ by definition has a continuous parametrization $\zeta : [a, b] \rightarrow \mathbb{C}$ with $\zeta(a) = p$, $\zeta(b) = q$. However, the parametrization is not unique, and is not intrinsic to $\gamma$ (only the equivalence class of the parametrization is part of the definition). But since $\gamma$ is rectifiable, it has an intrinsic parametrization by arc length starting at $p$ ($\gamma$). More importantly, $\gamma$ has an orientation, or specified direction of motion, with initial point $p$ and final point $q$. There is an opposite contour $-\gamma$, which is $\gamma$ traversed from $q$ to $p$. If $\zeta : [a, b] \rightarrow \mathbb{C}$ is a parametrization of $\gamma$, then $\tilde{\zeta} : [0, b - a] \rightarrow \mathbb{C}$ defined by $\tilde{\zeta}(t) = \zeta(b - t)$ is a parametrization of $-\gamma$. The interval a parametrization is defined on is not important, and can be changed to any other (closed bounded) interval by a linear change of variables.

We will often consider closed contours, ones whose initial and final points coincide. A closed contour still has an orientation, and if $\gamma$ is a simple closed contour, i.e. the image is homeomorphic to a circle, it also makes sense to say how many (net) times $\gamma$ is traversed in a counterclockwise direction ($\gamma$).

We will almost always concern ourselves only with the special case where $\gamma$ is piecewise-smooth, i.e. has a piecewise-smooth parametrization ($\gamma$). If $\gamma$ is piecewise-smooth, parametrization by arc length is a piecewise-smooth parametrization ($\gamma$).

X.2.1.3. The goal of this section is to show that if $\gamma$ is a contour in $\mathbb{C}$, and $f$ is a continuous complex-valued function on $\mathbb{C}$, then there is a well-defined complex number called the (contour) integral of $f$ along $\gamma$, denoted

$$\int_{\gamma} f = \int_{\gamma} f(\zeta) d\zeta$$

with the usual properties of an integral. The integral does not depend on a parametrization of $\gamma$, although it is usually calculated using a parametrization. It does, however, depend on the orientation of $\gamma$: we will have

$$\int_{-\gamma} f = -\int_{\gamma} f.$$

Although contour integrals of somewhat more general functions can be defined, we will restrict to the case of continuous functions for simplicity, and because this is the crucial case for applications. In fact, almost all applications involve only contour integrals of holomorphic functions.
Integration on an Interval

Definition of the Contour Integral

Properties of Contour Integrals

The Fundamental Inequality

The next fundamental estimate is an easy consequence of the definition:

\textbf{X.2.1.4. Proposition.} Let \( \gamma : [a, b] \to \mathbb{C} \) be a rectifiable curve, and \( f \) a continuous function on \( \gamma \). If \( |f(z)| \leq M \) for all \( z \in \gamma \), then

\[
\left| \int_{\gamma} f \right| \leq M \cdot \ell(\gamma) .
\]

\textbf{Proof:} Let \( \mathcal{P} = \{a = t_0, t_1, \ldots, t_n = b\} \) be a partition of \([a, b]\). Then by the triangle inequality we have

\[
\left| \sum_{k=1}^{n} f(\gamma(t_k))(\gamma(t_k) - \gamma(t_{k-1})) \right| \leq \sum_{k=1}^{n} |f(\gamma(t_k))||\gamma(t_k) - \gamma(t_{k-1})| \leq M \sum_{k=1}^{n} |\gamma(t_k) - \gamma(t_{k-1})| .
\]

As the mesh of \( \mathcal{P} \) goes to zero, the left side approaches \( \int_{\gamma} f \) and the right side approaches \( M \cdot \ell(\gamma) \). \( \square \)

An important consequence is:

\textbf{X.2.1.5. Corollary.} Let \( \gamma : [a, b] \to \mathbb{C} \) be a rectifiable curve, and \((f_n)\) a sequence of continuous functions on \( \gamma \) converging uniformly on \( \gamma \) to a (continuous) function \( f \). Then

\[
\int_{\gamma} f_n \to \int_{\gamma} f .
\]

Calculation of Contour Integrals

On piecewise-smooth curves, contour integrals can be computed by an ordinary integral:

\textbf{X.2.1.6. Theorem.} If \( \gamma : [a, b] \to \mathbb{C} \) is a piecewise-smooth curve in \( \mathbb{C} \) and \( f \) is a complex-valued function on \( \gamma \), then

\[
\int_{\gamma} f = \int_{a}^{b} f(\gamma(t))\gamma'(t) \, dt .
\]
X.2.1.7. Example. Here is perhaps the most important example of a contour integral. Let $\gamma$ be the unit circle in $\mathbb{C}$, parametrized once around counterclockwise. Let $f(z) = \frac{1}{z}$ for $|z| = 1$. Then

$$\int_{\gamma} f = \int_{0}^{2\pi} \frac{1}{e^{it}} e^{it} dt = 2\pi i .$$

This integral will appear over and over in many parts of complex analysis, and many of the fundamental theorems and formulas of the subject are based on it.

The Fundamental Theorem of Calculus

The contour integral of a function with an antiderivative is easy to compute:

X.2.1.8. Proposition. If $f$ is a continuous function on an open set $\Omega$ in $\mathbb{C}$ with an antiderivative $F$ on $\Omega$, and $\gamma : [a, b] \to \Omega$ is a piecewise-smooth contour from $p$ to $q$, then

$$\int_{\gamma} f = F(q) - F(p) .$$

In particular, the contour integral of $f$ along any contour depends only on the endpoints. The contour integral of $f$ around any closed contour is 0.

Proof: This just looks like the Fundamental Theorem of Calculus, but it does not follow immediately from the real FTC but requires a bit of calculation using the Chain Rule of vector calculus and the Cauchy-Riemann equations. By subdividing $[a, b]$, we may assume $\gamma$ is smooth. Write

$$F(x + iy) = U(x, y) + iV(x, y)$$

so that

$$f(x + iy) = \frac{\partial U}{\partial x}(x, y) + i \frac{\partial V}{\partial x}(x, y) .$$

Write

$$\gamma(t) = \gamma_1(t) + i\gamma_2(t)$$
$$G(t) = U(\gamma_1(t), \gamma_2(t))$$
$$H(t) = V(\gamma_1(t), \gamma_2(t))$$

so that $F(\gamma(t)) = G(t) + iH(t)$. By the vector calculus Chain Rule,

$$G'(t) = \frac{\partial U}{\partial x}(\gamma_1(t), \gamma_2(t))\gamma_1'(t) + \frac{\partial U}{\partial y}(\gamma_1(t), \gamma_2(t))\gamma_2'(t)$$
$$H'(t) = \frac{\partial V}{\partial x}(\gamma_1(t), \gamma_2(t))\gamma_1'(t) + \frac{\partial V}{\partial y}(\gamma_1(t), \gamma_2(t))\gamma_2'(t) .$$

Then

$$\int_{\gamma} f = \int_{a}^{b} f(\gamma(t)) \gamma'(t) dt$$
\[\int_a^b \left[ \frac{\partial U}{\partial x}(\gamma_1(t), \gamma_2(t)) + i \frac{\partial V}{\partial x}(\gamma_1(t), \gamma_2(t)) \right] \left[ \gamma_1'(t) + i \gamma_2'(t) \right] dt\]

\[= \int_a^b \left[ \frac{\partial U}{\partial x}(\gamma_1(t), \gamma_2(t)) \gamma_1'(t) - \frac{\partial V}{\partial x}(\gamma_1(t), \gamma_2(t)) \gamma_2'(t) \right] dt + i \int_a^b \left[ \frac{\partial V}{\partial x}(\gamma_1(t), \gamma_2(t)) \gamma_1'(t) + \frac{\partial U}{\partial x}(\gamma_1(t), \gamma_2(t)) \gamma_2'(t) \right] dt\]

\[= \int_a^b \frac{\partial U}{\partial x}(\gamma_1(t), \gamma_2(t)) \gamma_1'(t) dt + i \int_a^b \frac{\partial V}{\partial x}(\gamma_1(t), \gamma_2(t)) \gamma_1'(t) dt + \int_a^b \frac{\partial U}{\partial y}(\gamma_1(t), \gamma_2(t)) \gamma_2'(t) dt + i \int_a^b \frac{\partial V}{\partial y}(\gamma_1(t), \gamma_2(t)) \gamma_2'(t) dt\]

\[= \int_a^b G'(t) dt + i \int_a^b H'(t) dt = (G(b) - G(a)) + i(H(b) - H(a)) = F(q) - F(p).
\]

The Complex Mean Value Inequality

The next result is a complex version of the Mean Value Inequality (V.8.2.10):

**X.2.1.9. PROPOSITION.** Let \( f \) be a holomorphic function on an open set \( \Omega \) in \( \mathbb{C} \) (with \( f' \) continuous), and \( A \) a convex subset of \( \Omega \). If \( |f'(z)| \leq M \) for all \( z \in A \), then

\[ |f(z) - f(w)| \leq M|z - w| \]

for all \( z, w \in A \).

The requirement that \( f' \) be continuous turns out to be automatic (X.3.3.6.).

**PROOF:** Let \( \gamma \) be the straight line segment from \( w \) to \( z \); then \( \gamma \subseteq A \) since \( A \) is convex.

\[ |f(z) - f(w)| = \left| \int_\gamma f' \right| \leq M|\ell(\gamma)| = M|z - w| . \]

Relation with Line Integrals

Green’s Theorem for Complex Functions

**X.3. The Big Theorems**

In this section, we use contour integration to prove some of the big theorems of elementary Complex Analysis: Cauchy’s Theorem, the Cauchy Integral Formula, Morera’s Theorem, Cauchy’s Inequalities, and Liouville’s Theorem.

These are, of course, not all the theorems of Complex Analysis which can be called “big theorems.” A few more big theorems concerning power series representation and analysis of singularities will be discussed in the next sections. Other big theorems such as the Riemann Mapping Theorem (and many others) are discussed later or are beyond the scope of this book.
X.3.1. Goursat’s Theorem

We begin by proving a special case of Cauchy’s Theorem, due to E. Goursat in 1883. This result is a considerable technical improvement over Cauchy’s original theorem, since it assumes nothing about the properties of the derivative of a holomorphic function, and in particular makes no continuity assumption about the derivative (in fact, it will turn out later that the derivative of a holomorphic function is not only automatically continuous, but even itself holomorphic, but we do not want to assume anything about the derivative in developing the theory).

The form of Goursat’s Theorem we give (originally due to A. Pringsheim in 1901) uses triangles. It can be equally well stated and proved for rectangles, or for any other polygonal region that can be subdivided into a finite number of congruent pieces of smaller diameter and perimeter (Goursat used squares). The use of triangles gives a more flexible result which simplifies succeeding proofs.

X.3.1.1. Theorem. [Goursat’s Theorem] Let $\Omega$ be an open set in $\mathbb{C}$, and $f$ a holomorphic function on $\Omega$. If $T$ is a (solid) triangle contained in $\Omega$, and $\gamma$ is the boundary of $T$ parametrized once around counterclockwise, then

$$\int_{\gamma} f = 0.$$ 

Proof: Let $d$ and $p$ be the diameter and perimeter of $T$ respectively. Divide $T$ into four subtriangles $T_{1}^{(1)}, \ldots, T_{1}^{(4)}$ whose vertices are the vertices of $T$ and the midpoints of the edges of $T$. Then each $T_{1}^{(k)}$ is similar to $T$. If $\gamma_{1}^{(k)}$ is the perimeter of $T_{1}^{(k)}$, parametrized once around counterclockwise, then we have

$$\int_{\gamma} f = \int_{\gamma_{1}^{(1)}} f + \int_{\gamma_{1}^{(2)}} f + \int_{\gamma_{1}^{(3)}} f + \int_{\gamma_{1}^{(4)}} f$$

since all interior edges are traversed once in each direction, so those contour integrals cancel. Thus there is a $k$ such that

$$\left| \int_{\gamma} f \right| \leq 4 \left| \int_{\gamma_{1}^{(k)}} f \right|.$$ 

Set $T_{1} = T_{1}^{(k)}$ and $\gamma_{1} = \gamma_{1}^{(k)}$ for this $k$. Repeat the process inductively using $T_{n}$ in place of $T$ to obtain a decreasing sequence $(T_{n})$ of triangles with boundary $\gamma_{n}$, with

$$\left| \int_{\gamma} f \right| \leq 4^{n} \left| \int_{\gamma_{n}} f \right|$$

for all $n$. We have that the diameter $d_{n}$ and perimeter $p_{n}$ of $T_{n}$ satisfy $d_{n} = 2^{-n}d$ and $p_{n} = 2^{-n}p$. We have that

$$\cap_{n}T_{n} = \{ z_{0} \}$$

for some $z_{0} \in T$.

Since $f$ is differentiable at $z_{0}$, for $z \in \Omega \setminus \{ z_{0} \}$ we may set

$$g(z) = \frac{f(z) - f(z_{0})}{z - z_{0}} - f'(z_{0}).$$

911
If we set $g(z_0) = 0$, then $g$ is continuous on $\Omega$ and we may write
\[
f(z) = f(z_0) + f'(z_0)(z - z_0) + g(z)(z - z_0)
\]
for $z \in \Omega$. Thus we have
\[
\int_{\gamma_n} f(\zeta) \, d\zeta = \int_{\gamma_n} f(z_0) \, d\zeta + \int_{\gamma_n} f'(z_0)(\zeta - z_0) \, d\zeta + \int_{\gamma_n} g(\zeta)(\zeta - z_0) \, d\zeta
\]
for any $n$. The first two integrals on the right are always zero since the integrands have antiderivatives on $\Omega$ (they are a constant function and a linear function respectively); thus for any $n$ we have
\[
\int_{\gamma_n} f(\zeta) \, d\zeta = \int_{\gamma_n} g(\zeta)(\zeta - z_0) \, d\zeta.
\]

Let $\epsilon > 0$. Choose $\delta > 0$ such that $|g(z)| < \epsilon$ whenever $|z - z_0| < \delta$. Then for any $n$ large enough that $d_n < \delta$, we have
\[
\left| \int_{\gamma_n} f(\zeta) \, d\zeta \right| = \left| \int_{\gamma_n} g(\zeta)(\zeta - z_0) \, d\zeta \right| \leq \epsilon d_n p_n.
\]
Combining the inequalities, for $n$ sufficiently large we have
\[
\left| \int_{\gamma} f \right| \leq \epsilon \left| \int_{\gamma_n} f \right| \leq 4^n \epsilon d_n p_n = \epsilon dp.
\]
Since $\epsilon > 0$ is arbitrary, we obtain $\int_{\gamma} f = 0$. \(\square\)

It will be convenient to have a technical strengthening of this theorem:

**X.3.1.2. COROLLARY.** Let $\Omega$ be an open set in $\mathbb{C}$, \{z$_1$, \ldots, z$_n$\} a finite set of points in $\Omega$, and $f$ a holomorphic function on $\Omega \setminus \{z_1, \ldots, z_n\}$. Suppose
\[
\lim_{z \to z_k} f(z)(z - z_k) = 0
\]
for $1 \leq k \leq n$. If $T$ is a (solid) triangle contained in $\Omega$, and the boundary $\gamma$ of $T$ (parametrized once around counterclockwise) contains no $z_k$, then
\[
\int_{\gamma} f = 0.
\]

**PROOF:** $T$ can be subdivided into smaller triangles, with some of the subtriangles $T_1, \ldots, T_m$ each containing exactly one of the $z_k$ in its interior, and the rest of the subtriangles contained in $\Omega \setminus \{z_1, \ldots, z_n\}$. Let $\gamma_j$ be the boundary of $T_j$ ($1 \leq j \leq m$). Then
\[
\int_{\gamma} f = \sum_{j=1}^{n} \int_{\gamma_j} f.
\]
since the integrals around the other triangles are 0 and all edges not part of \( \gamma \) or one of the \( \gamma_j \) are traversed once in each direction. Thus it suffices to show that \( \int_{\gamma_j} f = 0 \) for each \( j \), i.e. it suffices to show the result in the case where \( T \) contains exactly one \( z_k \) in its interior.

Changing notation, we assume \( z_j \) is the only \( z_k \) in the interior of \( T \). By a similar subdivision argument, the integral of \( f \) around any other triangle in \( \Omega \) containing only \( z_j \) in its interior is the same. Thus we may assume \( T \) has arbitrarily small diameter \( d \) and circumference \( p \).

Let \( \epsilon > 0 \), and choose \( > 0 \) such that \( |f(z)(z-z_j)| < \epsilon \) whenever \( 0 < |z-z_j| < \delta \). Choose \( T \) with \( p < \delta \) (and hence \( d < \delta \) also). If \( \zeta \in \gamma \), we then have \( |f(\zeta)| < \frac{\epsilon}{\delta} \). We then have

\[
\left| \int_{\gamma} f \right| \leq \frac{\epsilon}{\delta} d < \epsilon.
\]

Since the integral is independent of which \( T \) is chosen, and \( \epsilon > 0 \) is arbitrary, we have \( \int_{\gamma} f = 0 \).

X.3.2. The Antiderivative Theorem and Cauchy’s Theorem for Convex Sets

**X.3.2.1. Theorem.** [Antiderivative Theorem for Convex Sets] Let \( \Omega \) be a convex open set in \( \mathbb{C} \). Let \( f \) be a complex-valued continuous function on \( \Omega \). If

\[
\int_{\gamma} f = 0
\]

for every triangular contour \( \gamma \) in \( \Omega \), then \( f \) has an antiderivative on \( \Omega \): there is a holomorphic function \( F \) on \( \Omega \) with \( F' = f \) on \( \Omega \).

**Proof:** Fix \( z_0 \in \Omega \). For any \( z \in \Omega \), define

\[
F(z) = \int_{\gamma} f
\]

where \( \gamma \) is the straight line segment from \( z_0 \) to \( z \). If \( z \) and \( w \) are in \( \Omega \), then

\[
F(w) - F(z) = \int_{\gamma} f
\]

where \( \gamma \) is the straight line segment from \( z \) to \( w \), since the integral of \( f \) around the triangle with vertices \( z_0 \), \( z \), and \( w \) is 0 by assumption.

Now fix \( z \in \Omega \), and fix \( \eta > 0 \) such that \( B_{\eta}(z) \subseteq \Omega \). If \( h \in \mathbb{C} \), \( |h| < \eta \), then

\[
\frac{F(z+h) - F(z)}{h} = \frac{1}{h} \int_{\gamma_h} f
\]

where \( \gamma_h \) is the straight line segment from \( z \) to \( z+h \). We have

\[
\int_{\gamma_h} f(\zeta) d\zeta = \int_{\gamma_h} [f(\zeta) - f(z)] d\zeta + \int_{\gamma_h} f(z) d\zeta.
\]
The second integral is the contour integral of the constant function \( f(z) \) (\( z \) is fixed), hence equals \( f(z)h \).

Since \( f \) is continuous at \( z \), for any \( \epsilon > 0 \) there is a \( \delta > 0 \), \( \delta \leq \eta \), such that \( |f(\zeta) - f(z)| < \epsilon \) whenever \( |\zeta - z| < \delta \). Thus if \( |h| < \delta \), we have

\[
\left| \int_{\gamma_h} [f(\zeta) - f(z)] \, d\zeta \right| < \epsilon |h|.
\]

Thus

\[
\lim_{h \to 0} \frac{F(z + h) - F(z)}{h} = \lim_{h \to 0} \frac{1}{h} \int_{\gamma_n} f = \lim_{h \to 0} \frac{1}{h} \int_{\gamma_h} [f(\zeta) - f(z)] \, d\zeta + \lim_{h \to 0} \frac{1}{h} \int_{\gamma_h} f(z) \, d\zeta = f(z)
\]

since the first limit on the right is 0 and the second expression is exactly \( f(z) \) for all \( h \). Thus \( F'(z) \) exists and equals \( f(z) \) for any \( z \in \Omega \).

The proof actually shows the following slightly more general version:

**X.3.2.2. Theorem.** Let \( \Omega \) be a convex open set in \( \mathbb{C} \), \( \{z_1, \ldots, z_n\} \) a finite set of points in \( \Omega \), and \( f \) a continuous function on \( \Omega \setminus \{z_1, \ldots, z_n\} \). If

\[
\int_\gamma f = 0
\]

for every triangular contour \( \gamma \) in \( \Omega \) not passing through one of the \( z_k \), then \( f \) has an antiderivative on \( \Omega \setminus \{z_1, \ldots, z_n\} \): there is a holomorphic function \( F \) on \( \Omega \setminus \{z_1, \ldots, z_n\} \) with \( F' = f \) on \( \Omega \setminus \{z_1, \ldots, z_n\} \).

**Proof:** There are only a few slight modifications needed to the proof. Take \( z_0 \in \Omega \setminus \{z_1, \ldots, z_n\} \), and for \( z \in \Omega \setminus \{z_1, \ldots, z_n\} \) we take

\[
F(z) = \int_\gamma f
\]

where \( \gamma \) is a path from \( z_0 \) to \( z \) consisting of at most two line segments in \( \Omega \setminus \{z_1, \ldots, z_n\} \) (by hypothesis, \( F \) is well defined; such angled paths will sometimes be necessary since the straight line segment from \( z_0 \) to \( z \) may pass through a \( z_k \)). If \( z \in \Omega \setminus \{z_1, \ldots, z_n\} \), choose \( \eta > 0 \) such that \( B_\eta(z) \subseteq \Omega \setminus \{z_1, \ldots, z_n\} \). The rest of the proof is identical.

There is a version for general open sets, whose proof is essentially identical:

**X.3.2.3. Theorem.** [Antiderivative Theorem] Let \( \Omega \) be an open set in \( \mathbb{C} \). Let \( f \) be a complex-valued continuous function on \( \Omega \). If

\[
\int_\gamma f = 0
\]

for every closed contour \( \gamma \) in \( \Omega \), then \( f \) has an antiderivative on \( \Omega \): there is a holomorphic function \( F \) on \( \Omega \) with \( F' = f \) on \( \Omega \).

**Proof:** We may assume \( \Omega \) is connected since \( F \) may be defined separately on each component. Fix \( z_0 \in \Omega \), and for \( z \in \Omega \) define

\[
F(z) = \int_\gamma f
\]

914
where $\gamma$ is any contour in $\Omega$ from $z_0$ to $z$. If $\gamma_1$ and $\gamma_2$ are two such contours, then

$$\int_{\gamma_1} f - \int_{\gamma_2} f = \int_{\gamma_1 - \gamma_2} f = 0$$

by assumption, so $F$ is well defined. If $z$ and $w$ lie in a convex open subset of $\Omega$ (e.g. a small disk), then

$$F(w) - F(z) = \int_{\gamma} f$$

where $\gamma$ is the straight line segment from $z$ to $w$, since $F(w)$ can be calculated by taking a contour from $z_0$ to $z$ and appending this line segment.

The rest of the proof is identical to the proof of X.3.2.1.

The advantage of X.3.2.1. on convex sets is that only triangular contours need to be checked. Putting X.3.2.1. together with Goursat’s Theorem and (1), we obtain:

**X.3.2.4.** [Cauchy’s Theorem for Convex Sets] Let $\Omega$ be a convex open set in $\mathbb{C}$, and $f$ a holomorphic function on $\Omega$. Then $f$ has an antiderivative on $\Omega$, and if $\gamma$ is any piecewise-smooth closed curve in $\Omega$, then

$$\int_{\gamma} f = 0.$$  

**X.3.2.5.** Example. This result can fail if $\Omega$ is not convex. For example, let $\Omega = \mathbb{C} \setminus \{0\}$, and $f(z) = \frac{1}{z}$. Then $f$ is holomorphic on $\Omega$, but the integral of $f$ around the unit circle is nonzero (1) and $f$ does not have an antiderivative on $\Omega$ (i.e. $\log z$ cannot be defined as a holomorphic function on all of $\Omega$).

Cauchy’s Theorem is true if $\Omega$ is simply connected (1).

We do get a slight extension by using X.3.2.2. together with X.3.1.2.:

**X.3.2.6.** Theorem. Let $\Omega$ be a convex open set in $\mathbb{C}$, $\{z_1, \ldots, z_n\}$ a finite set of points in $\Omega$, and $f$ a holomorphic function on $\Omega \setminus \{z_1, \ldots, z_n\}$. Suppose

$$\lim_{z \to z_k} f(z)(z - z_k) = 0$$

for $1 \leq k \leq n$. Then $f$ has an antiderivative on $\Omega \setminus \{z_1, \ldots, z_n\}$, and if $\gamma$ is any piecewise-smooth closed curve in $\Omega \setminus \{z_1, \ldots, z_n\}$, then

$$\int_{\gamma} f = 0.$$  

The next result can be generalized using the general form of Cauchy’s Theorem, but this form is already very useful. Circles can be replaced by convex or, more generally, starlike polygonal arcs such as triangles or rectangles with the same proof (which even simplifies in this case).
X.3.2.7. Theorem. Let $f$ be holomorphic on an open set $\Omega$, and $\gamma_1$ and $\gamma_2$ circles in $\Omega$ (not necessarily concentric), parametrized once around counterclockwise, with $\gamma_2$ contained in the interior of $\gamma_1$. If the region between $\gamma_1$ and $\gamma_2$ is contained in $\Omega$, then

$$\int_{\gamma_1} f = \int_{\gamma_2} f.$$

Note that the integrals around $\gamma_1$ and $\gamma_2$ are not necessarily 0!

Proof: The inner circle $\gamma_2$ can be subdivided into arcs with consecutive endpoints $z_1, \ldots, z_n$ such that the line segments between pairs of consecutive points, and the region between the segment and the circle, are contained in $\Omega$ (cover the circle with finitely many open disks contained in $\Omega$). Thus, if radial line segments are drawn outward from each $z_k$ to $\gamma_1$, each wedge is contained in a convex open subset of $\Omega$, and hence the contour integral of $f$ around each, once around counterclockwise, is 0:

The sum of these integrals is

$$\int_{\gamma_1} f - \int_{\gamma_2} f$$

since each radial segment is traversed once in each direction, so those contour integrals cancel. Thus

$$\int_{\gamma_1} f - \int_{\gamma_2} f = 0.$$

X.3.3. The Cauchy Integral Formula

X.3.3.1. A remarkable consequence of the theorems obtained so far is that if a function $f$ is holomorphic on and inside a circle (or more general simple closed curve) $\gamma$, then the values of $f$ on $\gamma$ completely determine the values of $f$ at all points inside $\gamma$, and in fact there is a simple formula involving a contour integral.

X.3.3.2. Theorem. [Cauchy Integral Formula] Let $f$ be holomorphic on an open set $\Omega$ in $\mathbb{C}$. Then for each $z \in \Omega$ we have

$$f(z) = \frac{1}{2\pi i} \int_{\gamma} \frac{f(\zeta)}{\zeta - z} \, d\zeta,$$

where $\gamma$ is any circle in $\Omega$ bounding an open disk contained in $\Omega$ and containing $z$, parametrized once around counterclockwise.

Proof: Fix $z$ inside $\gamma$. If $\delta > 0$ is small enough that the circle $\gamma_\delta$ of radius $\delta$ centered at $z$ is in the interior of $\gamma$, we have

$$\int_{\gamma} \frac{f(\zeta)}{\zeta - z} \, d\zeta = \int_{\gamma_\delta} \frac{f(\zeta)}{\zeta - z} \, d\zeta,$$

by X.3.2.7. Thus it suffices to prove the result for the $\gamma_\delta$, in fact to show that

$$f(z) = \lim_{\delta \to 0} \frac{1}{2\pi i} \int_{\gamma_\delta} \frac{f(\zeta)}{\zeta - z} \, d\zeta.$$
Let $\epsilon > 0$. Since $f$ is continuous, if $\delta$ is sufficiently small then $|f(\zeta) - f(z)| < \epsilon$ for $\zeta \in \gamma_\delta$. We then have, for $\gamma_\delta$ inside $\gamma$,

$$\int_{\gamma_\delta} \frac{f(\zeta)}{\zeta - z} \, d\zeta = \int_{\gamma_\delta} \frac{f(\zeta) - f(z)}{\zeta - z} \, d\zeta + \int_{\gamma_\delta} \frac{f(z)}{\zeta - z} \, d\zeta .$$

If $\delta$ is small enough that $|f(\zeta) - f(z)| < \epsilon$ for $\zeta \in \gamma_\delta$, the first integral satisfies

$$\left| \int_{\gamma_\delta} \frac{f(\zeta) - f(z)}{\zeta - z} \, d\zeta \right| \leq \frac{\epsilon}{\delta} \cdot 2\pi \delta = 2\pi \epsilon$$

and thus the first integral approaches 0 as $\delta \to 0$. The second integral can be computed by taking $\zeta(t) = z + \delta e^{it}$, $0 \leq t \leq 2\pi$; thus

$$\int_{\gamma_\delta} \frac{f(z)}{\zeta - z} \, d\zeta = f(z) \int_{0}^{2\pi} \frac{1}{\delta e^{it}} i\delta e^{it} \, dt = 2\pi i f(z) .$$

An interesting reformulation is that if $D$ is a closed disk and $f$ is holomorphic on and inside $D$, then the value of $f$ at the center of the disk is the average of the values on the boundary circle:

**X.3.3.3. Corollary.** Let $f$ be holomorphic on an open set $\Omega$, and $D$ a closed disk in $\Omega$ of radius $r$, centered at $z_0$. Then

$$f(z_0) = \frac{1}{2\pi} \int_{0}^{2\pi} f(z_0 + r e^{it}) \, dt .$$

**Proof:** Parametrize the boundary circle by $\zeta(t) = z_0 + r e^{it}$, $0 \leq t \leq 2\pi$. Then

$$f(z_0) = \frac{1}{2\pi i} \int_{0}^{2\pi} \frac{f(z_0 + r e^{it})}{r e^{it}} i\delta e^{it} \, dt .$$

**The Cauchy Integral Formula for Derivatives**

**X.3.3.4.** We now obtain another remarkable consequence of the Cauchy Integral Formula. The integrand in the formula is a function of $z$ and $\zeta$; since we integrate with respect to $\zeta$, it should be possible to differentiate with respect to $z$ under the integral sign, in analogy with XIV.3.5.1., to obtain an integral formula for $f'$. In fact, since the integrand is infinitely differentiable in $z$, we could expect that the function defined by the integral, namely $f$, is also infinitely differentiable and all its derivatives are obtained by successive differentiation under the integral sign. This expectation is valid (X.3.3.6.). In fact, a more general result along the same lines holds, which is also useful for other purposes:
X.3.3.5. **Theorem.** Let $\gamma$ be a contour in $\mathbb{C}$ (not necessarily a closed contour), and $\phi$ a complex-valued continuous function on $\gamma$. For $z \in \mathbb{C} \setminus \gamma$, define

$$f(z) = \int_\gamma \frac{\phi(\zeta)}{\zeta - z} \, d\zeta.$$ 

Then $f$ is infinitely differentiable on $\mathbb{C} \setminus \gamma$, and for each $z \in \mathbb{C} \setminus \gamma$ and each $n$ we have

$$f^{(n)}(z) = n! \int_\gamma \frac{\phi(\zeta)}{(\zeta - z)^{n+1}} \, d\zeta.$$ 

**Proof:** By induction on $n$. The case $n = 0$ holds by assumption. Assume the result is true for $n - 1$, i.e. for any $z \in \mathbb{C} \setminus \gamma$,

$$f^{(n-1)}(z) = (n - 1)! \int_\gamma \frac{\phi(\zeta)}{(\zeta - z)^n} \, d\zeta.$$ 

Fix $z \in \mathbb{C} \setminus \gamma$, and fix $\delta > 0$ such that the closed disk of radius $\delta$ around $z$ is contained in $\mathbb{C} \setminus \gamma$. If $|h| < \delta$, then

$$\frac{f^{(n-1)}(z + h) - f^{(n-1)}(z)}{h} = (n - 1)! \int_\gamma \frac{\phi(\zeta)}{h} \left[ \frac{1}{(\zeta - z - h)^n} - \frac{1}{(\zeta - z)^n} \right] \, d\zeta.$$ 

Set

$$a = \frac{1}{\zeta - z - h}, \quad b = \frac{1}{\zeta - z}$$

and recall the formula

$$a^n - b^n = (a - b)(a^{n-1} + a^{n-2}b + \cdots + ab^{n-2} + b^{n-1})$$

(the second factor is 1 if $n = 1$). We have

$$a - b = \frac{1}{\zeta - z - h} - \frac{1}{\zeta - z} = \frac{h}{(\zeta - z - h)(\zeta - z)}$$

so we have

$$\frac{f^{(n-1)}(z + h) - f^{(n-1)}(z)}{h} = (n - 1)! \int_\gamma \frac{\phi(\zeta)}{(\zeta - z - h)(\zeta - z)} \left[ a^{n-1} + a^{n-2}b + \cdots + ab^{n-2} + b^{n-1} \right] \, d\zeta.$$ 

Since the disk of radius $\delta$ around $z$ is bounded away from $\gamma$, as $h \to 0$ we have that $\frac{1}{\zeta - z - h}$ converges uniformly in $\zeta$ to $\frac{1}{\zeta - z}$ on $\gamma$ (i.e. $a \to b$ uniformly on $\gamma$). Since the other factors $\phi(\zeta)$ and $\frac{1}{\zeta - z}$ are uniformly bounded on $\gamma$ and do not depend on $h$, as $h \to 0$ we have

$$\frac{\phi(\zeta)}{(\zeta - z - h)(\zeta - z)} \left[ a^{n-1} + a^{n-2}b + \cdots + ab^{n-2} + b^{n-1} \right] \to \frac{\phi(\zeta)}{(\zeta - z)^2} \cdot nb^{n-1} = n \cdot \frac{f(\zeta)}{(\zeta - z)^{n+1}}$$

uniformly in $\zeta$ on $\gamma$. Thus the integrals around $\gamma$ also converge. So

$$f^{(n)}(z) = \lim_{h \to 0} \frac{f^{(n-1)}(z + h) - f^{(n-1)}(z)}{h}$$

918
exists and equals
\[
\lim_{h \to 0} (n-1)! \int_{\gamma} \frac{\phi(\zeta)}{(\zeta - z - h)(\zeta - z)} \left[ a^{n-1} + a^{n-2}b + \cdots + ab^{n-2} + b^{n-1} \right] d\zeta = n! \int_{\gamma} \frac{\phi(\zeta)}{(\zeta - z)^{n+1}} d\zeta.
\]

**X.3.3.6. Corollary. [Cauchy Integral Formula for Derivatives]** Let \( f \) be holomorphic on an open set \( \Omega \) in \( \mathbb{C} \). Then \( f \) is infinitely differentiable on \( \Omega \), and for each \( z \in \Omega \) and each \( n \) we have
\[
f^{(n)}(z) = \frac{n!}{2\pi i} \int_{\gamma} \frac{f(\zeta)}{(\zeta - z)^{n+1}} d\zeta
\]
where \( \gamma \) is any circle in \( \Omega \) bounding an open disk \( D \) contained in \( \Omega \) and containing \( z \), parametrized once around counterclockwise.

**Proof:** For \( \zeta \in \gamma \), set \( \phi(\zeta) = \frac{f(\zeta)}{2\pi i} \). Then, for \( z \) inside \( \gamma \), by X.3.3.2.
\[
f(z) = \int_{\gamma} \frac{\phi(\zeta)}{\zeta - z} d\zeta.
\]

**X.3.3.7.** Note that in the special case of X.3.3.6., for \( \zeta \in \gamma \) we have that \( \phi(\zeta) \) is, up to a factor of \( 2\pi i \), the limit of \( f(z) \) as \( z \to \zeta \) from inside the circle. But in the general situation of X.3.3.5., there is no such simple relationship (for example, in the situation of X.3.3.6., the function defined by the integral is identically 0 outside \( \gamma \) by (i)). In fact, there is no way to recover \( \phi \) from \( f \) in general, although there is in many cases (i).

**Morera’s Theorem**

Morera’s Theorem is a converse to Cauchy’s Theorem:

**X.3.3.8. Theorem. [Morera’s Theorem]** Let \( \Omega \) be an open set in \( \mathbb{C} \), and \( f \) a complex-valued continuous function on \( \Omega \). If the contour integral of \( f \) around the boundary of every solid triangle contained in \( \Omega \) is zero, then \( f \) is holomorphic on \( \Omega \).

**Proof:** It suffices to show that \( f \) is holomorphic in every open disk contained in \( \Omega \), i.e. we may assume \( \Omega \) is a disk. Then \( f \) has an antiderivative \( F \) on \( \Omega \) by X.3.2.1.. But \( F \) is infinitely differentiable on \( \Omega \), hence so is \( F' = f \).

**Cauchy’s Inequalities**

Cauchy’s Inequalities are an immediate consequence of the Cauchy Integral Formula and the usual estimate for the size of a contour integral. They say that the higher derivatives of a holomorphic do not grow too rapidly at any point.
X.3.3.9. **Theorem.** [Cauchy’s Inequalities] Let $f$ be holomorphic on an open set $\Omega$ in $\mathbb{C}$, and $z_0 \in \Omega$. If the closed disk of radius $R$ centered at $z_0$ is contained in $\Omega$, then for all $n$

$$|f^{(n)}(z_0)| \leq \frac{n!}{R^n} \max_{|\zeta - z_0| = R} |f(\zeta)| .$$

Note that the quantity $\max_{|\zeta - z_0| = R} |f(\zeta)|$, the maximum of $|f|$ on the boundary circle, depends on $R$ but not on $n$.

**Liouville’s Theorem**

An immediate consequence of Cauchy’s Inequality for $n = 1$ is the following remarkable result:

X.3.3.10. **Theorem.** [Liouville’s Theorem] A bounded entire function is constant.

**Proof:** Let $f$ be a bounded entire function, and fix $M$ with $|f(z)| \leq M$ for all $z \in \mathbb{C}$. Fix $z_0 \in \mathbb{C}$. Then for any $R > 0$ we have

$$|f'(z_0)| \leq \frac{M}{R}$$

and thus $f'(z_0) = 0$. Since $z_0 \in \mathbb{C}$ is arbitrary, $f'$ is identically 0.

This can be used, among many other things, to give a proof of the Fundamental Theorem of Algebra (Exercise X.8.2.3.).

The result can be sharpened:

X.3.3.11. **Corollary.** Let $f$ be a nonconstant entire function. Then the range of $f$ is dense in $\mathbb{C}$.

**Proof:** Suppose the range is not dense. Then there is a $w \in \mathbb{C}$ and an $\epsilon > 0$ such that $|f(z) - w| \geq \epsilon$ for all $z \in \mathbb{C}$. Set

$$g(z) = \frac{1}{f(z) - w} .$$

Then $g$ is an entire function, and $|g(z)| \leq \frac{1}{\epsilon}$ for all $z$. Thus $g$, and hence $f$, is constant, a contradiction.

In fact, the following stronger result holds. See e.g. [] for a proof.

X.3.3.12. **Theorem.** [Little Picard Theorem] Let $f$ be an entire function. Then the range of $f$ is all of $\mathbb{C}$ except possibly one point.

This theorem is the best possible: $f(z) = e^z$ is never 0. See X.5.2.19. for the “Big Picard Theorem” which is an even stronger statement.
X.3.4. The Homotopy Theorem for Contour Integrals

Cauchy’s Theorem roughly states that the contour integral of a holomorphic function along a path \( \gamma \) depends only on the endpoints of \( \gamma \) and not on which path is chosen, or alternatively that the contour integral around a closed contour is 0. But this is not literally true in general ().

To prove, or even state, the general version of Cauchy’s Theorem, we will show that if \( f \) is a holomorphic function on a region \( \Omega \) and the path \( \gamma \) is “continuously deformed” within \( \Omega \) leaving the endpoints fixed, the contour integral along \( \gamma \) does not change. This will imply that the integral around any closed curve in \( \Omega \) which can be “continuously shrunk” to the initial point within \( \Omega \) is zero.

The careful formulation of a “continuous deformation” is a homotopy:

X.3.4.1. Definition. Let \( \Omega \) be an open set in \( \mathbb{C} \), \( p,q \in \Omega \). Let \( \gamma_0 \) and \( \gamma_1 \) be contours from \( p \) to \( q \) in \( \Omega \) with parametrizations \( \zeta_0(t), \zeta_1(t) \) defined on the same interval \([a,b]\). A homotopy from \( \gamma_0 \) to \( \gamma_1 \) in \( \Omega \) is a continuous function \( h : [0,1] \times [a,b] \to \Omega \) such that \( h(0,t) = \zeta_0(t) \) and \( h(1,t) = \zeta_1(t) \) for all \( t \in [a,b] \), and \( h(s,0) = p \) and \( h(s,1) = q \) for all \( s \in [0,1] \). We say \( \gamma_0 \) and \( \gamma_1 \) are homotopic (relative to \( p \) and \( q \) ) if there is a homotopy from \( \gamma_0 \) to \( \gamma_1 \).

Technically, what we have defined is a homotopy between the parametrizations \( \zeta_0 \) and \( \zeta_1 \) relative to \( p \) and \( q \), but by slight abuse of terminology we will call it a homotopy from \( \gamma_0 \) to \( \gamma_1 \).

X.3.4.2. If \( s \) is fixed, then \( \zeta_s(t) = h(s,t) \) defines a parametrized curve \( \gamma_s \) in \( \Omega \) from \( p \) to \( q \), and as \( s \) varies these curves “move continuously” from \( \gamma_0 \) to \( \gamma_1 \), and conversely if “continuous deformation” is defined reasonably, the function \( h(s,t) = \zeta_s(t) \) is a homotopy from \( \gamma_0 \) to \( \gamma_1 \). Thus \( \gamma_0 \) and \( \gamma_1 \) are homotopic in \( \Omega \) if and only if \( \gamma_0 \) can be “continuously deformed” to \( \gamma_1 \) within \( \Omega \).

X.3.4.3. A closed contour \( \gamma \) in an open set \( \Omega \subseteq \mathbb{C} \) is contractible in \( \Omega \) if it is homotopic in \( \Omega \) to a constant contour, i.e. if \( \gamma \) is parametrized by \( \zeta : [a,b] \to \mathbb{C} \) with \( \zeta(a) = \zeta(b) = p \), there is a continuous \( h : [0,1] \times [a,b] \to \Omega \) with \( h(0,t) = \zeta(t) \) and \( h(1,t) = h(1,0) \) for all \( t \) and \( h(s,0) = h(s,1) \) for all \( s \). If \( \gamma \) is contractible, there is such a homotopy with \( h(s,0) = h(s,1) = h(1,t) \) for all \( t \), i.e. the point \( p \) is fixed as the base point of each contour \( \gamma_s \).

X.3.4.4. Theorem. [Homotopy Theorem for Contour Integrals] Let \( f \) be holomorphic on an open set \( \Omega \), and \( p,q \in \Omega \). If \( \gamma_0 \) and \( \gamma_1 \) are homotopic contours in \( \Omega \) from \( p \) to \( q \), then

\[
\int_{\gamma_0} f = \int_{\gamma_1} f.
\]

Proof: We first give a simple argument which “almost” proves the theorem but which has a serious flaw. (This argument is represented as a proof of the theorem in some Complex Analysis texts.)

Suppose \( \zeta_0 \) and \( \zeta_1 \) are parametrizations of \( \gamma_0 \) and \( \gamma_1 \) on the same interval, which we may take to be \([0,1]\) to simplify notation, and \( h : [0,1]^2 \to \Omega \) a homotopy from \( \zeta_0 \) to \( \zeta_1 \) relative to \( p,q \). Fix partitions \( \mathcal{P} = \{0 = s_0, s_1, \ldots, s_m = 1\} \) and \( \mathcal{Q} = \{0 = t_0, t_1, \ldots, t_n = 1\} \) of \([0,1]\). For each \( j \) and \( k \) define the curvilinear “rectangle”

\[ R_{jk} = \{ h(s,t) : s_{j-1} \leq s \leq s_j, t_{k-1} \leq t \leq t_k \} \]
(this curvilinear “rectangle” is a curvilinear “triangle” if \( k = 1 \) or \( k = n \)). We have that the image of \( h \) is compact, so there is an \( \epsilon > 0 \) such that the ball of radius \( \epsilon \) around any point of the image of \( h \) is contained in \( \Omega \). Since \( h \) is uniformly continuous on \([0,1]^2\), there is a \( \delta > 0 \) such that \( |h(s',t') - h(s,t)| < \epsilon \) whenever \( s,s',t,t' \in [0,1] \), \( |s - s'| < \delta \), and \( |t - t'| < \delta \). Thus if \( P \) and \( Q \) are sufficiently fine, for each \( j \) and \( k \) the “rectangle” \( R_{jk} \) is contained within an open disk in \( \Omega \). So if we integrate \( f \) around the boundary curve \( \gamma_{jk} \) of \( R_{jk} \) obtained by setting \( s = s_{j-1} \) and letting \( t \) vary from \( t_{k-1} \) to \( t_k \), and similarly for the other edges, we have that

\[
\int_{\gamma_{jk}} f = 0
\]

by X.3.2.4. But

\[
\sum_{j,k} \int_{\gamma_{jk}} f = \int_{\gamma_0} f - \int_{\gamma_1} f
\]

since all the other edges are traversed once each direction, so those contour integrals cancel.

The problem with this argument is that while the \( \gamma_{jk} \) are continuous curves, they are not piecewise-smooth or even rectifiable in general, so \( \int_{\gamma_{jk}} f \) is not even defined in general. (In fact, this “curve” does not even have to look anything like an ordinary curve topologically; it is just a continuous image of \([0,1]\).) To make this proof work as written, the homotopy \( h \) must be “piecewise-smooth,” and it must be shown that homotopic piecewise-smooth contours are actually homotopic by a piecewise-smooth homotopy. This can be shown to be true (the argument below can be developed into a proof).

We will proceed differently, avoiding the difficulty by a trick (see [?], p. 338 for a different way around the problem). Choose the partitions and define the \( R_{jk} \) as above. However, replace \( \gamma_{jk} \) by the curve \( \tilde{\gamma}_{jk} \) consisting of the straight line segments from \( h(s_{j-1},t_{k-1}) \) to \( h(s_j,t_{k-1}) \), then to \( h(s_j,t_k) \), then to \( h(s_{j-1},t_k) \), then back to \( h(s_{j-1},t_{k-1}) \) (some of these line segments may be degenerate). If \( j = 1 \) or \( j = m \), one of the edge curves of \( R_{jk} \) is a piece of \( \gamma_0 \) or \( \gamma_1 \), and we use this piece in \( \tilde{\gamma}_{jk} \) instead of the straight line segment.

Note that since \( R_{jk} \) is contained in a disk in \( \Omega \), which is convex, these line segments are also contained in the same disk. Then for each \( j \) and \( k \), \( \tilde{\gamma}_{jk} \) is a piecewise-smooth closed contour contained in a disk inside \( \Omega \). We thus have

\[
\int_{\tilde{\gamma}_{jk}} f = 0
\]

by X.3.2.4. But

\[
\sum_{j,k} \int_{\tilde{\gamma}_{jk}} f = \int_{\gamma_0} f - \int_{\gamma_1} f
\]

since all the other edges are traversed once each direction, so those contour integrals cancel.

\[
\text{The Winding Number of a Closed Curve}
\]

If \( \gamma \) is a closed contour and \( z \) is a point of \( \mathbb{C} \) not on \( \gamma \), then intuitively \( \gamma \) “winds around \( z \)” some net number of times in the counterclockwise sense (this number can be zero or negative as well as positive). If \( \gamma \) is a circle parametrized once around counterclockwise, this winding number should be 1 if \( z \) is inside \( \gamma \) and 0 if \( z \) is outside. We can make this notion precise:
**X.3.4.5.** Proposition. Let $\gamma$ be a closed piecewise-smooth contour in $\mathbb{C}$, and $z$ a point of $\mathbb{C}$ not on $\gamma$. Then
\[ \int_{\gamma} \frac{1}{\zeta - z} \, d\zeta \]
is an integer multiple of $2\pi i$.

**Proof:** [Ahl78] Let $\zeta : [a, b] \to \mathbb{C}$ be a piecewise-smooth parametrization of $\gamma$ with $\zeta(a) = \zeta(b) = p$. Then
\[ \int_{\gamma} \frac{1}{\zeta - z} \, d\zeta = \int_{a}^{b} \frac{\zeta'(t)}{\zeta(t) - z} \, dt . \]
For $a \leq x \leq b$, set
\[ \phi(x) = \int_{a}^{x} \frac{\zeta'(t)}{\zeta(t) - z} \, dt . \]
Then $\phi$ is differentiable at $t$ and
\[ \phi'(t) = \frac{\zeta'(t)}{\zeta(t) - z} \]
whenever $a \leq t \leq b$ and $\zeta'$ is continuous at $t$, i.e. for all but possibly finitely many $t \in [a, b]$. The function
\[ \psi(t) = e^{-\phi(t)}(\zeta(t) - z) \]
is continuous on $[a, b]$, and satisfies
\[ \psi'(t) = -e^{-\phi(t)}\phi'(t)(\zeta(t) - z) + e^{-\phi(t)}\zeta'(t) = 0 \]
whenever $\zeta'$ is continuous. Thus $\psi$ is constant on $[a, b]$. We have $\psi(a) = p - z$, so
\[ e^{\phi(t)} = \frac{\zeta(t) - z}{p - z} \]
for $a \leq t \leq b$. We have $e^{\phi(b)} = 1$, so $\phi(b) = 2\pi in$ for some $n \in \mathbb{Z}$. \hfill \(\Box\)

**X.3.4.6.** Definition. Let $\gamma$ be a closed piecewise-smooth contour in $\mathbb{C}$, and $z \in \mathbb{C} \setminus \gamma$. The **winding number** of $\gamma$ around $z$ is
\[ w(\gamma, z) = \frac{1}{2\pi i} \int_{\gamma} \frac{1}{\zeta - z} \, d\zeta . \]

By X.3.4.5., $w(\gamma, z)$ is an integer.

**X.3.4.7.** Proposition. Fix a closed piecewise-smooth contour $\gamma$. The function $\omega(z) = w(\gamma, z)$ is constant on connected components of $\mathbb{C} \setminus \gamma$ and is zero on the unbounded component.

**Proof:** The function $\omega$ is clearly a continuous function of $z$, and
\[ \lim_{z \to \infty} |\omega(z)| = 0 . \]
Since $\omega$ takes only integer values, the result follows. \hfill \(\Box\)
There is another interpretation of $w(\gamma, z)$. Let $T$ be the unit circle in $\mathbb{C}$. Given a parametrization $\zeta$ of $\gamma$, which we may assume is on $[0, 1]$, define

$$\tilde{\gamma}(t) = \frac{\zeta(t) - z}{|\zeta(t) - z|}$$

(this closed contour is essentially the radial projection of $\gamma$ onto a circle centered at $z$, translated to 0). Then $\tilde{\gamma}$ is a loop in $T$ as defined in (), and $w(\gamma, z)$ is precisely the index of this loop.

If $\gamma_0$ and $\gamma_1$ are closed contours not passing through $z$, and $\gamma_0$ and $\gamma_1$ are homotopic in $\mathbb{C} \setminus \{z\}$ (not necessarily with endpoint fixed), then the corresponding loops $\tilde{\gamma}_0$ and $\tilde{\gamma}_1$ are homotopic as loops in $T$. Thus their indices are the same (). So we obtain:

**Proposition.** If $\gamma_0$ and $\gamma_1$ are closed contours not passing through $z$, and $\gamma_0$ and $\gamma_1$ are homotopic in $\mathbb{C} \setminus \{z\}$ (not necessarily with endpoint fixed), then

$$w(\gamma_0, z) = w(\gamma_1, z).$$

We may restate the Cauchy Integral Formula:

**Theorem.** Let $f$ be holomorphic on a convex open set $\Omega$, $\gamma$ a closed piecewise-smooth contour in $\Omega$, and $z \in \Omega$ not on $\gamma$. Then

$$f(z)w(\gamma, z) = \frac{1}{2\pi i} \int_{\gamma} \frac{f(\zeta)}{\zeta - z} \, d\zeta.$$

**Homology of Contours**

There is another useful relation on closed contours called *homology*, which is closely related to homotopy (and in fact slightly more general). Although we will primarily use this notion for closed contours, it is convenient to define it more generally for cycles:

**Definition.** Let $\Omega$ be an open set in $\mathbb{C}$. Two cycles $\gamma_0$ and $\gamma_1$ in $\Omega$ are *homologous in $\Omega$* if $w(\gamma_0, z) = w(\gamma_1, z)$ for all $z \in \mathbb{C} \setminus \Omega$. A cycle $\gamma$ is *homologous to zero in $\Omega$* if $w(\gamma, z) = 0$ for all $z \in \mathbb{C} \setminus \Omega$.

The notion of homology of cycles depends on $\Omega$. Indeed, every cycle is homologous to zero in $\mathbb{C}$. Cycles $\gamma_0$ and $\gamma_1$ in $\Omega$ are homologous in $\Omega$ if and only if $\gamma_1 - \gamma_0$ is homologous to zero in $\Omega$. If $\gamma_0$ is homologous to zero in $\Omega$, so is $-\gamma_0$; and $\gamma_0 + \gamma_1$ is homologous to $\gamma_1$ in $\Omega$ for any cycle $\gamma_1$ in $\Omega$. If $\gamma_1, \check{\gamma}_1, \check{\gamma}_2$, and $\check{\gamma}_2$ are cycles in $\Omega$, and $\gamma_j$ and $\check{\gamma}_j$ are homologous in $\Omega$ for $j = 1, 2$, then $\gamma_1 + \gamma_2$ and $\check{\gamma}_1 + \check{\gamma}_2$ are homologous in $\Omega$.
X.3.5.3. If two closed contours $\gamma_0$ and $\gamma_1$ in $\Omega$ are homotopic in $\Omega$, then it follows immediately from X.3.4.10. that $\gamma_0$ and $\gamma_1$ are homologous in $\Omega$. In particular, if $\gamma$ is contractible in $\Omega$, then $\gamma$ is homologous to zero in $\Omega$. The following example shows that the converse is false in general:

X.3.5.4. Example. Let $\Omega = \mathbb{C} \setminus \{-1, 1\}$. Let $C_1$ be the circle of radius 1 centered at 1, and $C_{-1}$ the circle of radius 1 centered at $-1$. Let $\gamma_1$ be the circle $C_1$ parametrized once around counterclockwise starting at 0, and $\gamma_2$ the circle $C_{-1}$ parametrized once around counterclockwise starting at 0. Set

$$\gamma = \gamma_1 + \gamma_2 - \gamma_1 - \gamma_2 .$$

Then $\gamma$ is a piecewise-smooth closed contour in $\Omega$, and it is easily checked that $\gamma$ is homologous to zero in $\Omega$. However, $\gamma$ is not contractible in $\Omega$; this fact, while fairly evident intuitively, is not so easy to prove rigorously (see [?, p. 356-358] for a nice proof).

This example shows that addition of closed contours is not commutative up to homotopy. In fact, the closed contours $\gamma_1 + \gamma_2$ and $\gamma_2 + \gamma_1$ are not homotopic in $\Omega$.

The underlying reason for this example is that the fundamental group $\pi_1(\Omega)$ is not abelian. In fact, it is a free group generated by the classes $[\gamma_1]$ and $[\gamma_2]$.

X.3.6. Cauchy’s Theorem, General Versions

The first general version of Cauchy’s Theorem is an immediate corollary of X.3.4.4:

X.3.6.1. Corollary. [Cauchy’s Theorem, Version 1] Let $f$ be holomorphic on an open set $\Omega$, and $\gamma$ a closed contour in $\Omega$ which is contractible in $\Omega$. Then

$$\int_{\gamma} f = 0 .$$

Using the Jordan-Schönflies Theorem, it can be shown that if $\gamma$ is a simple closed contour in $\Omega$ whose interior is also in $\Omega$, then $\gamma$ is contractible in $\Omega$. Thus we obtain another standard version of Cauchy’s Theorem:

X.3.6.2. Corollary. [Cauchy’s Theorem, Version 2] Let $f$ be holomorphic on an open set $\Omega$, and $\gamma$ a simple closed contour in $\Omega$ whose interior is also in $\Omega$. Then

$$\int_{\gamma} f = 0 .$$

X.3.6.3. Definition. An open set $\Omega$ in $\mathbb{C}$ is simply connected if it is connected and every closed contour in $\Omega$ is contractible in $\Omega$.

The same definition works (path-connectedness is required in general, not just connectedness), and is important, in a general topological space.
Informally, a connected open set is simply connected if it has no “holes.” In particular, any convex or star-shaped open set is simply connected, as is $\mathbb{C}$ with a branch cut removed (this set is actually star-shaped). But a plane or open disk with a point removed, or an annulus, is not simply connected. Any set homeomorphic to a simply connected open set is simply connected (and open).

For open sets in the plane, there are many equivalent characterizations of simple connectedness, such as the following (there are many more):

**X.3.6.5. THEOREM.** Let $\Omega$ be a connected open set in the plane. The following are equivalent:

(i) $\Omega$ is simply connected.

(ii) Whenever $\gamma$ is a simple closed contour in $\Omega$, the interior of $\gamma$ is also contained in $\Omega$.

(iii) Whenever $\gamma$ is a closed contour in $\Omega$, the winding number $\text{w}_\gamma$ of $\gamma$ around any point of $\mathbb{C} \setminus \Omega$ is 0.

If $\Omega$ is bounded, these are also equivalent to

(iv) The boundary $\partial \Omega$ is connected.

(v) The complement $\mathbb{C} \setminus \Omega$ is connected.

Condition (iii) may be rephrased:

(iii') Every cycle in $\Omega$ is homologous to zero in $\Omega$.

**X.3.6.6.** If $\Omega$ is unbounded, (iv) and (v) are still equivalent and imply (i)–(iii), but not conversely in general: consider a horizontal strip in $\mathbb{C}$. (If we work in the Riemann Sphere, the one-point compactification of $\mathbb{C}$, (i)–(v) are equivalent even if $\Omega$ is unbounded.) Also, (ii)–(v) can hold if $\Omega$ is not connected: consider a figure 8. It is not true that if $\Omega$ is simply connected, then the interior of the complement of $\Omega$ is necessarily connected, e.g. if $\Omega$ is one of the Lakes of Wada (). This example shows that simply connected open sets in $\mathbb{C}$ can be quite complicated. However, it is a (deep) theorem that every nonempty simply connected open set in $\mathbb{C}$ is homeomorphic to a disk (or, equivalently, to $\mathbb{C}$ itself). In fact, much more is true: every nonempty simply connected open proper subset of $\mathbb{C}$ is conformally equivalent to the open unit disk by the Riemann Mapping Theorem ( ).

We then get the most commonly stated version of Cauchy’s Theorem:

**X.3.6.7. COROLLARY. [CAUCHY’S THEOREM, SIMPLY CONNECTED VERSION]** Let $f$ be holomorphic on a simply connected open set $\Omega$. Then $f$ has an antiderivative on $\Omega$, and if $\gamma$ is any closed contour in $\Omega$, then

$$\int_\gamma f = 0.$$ 

The most general version of Cauchy’s Theorem which can be reasonably stated is:
**X.3.6.8. Theorem.** [Cauchy’s Theorem, Homology Version] Let $f$ be holomorphic on an open set $\Omega$. Then

$$\int_{\gamma} f = 0$$

for every cycle $\gamma$ in $\Omega$ homologous to zero in $\Omega$.

This version is somewhat complicated to prove rigorously. See e.g. [Ahl78] or [?].

We get as a special case a general version of **X.3.2.7.**:

**X.3.6.9. Corollary.** Let $f$ be holomorphic on an open set $\Omega$, and $\gamma_1$ and $\gamma_2$ simple closed contours in $\Omega$, parametrized once around counterclockwise, with $\gamma_2$ contained in the interior of $\gamma_1$. If the region between $\gamma_1$ and $\gamma_2$ is contained in $\Omega$, then

$$\int_{\gamma_1} f = \int_{\gamma_2} f .$$

**Proof:** It is easily checked that $\gamma_1 - \gamma_2$ is homologous to zero in $\Omega$.

Note that the integrals around $\gamma_1$ and $\gamma_2$ are not necessarily 0!

**X.3.7. The Cauchy Integral Formula, General Versions**

927
X.4. Sequences and Series of Holomorphic Functions; Analytic Functions

In this section, we show the remarkable fact that holomorphic functions can be expanded in power series around any point in the domain.

X.4.1. Sequences and Series of Holomorphic Functions

We begin by establishing some general results about sequences and series of holomorphic functions.

X.4.1.1. In complex analysis, u.c. convergence (IV.3.2.1) of sequences of holomorphic functions on an open set in \( \mathbb{C} \) is usually called normal convergence.

The first result is an immediate corollary of Cauchy’s Theorem and Morera’s Theorem:

X.4.1.2. Proposition. Let \( \Omega \) be an open set in \( \mathbb{C} \), and \((f_n)\) a sequence of functions from \( \Omega \) to \( \mathbb{C} \) converging normally on \( \Omega \) to a function \( f \). If each \( f_n \) is holomorphic on \( \Omega \), then \( f \) is also holomorphic on \( \Omega \).

Proof: It suffices to show that \( f \) is holomorphic on each open disk contained in \( \Omega \); so we may assume \( \Omega \) is a disk. If \( \gamma \) is any closed contour in \( \Omega \), then

\[
\int_{\gamma} f_n \to \int_{\gamma} f
\]

by (\( \ast \)). But \( \int_{\gamma} f_n = 0 \) for all \( n \) by Cauchy’s Theorem for Convex Sets (X.3.2.4.), so \( \int_{\gamma} f = 0 \). This is true for every \( \gamma \), so \( f \) is holomorphic by Morera’s Theorem.

X.4.1.3. This is one more surprising property of holomorphic functions. The real analog of this statement fails spectacularly: any continuous function on a closed bounded interval, even one not differentiable anywhere (\( \ast \)), is a uniform limit of polynomials.

Actually, the situation is even nicer for holomorphic functions, again in stark contrast to the real case (\( \ast \)):

X.4.1.4. Theorem. Let \( \Omega \) be an open set in \( \mathbb{C} \), and \((f_n)\) a sequence of functions from \( \Omega \) to \( \mathbb{C} \) converging normally on \( \Omega \) to a function \( f \). If each \( f_n \) is holomorphic on \( \Omega \), then \( f \) is also holomorphic on \( \Omega \), and \( f'_n \to f' \) normally on \( \Omega \).

In this result, normal convergence cannot be replaced by uniform convergence in general: even if \( f_n \to f \) uniformly on \( \Omega \), \( f'_n \) does not converge uniformly on \( \Omega \) to \( f' \) in general, only u.c. (Exercise X.8.2.2.).

Proof: This is a fairly easy, although slightly delicate, consequence of the Cauchy Integral Formula for derivatives (X.3.3.6.); the argument also gives another proof of X.4.1.2. By IV.3.2.5., it suffices to show that for any \( z_0 \in \Omega \), there is an open disk \( D \) centered at \( z_0 \) and contained in \( \Omega \) on which \( f \) is holomorphic and such that \( f'_n \to f' \) uniformly on \( D \). In fact, let \( D \) be any open disk centered at \( z_0 \) whose closure \( \overline{D} \) is contained in \( \Omega \) (there is always such a disk for any \( z_0 \in \Omega \)). Let \( R \) be the radius of \( D \). For sufficiently small
δ > 0, the closed disk of radius R + δ around z₀ is contained in Ω. Fix such a δ, and let γ be the circle centered at z₀ of radius R + δ, parametrized once around counterclockwise. For \( z \in \mathbb{C} \setminus \gamma \), set

\[
g(z) = \frac{1}{2\pi i} \int_{\gamma} \frac{f(\zeta)}{\zeta - z} \, d\zeta
\]

and note that g is holomorphic on \( C \setminus \gamma \) by X.3.3.5. By the Cauchy Integral Formula, if z is inside γ,

\[
f_n(z) = \frac{1}{2\pi i} \int_{\gamma} \frac{f_n(\zeta)}{\zeta - z} \, d\zeta
\]

for each n. We have that \( f_n \to f \) uniformly on γ. As \( n \to \infty \), the sequence

\[
\frac{f_n(\zeta)}{\zeta - z}
\]

converges uniformly on γ (for fixed \( z \) inside γ) to

\[
\frac{f(\zeta)}{\zeta - z}
\]

since the numerators converge uniformly and the absolute value of the denominator is always \( \geq \delta \). Thus we have

\[
f_n(z) = \frac{1}{2\pi i} \int_{\gamma} f_n(\zeta) \, d\zeta \to \frac{1}{2\pi i} \int_{\gamma} f(\zeta) \, d\zeta = g(z)
\]

and since \( f_n \to f \) pointwise on Ω, we conclude that \( f(z) = g(z) \) for all z inside γ, and \( f \) is holomorphic on \( D \). Since \( z_0 \) and \( D \) are arbitrary, \( f \) is holomorphic on Ω.

By a similar but slightly more delicate argument, if \( z_0, D, \) and \( \gamma \) are as above, we have that

\[
\frac{f_n(\zeta)}{\zeta - z} \to \frac{f(\zeta)}{\zeta - z} \quad \text{uniformly for } \zeta \in \gamma \text{ and } z \in \bar{D},
\]

since the numerators converge uniformly and the absolute value of the denominator is always \( \geq \delta^2 \), i.e. for any \( \epsilon > 0 \) there is an \( N \) such that

\[
\left| \frac{f_n(\zeta)}{(\zeta - z)^2} - \frac{f(\zeta)}{(\zeta - z)^2} \right| < \epsilon
\]

for all \( n \geq N \) and all \( \zeta \in \gamma \) and \( z \in \bar{D} \). Thus, for \( z \in \bar{D} \),

\[
f_n(z) = \frac{1}{2\pi i} \int_{\gamma} \frac{f_n(\zeta)}{(\zeta - z)^2} \, d\zeta \to \frac{1}{2\pi i} \int_{\gamma} \frac{f(\zeta)}{(\zeta - z)^2} \, d\zeta = f'(z)
\]

uniformly on \( \bar{D} \) by the Cauchy Integral Formula for derivatives.

X.4.1.5. The proof of this theorem is a bit delicate. However, the “converse,” the complex analog of V.8.5.5., is simpler:
X.4.1.6. THEOREM. Let \( \Omega \) be a connected open set in \( \mathbb{C} \), and \((f_n)\) a sequence of functions from \( \Omega \) to \( \mathbb{C} \). If

1. Each \( f_n \) is holomorphic on \( \Omega \).
2. The sequence \((f'_n)\) converges normally on \( \Omega \) to a function \( g \).
3. There is a \( z_0 \in \Omega \) such that the sequence \((f_n(z_0))\) converges.

Then the sequence \((f_n)\) converges normally on \( \Omega \) to a function \( f \); \( f \) is holomorphic on \( \Omega \), and \( f' = g \) on \( \Omega \).

PROOF: The proof of V.8.5.5. uses the Mean Value Theorem, which is unavailable in \( \mathbb{C} \). However, we may mimic the simpler proof of the special case \((f)\). We first show that \((f_n)\) converges uniformly on a neighborhood of \( z_0 \) (in fact, on any closed disk centered at \( z_0 \) contained in \( \Omega \)) to an antiderivative for \( g \). Fix a closed disk \( D \) of radius \( r \) centered at \( z_0 \) and contained in \( \Omega \). Suppose \( f_n(z_0) \to c \). If \( z \in D \), let \( \gamma_z \) be the line segment from \( z_0 \) to \( z \). Then

\[
\int_{\gamma_z} f'_n = f_n(z) - f_n(z_0)
\]

for any \( n \) by \((f)\); and if we define

\[
f(z) = c + \int_{\gamma_z} g
\]

then \( f' = g \) on the interior of \( D \). For any \( \epsilon > 0 \) there is an \( N \) such that, for all \( n \geq N \), \(|f'_n(z) - g(z)| < \frac{\epsilon}{2r}\) for all \( z \in D \) and \(|f_n(z_0) - c| < \frac{\epsilon}{2r}\). Then, for \( n \geq N \) and \( z \in D \),

\[
|f_n(z) - f(z)| = |f_n(z_0) + \int_{\gamma_z} f'_n - c - \int_{\gamma_z} g| \leq |f_n(z_0) - c| + \left| \int_{\gamma_z} (f'_n - g) \right| < \frac{\epsilon}{2} + \frac{\epsilon}{2r}r = \epsilon.
\]

Thus \( f_n \to f \) uniformly on \( D \).

Now let \( U \) be the set of all \( z \in \Omega \) such that \((f_n)\) converges uniformly to an antiderivative for \( g \) on a neighborhood of \( z \). Then \( U \) is obviously open, and \( z_0 \in U \). If \( w \in U \), then \((f_n)\) converges uniformly on any closed disk centered at \( w \) contained in \( U \) to an antiderivative for \( g \) by the first part of the proof (with \( w \) in place of \( z_0 \)). If \( w \in \Omega \) is in the closure of \( U \), there is a sequence \((z_n)\) in \( U \) with \( z_n \to z \). There is an \( \epsilon > 0 \) such that the disk of radius \( \epsilon \) around \( w \) is contained in \( \Omega \). Fix \( n \) with \(|z_n - w| < \frac{\epsilon}{2}\); then the closed disk around \( z_n \) of radius \( \frac{\epsilon}{2} \) is contained in \( \Omega \), and is a neighborhood of \( w \) on which \((f_n)\) converges uniformly to an antiderivative for \( g \). Thus \( w \in U \). So \( U \) is relatively closed in \( \Omega \), and since \( \Omega \) is connected, \( U = \Omega \). Thus \((f_n)\) converges uniformly to an antiderivative for \( g \) on any closed disk contained in \( \Omega \); so \((f_n)\) converges pointwise on \( \Omega \) to a function \( f \) which is an antiderivative for \( g \). Since any compact subset of \( \Omega \) is contained in a finite union of closed disks in \( \Omega \), \( f_n \to f \) u.c. on \( \Omega \).

As usual, the sequence results have series versions, proved by applying the sequence results to the partial sums:
X.4.1.7. PROPOSITION. Let \( \Omega \) be an open set in \( \mathbb{C} \), and

\[ \sum_{k=1}^{\infty} f_k \]

an infinite series of functions from \( \Omega \) to \( \mathbb{C} \) converging normally on \( \Omega \) to a function \( f \). If each \( f_n \) is holomorphic on \( \Omega \), then \( f \) is also holomorphic on \( \Omega \).

X.4.1.8. THEOREM. Let \( \Omega \) be an open set in \( \mathbb{C} \), and

\[ \sum_{k=1}^{\infty} f_k \]

an infinite series of functions from \( \Omega \) to \( \mathbb{C} \) converging normally on \( \Omega \) to a function \( f \). If each \( f_n \) is holomorphic on \( \Omega \), then \( f \) is also holomorphic on \( \Omega \), and

\[ \sum_{k=1}^{\infty} f_k' \]

converges normally to \( f' \) on \( \Omega \).

X.4.1.9. THEOREM. Let \( \Omega \) be a connected open set in \( \mathbb{C} \), and

\[ \sum_{k=1}^{\infty} f_k \]

an infinite series of functions from \( \Omega \) to \( \mathbb{C} \). If

1. Each \( f_k \) is holomorphic on \( \Omega \).
2. The infinite series

\[ \sum_{k=1}^{\infty} f_k' \]

converges normally on \( \Omega \) to a function \( g \).
3. There is a \( z_0 \in \Omega \) such that the series

\[ \sum_{k=1}^{\infty} f_k(z_0) \]

converges.

Then the infinite series

\[ \sum_{k=1}^{\infty} f_k \]

converges normally on \( \Omega \) to a function \( f \); \( f \) is holomorphic on \( \Omega \), and \( f' = g \) on \( \Omega \).
X.4.2. Power Series

We recall some of the important general facts about power series from V.15.3. in the complex case.

X.4.2.1. Definition. If \( z \) is a complex number, a (complex) power series centered at \( z_0 \) is an expression of the form

\[
\sum_{k=0}^{\infty} a_k (z - z_0)^k
\]

where the \( a_k \) are complex numbers.

X.4.2.2. A power series is regarded as an infinite series of functions. It is conventional when working with power series to regard \((z - z_0)^0 = 1\) no matter how \( z - z_0 \) is interpreted; thus the \( k = 0 \) term of the power series is just the constant function \( a_0 \).

X.4.2.3. A power series is, at first, only a formal expression, but it can be regarded as defining a function \( f \) of \( z \), whose domain is the set of all \( z \) for which the series converges. Because of our convention, \( z_0 \) is always in the domain of the defined function \( f \), with \( f(z_0) = a_0 \). It can happen that the domain of \( f \) consists only of \( \{z_0\} \) (such power series are not very interesting as functions).

The most important basic property of power series is X.4.2.5., which says that the domain of the defined function is a disk, or degenerate disk, centered at \( z_0 \).

X.4.2.4. Definition. Let \( \sum_{k=0}^{\infty} a_k (z - z_0)^k \) be a power series, and define

\[
L = \limsup_{k \to \infty} |a_k|^{1/k} = \limsup_{k \to \infty} \sqrt[k]{|a_k|}
\]

and let \( R = \frac{1}{L} \) if \( 0 < L < +\infty \), \( R = 0 \) if \( L = +\infty \), and \( R = +\infty \) if \( L = 0 \). \( R \) is called the radius of convergence of the power series.

Note that the radius of convergence of a power series depends only on the coefficients \( a_k \), not on the center \( z_0 \), of the power series. The slower the coefficients grow in size, or the faster they approach zero, the larger the radius of convergence.

The term “radius of convergence” is justified by the next result:

X.4.2.5. Theorem. Let \( \sum_{k=0}^{\infty} a_k (z - z_0)^k \) be a power series, with radius of convergence \( R \). Then

(i) If \( z \in \mathbb{C} \) and \( |z - z_0| < R \), then the series \( \sum_{k=0}^{\infty} a_k (z - z_0)^k \) converges absolutely.

(ii) If \( z \in \mathbb{C} \) and \( |z - z_0| > R \), then the series \( \sum_{k=0}^{\infty} a_k (z - z_0)^k \) diverges.
(iii) If \( r \in \mathbb{R} \) and \( 0 < r < R \), then the series \( \sum_{k=0}^{\infty} a_k(z - z_0)^k \) converges uniformly on the closed disk \( \{z : |z - z_0| \leq r\} \).
(Of course, (i) and (iii) are vacuous if \( R = 0 \) and (ii) is vacuous if \( R = +\infty \).)

**Proof:** In cases (i) and (ii), apply the Root Test (\( \star \)) to the series \( \sum_{k=0}^{\infty} |a_k(z - z_0)^k| \). We have

\[
\limsup |a_k(z - z_0)^k|^{1/k} = |z - z_0| \limsup |a_k|^{1/k} = \frac{|z - z_0|}{R}
\]

(it is \( +\infty \) if \( z \neq z_0 \) and \( R = 0 \), and 0 if \( R = +\infty \) or \( z = z_0 \)). Thus the series converges absolutely if \( |z - z_0| < R \) or \( z = z_0 \) and diverges since the terms do not go to zero if \( |z - z_0| > R \).

For (iii), use the Weierstrass M-test (\( \star \)). Set \( M_k = |a_k|r^k \). Then \( |a_k(z - z_0)^k| \leq M_k \) for all \( k \) and for all \( x \), \( |z - z_0| \leq r \). We have

\[
\limsup M_k^{1/k} = r \limsup |a_k|^{1/k} = \frac{r}{R} < 1
\]

if \( 0 < R < \infty \), and \( \limsup M_k^{1/k} = 0 \) if \( R = +\infty \). Thus \( \sum_{k=0}^{\infty} M_k \) converges by the Root Test. \( \star \)

**X.4.2.6.** Thus the set on which a power series centered at \( z_0 \) converges is a disk centered at \( z_0 \), possibly of radius zero, i.e. the degenerate disk \( \{z_0\} \), or of infinite radius, i.e. all of \( \mathbb{C} \), possibly including some or all of the points on the boundary, called the **disk of convergence** of the power series.

**X.4.2.7.** Convergence behavior of a complex series on the boundary circle of the disk of convergence is quite subtle. The series can diverge everywhere on this circle (e.g. \( \sum_{k=0}^{\infty} (z - z_0)^k \)) or it can converge absolutely at all points of the circle (e.g. \( \sum_{k=1}^{\infty} \frac{1}{k^2} (z - z_0)^k \)), or it can converge conditionally on some subset \( S \) of the boundary circle. But \( S \) cannot be an arbitrary subset of the circle (it must be an \( F_{\sigma\delta} \) (\( \star \)), and not even all of these occur; see [Kör83]). The study of boundary behavior of analytic functions is a big topic in complex analysis, with important applications.

For the purposes of basic complex analysis, however, we want to restrict attention to open sets, so we generally consider only the **open disk of convergence** \( \{z : |z - z_0| < R\} \) (provided \( R > 0 \)).

Combining X.4.2.5. with X.4.1.7., we obtain:

**X.4.2.8.** **Corollary.** Let \( \sum_{k=0}^{\infty} a_k(z - z_0)^k \) be a power series, with radius of convergence \( R > 0 \). Then the series converges normally on the open disk of convergence, and the sum is holomorphic on this disk.

Using X.4.1.8., we can extend this:
**X.4.2.9. Corollary.** Let $\sum_{k=0}^{\infty} a_k (z - z_0)^k$ be a power series, with radius of convergence $R > 0$. Then the series converges normally on the open disk of convergence $\{ z : |z - z_0| < R \}$, and the sum $f$ is holomorphic on this disk. The power series

$$\sum_{k=1}^{\infty} k a_k (z - z_0)^{k-1}$$

of term-by-term derivatives converges normally on $\{ z : |z - z_0| < R \}$ to $f'$.

This can be also be proved by noting that the derived series has the same radius of convergence as the original series (V.15.3.21.) and applying X.4.1.9.

By iterating, we obtain, for each $n$, that the $n$’th derived power series

$$\sum_{k=n}^{\infty} k(k-1) \cdots (k-n+1) a_k (z - z_0)^{k-n} = \sum_{k=n}^{\infty} \frac{k!}{(k-n)!} a_k (z - z_0)^{k-n}$$

converges u.c. to $f^{(n)}$ on $\{ z : |z - z_0| < R \}$.

The coefficients $a_k$ are thus uniquely determined by the function $f$ defined by the power series:

**X.4.2.10. Corollary.** Let $\sum_{k=0}^{\infty} a_k (z - z_0)^k$ be a power series, with radius of convergence $R > 0$, and let $f$ be the holomorphic function defined by the series on the open disk of convergence. Then, for any $n \geq 0$,

$$a_n = \frac{f^{(n)}(z_0)}{n!}.$$ 

The coefficients $a_k$ can also be computed by contour integration:

**X.4.2.11. Proposition.** Let $\sum_{k=0}^{\infty} a_k (z - z_0)^k$ be a power series with radius of convergence $R > 0$, and $f$ the function defined by the series on $\{ z : |z - z_0| < R \}$. Then, for any $k \geq 0$,

$$a_k = \frac{1}{2\pi i} \int_{\gamma} \frac{f(\zeta)}{(\zeta - z_0)^{k+1}} d\zeta$$

where $\gamma$ is any circle centered at $z_0$ of radius less than $R$.

**Proof:** By (), we have

$$\int_{\gamma} \frac{f(\zeta)}{(\zeta - z_0)^{k+1}} d\zeta = \int_{\gamma} (\zeta - z_0)^{-k-1} \left[ \sum_{j=0}^{\infty} a_j (\zeta - z_0)^j \right] d\zeta$$

934
All the terms in this sum are 0 except the term with $j = k$, which is $2\pi i a_k$.

This result can also be concluded from X.4.2.10. and the Cauchy Integral Formula for Derivatives (X.3.3.6.).

**X.4.2.12.** The radius of convergence of a power series $\sum_{k=0}^{\infty} a_k(z - z_0)^k$ can always be computed as

$$R = \frac{1}{\limsup |a_k|^{1/k}}$$

(with the usual conventions if the lim sup is 0 or $+\infty$), but it is not always easy to evaluate this expression. Sometimes the radius of convergence can be computed more simply by the following:

**X.4.2.13.** Proposition. Let $\sum_{k=0}^{\infty} a_k(z - z_0)^k$ be a power series, with all $a_k$ nonzero. If

$$\lim_{k \to \infty} \left| \frac{a_k}{a_{k+1}} \right|$$

exists (in the usual or extended sense), it equals the radius of convergence of the power series.

**Proof:** Let $S$ be this limit. Apply the Ratio Test () to show that $\sum_{k=0}^{\infty} a_k(z - z_0)^k$ converges absolutely if $|z - z_0| < S$ and diverges if $|z - z_0| > S$. Thus $S$ must be exactly the radius of convergence.

Note that in the limit of X.4.2.13., the $a_k$ and $a_{k+1}$ are reversed from the way they appear in the Ratio Test ().

Another convenient characterization of the radius of convergence is the following:

**X.4.2.14.** Proposition. Let $\sum_{k=0}^{\infty} a_k(z - z_0)^k$ be a power series. The power series has radius of convergence $R > 0$ if and only if, for all $r$, $0 < r < R$, there is a constant $M$ such that $|a_k| \leq \frac{M}{r^k}$ for all $k$, and there is no such $M$ if $r > R$.

**Proof:** Suppose the series has radius of convergence $R > 0$, and $0 < r < R$. Then

$$\limsup |a_k|^{1/k} < \frac{1}{r}$$
so there is a $k_0$ such that $|a_k| < \frac{1}{r^k}$ for all $k \geq k_0$. There is an $M \geq 1$ such that $|a_k| \leq \frac{M}{r^k}$ for $0 \leq k < k_0$. This $M$ works for all $k$.

Conversely, if the condition holds for all $r$ with $0 < r < R$ and no $r > R$, we have, for each such $r$ with $0 < r < R$,

$$\limsup |a_k|^{1/k} \leq \limsup \frac{M^{1/k}}{r} = \frac{1}{r}$$

for some constant $M$, so the radius of convergence $R'$ is $\geq R$. If $R' > R$, choose $r$ so that $R < r < R'$; then the condition holds for $r$ by the first half of the proof, a contradiction. 

\section{Inverse Power Series}

It will be convenient to extend the results about power series to closely related series we call inverse power series:

\subsection{Definition}

An inverse power series centered at $z_0 \in \mathbb{C}$ is an infinite series of the form

$$\sum_{k=1}^{\infty} \frac{b_k}{(z-z_0)^k}$$

where the $b_k \in \mathbb{C}$. (We could also allow a constant term $b_0$.)

\subsection{An inverse power series defines a complex-valued function whose domain is the set of $z$ for which the series converges. This set is (almost) nicely describable, as in the case of power series:}

\subsection{Theorem}

Let

$$\sum_{k=1}^{\infty} \frac{b_k}{(z-z_0)^k}$$

be an inverse power series, and set

$$S = \limsup_{k \to \infty} |b_k|^{1/k}.$$ 

Then

(i) If $S < \infty$ and $|z - z_0| > S$, then the series converges absolutely.

(ii) If $S > 0$ and $|z - z_0| < S$, then the series diverges.

(iii) If $S < \infty$ and $s > S$, then the series converges uniformly on

$$\{z : |z - z_0| \geq s\}$$

and in particular the series converges normally on

$$\{z : |z - z_0| > S\}.$$ 

936
Proof: This follows almost immediately from X.4.2.5. by considering the power series
\[ \sum_{k=1}^{\infty} b_k w^k \]
which has radius of convergence \( R = \frac{1}{S} \). If \( w = \frac{1}{z-z_0} \), then \(|w| < R\) if and only if \(|z-z_0| > S\), etc. ✐

X.4.3.4. The number \( S \) is called the inverse radius of convergence and the set
\[ \{z : |z-z_0| > S\} \]
is called the open disk complement of convergence of the inverse power series. If \( S = 0 \), this set is the entire complex plane with \( z_0 \) removed. (The series never converges for \( z = z_0 \). If \( S = \infty \), the series does not converge for any \( z \in \mathbb{C} \). If \( 0 < S < \infty \), the series may converge for some or all \( z \) with \(|z-z_0| = S\), but not necessarily; cf. X.4.2.7.)

X.4.3.5. Proposition. Let
\[ \sum_{k=1}^{\infty} \frac{b_k}{(z-z_0)^k} \]
be an inverse power series with finite inverse radius of convergence. Then the series defines a holomorphic function \( f \) on its open disk complement of convergence \( \Omega \), and the series
\[ \sum_{k=1}^{\infty} \frac{-kb_k}{(z-z_0)^{k+1}} \]
of term-by-term derivatives converges normally to \( f' \) on \( \Omega \).

The fact that \( f \) is holomorphic is immediate from X.4.1.7., and that term-by-term differentiation is valid follows from X.4.1.8.. Alternatively, both parts follow from X.4.1.9. and the fact that the derived series has the same inverse radius of convergence (cf. V.15.3.21.) and thus converges u.c. on \( \Omega \).

The coefficients \( b_k \) can be computed by contour integration:

X.4.3.6. Proposition. Let
\[ \sum_{k=1}^{\infty} \frac{b_k}{(z-z_0)^k} \]
be an inverse power series with finite inverse radius of convergence \( S \), and \( f \) the function defined by the series on \( \Omega = \{z : |z-z_0| > S\} \). Then, for any \( k \geq 1 \),
\[ b_k = \frac{1}{2\pi i} \oint_{\gamma} f(\zeta)(\zeta-z_0)^{k-1} d\zeta \]
where \( \gamma \) is any circle centered at \( z_0 \) of radius greater than \( S \).
Proof: By (), we have

\[
\int_\gamma f(\zeta)(\zeta - z_0)^{k-1} d\zeta = \int_\gamma (\zeta - z_0)^{k-1} \left[ \sum_{j=1}^{\infty} \frac{b_j}{(\zeta - z_0)^j} \right] d\zeta \\
= \sum_{j=1}^{\infty} \left[ \int_\gamma b_j(\zeta - z_0)^{k-1-j} d\zeta \right] .
\]

All the terms in this sum are 0 except the term with \( j = k \), which is \( 2\pi ib_k () \).

X.4.4. Analytic Functions

X.4.4.1. Definition. Let \( \Omega \) be an open set in \( \mathbb{C} \), and \( f \) a complex-valued function on \( \Omega \). Then \( f \) is analytic on \( \Omega \) if for every \( z_0 \in \Omega \) there is a power series centered at \( z_0 \) which converges to \( f \) on some open disk centered at \( z_0 \).

Note that the power series representation of \( f \) around \( z_0 \) need not converge to \( f \) on all of \( \Omega \), only on some open disk centered at \( z_0 \). Thus analyticity is a local property: if for each \( z_0 \in \Omega \) there is some neighborhood of \( z_0 \) in \( \Omega \) on which \( f \) is analytic, then \( f \) is analytic on \( \Omega \).

The following facts are immediate from X.4.2.9.:

X.4.4.2. Corollary. Let \( \Omega \) be an open set in \( \mathbb{C} \), and \( f \) a complex-valued function on \( \Omega \). If \( f \) is analytic on \( \Omega \), then \( f \) is holomorphic on \( \Omega \) and \( f' \) is also analytic on \( \Omega \).

X.4.4.3. Conversely, it follows easily from X.4.1.9. that if \( f \) is holomorphic on \( \Omega \) and \( f' \) is analytic on \( \Omega \), then \( f \) is analytic on \( \Omega \). We omit details since we will presently prove a much stronger result (X.4.4.7.).

We also obtain as a consequence of X.4.2.10.:

X.4.4.4. Corollary. Let \( \Omega \) be an open set in \( \mathbb{C} \), and \( f \) an analytic function on \( \Omega \). For any \( z_0 \in \Omega \), the power series centered at \( z_0 \) representing \( f \) in an open disk around \( z_0 \) is unique, and is

\[
\sum_{k=0}^{\infty} \frac{f^{(k)}(z_0)}{k!}(z - z_0)^k
\]

which is called the Taylor series for \( f \) around \( z_0 \).
**X.4.4.5.** For real functions on an interval $I$, the following classes of functions are successively considerably larger:

(i) The class of analytic functions on $I$.

(ii) The class of $C^\infty$ functions on $I$.

(iii) The class of $C^1$ functions on $I$.

(iv) The class of differentiable functions on $I$.

The following spectacular theorem, which is the main result of this section, implies that for complex functions on an open set $\Omega$, the above four classes of functions coincide.

**X.4.4.6.** Theorem. Let $\Omega$ be an open set in $\mathbb{C}$ and $f$ a holomorphic function on $\Omega$. If $z_0 \in \Omega$ and $D$ is an open disk centered at $z_0$ contained in $\Omega$, then the Taylor series for $f$ around $z_0$ converges to $f(z)$ for every $z \in D$.

Combining this with X.4.4.2., we obtain:

**X.4.4.7.** Corollary. Let $\Omega$ be an open set in $\mathbb{C}$ and $f$ a complex-valued function on $\Omega$. Then $f$ is analytic on $\Omega$ if and only if it is holomorphic on $\Omega$.

**Proof:** Suppose $f$ is holomorphic on $\Omega$. Fix $z_0 \in \Omega$ and an open disk $D$ of radius $R$ centered at $z_0$ contained in $\Omega$. Fix $z \in D$, and let $\gamma$ be a circle centered at $z_0$ with radius $r$ for some $r$, $|z-z_0| < r < R$, parametrized once around counterclockwise. Thus

$$f(z) = \frac{1}{2\pi i} \int_\gamma \frac{f(\zeta)}{\zeta - z} d\zeta$$

by the Cauchy Integral Formula.

Since $\left| \frac{z-z_0}{\zeta - z_0} \right| = \frac{|z-z_0|}{r} < 1$ for all $\zeta \in \gamma$, the infinite series

$$\sum_{k=0}^{\infty} \left( \frac{z-z_0}{\zeta - z_0} \right)^k$$

converges uniformly on $\gamma$ to

$$\frac{1}{1 - \frac{z-z_0}{\zeta - z_0}} = \frac{\zeta - z_0}{\zeta - z}$$

i.e. for $\zeta \in \gamma$ we have

$$\frac{1}{\zeta - z} = \frac{1}{\zeta - z_0} \sum_{k=0}^{\infty} \left( \frac{z-z_0}{\zeta - z_0} \right)^k = \sum_{k=0}^{\infty} \left( \frac{z-z_0}{\zeta - z_0} \right)^k$$

where the series converges uniformly on $\gamma$. Thus the series

$$\sum_{k=0}^{\infty} \left( \frac{z-z_0}{\zeta - z_0} \right)^k \int_\gamma \frac{f(\zeta)}{(\zeta - z_0)^{k+1}} d\zeta = \int_\gamma f(\zeta) \left[ \sum_{k=0}^{\infty} \left( \frac{z-z_0}{\zeta - z_0} \right)^k \right] d\zeta$$

939
converges to

\[ \int f(\zeta) \frac{d\zeta}{\zeta - z} = 2\pi i f(z). \]

In other words, the power series

\[ \sum_{k=0}^{\infty} a_k(z - z_0)^k \]

converges to \( f(z) \), where

\[ a_k = \frac{1}{2\pi i} \int_{\gamma} \frac{f(\zeta)}{(\zeta - z_0)^{k+1}} d\zeta \]

for each \( k \).

**X.4.4.8.** The proof of the theorem as stated is then completed by either identifying \( a_k \) with \( \frac{f^{(k)}(z_0)}{k!} \) by the Cauchy Integral Formula for Derivatives (X.3.3.6.) or by using X.4.2.10.. In fact, by combining the above proof with X.4.2.10., we can obtain an alternate proof of the Cauchy Integral Formula for Derivatives. Note that the proof of X.4.4.6. makes crucial use of the ordinary Cauchy Integral Formula.

**X.4.4.9.** Note that X.4.4.6. says more than just that \( f \) is analytic on \( \Omega \): if \( z_0 \in \Omega \), then the Taylor series for \( f \) around \( z_0 \) does not merely converge to \( f \) on some open disk centered at \( z_0 \), but actually converges to \( f \) on the largest open disk centered at \( z_0 \) contained in \( \Omega \) (if \( \Omega \neq \mathbb{C} \)). If \( \Omega = \mathbb{C} \), i.e. if \( f \) is an entire function, this Taylor series converges to \( f \) on all of \( \mathbb{C} \).

This result is again in stark contrast to the real case (cf. (i)).

**Holomorphic Functions on an Annulus**

We can also obtain a similar series representation for a holomorphic function on an annulus, involving both a power series and an inverse power series in general.

**X.4.4.10.** Definition. Let \( z_0 \in \mathbb{C} \), and fix \( r \) and \( R \) with \( 0 \leq r < R \leq +\infty \). The (open) annulus centered at \( z_0 \) with inner radius \( r \) and outer radius \( R \) is the set

\[ \{ z \in \mathbb{C} : r < |z - z_0| < R \}. \]

If \( 0 < r < R < +\infty \), this annulus is the open region between the circles of radius \( r \) and \( R \) centered at \( z_0 \). If \( r = 0 \) and \( R < +\infty \), the annulus is the punctured open disk of radius \( R \) centered at \( z_0 \) with \( z_0 \) removed. If \( r = 0 \) and \( R = +\infty \), it is the punctured plane with \( z_0 \) removed; if \( r > 0 \) and \( R = +\infty \), it is the plane with the closed disk of radius \( r \) centered at \( z_0 \) removed. (It is convenient to include these degenerate cases.)
**X.4.4.11. Theorem.** Let $\Omega$ be an open annulus centered at $z_0$ with inner radius $r$ and outer radius $R$, and $f$ a holomorphic function on $\Omega$. Then there are a unique power series

$$\sum_{k=0}^{\infty} a_k (z - z_0)^k$$

and a unique inverse power series

$$\sum_{k=1}^{\infty} \frac{b_k}{(z - z_0)^k}$$

which both converge normally on $\Omega$, and for which

$$f(z) = \sum_{k=0}^{\infty} a_k (z - z_0)^k + \sum_{k=1}^{\infty} \frac{b_k}{(z - z_0)^k}$$

for all $z \in \Omega$. For each $k \geq 0$ we have

$$a_k = \frac{1}{2\pi i} \int_{\gamma} f(\zeta) (\zeta - z_0)^{k+1} d\zeta$$

and for each $k \geq 1$ we have

$$b_k = \frac{1}{2\pi i} \int_{\gamma} f(\zeta)(\zeta - z_0)^{k-1} d\zeta$$

where $\gamma$ is any circle centered at $z_0$ whose radius $\rho$ satisfies $r < \rho < R$.

**Proof:** The argument is similar to the previous ones. Fix $z \in \Omega$, and let $\gamma_1$ and $\gamma_0$ be circles centered at $z_0$ of radius $S$ and $s$ respectively, where $0 < s < |z - z_0| < S < R$, parametrized once around counterclockwise. Then

$$f(z) = \frac{1}{2\pi i} \int_{\gamma_1} f(\zeta) d\zeta = \frac{1}{2\pi i} \int_{\gamma_1} \frac{f(\zeta)}{\zeta - z} d\zeta - \frac{1}{2\pi i} \int_{\gamma_0} \frac{f(\zeta)}{\zeta - z} d\zeta$$

by (). We analyze the two integrals on the right separately.

Since $|\frac{z - z_0}{\zeta - z_0}| = \frac{|z - z_0|}{S} < 1$ for all $\zeta \in \gamma_1$, the infinite series

$$\sum_{k=0}^{\infty} \left( \frac{z - z_0}{\zeta - z_0} \right)^k$$

converges uniformly on $\gamma_1$ to

$$\frac{1}{1 - \frac{z - z_0}{\zeta - z_0}} = \frac{\zeta - z_0}{\zeta - z}$$

i.e. for $\zeta \in \gamma_1$ we have

$$\frac{1}{\zeta - z} = \frac{1}{\zeta - z_0} \sum_{k=0}^{\infty} \left( \frac{z - z_0}{\zeta - z_0} \right)^k = \sum_{k=0}^{\infty} \frac{(z - z_0)^k}{(\zeta - z_0)^{k+1}}$$

941
where the series converges uniformly on $\gamma_1$. Thus the series

$$\sum_{k=0}^{\infty} \left[ (z - z_0)^k \int_{\gamma_1} \frac{f(\zeta)}{(\zeta - z_0)^{k+1}} d\zeta \right] = \int_{\gamma_1} f(\zeta) \left[ \sum_{k=0}^{\infty} \frac{(z - z_0)^k}{(\zeta - z_0)^{k+1}} \right] d\zeta$$

collapses to

$$\int_{\gamma_1} \frac{f(\zeta)}{\zeta - z} d\zeta.$$

Similarly, since $\left| \frac{\zeta - z_0}{z - z_0} \right| = \frac{s}{|z - z_0|} < 1$ for all $\zeta \in \gamma_0$, the infinite series

$$\sum_{j=0}^{\infty} \left( \frac{\zeta - z_0}{z - z_0} \right)^j$$

collapses uniformly on $\gamma_0$ to

$$\frac{1}{1 - \frac{\zeta - z_0}{z - z_0}} = \frac{z - z_0}{\zeta - z},$$

i.e. for $\zeta \in \gamma_0$ we have

$$\frac{1}{\zeta - z} = -\frac{1}{z - z_0} \sum_{j=0}^{\infty} \left( \frac{\zeta - z_0}{z - z_0} \right)^j = -\sum_{j=0}^{\infty} \frac{(\zeta - z_0)^j}{(z - z_0)^{j+1}}$$

where the series converges uniformly on $\gamma_0$. Thus the series

$$\sum_{k=1}^{\infty} \left[ \frac{1}{(z - z_0)^k} \int_{\gamma_0} f(\zeta)(\zeta - z_0)^{k-1} d\zeta \right]$$

$$= \sum_{j=0}^{\infty} \left[ \frac{1}{(z - z_0)^{j+1}} \int_{\gamma_0} f(\zeta)(\zeta - z_0)^j d\zeta \right] = \int_{\gamma_0} f(\zeta) \left[ \sum_{j=0}^{\infty} \frac{(\zeta - z_0)^j}{(z - z_0)^{j+1}} \right] d\zeta$$

collapses to

$$-\int_{\gamma_0} \frac{f(\zeta)}{\zeta - z} d\zeta.$$

So we have that both series converge and that

$$f(z) = \sum_{k=0}^{\infty} a_k (z - z_0)^k + \sum_{k=1}^{\infty} \frac{b_k}{(z - z_0)^k}$$

where

$$a_k = \frac{1}{2\pi i} \int_{\gamma_1} \frac{f(\zeta)}{(\zeta - z_0)^{k+1}} d\zeta$$

$$b_k = \frac{1}{2\pi i} \int_{\gamma_0} f(\zeta)(\zeta - z_0)^{k-1} d\zeta.$$
The circles $\gamma_1$ and $\gamma_0$ depend on $z$. But note that if $\gamma$ is any circle centered at $z_0$ contained in $\Omega$, then, for any $k$,

$$\int_{\gamma} \frac{f(\zeta)}{(\zeta - z_0)^{k+1}} d\zeta = \int_{\gamma_1} \frac{f(\zeta)}{(\zeta - z_0)^{k+1}} d\zeta$$

$$\int_{\gamma} f(\zeta) (\zeta - z_0)^{-k-1} d\zeta = \int_{\gamma_0} f(\zeta) (\zeta - z_0)^{-k-1} d\zeta$$

so the $a_k$ and $b_k$ are independent of the choice of $\gamma_1$ and $\gamma_0$, i.e. the same series are obtained for all $z \in \Omega$, and these series converge pointwise on $\Omega$.

Since the power series converges pointwise on $\Omega$, its radius of convergence is at least $R$, hence it converges u.c. on $\Omega$. Similarly, the inverse radius of convergence of the inverse power series is at most $r$, so it converges u.c. on $\Omega$.

It remains to show uniqueness. If there are series with coefficients $c_k$ and $d_k$, converging u.c. on $\Omega$ with

$$f(z) = \sum_{k=0}^{\infty} a_k(z - z_0)^k + \sum_{k=1}^{\infty} \frac{d_k}{(z - z_0)^k}$$

then for any $k \geq 0$ and any circle $\gamma$ in $\Omega$ centered at $z_0$ we have

$$2\pi i a_k = \int_{\gamma} \frac{f(\zeta)}{(\zeta - z_0)^{k+1}} d\zeta = \sum_{j=0}^{\infty} \left[ \int_{\gamma} c_j (\zeta - z_0)^{j-k-1} d\zeta \right] + \sum_{j=1}^{\infty} \left[ \int_{\gamma} \frac{d_k}{(\zeta - z_0)^{j+k+1}} d\zeta \right]$$

where term-by-term integration is justified by u.c. convergence. But all terms in the second sum are zero, and all terms in the first are also zero except the term with $j = k$, which is $2\pi i c_k$. Thus $c_k = a_k$. Similarly, if $k \geq 1$ we have

$$2\pi i b_k = \int_{\gamma} f(\zeta) (\zeta - z_0)^{-k-1} d\zeta = \sum_{j=0}^{\infty} \left[ \int_{\gamma} c_j (\zeta - z_0)^{j+k-1} d\zeta \right] + \sum_{j=1}^{\infty} \left[ \int_{\gamma} \frac{d_k}{(\zeta - z_0)^{j-k+1}} d\zeta \right]$$

and the term in the second sum with $j = k$ is $2\pi i d_k$ and all other terms are zero.

The uniqueness statement in this theorem can be extended:

**X.4.4.12. Corollary.** Let $\Omega$ be an open annulus centered at $z_0$ with inner radius $r$ and outer radius $R$, and $f$ a holomorphic function on $\Omega$, with expansion

$$f(z) = \sum_{k=0}^{\infty} a_k(z - z_0)^k + \sum_{k=1}^{\infty} \frac{b_k}{(z - z_0)^k}$$

as in X.4.4.11.. Suppose there are a power series

$$\sum_{k=0}^{\infty} c_k(z - z_0)^k$$

943
and an inverse power series
\[ \sum_{k=1}^{\infty} \frac{d_k}{(z-z_0)^k} \]
converging pointwise on \( \Omega \) with
\[ f(z) = \sum_{k=0}^{\infty} c_k(z-z_0)^k + \sum_{k=1}^{\infty} \frac{d_k}{(z-z_0)^k} \]
for all \( z \in \Omega \). Then \( c_k = a_k \) and \( d_k = b_k \) for all \( k \).

**Proof:** Since
\[ \sum_{k=0}^{\infty} c_k(z-z_0)^k \]
converges pointwise on \( \Omega \), its radius of convergence is at least \( R \), so the series converges u.c. on \( \Omega \). Similarly, the inverse power series
\[ \sum_{k=1}^{\infty} \frac{d_k}{(z-z_0)^k} \]
converges pointwise on \( \Omega \), so its inverse radius of convergence is at most \( r \), so this series converges u.c. on \( \Omega \). The result now follows from X.4.4.11.

**X.4.4.13.** If we set \( a_{-k} = b_k \) for \( k \geq 1 \), we can more compactly write the expansion in X.4.4.11. as
\[ f(z) = \sum_{k=0}^{\infty} a_k(z-z_0)^k \]
which is called the *Laurent expansion* of \( f \) around \( z_0 \) (it is technically only a Laurent series (III.5.3.3.) if only finitely many \( b_k \) are nonzero, which turns out to often be the case if \( r = 0 \)). But the proper phrasing of convergence of such a series is somewhat tricky, so it is better to consider the positive and negative powers separately in general.

**X.4.4.14.** One important difference between X.4.4.11. and X.4.4.6. is that there is no obvious interpretation of the coefficients \( a_k \) (or \( b_k \)) as values of derivatives of \( f \) at \( z_0 \), which of course do not make sense if \( f \) is defined only on an annulus around \( z_0 \). However, in at least some cases (e.g. if only finitely many \( b_k \) are nonzero) there is an analogous interpretation ().
X.4.5. Normal Families and Montel’s Theorem

There is an important compactness-like property for families of holomorphic functions which we discuss in this section.

Normal Families

X.4.5.1. Definition. Let $\Omega$ be an open set in $\mathbb{C}$, and $F$ a family of holomorphic functions on $\Omega$. Then $F$ is a normal family if every sequence in $F$ has a subsequence which converges normally (u.c.) on $\Omega$.

X.4.5.2. Normal families turn out to exist in abundance in Complex Analysis, and this fact is the key to many advanced results: they are used to construct holomorphic functions with an exact set of specified properties from families of functions approximately satisfying the properties.

Here is a nice technical simplification used in proving normality for families of holomorphic functions:

X.4.5.3. Proposition. Let $\Omega$ be an open set in $\mathbb{C}$, and $F$ a family of holomorphic functions on $\Omega$. Suppose there is a sequence $(D_j)$ of compact subsets of $\Omega$ such that

(i) Every compact subset of $\Omega$ is contained in the union of finitely many $D_j$.

(ii) For every $j$, every sequence in $F$ has a subsequence converging uniformly on $D_j$.

Then $F$ is a normal family.

Proof: If $(f_n)$ is a sequence in $F$, then there is a subsequence $(f_{n_k,1})$ which converges uniformly on $D_1$. This subsequence has a subsequence $(f_{n_k,2})$ which converges uniformly on $D_2$. Continue inductively to get, for each $j$, a subsequence $f_{n_k,j}$ converging uniformly on $D_j$. The diagonal subsequence $(f_{n_k,k})$ then converges uniformly on $D_j$ for each $j$, and hence on any finite union of the $D_j$; thus it converges normally on $\Omega$.

X.4.5.4. Corollary. Let $\Omega$ be an open set in $\mathbb{C}$, and $F$ a family of holomorphic functions on $\Omega$. Then $F$ is a normal family if and only if, for every closed disk $D$ in $\Omega$, any sequence in $F$ has a subsequence which converges uniformly on $D$.

The proof of this Corollary really involves no Complex Analysis, only topology. The key is the following topological lemma:

X.4.5.5. Lemma. Let $\Omega$ be an open set in $\mathbb{C}$. Then there is a sequence $(D_j)$ of closed disks in $\Omega$ such that every compact subset of $\Omega$ is contained in the union of finitely many of the $D_j$.

Proof: First note that there is a sequence $(K_n)$ of compact sets whose union is $\Omega$: for example, set

$$K_n = \left\{ z \in \Omega : d(z, \mathbb{C} \setminus \Omega) \geq \frac{1}{n}, |z| \leq n \right\}.$$
For each $z \in \Omega$, there is an open disk $B_z$ centered at $z$ whose closure is contained in $\Omega$. For each $n$, finitely many of the $B_z$ cover $K_n$; thus countably many of the $B_z$ cover $\Omega$, say \( \{ B_{z_1}, B_{z_2}, \ldots \} \). If $K$ is any compact subset of $\Omega$, finitely many of the $B_{z_j}$ cover $K$. Take $D_j = B_{z_j}$.

This proof works essentially verbatim for any open set in any locally compact, $\sigma$-compact metric space ().

**Montel’s Theorem**

**X.4.5.6. Theorem.** [Montel’s Theorem] Let $\Omega$ be an open set in $\mathbb{C}$, and $F$ a family of holomorphic functions on $\Omega$. If $F$ is uniformly bounded on every closed disk in $\Omega$, then $F$ is a normal family.

**Proof:** We will use X.4.5.3. for a carefully chosen sequence $(D_j)$ of closed disks. The result will follow immediately from the Arzela-Ascoli Theorem () if $F$ is equicontinuous on each $D_j$. We proceed similarly to the proof of X.4.5.5.: for each $z \in \Omega$ there is an $r > 0$ (depending on $z$) such that the closed disk of radius $2r$ around $z$ is contained in $\Omega$. Let $B_z$ be the open disk of radius $r$ centered at $z$. As in the proof of X.4.5.5., there is a sequence $(B_{z_j})$ such that every compact subset of $\Omega$ is covered by finitely many $B_{z_j}$. Set $D_j = B_{z_j}$.

Equicontinuity of $F$ on $D_j$ follows from the first Cauchy Inequality, as follows. Fix $j$. If $r$ is the radius of $D_j$, then the closed disk $D$ of radius $2r$ centered at $z_j$ is contained in $\Omega$, and if $z \in D_j$, then the closed disk of radius $r$ around $z$ is contained in $D$. So if $M$ is a bound for $F$ on $D$, we have $|f'(z)| \leq \frac{M}{r}$ for all $f \in F$ and $z \in D_j$. Then, since $D_j$ is convex, for any $z, w \in D_j$ we have

$$|f(z) - f(w)| \leq \frac{M}{r} |z - w|$$

for all $f \in F$ by X.2.1.9., and equicontinuity of $F$ on $D_j$ follows.

The most commonly used special case is called Montel’s Theorem in many references:

**X.4.5.7. Corollary.** Let $\Omega$ be an open set in $\mathbb{C}$, and $F$ a family of holomorphic functions on $\Omega$. If $F$ is uniformly bounded on $\Omega$, then $F$ is a normal family.

**X.4.5.8. These are not the most general theorems proved by Montel. In [Gam01], X.4.5.7. is called the “thesis grade” Montel Theorem since Montel proved it in his Ph.D. thesis. He later proved a spectacular generalization of X.4.5.7. (not quite a generalization of X.4.5.6.) related to the Picard Theorems, which is beyond the scope of this book; see e.g. [Gam01].**

946
X.5. Zeroes and Singularities

The existence of local power series representations for holomorphic functions has some surprising and pleasant rigidity consequences, and the closely related existence of Laurent expansions around isolated singularities yields more consequences which shed great light on the global properties of holomorphic functions. In fact, it was the philosophy of CAUCHY and, especially, RIEMANN that a holomorphic (analytic) function should be primarily understood through its zeroes and singularities.

X.5.1. Zeroes of Holomorphic Functions

The first result is immediate from X.4.4.6., and underlies the rest of the results of this section:

X.5.1.1. Corollary. Let \( \Omega \) be an open set in \( \mathbb{C} \), \( f \) holomorphic on \( \Omega \), and \( z_0 \in \Omega \) with \( f(z_0) = 0 \). Then either

(i) \( f \) is identically zero in a neighborhood of \( z_0 \)

or

(ii) There is a unique \( n \in \mathbb{N} \) and a unique function \( \phi \) which is holomorphic on \( \Omega \), with \( \phi(z_0) \neq 0 \), for which

\[
 f(z) = (z - z_0)^n \phi(z)
\]

for all \( z \in \Omega \); and there is a neighborhood \( U \) of \( z_0 \) containing no other zeroes of \( f \).

Proof: Let

\[
 \sum_{k=0}^{\infty} \frac{f^{(k)}(z_0)}{k!} (z - z_0)^k
\]

be the Taylor series for \( f \) around \( z_0 \) and \( D \) an open disk centered at \( z_0 \) on which this series converges to \( f \). Either \( f^{(k)}(z_0) = 0 \) for all \( k \), in which case this series is identically zero and \( f \) is identically zero on \( D \), or else there is a unique \( n \geq 1 \) such that \( f^{(n)}(z_0) \neq 0 \) and \( f^{(k)}(z_0) = 0 \) for all \( k < n \). In this case, the power series

\[
 \sum_{k=n}^{\infty} \frac{f^{(k)}(z_0)}{k!} (z - z_0)^{k-n}
\]

has the same radius of convergence as the Taylor series, and thus converges to a holomorphic function \( \phi \) on \( D \) which satisfies \( \phi(z_0) = \frac{f^{(n)}(z_0)}{n!} \neq 0 \) and

\[
 \phi(z) = \frac{f(z)}{(z - z_0)^n}
\]

for all \( z \in D \setminus \{z_0\} \). We may thus extend \( \phi \) to a function holomorphic on \( \Omega \) with the same properties by setting \( \phi(z) = \frac{f(z)}{(z - z_0)^n} \) for \( z \in \Omega \setminus D \). Uniqueness of \( n \) and \( \phi \) is clear.

For the last statement, since \( \phi \) is continuous and \( \phi(z_0) \neq 0 \), there is a neighborhood \( U \) of \( z_0 \) on which \( \phi(z) \neq 0 \) for all \( z \in U \). Then

\[
 f(z) = (z - z_0)^n \phi(z) \neq 0
\]

for all \( z \in U \setminus \{z_0\} \) since both factors are nonzero.

A crucial property of holomorphic functions follows, that the zeroes of a nonconstant holomorphic function are isolated:
X.5.1.2. **Corollary.** Let $\Omega$ be a connected open set in $\mathbb{C}$, and $f$ a holomorphic function on $\Omega$. Suppose there is a sequence $(z_n) \in \Omega$ of distinct points such that $f(z_n) = 0$ for all $n$, and that $z_n \to z_0$ for some $z_0 \in \Omega$. Then $f$ is identically zero on $\Omega$.

**Proof:** We have that $f(z_0) = 0$ by continuity, and thus $f$ is identically zero in a neighborhood of $z_0$ by X.5.1.1.. Let $U$ be the set of all $z \in \Omega$ such that $f$ is identically zero in a neighborhood of $z$. Then $U$ is open and contains $z_0$. If $w \in \bar{U} \cap \Omega$, then there is a sequence $(w_n) \in U$ with $w_n \to w$, and thus $w \in U$ as in the first statement of the proof. So $U$ is relatively closed in $\Omega$. Since $\Omega$ is connected, $U = \Omega$.

X.5.1.3. This result says that the zeroes of a nonconstant holomorphic function on a connected $\Omega$ cannot have an accumulation point in $\Omega$. Note that they can have an accumulation point outside $\Omega$: set $\Omega = \mathbb{C} \setminus \{0\}$ and $f(z) = \sin \frac{1}{z}$. Then $f$ is holomorphic and nonconstant on $\Omega$ and $f$ has a sequence of zeroes (at $\frac{1}{\pi n}$) converging to 0.

Connectedness of $\Omega$ is essential: a holomorphic function on a nonconnected $\Omega$ could be identically zero on a component of $\Omega$ and not on another component.

The statement of X.5.1.2. becomes seemingly much more powerful by the simple trick of considering $f - g$:

X.5.1.4. **Theorem.** [Rigidity Theorem] Let $\Omega$ be a connected open set in $\mathbb{C}$, and $f$ and $g$ holomorphic functions on $\Omega$. Suppose there is a sequence $(z_n) \in \Omega$ of distinct points such that $f(z_n) = g(z_n)$ for all $n$, and that $z_n \to z_0$ for some $z_0 \in \Omega$. Then $f$ and $g$ are identically equal on $\Omega$.

X.5.1.5. This result is called the Rigidity Theorem because it means that if $f$ is holomorphic on $\Omega$, the values of $f$ on any small subregion of $\Omega$ (or even subset of $\Omega$ large enough to have an accumulation point in $\Omega$) completely determine the values of $f$ throughout all of $\Omega$ (if $\Omega$ is connected).

X.5.1.6. If a holomorphic function $f$ has an isolated zero at $z_0$, the number $n$ in X.5.1.1. is called the order of the zero at $z_0$. This language extends the usual notion of order of a zero of a polynomial. Part of the content of X.5.1.1. is that an isolated zero of a holomorphic function has finite order.

**Limits of Sequences of Holomorphic Functions**

Using Montel’s Theorem (), we can obtain a considerable extension of the Rigidity Theorem:

X.5.1.7. **Theorem.** Let $\Omega$ be a connected open set in $\mathbb{C}$, $(f_k)$ a sequence of holomorphic functions on $\Omega$, and $(z_n)$ a sequence of distinct points in $\Omega$ converging to $z_0 \in \Omega$. Suppose the $f_k$ are uniformly bounded on compact subsets of $\Omega$, and that $w_n := \lim_{k \to \infty} f_k(z_n)$ exists for all $n$. Then there is a unique holomorphic function $f$ on $\Omega$ such that $f(z_n) = w_n$ for all $n$, and $f_n \to f$ normally on $\Omega$.

**Proof:** By Montel’s Theorem, there is a subsequence of $(f_k)$ converging u.c. to a holomorphic function $f$ on $\Omega$, and we must have $f(z_n) = w_n$ for all $n$. Similarly, if $(f_{m_k})$ is any subsequence of $(f_k)$, then $(f_{m_k})$ has a subsequence converging u.c. on $\Omega$ to a holomorphic function $g$ with $g(z_n) = w_n$ for all $n$. By the Rigidity
Theorem, \( g = f \) on all of \( \Omega \). Thus, if \( K \) is a compact subset of \( \Omega \) containing all the \( z_n \), every subsequence of \( (f_n) \) has a subsubsequence converging uniformly to \( f \) on \( K \); so \( f_n \to f \) uniformly on \( K \).

This is a powerful result since it shows that to prove that a sequence of holomorphic functions converges normally on \( \Omega \), it suffices to show the sequence is uniformly bounded on compact subsets of \( \Omega \) (a necessary condition for normal convergence) and converges pointwise on a subset of \( \Omega \) with a limit point in \( \Omega \) (e.g. a small subregion of \( \Omega \)). Note that the Rigidity Theorem is the uniqueness part applied to a constant sequence. But the Rigidity Theorem cannot be considered a corollary of this result since it is used in the proof.

### X.5.2. Singularities

#### X.5.2.1. Definition. Let \( f \) be holomorphic on an open set \( \Omega \). Then \( f \) has an isolated singularity at \( z_0 \in \mathbb{C} \setminus \Omega \) if there is a deleted neighborhood of \( z_0 \) contained in \( \Omega \).

In other words, \( f \) has an isolated singularity at \( z_0 \) if it is holomorphic in a neighborhood of \( z_0 \) except at \( z_0 \).

#### X.5.2.2. Examples. (i) The function

\[
    f(z) = \frac{z - 1}{z^2 - 1}
\]

has isolated singularities at 1 and \(-1\).

(ii) The function \( f(z) = e^{1/z} \) has an isolated singularity at 0.

(iii) The function \( f(z) = \tan \frac{z}{n!} \) has isolated singularities at \( \frac{2}{n!} \) for all odd \( n \), and a “singularity” at 0 which is not an isolated singularity.

(iv) The functions \( \log z \) and \( z^c, c \) not an integer, have a “singularity” at 0. But these functions cannot be defined as holomorphic functions on any deleted neighborhood of 0, so no version of them has an isolated singularity at 0. (If \( e \) is a negative integer, \( z^c \) is a well-defined holomorphic function on \( \mathbb{C} \setminus \{0\} \) which has an isolated singularity at 0.)

#### X.5.2.3. We will not consider “singularities” such as the ones at 0 in (iii) or (iv) which are not isolated singularities: we will use the term singularity to mean “isolated singularity.”

The three singularities in (i) and (ii) are examples of the three types of singularity discussed below.

#### X.5.2.4. If \( f \) has a singularity at \( z_0 \), then by X.4.4.11. there is a unique Laurent expansion

\[
    f(z) = \sum_{k=0}^{\infty} a_k (z - z_0)^k + \sum_{k=1}^{\infty} \frac{b_k}{(z - z_0)^k}
\]

which converges u.c. in a deleted neighborhood of \( z_0 \).

### Removable Singularities

A singularity such as the one at 1 in X.5.2.2 (i) is “artificial” since the function can be defined there in such a way that the extended function is holomorphic in a whole neighborhood of 1.
**X.5.2.5. Definition.** If \( f \) has a singularity (isolated singularity) at \( z_0 \), the singularity is a **removable singularity** if there is a function \( g \), holomorphic in a neighborhood of \( z_0 \), such that \( f = g \) on a deleted neighborhood of \( z_0 \).

**X.5.2.6. Examples.**

(i) The function \( f(z) = \frac{z-1}{z^2} \) has singularities at 1 and \(-1\). The singularity at 1 is removable, since \( f(z) = g(z) = \frac{1}{z^2} \) in a deleted neighborhood of 1, and \( g \) is holomorphic in a neighborhood of 1. The singularity of \( f \) at \(-1\) is not removable.

(ii) The function
\[
f(z) = \frac{\sin z}{z}
\]
has a singularity at 0. It is not so easy to prove directly that
\[
\lim_{z \to 0} \frac{\sin z}{z}
\]
does not exist (it does, and equals 1). But on \( \mathbb{C} \setminus \{0\} \) \( f \) agrees with the entire function \( g \) defined by the power series
\[
g(z) = \sum_{k=0}^{\infty} \frac{(-1)^k}{(2k+1)!} z^{2k}
\]
and thus the singularity is removable.

If \( f \) has a removable singularity at \( z_0 \), it is obvious that
\[
\lim_{z \to z_0} f(z)
\]
exists. It is remarkable that this condition is also sufficient for the singularity to be removable; in fact, apparently much weaker conditions are also sufficient:

**X.5.2.7. Theorem.** If \( f \) has a singularity at \( z_0 \), the following are equivalent:

(i) The singularity at \( z_0 \) is removable.

(ii) \( \lim_{z \to z_0} f(z) \) exists.

(iii) \( f \) is bounded in a deleted neighborhood of \( z_0 \).

(iv) \( \lim_{z \to z_0} f(z)(z-z_0) = 0 \).

(v) In the Laurent expansion of \( f \) around \( z_0 \), all \( b_k \) are zero.

**Proof:** (i) \( \Rightarrow \) (ii) \( \Rightarrow \) (iii) \( \Rightarrow \) (iv) are obvious.

(iv) \( \Rightarrow \) (i): Let \( D \) be an open disk centered at \( z_0 \) such that \( f \) is holomorphic on \( D \setminus \{z_0\} \), and let \( \gamma \) be a circle of radius \( r \) centered at \( z_0 \) contained in \( D \setminus \{z_0\} \). Then, for each \( z \) inside \( \gamma \), \( z \neq z_0 \),
\[
f(z) = \frac{1}{2\pi i} \int_{\gamma} \frac{f(\zeta)}{\zeta - z} d\zeta - \frac{1}{2\pi i} \int_{\gamma} \frac{f(\zeta)}{\zeta - z} d\zeta
\]

950
where \( \gamma_\delta \) is any circle centered at \( z_0 \) of radius \( \delta < |z - z_0| \). Note that, for fixed \( z \), the second integral is independent of \( \delta \), as long as \( 0 < \delta < |z - z_0| \).

Fix \( z \) inside \( \gamma \), and let \( \epsilon > 0 \). If \( \delta > 0 \) is sufficiently small, then \( |f(\zeta)(\zeta - z_0)| < \epsilon \) whenever \( 0 < |\zeta - z_0| \leq \delta \).

We may assume \( \delta \leq \frac{|z - z_0|}{2} \). Then

\[
|f(\zeta)| < \frac{\epsilon}{\delta}
\]

for \( \zeta \in \gamma_\delta \), so

\[
\left| \int_{\gamma_\delta} \frac{f(\zeta)}{\zeta - z} \, d\zeta \right| < \frac{2\epsilon}{\delta |z - z_0|} \cdot 2\pi \delta = \frac{4\pi \epsilon}{|z - z_0|}.
\]

Since the integral is independent of \( \delta \), and \( \epsilon > 0 \) is arbitrary, we have

\[
\int_{\gamma_\delta} \frac{f(\zeta)}{\zeta - z} \, d\zeta = 0
\]

for \( \zeta \in \gamma \), so

\[
f(z) = \frac{1}{2\pi i} \int_{\gamma} \frac{f(\zeta)}{\zeta - z} \, d\zeta.
\]

This is true for each \( z \) inside \( \gamma \), \( z \neq z_0 \). But the function

\[
g(z) = \frac{1}{2\pi i} \int_{\gamma} \frac{f(\zeta)}{\zeta - z} \, d\zeta
\]

is holomorphic on the entire disk inside \( \gamma \) by (i).

(v) \( \iff \) (i): Let \( D \) be an open disk centered at \( z_0 \) such that \( f \) is holomorphic on \( D \setminus \{ z_0 \} \), of radius \( r \). If all \( b_k = 0 \), the Laurent series for \( f \) around \( z_0 \) is a power series which converges to \( f \) on \( D \setminus \{ z_0 \} \); thus its radius of convergence is at least \( r \) and it defines a function \( g \) which is holomorphic on \( D \) and agrees with \( f \) on \( D \setminus \{ z_0 \} \). Conversely, if \( g \) is a holomorphic function on an open disk \( D \) centered at \( z_0 \) such that \( f = g \) on \( D \setminus \{ z_0 \} \), the Taylor series for \( g \) around \( z_0 \) converges to \( f \) on \( D \setminus \{ z_0 \} \), so must be the Laurent series for \( f \) around \( z_0 \) by uniqueness of Laurent expansions.

There is a simpler proof that (iii) \( \Rightarrow \) (i) (Exercise X.8.2.12.), and an even simpler proof that (ii) \( \Rightarrow \) (i) (Exercise X.8.2.13.).

\( X.5.2.8. \) The implication (ii) \( \Rightarrow \) (i) means that a continuous function from \( \mathbb{C} \) (or an open subset) to \( \mathbb{C} \) cannot have an isolated point where it is not differentiable (cf. Exercise X.8.2.13.). This is in contrast to the real case, e.g. for the function \( f(x) = |x| \). The theorem also rules out complex analogs of \( g(x) = \sin \frac{1}{x} \) ((iii) \( \Rightarrow \) (i)) and \( h(x) = \frac{1}{\sqrt{|x|}} \) ((iv) \( \Rightarrow \) (i)). (The function \( g(z) = \sin \frac{1}{z} \) is holomorphic with an isolated singularity at 0, but \( g \) is not bounded near 0; in fact the singularity is an essential singularity.)

Poles

\( X.5.2.9. \) Definition. If \( f \) has a singularity (isolated singularity) at \( z_0 \), the singularity is a pole of order \( n \) if \( \frac{1}{f} \) has a removable singularity at \( z_0 \) which is a zero of order \( n \). A pole of order 1 is called a simple pole.

Poles can be simply characterized:
X.5.2.10. Proposition. Suppose $f$ has a singularity at $z_0$. Then $f$ has a pole at $z_0$ if and only if
\[ \lim_{z \to z_0} |f(z)| = +\infty \]
i.e. for any $M > 0$ there is a $\delta > 0$ such that $|f(z)| > M$ whenever $0 < |z - z_0| < \delta$.

Proof: If $f$ has a pole at $z_0$ of order $n$, and $\frac{1}{f} = g$ in a deleted neighborhood of $z_0$ and $g$ has a zero of order $n$ at $z_0$, then there is a deleted neighborhood $U$ of $z_0$ such that $g$ has no zeroes in $U$, and we have
\[ \lim_{z \to z_0} g(z) = 0 \]
and it follows that
\[ \lim_{z \to z_0} |f(z)| = +\infty . \]
Conversely, if
\[ \lim_{z \to z_0} |f(z)| = +\infty \]
there is a deleted neighborhood of $z_0$ on which $f$ is nonzero, so $h = \frac{1}{f}$ is defined in a deleted neighborhood of $z_0$. We have
\[ \lim_{z \to z_0} h(z) = 0 \]
so $h$ has a removable singularity at $z_0$ and the extended function $g$ has an isolated zero at $z_0$.

X.5.2.11. Theorem. If $f$ has a singularity at $z_0$, the following are equivalent:

(i) $f$ has a pole of order $n$ at $z_0$.

(ii) There is a function $\phi$ which is holomorphic in a neighborhood of $z_0$ with $\phi(z_0) \neq 0$, such that
\[ f(z) = \frac{\phi(z)}{(z - z_0)^n} \]
for all $z$ in a deleted neighborhood of $z_0$.

(iii) In the Laurent expansion for $f$ around $z_0$ (X.5.2.4.), $b_n \neq 0$ but $b_k = 0$ for all $k > n$.

Proof: (i) $\Rightarrow$ (ii): There is a function $g$, holomorphic in a neighborhood of $z_0$, such that $\frac{1}{f(z)} = g(z)$ for $z$ in a deleted neighborhood of $z_0$, and there is a function $\psi$, holomorphic in a neighborhood of $z_0$ with $\psi(z_0) \neq 0$, such that $g(z) = (z - z_0)^n \psi(z)$ in a neighborhood of $z_0$. Then $\psi(z) \neq 0$ in a neighborhood $U$ of $z_0$, and for all $z \in U \setminus \{z_0\}$,
\[ f(z) = \frac{1}{(z - z_0)^n} \cdot \frac{1}{\psi(z)} . \]

(ii) $\Rightarrow$ (i): There is a neighborhood $U$ of $z_0$ such that $\phi(z) \neq 0$ for all $z \in U$ and $f(z) = \frac{\phi(z)}{(z - z_0)^n}$ for all $z \in U \setminus \{z_0\}$. Then
\[ g(z) = (z - z_0)^n \frac{1}{\phi(z)} . \]
is holomorphic on \( U \), has a zero of order \( n \) at \( z_0 \), and agrees with \( \frac{1}{f} \) on \( U \setminus \{z_0\} \).

(ii) \( \Rightarrow \) (iii): Suppose the equation holds on \( D \setminus \{z_0\} \), where \( D \) is an open disk centered at \( z_0 \). Let

\[
\sum_{k=0}^{\infty} c_k (z - z_0)^k
\]

be the Taylor expansion of \( \phi \) around \( z_0 \), which converges to \( \phi \) on \( D \). Then \( c_0 = \phi(z_0) \neq 0 \). Then, for \( z \in D \setminus \{z_0\} \),

\[
f(z) = \frac{c_0}{(z - z_0)^n} + \cdots + \frac{c_{n-1}}{z - z_0} + \sum_{k=n}^{\infty} c_k (z - z_0)^{k-n}
\]

where the power series converges u.c. on \( D \). This must be the Laurent expansion for \( f \) around \( z_0 \) by uniqueness of Laurent expansions.

(iii) \( \Rightarrow \) (ii): Suppose

\[
f(z) = \frac{b_n}{(z - z_0)^n} + \cdots + \frac{b_1}{z - z_0} + \sum_{k=0}^{\infty} a_k (z - z_0)^k
\]

is the Laurent expansion of \( f \) around \( z_0 \), with \( b_n \neq 0 \), converging u.c. on \( D \setminus \{z_0\} \), for an open disk \( D \) centered at \( z_0 \). Set \( c_k = b_{n-k} \) for \( 0 \leq k \leq n - 1 \) and \( c_k = a_{k-n} \) for \( k \geq n \). Then the power series

\[
\sum_{k=0}^{\infty} c_k (z - z_0)^k
\]

converges u.c. on \( D \) to a holomorphic function \( \phi \), with the required properties.

\[\Box\]

\textbf{X.5.2.12.} There is thus a symmetry between poles and zeroes: a pole of order \( n \) can be thought of as a zero of order \( -n \), or a zero of order \( n \) can be considered a pole of order \( -n \). Indeed, if \( f \) is holomorphic in a deleted neighborhood of \( z_0 \) and has a pole or removable singularity at \( z_0 \), or is already defined and differentiable also at \( z_0 \), then the Laurent expansion of \( f \) around \( z_0 \) is of the form

\[
f(z) = \sum_{k=-n}^{\infty} a_k (z - z_0)^k
\]

where \( n \in \mathbb{Z} \) may be positive, negative, or 0 and \( a_n \neq 0 \). If \( n > 0 \), \( f \) has a zero of order \( n \) at \( z_0 \) (perhaps after a singularity at \( z_0 \) has been removed). If \( n < 0 \), \( f \) has a pole of order \( -n \) at \( z_0 \). If \( n = 0 \), then \( f \) is holomorphic around \( z_0 \) and \( f(z_0) \neq 0 \), and we may regard \( f \) as having a zero or pole at \( z_0 \) of order 0.

\textbf{X.5.2.13.} Examples. The function \( f(z) = \frac{1}{(z - z_0)^n} \) has a pole of order \( n \) at \( z_0 \), as does the function

\[
g(z) = \frac{e^z}{(z - z_0)^n}.
\]

Since the Taylor series for \( e^z \) around \( z_0 \) is

\[
e^z = \sum_{k=0}^{\infty} \frac{e^{z_0}}{k!} (z - z_0)^k
\]

953
we have that the Laurent series of \( g \) around \( z_0 \) is
\[
e^{z_0} \frac{e^{z_0}}{(z - z_0)^n} + \cdots + \frac{e^{z_0}}{(n - 1)! (z - z_0)^{n-1}} + \sum_{k=n}^{\infty} \frac{e^{z_0}}{k!} (z - z_0)^{k-n}.
\]

**Essential Singularities**

**X.5.2.14.** Definition. If \( f \) has a singularity (isolated singularity) at \( z_0 \), the singularity is an essential singularity if it is not a removable singularity or a pole.

**X.5.2.15.** We should emphasize that the term essential singularity is used only for isolated singularities. Thus the “singularities” at 0 in X.5.2.2. (iii)–(iv) are not essential singularities (these “singularities” are even more “essential” than essential singularities!)

Essential singularities can be characterized from the Laurent expansion by a process of elimination:

**X.5.2.16.** Proposition. If \( f \) has a singularity at \( z_0 \), and
\[
f(z) = \sum_{k=0}^{\infty} a_k (z - z_0)^k + \sum_{k=1}^{\infty} \frac{b_k}{(z - z_0)^k}
\]
is its Laurent expansion around \( z_0 \), then the singularity at \( z_0 \) is an essential singularity if and only if infinitely many \( b_k \) are nonzero.

**Proof:** The singularity is removable if and only if all \( b_k \) are zero, and a pole if and only if at least one \( b_k \), but only finitely many, is nonzero.

**X.5.2.17.** Examples. (i) Let \( f(z) = e^{1/z} \). Then \( f \) has a singularity at 0. As \( z \to 0 \) along the positive real axis, \( |f(z)| \to +\infty \), so the singularity at 0 is not removable. And as \( z \to 0 \) along the negative real axis, \( f(z) \to 0 \), so the singularity is not a pole. Thus it is an essential singularity.

This can be seen another way. If \( z \neq 0 \), the inverse power series
\[
\sum_{k=1}^{\infty} \frac{1}{k!} \frac{1}{z^k}
\]
converges to \( e^{1/z} \). Thus this is the Laurent expansion of \( f \) around 0. Since infinitely many negative power coefficients are nonzero, the singularity is essential.

(ii) A closely related example is Cauchy’s example (V.17.2.2.) of a \( C^\infty \) function from \( \mathbb{R} \) to \( \mathbb{R} \) which is not (real) analytic. Let \( f(z) = e^{-1/z^2} \). This function is holomorphic on \( \mathbb{C} \setminus \{0\} \). As \( z \to 0 \) along the real axis, \( f(z) \to 0 \), and if we define \( f(0) = 0 \), it becomes \( C^\infty \) as a function from \( \mathbb{R} \) to \( \mathbb{R} \). But if \( z \to 0 \) along the imaginary axis, \( |f(z)| \to +\infty \). Thus \( f \), as a function from \( \mathbb{C} \setminus \{0\} \) to \( \mathbb{C} \), has an essential singularity at 0.

The next result shows that the behavior of a holomorphic function near an essential singularity is very complicated.
Theorem. [Casorati-Weierstrass] Let \( f \) have an essential singularity at \( z_0 \), and \( U \) a deleted neighborhood of \( z_0 \) contained in the domain of \( f \). Then the image of \( U \) under \( f \) is dense in \( \mathbb{C} \). If \( w \in \mathbb{C} \), then there is a sequence \((z_n)\) in \( U \) with \( z_n \to z_0 \) and \( f(z_n) \to w \).

Proof: The two statements are obviously equivalent (the second follows from the first by taking a decreasing sequence of such neighborhoods), so we prove the first. The proof is very similar to the proof of X.3.3.11. Suppose \( f(U) \) is not dense in \( \mathbb{C} \). Then there is a \( w \in \mathbb{C} \) and an \( \epsilon > 0 \) such that \( |f(z) - w| \geq \epsilon \) for all \( z \in U \). Set

\[
g(z) = \frac{1}{f(z) - w}
\]

for \( z \in U \); then \( g \) is holomorphic on \( U \) and has a singularity at \( z_0 \). We have \( |g(z)| \leq \frac{1}{\epsilon} \) for all \( z \in U \), so by X.5.2.7. this singularity is removable, i.e.

\[
c = \lim_{z \to z_0} g(z)
\]

exists. Then, if \( c \neq 0 \), we have

\[
\lim_{z \to z_0} f(z) = w + \frac{1}{c}
\]

so the singularity of \( f \) at \( z_0 \) is removable, a contradiction. And if \( c = 0 \), we have

\[
\lim_{z \to z_0} |f(z)| = +\infty
\]

so the singularity of \( f \) at \( z_0 \) is a pole, another contradiction.

Actually, a much stronger result is true:

Theorem. [Big Picard Theorem] Let \( f \) have an essential singularity at \( z_0 \), and \( U \) a deleted neighborhood of \( z_0 \) contained in the domain of \( f \). Then, with at most one exception, \( f \) takes every complex value infinitely many times in \( U \).

This result is the best possible: \( e^{1/z} \) never takes the value 0. The proof is beyond the scope of this book; see e.g. [3]. The Big Picard Theorem implies the Little Picard Theorem X.3.3.12.; cf. Exercise X.8.2.14..

Behavior at Infinity

It also makes sense to say that certain functions have singularities at infinity:

Definition. Let \( f \) be holomorphic on a set \( \{ z : |z| > R \} \) for some \( R \). Then \( f \) has a singularity at infinity. We say \( f \) has a removable singularity [resp. pole, essential singularity] at infinity if the function \( g(z) = f \left( \frac{1}{z} \right) \) has a removable singularity [resp. pole, essential singularity] at 0.

We can characterize the types of singularities at infinity:
**X.5.3.2.** **Proposition.** Let $f$ have a singularity at infinity. Then

(i) The singularity at infinity is removable if and only if $\lim_{z \to \infty} f(z)$ exists, i.e. there is a number $c \in \mathbb{C}$ such that, for every $\epsilon > 0$, there is an $M$ such that $|f(z) - c| < \epsilon$ whenever $|z| > M$.

(ii) The singularity at infinity is a pole if and only if $\lim_{z \to \infty} |f(z)| = +\infty$, i.e. for every $N$ there is an $M$ such that $|f(z)| > N$ whenever $|z| > M$.

(iii) Otherwise, the singularity at infinity is an essential singularity.

**X.5.3.3.** If $f$ has a singularity at infinity, i.e. it is holomorphic on an annulus $\Omega = \{ z : |z| > R \}$, then it has a Laurent expansion

$$f(z) = \sum_{k=0}^{\infty} a_k z^k + \sum_{k=1}^{\infty} b_k \frac{1}{z^k}$$

around 0 which converges on $\Omega$. If $g(z) = f \left( \frac{1}{z} \right)$, then the Laurent expansion of $g$ around 0 converging on $\{ z : 0 < |z| < 1/R \}$ is obtained by replacing $z$ by $z^{-1}$ in this expansion, effectively interchanging the $a_k$ and $b_k$. Thus we obtain a classification of singularities at infinity from the Laurent expansion:

**X.5.3.4.** **Proposition.** If $f$ is holomorphic on the annulus $\Omega = \{ z : |z| > R \}$, with Laurent expansion

$$f(z) = \sum_{k=0}^{\infty} a_k z^k + \sum_{k=1}^{\infty} b_k \frac{1}{z^k}$$

around 0 which converges on $\Omega$, then the singularity at infinity is

(i) Removable if (and only if) all $a_k \ (k \geq 1)$ are 0.

(ii) A pole if (and only if) some $a_k \ (k \geq 1)$, but only finitely many, are nonzero.

(iii) Essential if (and only if) infinitely many $a_k$ are nonzero.

As a corollary, we get an important property of entire functions:

**X.5.3.5.** **Corollary.** Let $f$ be an entire function. Then the singularity at infinity is

(i) Removable if $f$ is constant.

(ii) A pole if $f$ is a nonconstant polynomial.

(iii) Essential otherwise.

**Proof:** The Laurent expansion of $f$ on any annulus centered at 0 is just the Taylor series of $f$ around 0. 

The fact that a nonconstant polynomial has a pole at infinity is the essential content of Lemma X.1.4.1.
X.5.3.6. We can also define the order of a pole of \( f \) at infinity to be the order of the pole of \( g(z) = f \left( \frac{1}{z} \right) \) at 0. And we can consider a zero at infinity: \( f \) has a zero at infinity if \( g \) has a removable singularity at 0 which, when removed, is a zero. The order of the zero of \( f \) at infinity is the order of this zero of \( g \). These orders can be read from the Laurent expansion of \( f \) in an unbounded annulus in the obvious way, as the largest \( n \) for which \( a_n \neq 0 \) for a pole, and similarly for the \( b_n \) for a zero.

X.5.3.7. We have used expansions around 0 converging in an unbounded annulus centered at 0 merely for convenience. The same results hold if we use unbounded annuli centered at any \( z_0 \) by using \( g(z) = f \left( \frac{1}{z-z_0} + z_0 \right) \), i.e. \( g(z - z_0) = f \left( \frac{1}{z-z_0} \right) \). This is occasionally useful when \( f \) is naturally expanded around some \( z_0 \neq 0 \).

X.5.4. Meromorphic Functions

X.5.5. The Residue Theorem

X.5.5.1. It has been suggested that Cauchy got the idea for this theorem from his dog, which left a residue at every pole. [Actually Cauchy did not use the term pole, although he did introduce and use résidue.]

X.5.6. Principle of the Argument

Hurwitz’s Theorem

The following theorem has several interesting and useful corollaries, any of which can be called “Hurwitz’s Theorem” (and are in various references).

X.5.6.1. Theorem. [Hurwitz’s Theorem] Let \( \Omega \) be an open set in \( \mathbb{C} \), and \((f_n)\) a sequence of holomorphic functions on \( \Omega \) converging normally on \( \Omega \) to a (holomorphic) function \( f \). Suppose \( f \) has a zero of order \( m \) at \( z_0 \in \Omega \), and let \( \gamma \) be a circle centered at \( z_0 \) bounding a closed disk contained in \( \Omega \) and containing no other zeroes of \( f \). Then, for all sufficiently large \( n \), \( f_n \) has exactly \( m \) zeroes inside \( \gamma \), counted with multiplicity.

Proof: Since \( f_n \to f \) uniformly on \( \Omega \), \( f_n \) has no zeroes on \( \gamma \) for sufficiently large \( n \). Thus, passing to a tail of the sequence \((f_n)\), we may assume no \( f_n \) has zeroes on \( \gamma \). Then \( \frac{f'_n}{f_n} \to \frac{f'}{f} \) uniformly on \( \gamma \), so if \( Z_{f_n} \) is the number of zeroes of \( f_n \) inside \( \gamma \), we have

\[
Z_{f_n} = \frac{1}{2\pi i} \int_{\gamma} \frac{f'_n}{f_n} \to \frac{1}{2\pi i} \int_{\gamma} \frac{f'}{f} = m. 
\]

\[\boxed{\text{Wow!}}\]
Let $\Omega$ be a connected open set in $\mathbb{C}$, and $(f_n)$ a sequence of holomorphic functions on $\Omega$ converging normally on $\Omega$ to a (holomorphic) function $f$ which is not identically 0. If $f(z_0) = 0$, then there is a sequence $(k_n)$ in $\mathbb{N}$ and a sequence $(z_n)$ in $\Omega$ with $z_n \to z_0$ and $f_{k_n}(z_n) = 0$ (informally, every zero of $f$ is a limit of zeroes of the $f_n$).

Proof: Let $(\gamma_n)$ be a sequence of circles centered at $z_0$ of radius decreasing to 0, within a closed disk contained in $\Omega$ containing no other zeroes of $f$. 😊

The restriction that $f$ be not identically 0 is necessary: consider the sequence $f_n(z) = e^{z_n}$.

Corollary. Let $\Omega$ be a connected open set in $\mathbb{C}$, and $(f_n)$ a sequence of holomorphic functions on $\Omega$ converging normally on $\Omega$ to a (holomorphic) function $f$ which is not identically 0. If each $f_n$ has at most $m$ zeroes in $\Omega$ (counted with multiplicity), then $f$ also has at most $m$ zeroes in $\Omega$ (counted with multiplicity).

Proof: Suppose $f$ has zeroes at $z_1, \ldots, z_r$ of multiplicity $m_1, \ldots, m_r$ respectively, with $m_1 + \cdots + m_r > m$. For each $k$, let $\gamma_k$ be a small circle centered at $z_k$ so that the circles do not overlap and the bounded closed disks are contained in $\Omega$ and contain no other zeroes of $f$. Then, for sufficiently large $n$, $f_n$ has $m_k$ zeroes inside $\gamma_k$ for each $k$, and hence more than $m$ zeroes in all, a contradiction. 😊

Under the hypotheses, even if all $f_n$ have exactly $m$ zeroes in $\Omega$, the limit function can have fewer than $m$ if the zeroes of the $f_n$ cluster on the boundary of $\Omega$. As a very simple case, let $\Omega$ be the open right half plane and $f_n(z) = z - \frac{1}{n}$ for each $n$.

The special case $m = 0$ is often stated as Hurwitz’s Theorem:

Corollary. Let $\Omega$ be a connected open set in $\mathbb{C}$, and $(f_n)$ a sequence of holomorphic functions on $\Omega$ converging normally on $\Omega$ to a (holomorphic) function $f$ which is not identically 0. If each $f_n$ is never zero in $\Omega$, then $f$ is also never zero in $\Omega$.

Again, the example $f_n(z) = z_n$ shows that the assumption that $f$ is not identically 0 is necessary.

The following consequence of a special case of Corollary. is especially important:

Corollary. Let $\Omega$ be a connected open set in $\mathbb{C}$, and $(f_n)$ a sequence of holomorphic functions on $\Omega$ converging normally on $\Omega$ to a (holomorphic) function $f$ which is not constant. If each $f_n$ is one-to-one, then $f$ is also one-to-one.

Proof: For any $w \in \mathbb{C}$, the function $g_n = f_n - w$ has at most one zero in $\Omega$, and hence the limit function $f - w$ also has at most one zero in $\Omega$. 😊

This result can be generalized: if each $f_n$ is at most $m$-to-one, and $f$ is not constant, then it is at most $m$-to-one too.
X.6. Conformal Equivalence and the Riemann Mapping Theorem

Throughout this section, we will let $\mathbb{D}$ denote the open unit disk in $\mathbb{C}$.

X.6.1. Conformal Equivalence

X.6.2. Simply Connected Sets in $\mathbb{C}$

It is a remarkable fact, partly topological and partly analytic, that the open sets in $\mathbb{C}$ which are conformally equivalent to $\mathbb{C}$ or $\mathbb{D}$ can be cleanly characterized in a number of ways. We first recall a special case of a definition from topology (5):

**X.6.2.1. Definition.** Let $\Omega$ be a nonempty open set in $\mathbb{C}$. Then $\Omega$ is *simply connected* if it is connected and every path in $\Omega$ is homotopic in $\Omega$ to a constant path.

Some authors do not require a simply connected space to be connected; but this seems a little silly, especially for open subsets of the plane. In fact, a simply connected space should be path-connected.

**X.6.2.2. Theorem.** Let $\Omega$ be a nonempty connected open set in $\mathbb{C}$ ($\mathbb{R}^2$). The following are equivalent:

**Topological conditions:**

(i) $\Omega$ is simply connected.

(ii) For any $p, q \in \Omega$, any two paths from $p$ to $q$ are homotopic in $\Omega$.

(iii) $\Omega$ is contractible.

(iv) $\Omega$ is homeomorphic to $\mathbb{C}$ and $\mathbb{D}$.

**Intermediate condition:**

(v) For every closed contour $\gamma$ in $\Omega$ and $z \in \mathbb{C} \setminus \Omega$, the winding number $w(\gamma, z)$ of $\gamma$ around $z$ is 0.

**Analytic conditions:**

(vi) The contour integral of any holomorphic function on $\Omega$ around any closed curve in $\Omega$ is 0.

(vii) The contour integral of any holomorphic function on $\Omega$ along any contour $\gamma$ in $\Omega$ depends only on the endpoints of $\gamma$.

(viii) Every holomorphic function on $\Omega$ has an antiderivative on $\Omega$.

(ix) $\Omega$ is conformally equivalent to $\mathbb{C}$ or $\mathbb{D}$.

If $\Omega$ is bounded, these are also equivalent to

(x) $\partial \Omega$ is connected.

(xi) $\mathbb{C} \setminus \Omega$ is connected.
X.6.2.3. The implications (iii) ⇒ (i) ⇔ (ii) hold in any topological space (.), and (ix) ⇒ (iv) ⇒ (iii) ⇒ (i) are trivial. The implication (x) ⇒ (xi) is true in great generality (.), but (xi) ⇒ (x) is much more difficult and special (.). Conditions (i)–(iv) and (x) make sense for open sets in \( \mathbb{R}^n \) for any \( n \) (and indeed much more generally; (iv) means \( \Omega \) is homeomorphic to \( \mathbb{R}^n \)), but are not equivalent for \( n \neq 2 \): the interior of a solid torus in \( \mathbb{R}^3 \) satisfies (x) but not (i), and the open region between two concentric spheres in \( \mathbb{R}^3 \) satisfies (i) but not (iii) or (x). And a contractible open set in \( \mathbb{R}^3 \) is not homeomorphic to \( \mathbb{R}^3 \) in general (.). (Note also that (i) ⇒ (x) fails for bounded open sets in \( \mathbb{R} \); (i)–(iv) are equivalent in \( \mathbb{R} \) since a simply connected open set in \( \mathbb{R} \) is just an open interval.) The implications (xi) ⇒ (i) and (iv) ⇒ (xi) do not hold for unbounded open sets in \( \mathbb{R}^2 \), e.g. \( \mathbb{C} \setminus \{0\} \) and an infinite open strip. (If we work in the Riemann sphere, (i), (x), and (xi) are equivalent.)

X.6.2.4. Condition (v) is called an “intermediate condition” since it is essentially topological, but only makes sense in \( \mathbb{R}^2 \) and is closely connected with contour integration. We have (v) ⇔ (vi) ⇔ (vii) ⇔ (viii) by (.) and (.) . If \( \Omega \) is bounded, (x) ⇒ (v) since winding number is constant on connected subsets of \( \mathbb{C} \setminus \Omega \) (.) and is 0 on the unbounded component. Also, (i) ⇒ (vi) is () .

X.6.2.5. Thus, we have the following implications:

\[
\text{(ix)} \Rightarrow \text{(iv)} \Rightarrow \text{(iii)} \Rightarrow \text{(i)} \Leftrightarrow \text{(ii)} \Leftrightarrow \text{(v)} \Leftrightarrow \text{(vi)} \Leftrightarrow \text{(vii)} \Leftrightarrow \text{(viii)}
\]

and, if \( \Omega \) is bounded, (x) ⇒ (v).

X.6.2.6. To finish the proof of the theorem, we will show (viii) ⇒ (ix) and, if \( \Omega \) is bounded, (v) ⇒ (x). The implication (viii) ⇒ (ix) is the most spectacular result, called the Riemann Mapping Theorem; the proof is complicated and is given in X.6.3. In [GK06], an open set satisfying (viii) is called holomorphically simply connected, which seems like good terminology.

X.6.2.7. Even the implication (i) ⇒ (iv), a purely topological result, is highly nontrivial. The simplest proof of this implication seems to be via (ix) using the Riemann Mapping Theorem, a much stronger result! As noted above, in Euclidean spaces this result is special to \( \mathbb{R}^2 \).

X.6.3. The Riemann Mapping Theorem
The Riemann Mapping Theorem is one of the major theorems of Complex Analysis:

X.6.3.1. Theorem. [RIEMANN MAPPING THEOREM] Let \( \Omega \) be a holomorphically simply connected open set in \( \mathbb{C} \), i.e. a nonempty open set satisfying (viii) of X.6.2.2., with \( \Omega \neq \mathbb{C} \). Then \( \Omega \) is conformally equivalent to \( \mathbb{D} \). More precisely, if \( z_0 \in \Omega \), then there is a unique conformal equivalence \( f : \Omega \to \mathbb{D} \) with \( f(z_0) = 0 \) and \( f'(z_0) \) a positive real number.

X.6.3.2. Note that the restriction \( \Omega \neq \mathbb{C} \) is necessary: a conformal bijection from \( \mathbb{C} \) to \( \mathbb{D} \) would be a bounded nonconstant entire function, contradicting Liouville’s Theorem (.) .
X.6.3.3. We first show uniqueness of $f$, assuming existence; we will first relax the last condition and show near uniqueness in that setting. Suppose $f$ and $g$ are conformal equivalences from $\Omega$ to $\mathbb{D}$ with $f(z_0) = g(z_0) = 0$. Set $h = f \circ g^{-1}$; then $h$ is a conformal bijection from $\mathbb{D}$ to $\mathbb{D}$, and $h(0) = 0$. Thus there is an $\alpha \in \mathbb{C}$, $|\alpha| = 1$, with $h(z) = \alpha z$ (note that $g'(z_0) \neq 0$ by (i)). As a consequence, $f(z) = \alpha g(z)$, i.e. $f$ is just $g$ followed by a rotation (and vice versa). By the Chain Rule we have

$$\alpha = h'(0) = f'(g^{-1}(0))(g^{-1})'(0) = f'(z_0)\frac{1}{g'(z_0)}$$

(note that $g'(z_0) \neq 0$ by (i)). If $f'(z_0)$ and $g'(z_0)$ are positive real numbers, then $\alpha$ is a positive real number of absolute value $1$, i.e. $\alpha = 1$, $f = g$.

X.6.3.4. To show existence, we roughly follow the exposition of [GK06]. Let $\mathcal{F}$ be the set of all one-to-one holomorphic functions $f : \Omega \rightarrow \mathbb{D}$ with $f(z_0) = 0$. We will show:

1. $\mathcal{F} \neq \emptyset$.
2. There is an $f \in \mathcal{F}$ for which $|f'(z_0)|$ is maximum for all functions in $\mathcal{F}$.
3. A function $f \in \mathcal{F}$ for which $|f'(z_0)|$ is maximum is a conformal bijection.
4. Such an $f$ can be adjusted to make $f'(z_0)$ a positive real number.

As pointed out in [GK06], this outline can be motivated by the case where $\Omega = \mathbb{D}$ and $z_0 = 0$: a holomorphic map $f$ from $\mathbb{D}$ to $\mathbb{D}$ with $f(0) = 0$ is a conformal bijection if and only if $|f'(0)| = 1$, which is the largest possible value of $|f'(0)|$ for holomorphic functions from $\mathbb{D}$ to $\mathbb{D}$ sending $0$ to $0$ by the Schwarz Lemma.

For both 1 and 3, we need the following lemma:

X.6.3.5. Lemma. Let $\Omega$ be a holomorphically simply connected open set in $\mathbb{C}$, and $f$ holomorphic on $\Omega$. Suppose $f$ is never $0$ on $\Omega$. Then

(i) There is a holomorphic function $g$ on $\Omega$ with $e^g = f$ (i.e. $g$ is a “logarithm” for $f$).

(ii) There is a holomorphic function $h$ on $\Omega$ with $h^2 = f$ (i.e. $h$ is a “square root” for $f$).

Proof: (i): Since $f$ is never $0$ on $\Omega$, $\frac{f'}{f}$ is holomorphic on $\Omega$. Let $\phi$ be an antiderivative for $\frac{f'}{f}$ on $\Omega$. Fix a $z_0 \in \Omega$ and $\alpha$ a value for $\log(f(z_0))$, i.e. so that $e^\alpha = f(z_0)$. Let $g(z) = \phi(z) + \alpha - \phi(z_0))$. Then $g$ is an antiderivative for $\frac{f'}{f}$, and $g(z_0) = \alpha$, so $e^{g(z)} = f(z_0)$. Then, if $\psi = \frac{e^{g}}{f}$, we have, for all $z \in \Omega$,

$$\psi'(z) = \frac{f(z)e^{g(z)}g'(z) - e^{g(z)}f'(z)}{|f(z)|^2} = \frac{f(z)e^{g(z)}f'(z) - e^{g(z)}f'(z)}{|f(z)|^2} = 0$$

so $\psi$ is constant since $\Omega$ is connected. Since $\psi(z_0) = 1$, we have $e^{g(z)} = f(z)$ for all $z \in \Omega$.

(ii): Let $g$ be as in (i), and let $h = e^{g/2}$.  

$\diamondsuit$
Lemma. By the Chain Rule, \[ s \text{Lemma} \]

Later that \( f \) and, since \( ! \)

where \( \phi \)

We have that \( d \)

Montel’s Theorem (\[ X.6.3.7. \])

and note that if \( B \)

is an open mapping, there is an \( h \)

never takes the value 0. By

to get an element of

We now prove 1. If \( X.6.3.6. \)

then \( s \)

\[ w \]

Set \( D \)

Thus \( X.6.3.8. \).

Set \( D \)

be the restriction to \( \Omega \)

onto \( \Omega \) and let \( h \)

is one-to-one, but if it takes the value \( 0 \). By \( \epsilon \)

This completes the proof of the Riemann Mapping Theorem. 

\[ X.6.3.9. \]

Step 4 is easy: If \( f \) is a conformal bijection from \( \Omega \) to \( D \) (e.g. the one constructed in 2), then \( f'(z_0) \neq 0 \). Set \( \alpha = \frac{f'(z_0)}{f(z_0)} \) and \( g(z) = \alpha f(z) \). Then \( g \) is also a conformal bijection with \( g(z_0) = 0 \), and \( g'(z_0) = |f'(z_0)| > 0 \).

This completes the proof of the Riemann Mapping Theorem.
X.7. Analytic Continuation and Riemann Surfaces

In this section we will assume all open sets we work on are connected. We will use the term region to mean a nonempty connected open subset of \( \mathbb{C} \).

X.7.1. Analytic Function Elements

The Rigidity Theorem implies that if \( \Omega \) and \( \bar{\Omega} \) are regions in \( \mathbb{C} \), whose intersection is nonempty, and \( f \) is holomorphic on \( \Omega \), then there is at most one function \( \tilde{f} \) which is holomorphic on \( \bar{\Omega} \) and agrees with \( f \) on the intersection. There may or may not be such an \( \tilde{f} \); but if there is, \( f \) and \( \tilde{f} \) can be reasonably considered to be “pieces” of the same function which is holomorphic on some unspecified domain containing both \( \Omega \) and \( \bar{\Omega} \).

Things can be more complicated, however. The intersection of \( \Omega \) and \( \bar{\Omega} \) is not necessarily connected, and the functions \( f \) and \( \tilde{f} \) can agree on part of the intersection but not all. An example is two branches of \( \log z \) \((\alpha, \beta)\) corresponding to \( \alpha \) and \( \beta \) with \( |\alpha - \beta| < 2\pi \).

A related difficulty which actually provides a solution to the first difficulty is that if \( \Omega_1, \Omega_2, \) and \( \Omega_3 \) are regions, and \( f_j \) is holomorphic on \( \Omega_j \), if \( f_1 = f_2 \) on \( \Omega_1 \cap \Omega_2 \) and \( f_2 = f_3 \) on \( \Omega_2 \cap \Omega_3 \), then \( f_1 \) and \( f_3 \) should be regarded as “pieces” of the same function even if \( \Omega_1 \) and \( \Omega_3 \) are disjoint, or if they overlap but \( f_1 \) and \( f_3 \) do not agree on \( \Omega_1 \cap \Omega_3 \), as can happen, e.g. with suitable branches of the logarithm. The solution is to regard \( f \) on \( \Omega \) and \( \tilde{f} \) on \( \bar{\Omega} \) as “pieces” of the same function if there is a finite chain of intermediate “pieces” \( f_j \) on \( \Omega_j \) which agree on consecutive overlaps. Using this extension of equivalence, we may regard any two branches of \( \log z \), even ones whose angles differ by more than \( 2\pi \), to be “pieces” of the same big function. The domain of this big function is not a subset of \( \mathbb{C} \), but a large abstract set made up of overlapping pieces which can be identified with regions in \( \mathbb{C} \) (technically a complex 1-manifold \( (\cdot) \)). This domain is called the Riemann surface of the function.

We now discuss the details.

X.7.1.1. Definition. An analytic function element is a pair \((\Omega, f)\), where \( \Omega \) is a region (nonempty connected open set) in \( \mathbb{C} \) and \( f \) is holomorphic on \( \Omega \).

Two analytic function elements \((\Omega, f)\) and \((\bar{\Omega}, \tilde{f})\) are equivalent if there is a finite chain \((\Omega_1, f_1), (\Omega_n, f_n) = (\bar{\Omega}, \tilde{f})\) \((1 \leq j \leq n)\) such that \((\Omega_1, f_1) = (\Omega, f)\), \((\Omega_n, f_n) = (\bar{\Omega}, \tilde{f})\), and \(\Omega_j \cap \Omega_{j+1} \neq \emptyset\) and \(f_j = f_{j+1}\) on \(\Omega_j \cap \Omega_{j+1}\) for \(1 \leq j < n\).

A total analytic function is an equivalence class of analytic function elements.

X.7.1.2. It is obvious that equivalence of analytic function elements is indeed an equivalence relation. Every analytic function element determines a unique total analytic function, namely its equivalence class. Equivalent analytic function elements determine the same total analytic function.

X.7.1.3. Proposition. (i) If \((\Omega, f)\) and \((\bar{\Omega}, \tilde{f})\) are analytic function elements, \(\Omega \cap \bar{\Omega} \neq \emptyset\), and \(f = \tilde{f}\) on \(\Omega \cap \bar{\Omega}\), then \((\Omega, f)\) and \((\bar{\Omega}, \tilde{f})\) are equivalent.

(ii) If \((\Omega, f)\) is an analytic function element, \(\Omega\) a subregion of \(\Omega\), and \(\tilde{f} = f|_{\Omega}\), then the analytic function element \((\Omega, \tilde{f})\) is equivalent to \((\Omega, f)\).

(iii) If \(\{(\Omega_k, f_k) : k \in K\}\) are analytic function elements, such that \(f_j = f_k\) on \(\Omega_j \cap \Omega_k\) for all \(j\) and \(k\), and \(\Omega = \cup K \Omega_k\) is connected (e.g. if \(\cap K \Omega_k \neq \emptyset\)), set \(f = f_k\) on \(\Omega_k\) for each \(k\). Then \(f\) is a well-defined holomorphic function on \(\Omega\), and the analytic function element \((\Omega, f)\) is equivalent to each \((\Omega_k, f_k)\).
X.7.2. The Riemann Surface of a Total Analytic Function

X.7.2.1. We can put the domains of the elements of a total analytic function together to get a “surface” which is the natural domain of the function. Informally, we take the “union” of the domains of the elements, with points in overlapping elements identified provided the function agrees around these points. More precisely:

X.7.2.2. Definition. Let \( f = \{ (\Omega_k, f_k) : k \in K \} \) be a total analytic function, i.e. the \((\Omega_k, f_k)\) are equivalent analytic function elements. Let \( D_f \) be the disjoint union of the \( \Omega_k \) (even if \( \Omega_j = \Omega_k \) as subsets of \( \mathbb{C} \), if \( j \neq k \) they are disjoint subsets of \( D_f \)). Put an equivalence relation on \( D_f \) as follows. If \( z_j \in \Omega_j \), \( z_k \in \Omega_k \), set \( z_j \sim z_k \) if \( z_j = z_k \in \Omega_j \cap \Omega_k \subseteq \mathbb{C} \) and \( f_j(z) = f_k(z) \) for all \( z \) in a neighborhood of \( z_j = z_k \). Write \( \hat{\Omega}_k = \{ [z] : z \in \Omega_k \} \). Let \( S_f \) be the set of equivalence classes. \( S_f \) is the Riemann surface of the total analytic function \( f \).

The total analytic function \( f \) gives a well-defined function \( f \) from \( S_f \) to \( \mathbb{C} \) by \( f([z]) = f_k(z) \) for \( z \in \Omega_k \). The function \( f \) is called the (complete) analytic function defined by \( f \). Each \((\Omega_k, f_k)\) is a branch of \( f \) or \( f \).

X.7.2.3. There is a natural injective map \( \iota_k \) from \( \Omega_k \) to \( S_f \) for each \( k \), and the restriction of \( f \) to the image \( \hat{\Omega}_k \) of \( \Omega_k \) is exactly \( f_k \).

We topologize \( S_f \) by taking the \( \hat{\Omega}_k \) as a base for the topology. Then each \( \hat{\Omega}_k \) is an open subset of \( S_f \), and the inclusion of \( \Omega_k \) into \( S_f \) is a homeomorphism onto its image. The function \( f : S_f \to \mathbb{C} \) is continuous.

X.7.2.4. The natural identifications of the subsets \( \hat{\Omega}_k \) of \( S_f \) with the corresponding subsets \( \Omega_k \) of \( \mathbb{C} \) give an atlas defining the structure of a complex analytic 1-manifold on \( S_f \). This atlas has the special property that the transition functions between charts are identity maps on open sets in \( \mathbb{C} \). (This natural atlas is not a maximal atlas.)

The next proposition is an immediate corollary of ().

X.7.2.5. Proposition. Let \( f \) be a total analytic function, and \((\Omega_j, f_j)\) and \((\Omega_k, f_k)\) analytic function elements in \( f \). If \( z_0 \in \Omega_j \cap \Omega_k \), then either \( \iota_j(z) = \iota_k(z) \) for all \( z \) in a neighborhood of \( z_0 \) (if \( \iota_j(z_0) = \iota_k(z_0) \)), or \( f_j(z) \neq f_k(z) \) for all \( z \) in a deleted neighborhood of \( z_0 \) and in particular \( \iota_j(z) \neq \iota_k(z) \) for all \( z \) in a neighborhood of \( z_0 \) (if \( \iota_j(z_0) \neq \iota_k(z_0) \)).

X.7.2.6. Corollary. Let \( f \) be a total analytic function with Riemann surface \( S_f \). Then \( S_f \) is Hausdorff.

X.7.2.7. Proposition. Let \( f \) be a total analytic function with Riemann surface \( S_f \). Then \( S_f \) is path-connected.

Proof: Suppose \((\Omega_1, f_1), \ldots, (\Omega_n, f_n)\) are elements of \( f \), and \( z_j \in \Omega_j \), \( z_k \in \Omega_k \). Let \( (\Omega_1, f_1), \ldots, (\Omega_n, f_n) \) be a chain with \( (\Omega_1, f_1) = (\Omega_j, f_j), (\Omega_n, f_n) = (\Omega_k, f_k) \), and \( \Omega_m \cap \Omega_{m+1} \neq \emptyset \) and \( f_m = f_{m+1} \) on \( \Omega_m \cap \Omega_{m+1} \) for \( 1 \leq m < n \). For each \( m, 1 \leq m \leq n-1 \), choose \( z_m \in \Omega_m \cap \Omega_{m+1} \). We have \( \iota_m(z_m) = \iota_{m+1}(z_m) \) for each

964
There is a path from $z_j$ to $z_1$ in $\Omega_1$, a path from $z_m$ to $z_{m+1}$ in $\Omega_{m+1}$ for $1 \leq m \leq n - 2$, and a path from $z_{n-1}$ to $z_k$ in $\Omega_n$. The corresponding paths in the $\Omega_m$ match up at the endpoints and give a path in $S_f$ from $\iota_j(z_j)$ to $\iota_k(z_k)$.

X.7.2.8. EXAMPLES. (i) The Riemann surface of a total analytic function can sometimes be identified with a subset of $\mathbb{C}$. The simplest case is when $f$ is an entire function. Then $(\mathbb{C}, f)$ is an analytic function element, and the analytic function elements equivalent to it are precisely of the form $(\Omega, f|_{\Omega})$, where $\Omega$ is a region in $\mathbb{C}$. Since the functions in any two elements of the equivalence class agree on the intersection of the regions, every region in $S_f$ is identified with itself as a subset of $\mathbb{C}$. Thus $S_f \cong \mathbb{C}$.

(ii) Similarly, if $f$ is holomorphic on $\mathbb{C}$ except for isolated non-removable singularities, the set $P$ of (non-removable) singularities is a countable subset of $\mathbb{C}$ with no limit point. Then $(\mathbb{C} \setminus P, f)$ is an analytic function element, and as before every equivalent analytic function element is of the form $(\Omega, f|_{\Omega})$, where $\Omega$ is a region in $\mathbb{C} \setminus P$, and $S_f \cong \mathbb{C} \setminus P$. (If $f$ also has removable singularities, then $S_f$ is the domain of $f$ with the removable singularities removed.)

(iii) Here is one of the most important examples, of a total analytic function whose Riemann surface is not a subset of $\mathbb{C}$. If $\Omega$ is $\mathbb{C}$ with a branch cut (ray out from 0) removed (), then there are infinitely many branches of $\log z$ defined on $\Omega$. For each such $f$, $(\Omega, f)$ is an analytic function element, and the copies of $\Omega$ corresponding to different branches are disjoint. If $\bar{\Omega}$ is $\mathbb{C}$ with a different branch cut removed, then $\Omega \cap \bar{\Omega}$ is not connected, and the pieces are identified with parts of different copies of $\Omega$ in $S_f$. The Riemann surface for $\log z$ can be visualized by taking a sequence of copies of $\Omega$, and connecting each sheet along the branch cut with the sheet above, giving a helical surface (Figure X.1, from http://upload.wikimedia.org/wikipedia/commons/4/41/Riemann_surface_log.jpg). Choosing a branch cut just allows the surface to be constructed or visualized in this way; the branch cut has no intrinsic significance as part of the Riemann surface, and any other branch cut would work as well and give the same surface.
Figure X.1: Riemann Surface for $\log z$ (Three levels shown)
(iv) Similarly, the Riemann surface for $\sqrt{z}$ can be constructed by again taking a branch cut out from 0. This time, there are only two branches for each branch cut. The Riemann surface is obtained by gluing each copy of the plane with branch cut removed to the other copy along the branch cut (this cannot be physically accomplished in $\mathbb{R}^3$ since the surfaces would have to pass through each other along the branch cut, but can be done in $\mathbb{R}^4$ or $\mathbb{C}^2$; see Figure X.2, from http://en.wikipedia.org/wiki/File:Riemann_sqrt.jpg).

Figure X.2: Riemann Surface for $\sqrt{z}$

The Riemann surface for $\sqrt{z}$ is similar, with $n$ sheets, each attached to the next one along the branch cut and the last attached to the first.

(v) If $(\Omega_j, f_j)$ and $(\Omega_k, f_k)$ are branches of a total analytic function $f$, and $z \in \Omega_j \cap \Omega_k$, we may have $f_j(z) \neq f_k(z)$ even though $f_j(z) = f_k(z)$: the function with elements $(\Omega, g(z)|g(z) - 2\pi i|)$, where $\Omega$ is a simply connected open set in $\mathbb{C} \setminus \{0\}$ and $g$ is a branch of $\log z$ holomorphic on $\Omega$, has two distinct branches over neighborhoods of 1 both taking the value 0 at 1. (These branches differ at all points of a deleted neighborhood of 1.)

X.7.2.9. If $f$ is a total analytic function with Riemann surface $S_f$, there is a projection map $p_f$ from $S_f$ to $\mathbb{C}$ which sends each $\Omega$ on the surface to the corresponding subset $\Omega$ of $\mathbb{C}$. This projection is continuous and open, its range is an open subset of $\mathbb{C}$, and may be either one-to-one (e.g. in cases X.7.2.8.(i)–(ii)) or many-to-one (e.g. in cases X.7.2.8.(iii)–(iv)). If $p_f$ is one-to-one, it is a homeomorphism onto its image, and $S_f$ can be identified with an open set in $\mathbb{C}$; in this case, $f$ is said to be single-valued; if $p_f$ is not one-to-one, $f$ is said to be multivalued.

In cases X.7.2.8.(iii)–(v), the map $p_f$ is a covering map, but this is not true in general, and the inverse image of different points can even have different cardinality (each point inverse image is always finite or countable since it is relatively discrete in $S_f$). The range of $p_f$ is always a region in $\mathbb{C}$, but it may be quite small.

X.7.2.10. Any analytic function element $(\Omega, f)$ defines a unique total analytic function $f$ and hence a Riemann surface $S_f$, which is the “largest domain” $f$ can be extended to as a holomorphic function. But if $f$
is defined on a small open set \( \Omega \), e.g. on a finite disk by a power series with finite radius of convergence, it can be difficult if not impossible to determine the full Riemann surface of \( f \), or indeed whether \( f \) is single-valued or multivalued.

**X.7.3. Analytic Continuation**

**X.7.3.1.** We now change our point of view slightly, and discuss the problem from X.7.2.10. in more detail. Suppose \( f \) is a holomorphic function on a region \( \Omega \) (i.e. \( (\Omega, f) \) is an analytic function element). How far outside \( \Omega \) can \( f \) be extended as a holomorphic function, and to what degree is the extension unique?

**X.7.3.2.** The first question to discuss is: if \( z \) is a boundary point of \( \Omega \), can a (necessarily unique) holomorphic function \( g \) be defined on an open disk centered at \( z \) which agrees with \( f \) on the part of the disk contained in \( \Omega \)? If not, \( z \) is called a _singular point_ of the boundary (for \( f \)). The set of singular points is a closed subset of the boundary of \( \Omega \). In some cases, it can be shown that there must be singular boundary points, e.g.:

**X.7.3.3.** _Proposition._ Let

\[
\sum_{k=0}^{\infty} a_k (z - z_0)^k
\]

be a power series with radius of convergence \( R \), \( 0 < R < \infty \), and let \( \Omega \) be the open disk of radius \( R \) centered at \( z_0 \). If \( f \) is the holomorphic function on \( \Omega \) defined by the power series, then there is at least one singular point for \( f \) on the boundary of \( \Omega \).

**Proof:** Suppose not. Then for any \( z \) on the boundary circle there is an open disk \( D_z \) of radius \( \epsilon_z \) centered at \( z \) and a holomorphic function \( g_z \) on this disk agreeing with \( f \) on the part of the disk inside \( \Omega \). By the _Rigidity Theorem_, any two \( g_z \) must agree on the intersection of the \( D_z \). Thus there is a well-defined holomorphic function \( g \) on \( U = \Omega \cup \bigcup_z D_z \) which extends \( f \). But \( U \) is an open neighborhood of \( \bar{\Omega} \), which is compact, so \( U \) contains a disk of radius \( R + \epsilon \) centered at \( z_0 \), for some \( \epsilon > 0 \). Then by X.4.4.6. the Taylor series for \( f \) around \( z_0 \) has radius of convergence at least \( R + \epsilon \), a contradiction.

**X.7.3.4.** _Examples._ (i) There may be only one singular boundary point. The power series

\[
\sum_{k=0}^{\infty} z^k
\]

converges to \( f(z) = \frac{1}{1-z} \) on the open unit disk \( \mathbb{D} \). This function can be extended holomorphically to every boundary point of \( \mathbb{D} \) except \( z = 1 \). In fact, it extends to a function holomorphic on \( \mathbb{C} \setminus \{1\} \).

(ii) At the other extreme, all boundary points can be singular points. The power series

\[
\sum_{k=0}^{\infty} z^{2k}
\]
has radius of convergence 1, hence defines a holomorphic function on \( \mathbb{D} \). But if \( \theta \) is a dyadic rational multiple of \( 2\pi \), then it is easily checked that
\[
\lim_{r \to 1^-} |f(re^{i\theta})| = +\infty
\]
so \( e^{i\theta} \) is a singular point of the boundary. Since such points are dense in the unit circle and the set of singular points is closed, every boundary point is a singular point.

(iii) Here is an interesting variation of (ii), a holomorphic function on \( \mathbb{D} \) which can be extended continuously, even smoothly, to the boundary, but for which all boundary points are nonetheless singular. The power series
\[
\sum_{k=1}^{\infty} 2^{-k^2} z^{2^k}
\]
has radius of convergence 1 and converges uniformly on the closed unit disk \( \bar{\mathbb{D}} \), as do the derived series of all orders. Thus the function
\[
f(z) = 1 + 2z + \sum_{k=1}^{\infty} 2^{-k^2} z^{2^k}
\]
is a smooth function (in the vector calculus sense) on \( \bar{\mathbb{D}} \) which is holomorphic on \( \mathbb{D} \). But nonetheless all boundary points are singular by the Hadamard gap theorem. (It turns out that \( f \) is one-to-one on \( \mathbb{D} \), the reason for including the \( 2z \) term. Including the constant term 1 is conventional.)

Examples (ii) and (iii) are lacunary series, power series where the gaps between the indices of consecutive nonzero coefficients become arbitrarily large. There is a discussion of these and related series in [Rem98], where the comment is made that “The gap theorem is in some sense a paradox: power series that, because of their gaps, converge especially fast in the interior of their disk of convergence have singularities almost everywhere on the boundary precisely on account of these gaps.”

We now consider analytic continuation along a path.

**X.7.3.5. Definition.** Let \( \Omega \) be a region in \( \mathbb{C} \), and \( f \) a holomorphic function on \( \Omega \). Let \( \gamma \) a path in \( \mathbb{C} \) from \( z_0 \) to \( z_1 \), with \( z_0 \in \Omega \), parametrized by \( \zeta : [a, b] \to \mathbb{C} \). Then \( f \) can be analytically continued along \( \gamma \) if, for every \( t \in [a, b] \), there is an open disk \( D_t \) centered at \( \zeta(t) \) and a function \( f_t \) holomorphic on \( D_t \) such that, for every \( t_0 \in [a, b] \), \( f_t = f_{t_0} \) on \( D_t \cap D_{t_0} \) for all \( t \) sufficiently close to \( t_0 \), and such that \( f_a = f_{D_0} \).

The essential point is that the path \( \gamma \) begins in \( \Omega \) but may pass or end outside \( \Omega \). In fact this is the only interesting situation: if \( \gamma \) lies inside \( \Omega \), then \( f \) can be analytically continued along \( \gamma \) simply by restriction.

If \( \{(D_t, f_t) : t \in [a, b]\} \) is an analytic continuation of \( f \) along \( \gamma \), then each \( (D_t, f_t) \) is an analytic function element.

**X.7.3.6. Proposition.** If \( \{(D_t, f_t) : t \in [a, b]\} \) is an analytic continuation of \( f \) along \( \gamma \), all analytic function elements \( (D_t, f_t) \) are equivalent.

**Proof:** It is clear that for any \( t_0 \), the function elements \( (D_t, f_t) \) are equivalent to \( (D_{t_0}, f_{t_0}) \) for \( t \) sufficiently close to \( t_0 \). Thus the set of \( t \) in each equivalence class is open in \( [a, b] \). Since the complement of an equivalence class is the union of the other equivalence classes, the set of \( t \) in each equivalence class is also closed in \( [a, b] \). Thus there can be only one equivalence class since \( [a, b] \) is connected.

\[ \_ \]
X.7.3.7. Analytic continuation along a path \( \gamma \) can be alternately considered a finite process: if \( \{(D_t, f_t)\} \) is an analytic continuation, there is a finite partition \( \{a = t_0, t_1, \ldots, t_n = b\} \) of \([a, b]\) such that \( \zeta(t) \in D_{t_k} \cup D_{t_{k+1}} \) for \( t_k \leq t \leq t_{k+1} \), and \( f_{t_k} = f_{t_{k+1}} \) on \( D_{t_k} \cap D_{t_{k+1}} \) for \( 0 \leq k < n \). Conversely, if there is such a partition, disks \( D_k \) centered at \( \zeta(t) \) such that \( \zeta(t) \in D_{t_k} \cup D_{t_{k+1}} \) for \( t_k \leq t \leq t_{k+1} \), and functions \( f_k \) holomorphic on \( D_k \) agreeing on the consecutive overlaps, then \( (D_t, f_t) \) can be defined for each \( t \) by restricting \( f_k \) or \( f_{k+1} \) for \( t_k \leq t \leq t_{k+1} \) to a disk \( D_t \) centered at \( \zeta(t) \) contained in \( D_k \cup D_{k+1} \).

X.7.3.8. Proposition. Let \( \Omega \) be a region in \( \mathbb{C} \), and \( f \) a holomorphic function on \( \Omega \). Let \( \gamma \) a path in \( \mathbb{C} \) from \( z_0 \) to \( z_1 \), with \( z_0 \in \Omega \), parametrized by \( \zeta : [a, b] \to \mathbb{C} \). Then an analytic continuation of \( f \) along \( \gamma \), if it exists, is unique: if \( \{(D_t, f_t)\} \) and \( \{(\tilde{D}_t, g_t)\} \) are analytic continuations of \( f \) along \( \gamma \), then \( f_t = g_t \) on \( D_t \cap \tilde{D}_t \) for all \( t \).

Proof: Let \( S \) be the set of \( t \in [a, b] \) such that \( f_t = g_t \) on \( D_t \cap \tilde{D}_t \). Then \( a \in S \) since both \( f_a \) and \( g_a \) must agree with \( f \) on a neighborhood of \( z_0 \), hence everywhere on \( D_a \cap \tilde{D}_a \) by the Rigidity Theorem. \( S \) is obviously (relatively) open in \([a, b]\), again by the Rigidity Theorem. If \( t_0 \) is a limit point of \( S \), then \( f_{t_0} = g_{t_0} \) on a sequence of points in \( S \) converging to \( t_0 \), and thus \( f_{t_0} = g_{t_0} \) on all of \( D_{t_0} \cap \tilde{D}_{t_0} \) by the Rigidity Theorem, i.e. \( t_0 \in S \). Thus \( S \) is also closed. So \( S = [a, b] \) since \([a, b]\) is connected.

X.7.3.9. Thus, if \( f \) can be analytically continued along \( \gamma \), the value of \( f(\zeta(t)) \) is uniquely determined for each \( t \), and in particular a branch of \( f \) at \( z_1 \) is uniquely determined by the analytic continuation. Note, however, that the curve \( \gamma \) may cross itself, and at crossing or repeated points the value of \( f \) obtained can be different at different times. This is particularly common and important if \( \gamma \) is a closed curve. A good example is \( f(z) = \log z \), \( z_0 = z_1 = 1 \), \( \gamma \) the unit circle parametrized once around counterclockwise. This example also shows that the parametrization (or at least its equivalence class) is essential: if \( \gamma \) is parametrized once around clockwise, or more than once around, different values of \( f \) at \( z_1 \) are obtained.

X.7.3.10. Proposition. Let \( \Omega \) be a region in \( \mathbb{C} \), and \( f \) a holomorphic function on \( \Omega \). If \( \gamma \) is a (parametrized) curve in \( \mathbb{C} \) from \( z_0 \in \Omega \) to \( z_1 \in \mathbb{C} \), then \( f \) can be analytically continued along \( \gamma \) if and only if there is a (necessarily unique) curve \( \hat{\gamma} \) in \( S_f \) from the point \( z_0 \) corresponding to \( z_0 \) on the branch \( (\Omega, f) \) to another point \( \hat{z}_1 \), such that \( p(\hat{\gamma}) = \gamma \).

Proof: If there is such a \( \hat{\gamma} \), \( f \) can clearly be analytically continued along \( \gamma \). Conversely, if \( f \) can be analytically continued along \( \gamma \), there is a partition \( \{a = t_0, t_1, \ldots, t_n = b\} \) of the interval \([a, b]\) such that the disks \( D_{t_k} \) cover \( \gamma \) and \( f_{t_k} = f_{t_{k+1}} \) on \( D_{t_k} \cap D_{t_{k+1}} \) for each \( k \). The pieces of \( \gamma \) for \( t_k \leq t \leq t_{k+1} \) can be successively lifted to \( \tilde{D}_{t_k} \subset S_f \) in a unique way via the local homeomorphisms so that the entire lifted path is continuous.

X.7.3.11. As a result, if \( f \) can be analytically continued along \( \gamma \), there is a “largest” analytic continuation \( (D_t, f_t) \), where \( D_t \) is the open disk of convergence of the Taylor series for \( f_t \) around \( \zeta(t) \). We can use this analytic continuation as the standard one.
X.7.3.12. If $f$ can be analytically continued along $\gamma$, and $\gamma$ is not entirely contained inside $\Omega$, then there is a smallest $t$, say $t = t_1$, for which $\zeta(t_1) \in \partial\Omega$. Then $\zeta(t_1)$ is not a singular point of $\partial\Omega$. There is then a smallest $t_2 > t_1$ such that $\zeta(t_2) \in \partial(\Omega \cup D_{t_1})$ (unless $\gamma \subseteq \Omega \cup D_{t_1}$), and this point is not a singular point. The process can be continued.

Conversely, if $f$ cannot be analytically continued along $\gamma$, then there is a smallest $c \in [a, b]$ such that $f$ cannot be analytically continued along the restriction $\gamma_c$ of $\gamma$ to $[a, c]$. We have $c > a$ since $f$ can be analytically continued along $\gamma_d$ for $d > a$ small enough that $\gamma_d \subseteq \Omega$. Then $\zeta(c)$ can be regarded as a singular point of $f$ along $\gamma$. For example, if $z_0 \in \Omega$, $z_1 \in \partial\Omega$, and $\gamma$ is a path from $z_0$ to $z_1$ with $\zeta(t) \in \Omega$ for $a \leq t \leq b$, then $z_1$ is a singular point of $f$ along $\gamma$ if and only if $z_1$ is a singular point of $\partial\Omega$ in the sense of X.7.3.2. (There is not always such a path for every $z_1 \in \partial\Omega$ if $\partial\Omega$ is not well behaved topologically.)

X.7.3.13. If $f$ is holomorphic on $\Omega$, and $\gamma$ is a path beginning in $\Omega$ ending in a point $z_1$ outside $\Omega$ along which $f$ can be analytically continued, then there is a well-defined value for $f$ at $z_1$ (and for all $z$ in some neighborhood of $z_1$) given by the analytic continuation along $\gamma$. But if $\tilde{\gamma}$ is another path beginning in $\Omega$ and ending at $z_1$, the value of $f$ at $z_1$ defined by analytic continuation along this path need not be the same. A simple example is the principal branch of $\log z$ defined on the right half plane $\Omega$, and the upper and lower unit semicircles from 1 to $-1$. However, homotopic paths give the same result:

X.7.3.14. Theorem. [Monodromy Theorem] Let $f$ be holomorphic on a region $\Omega$, $z_0 \in \Omega$, $z_1 \in \mathbb{C}$. Let $\gamma_0$ and $\gamma_1$ be paths in $\mathbb{C}$ from $z_0$ to $z_1$, which are homotopic by a homotopy $h : [0, 1] \times [a, b]$ (X.3.4.1.). For each $s$, let $\gamma_s$ be the path parametrized by $\zeta_s$, where $\zeta_s(t) = h(s, t)$. Suppose $f$ can be analytically continued along $\gamma_s$ for every $s$. Then the values of $f$ at $z_1$ defined by analytic continuation along $\gamma_0$ and $\gamma_1$ are the same.

X.7.4. The Regular Riemann Surface of a Function

X.7.4.1. If $f$ is a total analytic function with Riemann surface $S_f$, and $f : S_f \rightarrow \mathbb{C}$ is the corresponding complete analytic function, then $f$ has a well-defined derivative at each point of $S_f$ obtained from a local function element representative, and in fact well-defined derivatives of all orders (hence a well-defined Taylor series representation) at each point.

Viewed another way, if $(\Omega_k, f_k)$ is a function element of $f$, then $(\Omega, f')$ is also an analytic function element, and the corresponding total analytic function $f'$ can be regarded as the derivative of the total analytic function $f$.

Although there is a natural map from $S_f$ to $S_{f'}$, which is surjective ($\rightarrow$), the Riemann surface $S_{f'}$ is not the same as the Riemann surface $S_f$ in general; it is only a quotient. (Consider the case of $\log z$; cf. Exercise ($\rightarrow$).) The map from $S_f$ to $S_{f'}$ is a covering map in general ($\rightarrow$).

X.7.4.2. If $f$ is a total analytic function with Riemann surface $S_f$, and $f$ is not constant, then the set of points of $S_f$ where $f'$ is zero is a closed subset $Z_f$ which is discrete in the relative topology ($\rightarrow$). Thus the complement $R_f = S_f \setminus Z_f$ is a dense open subset of $S_f$, called the regular Riemann surface of $f$.

X.7.4.3. If $\zeta \in R_f$, then there is a function element $(\Omega, g)$ of $f$ such that $\Omega$ is a neighborhood of $\zeta$ and $f$ is one-to-one on $\Omega$, i.e. $g$ is one-to-one on $\Omega$ ($\rightarrow$). Then $(g(\Omega), g^{-1})$ is an analytic function element which is a “branch” of $f^{-1}$. It is not hard to see that any two such function elements corresponding to small open sets
in \( R_f \) are equivalent, so the total analytic function defined by them can be called \( f^{-1} \). The correspondence \( \Omega \rightarrow g(\Omega) \) gives a conformal bijection between \( R_f \) and \( R_{f^{-1}} \); thus \( f \) can be regarded as a conformal bijection from \( R_f \) onto \( R_{f^{-1}} \).

**X.7.4.4.** Another way of viewing this is: if \( R_f \) and \( R_{f^{-1}} \) are identified in this way, and \( p \) and \( q \) are the natural projections from \( R_f \) and \( R_{f^{-1}} \) to \( \mathbb{C} \), then \( f \) is completely determined by the two projections \( p \) and \( q \). Thus an analytic function can be thought of as consisting of a Riemann surface and two projections to \( \mathbb{C} \).

**X.7.5. Branch Points**

**X.7.5.1.** The regular Riemann surface \( R_f \) naturally sits as a dense subset of \( S_f \), and the (isolated) points in \( Z_f = S_f \setminus R_f \) do not appear in the Riemann surface \( S_{f^{-1}} \). Conversely, there may be points in \( S_{f^{-1}} \) not corresponding to points of \( S_f \). The points of \( Z_f \) and \( Z_{f^{-1}} \) can all be added to \( R_f \cong R_{f^{-1}} \) to make a larger Riemann surface, and both \( f \) and \( f^{-1} \) can be extended in a meaningful way to these points. Such added points are called branch points.

**X.7.5.2.** Example. Here is a simple example. Let \( f(z) = \sqrt{z} \). Then the Riemann surface \( S_f = R_f \) is a two-sheeted surface which projects to \( \mathbb{C} \setminus \{0\} \) \((\text{X.7.2.8 (iv))}. The inverse function \( f^{-1}(z) = z^2 \) has \( S_{f^{-1}} = \mathbb{C} \) and \( R_{f^{-1}} = \mathbb{C} \setminus \{0\} \). The point 0 can be added to \( R_f \), and \( f \) can be defined to be 0 at this added point, so \( S_f \) can be extended by adding a branch point. There are in this case no branch points to be added to \( R_{f^{-1}} \). The roles of \( f \) and \( f^{-1} \) can of course be interchanged.

**X.7.5.3.** There is an intrinsic way to describe branch points. To motivate this, it is simplest to describe branch points of \( f^{-1} \) corresponding to points of \( Z_f \). Suppose \( \zeta_0 \in Z_f \). Set \( z_0 = p(\zeta_0) \). Then there is a small disk \( \Omega \) centered at \( z_0 \) such that the corresponding function element \((\Omega, g)\) of \( f \) has \( g'(z_0) = 0 \) and no other zeroes of \( g' \). Then \( z_0 \) is a zero of \( g \) of finite order \( n \), and \( g \) is exactly \( n \)-to-one on \( \Omega \setminus \{z_0\} \). The open set \( U \) in \( R_{f^{-1}} \) corresponding to \( \Omega \setminus \{z_0\} \) evenly covers a deleted neighborhood \( V \) of \( g(z_0) \) \( n \) times via \( g \), so there are locally \( n \) corresponding branches of \( f^{-1} \) over \( V \) which fit together like the branches of \( \sqrt{z} \) around 0. (Note that there is no reason there cannot be other branches of \( f^{-1} \) over points of \( V \) corresponding to different branches of \( f \) near \( z_0 \) than the one corresponding to \( \zeta_0 \).)

If \( C \) is a small circle in \( V \) centered at \( g(z_0) \), \( w_1 \) a point of \( C \), and \( \gamma_k \) is \( C \) parametrized \( k \) times around counterclockwise beginning and ending at \( w_1 \), and \( h \) is any of the \( n \) corresponding branches of \( g^{-1} \) in a small neighborhood of \( w_1 \), then \( h \) can be analytically continued along \( \gamma_k \) for any \( k \). For \( 1 \leq k < n \) the terminal branch of \( g^{-1} \) around \( w_1 \) differs from the initial branch chosen, but for \( k = n \) the terminal branch is the same as the initial branch. As the diameter of \( C \) approaches 0, all the values on the branches at \( w_1 \) approach \( z_0 \). So we can “unwind” \( U \), which is homeomorphic to a punctured disk, and add a center point where \( g^{-1} \) takes the value \( z_0 \).

**X.7.5.4.** In general, a branch point of \( f \) corresponds to an open set \( U \) in \( S_f \) homeomorphic to a punctured disk, such that \( p \) gives an even covering \( (\cdot) \) from \( U \) onto a punctured disk \( D \setminus \{z_0\} \) centered at a point \( z_0 \), and such that

\[
w_0 = \lim_{p(\zeta) \rightarrow z_0} f(\zeta)
\]
exists in the sense that for every $\epsilon > 0$ there is a $\delta > 0$ such that $|f(\zeta) - w_0| < \epsilon$ whenever $\zeta \in U$ and $|p(\zeta) - z_0| < \delta$ (it actually suffices that $f$ just be bounded on $U$ because of (1)). Then there is an $n \in \mathbb{N}$ such that $p|_{U}$ is exactly $n$-to-one, and the image of every simple closed curve in $U$ not homotopic to 0 has winding number $\pm n$ around $z_0$. If $n = 1$, there will be a point $\zeta_0$ in the closure of $U$ in $S_f$ such that $p(\zeta_0) = z_0$ and $p$ maps $U \cup \{\zeta_0\}$ homeomorphically onto $D$; and $f(\zeta_0) = w_0$. If $n > 1$, there is no such point on $S_f$; but we can then add a point $\zeta_0$ to $S_f$, and topologize $S_f \cup \{\zeta_0\}$ by taking sets of the form

$$\{\zeta_0\} \cup [U \cap p^{-1} \{\{z : |z - z_0| < \delta\}\}]$$

for $\delta > 0$ as a local base at $\zeta_0$. Extend $f$ to $S_f \cup \{\zeta_0\}$ by setting $f(\zeta_0) = w_0$.

**X.7.5.5.** The extended surface $S_f \cup \{\zeta_0\}$ is a topological 2-manifold with a natural structure as a complex 1-manifold, defined around $\zeta_0$ by taking a “local uniformizing variable.” Consider the map $h(s) = z_0 + s^n$ from a disk $\hat{D}$ centered at $0$ onto $D$. Fix an $s_1 \in \hat{D}$, $s_1 \neq 0$, and let $z_1 = h(s_1)$ be the corresponding point of $D$. Define a holomorphic function $G$ on $\hat{D}$ as follows. Fix a branch $g$ of $f$ on a neighborhood $\Omega$ of $z_1$ corresponding to a point $\zeta_1$ of $U$ lying above it. If $s \in \hat{D} \setminus \{0\}$, let $\gamma$ be a path from $s_1$ to $s$ in $\hat{D} \setminus \{0\}$; then $h(\gamma)$ is a path from $z_1$ to $h(s)$ within $D \setminus \{z_0\}$, and $g$ can be analytically continued along $h(\gamma)$ by (1) and X.7.3.10. Let $G(s)$ be the value of the analytic continuation at the terminal point $h(s)$. Then $G$ is well defined on $D \setminus \{0\}$ (cf. [Ahl78, p. 221-222]). We have

$$\lim_{s \to 0} G(s) = w_0$$

so $G$ has a removable singularity at 0. There is then an obvious induced homeomorphism $\phi$ from $\hat{D}$ to $U \cup \{\zeta_0\}$ sending 0 to $\zeta_0$ and $s_1$ to $\zeta_1$, for which $G = f \circ \phi$, and this homeomorphism can be used to transfer the analytic structure on $\hat{D}$ to $U \cup \{z_0\}$. This analytic structure agrees with the one already defined on $U$ as a subset of $S_f$. It is easily seen that this analytic structure does not depend on the choices made in the construction of $G$. If the branch point arises from a point of $S_{f^{-1}}$ as in X.7.5.3., this procedure gives the same analytic structure as the usual analytic structure from $S_{f^{-1}}$.

**X.7.5.6.** Example. Not all branch points of $f$ arise from $f^{-1}$. Consider $f(z) = z^{2/3}$. The Riemann surface $S_f$ has three sheets over $\mathbb{C} \setminus \{0\}$, and $f$ has a branch point of order 3 at 0. The inverse function is $f^{-1}(z) = z^{3/2}$, whose Riemann surface has two sheets over $\mathbb{C} \setminus \{0\}$ and a branch point of order 2 at 0.

**X.7.6. Points at Infinity and Meromorphic Functions**

Essentially everything done so far in this section works identically if we replace the complex plane $\mathbb{C}$ with the Riemann sphere $\hat{\mathbb{C}}$ and the words analytic and holomorphic with meromorphic.

**X.7.6.1.** Definition. A meromorphic function element is a pair $(\Omega, f)$, where $\Omega$ is a region in $\mathbb{C}$ and $f$ is a meromorphic function on $\Omega$. Two meromorphic function elements $(\Omega, f)$ and $(\Omega, \tilde{f})$ are equivalent if there is a finite chain $(\Omega_j, f_j)$ ($1 \leq j \leq n$) such that $(\Omega_1, f_1) = (\Omega, f)$, $(\Omega_n, f_n) = (\Omega, \tilde{f})$, and $\Omega_j \cap \Omega_{j+1} \neq \emptyset$ and $f_j = f_{j+1}$ on $\Omega_j \cap \Omega_{j+1}$ for $1 \leq j < n$.

A meromorphic function on $\Omega$ can be regarded as an analytic function from $\Omega$ to $\hat{\mathbb{C}}$ in the sense of (1). Any analytic function element is a meromorphic function element.
X.7.6.2. A total meromorphic function can be thought of as an equivalence class of meromorphic function elements (we will later give a slightly different definition, allowing meromorphic function elements including the point at infinity also).

If \( f = \{ (\Omega_k, f_k) \} \) is an equivalence class of meromorphic function elements, we can form a Riemann surface \( S_f \) as in the holomorphic case, where \( z_j \in \Omega_j \) is identified with \( z_k \in \Omega_k \) if \( z_j = z_k \) in \( \mathbb{C} \) and \( f_j = f_k \) on a deleted neighborhood of \( z_j = z_k \). (If we regard \( f_j \) and \( f_k \) as maps to \( \hat{\mathbb{C}} \), they then agree on a neighborhood of \( z_j = z_k \)). There is an induced function from \( S_f \) to \( \hat{\mathbb{C}} \). Thus every meromorphic function element gives a well-defined Riemann surface in this way corresponding to its equivalence class.

X.7.6.3. Note that each analytic function element \( (\Omega, f) \) defines a Riemann surface \( S_f^h \) as in X.7.2.2, when thought of as an analytic function element, and a Riemann surface \( S_f^m \) when thought of as a meromorphic function element. These are not the same in general. \( S_f^b \) is naturally a subset of \( S_f^h \); \( S_f^b \) is exactly the inverse image of \( \mathbb{C} \) in \( S_f^m \) under the induced function from \( S_f^m \) to \( \hat{\mathbb{C}} \). Thus \( S_f^m \) can be regarded as \( S_f^b \) with points added where the extended \( f \) has poles. For example, if \( f(z) = \frac{1}{z} \), then \( S_f^b \cong \mathbb{C} \setminus \{0\} \) and \( S_f^m \cong \mathbb{C} \).

X.7.6.4. We can incorporate the point at infinity more fully into this picture. A meromorphic function element \( (\Omega, f) \), where \( \Omega \) is a region in \( \mathbb{C} \) with bounded complement and \( f \) is a meromorphic function on \( \mathbb{C} \) which has a removable singularity or pole at \( \infty \) in the sense of () (this implies that \( f \) is holomorphic in the complement of a bounded set), can be regarded as a region in \( \hat{\mathbb{C}} \) containing \( \infty \) and an analytic function from this set to \( \hat{\mathbb{C}} \), and will be called a meromorphic function element at infinity.

For each meromorphic function element \( (\Omega, f) \) at infinity, for which \( 0 \notin \Omega \), define a meromorphic function element \( (\Omega, g) \), where

\[
\Omega = \{0\} \cup \left\{ \frac{1}{z} : z \in \Omega \right\} \\
g(z) = f \left( \frac{1}{z} \right) \text{ for } z \in \Omega, \quad g(0) = \lim_{z \to \infty} f(z) \in \hat{\mathbb{C}}.
\]

We incorporate \( (\Omega, g) \) into the construction of \( S_f \) by identifying \( w \in \Omega \setminus \{0\} \) with \( \frac{1}{z} \in \Omega \). This effectively adds a “point at infinity” to \( S_f \), at which \( f \) takes the value \( g(0) \). There may be many such points at infinity added corresponding to different branches of \( f \).

There is then a natural projection map \( p \) from the extended \( S_f \) to \( \hat{\mathbb{C}} \).

X.7.6.5. Branch points can then be defined and added as in the holomorphic case. A branch point corresponds to an open set \( U \) in \( S_f \) for which \( p \) is an even covering from \( U \) onto a deleted open disk \( D \setminus \{z_0\} \) in \( \hat{\mathbb{C}} \), where \( z_0 = \infty \) is allowed in which case \( D \setminus \{\infty\} \) is the complement of a closed disk in \( \mathbb{C} \) centered at \( 0 \), and

\[
w_0 = \lim_{p(\xi) \to z_0} f(\xi)
\]

exists in \( \hat{\mathbb{C}} \), i.e. \( w_0 = \infty \) is allowed.

When all points at infinity and branch points have been added, a Riemann surface \( \tilde{S}_f \) is obtained which is called the total Riemann surface of \( f \). If \( f \) is not constant, the total Riemann surfaces of \( f \) and \( f^{-1} \) are conformally equivalent ().
X.7.7. Germs of Analytic Functions

X.7.7.1. We now go to the opposite extreme from considering the Riemann surface of a total analytic function. If $z_0 \in \mathbb{C}$ is a fixed point of $\mathbb{C}$, and if $f$ is a total analytic function containing an analytic function element $(\Omega, f)$ with $z_0 \in \Omega$, then the restriction of $f$ to any neighborhood of $z_0$ completely determines $f$. Thus every function holomorphic in a neighborhood of $z_0$ determines a unique total analytic function, and two holomorphic functions agreeing on a neighborhood of $z_0$ determine the same total analytic function. (But two different holomorphic functions on small neighborhoods of $z_0$ can give different branches of the same total analytic function.)

X.7.7.2. Definition. Let $z_0 \in \mathbb{C}$. A germ of an analytic function at $z_0$ is an equivalence class of functions holomorphic in neighborhoods of $z_0$, where two such functions are equivalent if they agree on some neighborhood of $z_0$.

Thus the exact domain of a germ of an analytic function at $z_0$ is not specified or relevant.

X.7.7.3. The algebraic operations of addition, multiplication, and scalar multiplication are well defined on germs. If $f$ and $g$ are holomorphic on neighborhoods $U$ and $V$ of $z_0$, then $f + g$ is defined and holomorphic on $U \cap V$. If $\tilde{f}$ is holomorphic near $z_0$ and agrees with $f$ on $\tilde{U} \subseteq U$, and $\tilde{g}$ agrees with $g$ on $\tilde{V} \subseteq V$, then $\tilde{f} + \tilde{g}$ agrees with $f + g$ on $\tilde{U} \cap \tilde{V}$, so addition is well defined. The argument for multiplication and scalar multiplication is almost identical.

X.7.7.4. Thus the set $\mathcal{G}(z_0)$ of germs of analytic functions has a natural structure as a ring, actually an algebra over $\mathbb{C}$.

X.7.7.5. The algebra $\mathcal{G}(z_0)$ can be described in a different way. If $f$ is holomorphic in a neighborhood of $z_0$, then the Taylor series of $f$ around $z_0$ determines $f$ on at least a small disk centered at $z_0$. Conversely, any power series centered at $z_0$ with a positive radius of convergence defines a holomorphic function on a disk centered at $z_0$. Thus there is a one-one correspondence between germs of analytic functions at $z_0$ and power series centered at $z_0$ with a positive radius of convergence (we will call such a series a convergent power series centered at $z_0$). This correspondence preserves addition, multiplication, and scalar multiplication, i.e. is an algebra isomorphism.

Up to isomorphism, the algebra $\mathcal{G}(z_0)$ does not depend on $z_0$; the map $f(z) \to f(z + z_0)$ is an isomorphism of $\mathcal{G}(z_0)$ onto $\mathcal{G}(0)$, which is isomorphic to the algebra of convergent power series centered at 0. So $\mathcal{G}(0)$ can be identified with a subalgebra of the algebra $\mathbb{C}[[X]]$ of formal power series over $\mathbb{C}$.

X.7.7.6. Proposition. The algebra $\mathcal{G}(z_0)$ has no zero divisors: if $[f], [g]$ are nonzero elements of $\mathcal{G}(z_0)$, then $[f][g] \neq 0$. That is, $\mathcal{G}(z_0)$ is an integral domain.

Proof: This can be seen in at least two ways. $\mathcal{G}(z_0)$ is isomorphic to a subring of the integral domain $\mathbb{C}[[X]]$. Alternatively, if $[f]$ and $[g]$ are germs of analytic functions $f$ and $g$ respectively, neither of which are identically zero in a neighborhood of $z_0$, then $f$ and $g$ have at most an isolated zero at $z_0$, i.e. there is a deleted neighborhood $U$ of $z_0$ on which both $f$ and $g$ are never zero. Thus $fg$ is nonzero on $U$, i.e. $[fg] = [f][g] \neq 0$ in $\mathcal{G}(z_0)$.

975
Germs of Meromorphic Functions

We can extend the notion of germ to functions holomorphic on a neighborhood of \( z_0 \) except possibly for a pole at \( z_0 \).

X.7.7.7. Definition. Let \( z_0 \in \mathbb{C} \). A germ of a meromorphic function at \( z_0 \) is an equivalence class of functions holomorphic in deleted neighborhoods of \( z_0 \) with a removable singularity or pole at \( z_0 \), where two such functions are equivalent if they agree on some deleted neighborhood of \( z_0 \).

X.7.7.8. As before, the set \( M(z_0) \) of germs of meromorphic functions at \( z_0 \) is a complex algebra. There is an obvious injective homomorphism from \( G(z_0) \) to \( M(z_0) \), so we may identify \( G(z_0) \) with a subalgebra of \( M(z_0) \). We again have \( M(z_0) \cong M(0) \).

There is a one-one correspondence (algebra isomorphism) between \( M(z_0) \) and the algebra of Laurent series (\( \mathbb{C}((X)) \)) centered at \( z_0 \) which converge on a deleted neighborhood of \( z_0 \) (convergent Laurent series). Thus \( M(z_0) \) is isomorphic to a subalgebra of the algebra \( \mathbb{C}((X)) \) of formal Laurent series with complex coefficients (\( \mathbb{C} \)).

X.7.7.9. Proposition. The algebra \( M(z_0) \) is a field; in fact, it is the quotient field of the ring \( G(z_0) \).

Proof: If \( f \) is holomorphic on a deleted neighborhood of \( z_0 \) and has a pole at \( z_0 \), then \( \frac{1}{g} \) has a removable singularity at \( z_0 \), so agrees on a deleted neighborhood of \( z_0 \) with a function holomorphic in a neighborhood of \( z_0 \). Thus [\( f \)] is invertible in \( M(z_0) \), and its reciprocal is in \( G(z_0) \). And if [\( g \) \( \in G(z_0) \)], [\( g \) not the zero element (i.e. \( g \) not identically zero near \( z_0 \)), then either \( g(z_0) \neq 0 \), in which case [\( g \)] is already invertible in \( G(z_0) \), or \( g \) has an isolated zero at \( z_0 \), in which case \( \frac{1}{g} \) is holomorphic in a deleted neighborhood of \( z_0 \) and has a pole at \( z_0 \), i.e. [\( g \)] is invertible in \( M(z_0) \).

X.7.7.10. Note that this proposition cannot be proved simply by using the isomorphism with a subring of the field \( \mathbb{C}((X)) \), since it is not obvious (although it turns out to be true) that the inverse Laurent series to a convergent Laurent series is also convergent.

X.7.8. General Riemann Surfaces
X.8. Analytic Functions of Several Variables

We now describe the basic theory of complex analytic functions of several variables. Some aspects of the theory are virtually identical to the one-variable case, but there are also significant differences.

This is a large and active subject, and we only cover the most elementary aspects of it; even [BM48] gives a far more comprehensive treatment. The standard general reference for the theory of several complex variables is [GR09]. See [Gun90a]–[Gun90c] for a more modern and detailed study.

X.8.1. Elementary Theory

X.8.1.1. Definition. Let \( U \) be an open set in \( \mathbb{C}^n \). A function \( f : U \to \mathbb{C} \) is analytic if, for every \( c \in U \), \( f \) is represented in a neighborhood of \( c \) by a multivariable power series (VIII.7.1.4.) centered at \( c \). A function \( f = (f_1, \ldots, f_m) : U \to \mathbb{C}^m \) is analytic if each \( f_k \) is analytic.

X.8.1.2. As in the one-variable case, this definition is a local one: a function \( f \) on an open set \( U \) is analytic on \( U \) if and only if it is analytic on a neighborhood of \( c \) for each \( c \in U \). In particular, if \( U = \bigcup_j U_j \) is a union of open sets, then \( f \) is analytic on \( U \) if and only if it is analytic on each \( U_j \).

An immediate corollary of VIII.7.1.13. is:

X.8.1.3. Corollary. Let \( U \) be an open set in \( \mathbb{C}^n \), and \( f \) analytic on \( U \). Then \( f \) is \( C^\infty \) on \( U \), and for any multi-index \( \alpha \), \( \frac{\partial^n f}{\partial z^\alpha} \) is analytic on \( U \).

X.8.1.4. An analytic function \( f \) is “jointly analytic” in its variables. If all but one variable is fixed, it is analytic in the remaining variable in the usual sense of (), since the multivariable power series for \( f \) around any point has a drastic revision obtained by collecting together all terms of like power in the remaining variable, which will converge in a neighborhood of the point. (More generally, if some of the variables are fixed, the function is analytic in the remaining variables.) Thus an analytic function is “separately analytic” in its variables. Conversely, one of the major theorems of the subject is that a separately analytic function is (jointly) analytic:

X.8.1.5. Theorem. [Hartogs’ Theorem] Let \( U \) be an open set in \( \mathbb{C}^n \), and \( f : U \to \mathbb{C} \). Suppose \( f \) is analytic (holomorphic) on \( U \) in each variable separately when the other variables are held fixed, i.e. all first-order partials of \( f \) (in the complex sense) exist everywhere on \( U \). Then \( f \) is analytic on \( U \).

We will prove the theorem only under the additional assumption that \( f \) is continuous (which is of course a consequence of the theorem); for the considerably more difficult proof without this assumption, see [BM48].

X.8.1.6. Theorem. [Osgood’s Lemma] Let \( U \) be an open set in \( \mathbb{C}^n \), and \( f : U \to \mathbb{C} \). Suppose \( f \) is continuous on \( U \), and analytic (holomorphic) on \( U \) in each variable separately when the other variables are held fixed, i.e. all first-order partials of \( f \) (in the complex sense) exist everywhere on \( U \). Then \( f \) is analytic on \( U \).
Proof: The proof is a multidimensional version of the proof of X.4.4.6. Let \( c = (c_1, \ldots, c_n) \in U \), and let \( R = \{(z_1, \ldots, z_n) : |z_k - c_k| \leq r_k\} \) be a closed polydisk around \( c \) contained in \( U \). Fix \((z_1, \ldots, z_n)\) in the interior \( R^\circ \) of \( R \), i.e. \(|z_k - c_k| < r_k\) for all \( k \). We have, by repeated application of the Cauchy Integral Formula

\[
\frac{1}{2\pi i} \int_{\gamma_n} \frac{f(z_1, \ldots, z_{n-1}, \zeta_n) \zeta_n - z_n}{\zeta_n - z_n} \, d\zeta_n
\]

\[
= \frac{1}{2\pi i} \int_{\gamma_{n-1}} \left[ \frac{1}{2\pi i} \int_{\gamma_n} f(z_1, \ldots, z_{n-2}, \zeta_{n-1}, \zeta_n) \zeta_n - z_n \, d\zeta_n \right] \frac{1}{\zeta_{n-1} - z_{n-1}} \, d\zeta_{n-1}
\]

\[
= \cdots = \frac{1}{(2\pi i)^n} \int_{\gamma_1} \cdots \int_{\gamma_n} f(\zeta_1, \ldots, \zeta_n) \prod_{k=1}^n \frac{1}{(\zeta_k - z_k) \cdots (\zeta_n - z_n)} \, d\zeta_1 \cdots d\zeta_n
\]

where \( \gamma_k \) is the circle \( \{z_k : |z_k - c_k| = r_k\} \) parametrized once around counterclockwise.

By parametrizing the integrals, \( f(z_1, \ldots, z_n) \) becomes an iterated integral of a complex-valued continuous function over a rectangle in \( \mathbb{R}^n \). By Fubini’s Theorem, this integral can be converted to a multiple integral (or computed as an iterated integral in any order). We will symbolically denote this multiple integral by

\[
f(z_1, \ldots, z_n) = \frac{1}{(2\pi i)^n} \int_{\partial R} \frac{f(\zeta_1, \ldots, \zeta_n)}{(\zeta_1 - z_1) \cdots (\zeta_n - z_n)} \, d\zeta.
\]

For each \( k \) set \( b_k = \frac{|z_k - c_k|}{r_k} < 1 \). We have, for \((\zeta_1, \ldots, \zeta_n) \in \partial R\),

\[
\frac{1}{\zeta_k - z_k} = \frac{1}{\zeta_k - c_k} \frac{1 - \frac{z_k - c_k}{\zeta_k - c_k}}{1 - \frac{z_k - c_k}{\zeta_k - c_k}} = \frac{1}{\zeta_k - c_k} \sum_{m=0}^{\infty} \left[ \frac{z_k - c_k}{\zeta_k - c_k} \right]^m
\]

and the terms in the series are dominated in absolute value by the terms of \( \sum_{m=0}^{\infty} b_k^m \), so the series converges absolutely and uniformly on \( \partial R \). Iterating, the iterated sum

\[
\sum_{m_1=0}^{\infty} \sum_{m_2=0}^{\infty} \cdots \sum_{m_n=0}^{\infty} \frac{(z_1 - c_1)^{m_1} \cdots (z_n - c_n)^{m_n}}{(\zeta_1 - c_1)^{m_1+1} \cdots (\zeta_n - c_n)^{m_n+1}}
\]

converges absolutely and uniformly on \( \partial R \) to \( \frac{1}{(\zeta_1 - z_1) \cdots (\zeta_n - z_n)} \). Thus the unordered sum

\[
\sum_{(m_1, \ldots, m_n) \in \mathbb{N}_0^n} \frac{(z_1 - c_1)^{m_1} \cdots (z_n - c_n)^{m_n}}{(\zeta_1 - c_1)^{m_1+1} \cdots (\zeta_n - c_n)^{m_n+1}}
\]

converges uniformly on \( \partial R \) to \( \frac{1}{(\zeta_1 - z_1) \cdots (\zeta_n - z_n)} \). So we have

\[
f(z_1, \ldots, z_n) = \frac{1}{(2\pi i)^n} \int_{\partial R} f(\zeta_1, \ldots, \zeta_n) \left[ \sum_{(m_1, \ldots, m_n) \in \mathbb{N}_0^n} \frac{(z_1 - c_1)^{m_1} \cdots (z_n - c_n)^{m_n}}{(\zeta_1 - c_1)^{m_1+1} \cdots (\zeta_n - c_n)^{m_n+1}} \right] \, d\zeta
\]

\[
= \frac{1}{(2\pi i)^n} \int_{\partial R} \left[ \sum_{(m_1, \ldots, m_n) \in \mathbb{N}_0^n} (z_1 - c_1)^{m_1} \cdots (z_n - c_n)^{m_n} \frac{f(\zeta_1, \ldots, \zeta_n)}{(\zeta_1 - c_1)^{m_1+1} \cdots (\zeta_n - c_n)^{m_n+1}} \right] \, d\zeta.
\]

978
Since $f$ is bounded on $R$, by comparison the unordered sum

$$
\sum_{(m_1, \ldots, m_n) \in \mathbb{N}_0^n} (z_1 - c_1)^{m_1} \cdots (z_n - c_n)^{m_n} \frac{f(\zeta_1, \ldots, \zeta_n)}{(\zeta_1 - c_1)^{m_1+1} \cdots (\zeta_n - c_n)^{m_n+1}}
$$

converges uniformly on $\partial R$, and hence the summation can be moved past the integral ($\int$). Thus

$$
f(z_1, \ldots, z_n) = \sum_{(m_1, \ldots, m_n) \in \mathbb{N}_0^n} (z_1 - c_1)^{m_1} \cdots (z_n - c_n)^{m_n} \left[ \frac{1}{(2\pi i)^n} \int_{\partial R} \frac{f(\zeta_1, \ldots, \zeta_n)}{(\zeta_1 - c_1)^{m_1+1} \cdots (\zeta_n - c_n)^{m_n+1}} d\zeta \right]
$$

where

$$
a_{m_1, \ldots, m_n} = \frac{1}{(2\pi i)^n} \int_{\partial R} \frac{f(\zeta_1, \ldots, \zeta_n)}{(\zeta_1 - c_1)^{m_1+1} \cdots (\zeta_n - c_n)^{m_n+1}} d\zeta
$$

(where the last integral can be interpreted as an iterated contour integral in any order). Thus, since $(z_1, \ldots, z_n)$ is arbitrary in $R^o$, the multivariable power series

$$
\sum_{(m_1, \ldots, m_n) \in \mathbb{N}_0^n} a_{m_1, \ldots, m_n} (z_1 - c_1)^{m_1} \cdots (z_n - c_n)^{m_n}
$$

converges to $f$ on $R^o$, a neighborhood of $c$. Since $c \in U$ is arbitrary, $f$ is analytic on $U$. 

\[ \Box \]

**X.8.1.7.** Corollary. Let $U$ be an open set in $\mathbb{C}^n$, and $f : U \to \mathbb{C}$ a function. Then $f$ is analytic on $U$ if and only if $f$, when regarded as a function $f(x_1, y_1, \ldots, x_n, y_n)$ from $\mathbb{R}^{2n}$ to $\mathbb{R}^2$ with coordinate functions $u$ and $v$, is differentiable in the vector calculus sense on $U$ and the Cauchy-Riemann equations hold for each pair $(x_k, y_k)$, i.e. for all $k$,

$$
\frac{\partial u}{\partial x_k} = \frac{\partial v}{\partial y_k} \quad \text{and} \quad \frac{\partial u}{\partial y_k} = -\frac{\partial v}{\partial x_k}.
$$

**Proof:** If $f$ is analytic, it is differentiable in the vector calculus sense and separately analytic, so by X.1.1.5. the Cauchy-Riemann equations are satisfied. Conversely, if it is differentiable, hence continuous, and the Cauchy-Riemann equations are satisfied, apply X.1.1.5. to conclude that $f$ is separately analytic. 

\[ \Box \]

**X.8.1.8.** Using the Looman-Menchoff Theorem (X.1.1.6.), the assumption that $f$ be differentiable in the vector calculus sense can be relaxed to just assuming $f$ is continuous, and that the first-order partial derivatives of $u$ and $v$ (in the vector calculus sense) all exist everywhere on $U$ and satisfy the Cauchy-Riemann equations. The assumptions can be further relaxed using Hartogs’ Theorem, but they cannot be relaxed to simply assuming the partials exist everywhere and satisfy the Cauchy-Riemann equations (this does not imply analyticity even when $n = 1$; cf. X.8.2.1.).

As a corollary of the proof, we obtain a multidimensional version of the Cauchy Integral Formula and of X.4.4.6.:
X.8.1.9. **Corollary.** Let $U$ be an open set in $\mathbb{C}^n$, and $f : U \to \mathbb{C}$ an analytic function. For any $c = (c_1, \ldots, c_n) \in U$, we have:

(i) If $R$ is any closed polydisk in $U$ containing $c$ in its interior, we have

$$f(c) = \frac{1}{(2\pi i)^n} \int_{\partial R} \frac{f(\zeta_1, \ldots, \zeta_n)}{(\zeta_1 - c_1) \cdots (\zeta_n - c_n)} \, d\zeta$$

where the multiple integral can be regarded as an iterated contour integral in any order.

(ii) The multivariable power series

$$\sum_{(m_1, \ldots, m_n) \in \mathbb{N}_0^n} a_{m_1, \ldots, m_n} (z_1 - c_1)^{m_1} \cdots (z_n - c_n)^{m_n}$$

in standard form representing $f$ in a neighborhood of $c$ is unique and converges u.c. to $f$ on any open polydisk centered at $c$ contained in $U$; we have, for any $(m_1, \ldots, m_n) \in \mathbb{N}_0^n$,

$$\frac{\partial^{m_1 + \cdots + m_n}}{\partial z_1^{m_1} \cdots \partial z_n^{m_n}} f(c) = (m_1!) \cdots (m_n!) a_{m_1, \ldots, m_n} = \frac{(m_1!) \cdots (m_n!)}{(2\pi i)^n} \int_{\partial R} \frac{f(\zeta_1, \ldots, \zeta_n)}{(\zeta_1 - c_1)^{m_1+1} \cdots (\zeta_n - c_n)^{m_n+1}} \, d\zeta$$

for any closed polydisk $R$ contained in $U$ and containing $c$ in its interior. Thus

$$a_{m_1, \ldots, m_n} = \frac{1}{(2\pi i)^n} \int_{\partial R} \frac{f(\zeta_1, \ldots, \zeta_n)}{(\zeta_1 - c_1)^{m_1+1} \cdots (\zeta_n - c_n)^{m_n+1}} \, d\zeta$$

where the multiple integral can be regarded as an iterated contour integral in any order.
X.8.2. Exercises

X.8.2.1. (a) (H. Looman) For \( z \in \mathbb{C} \), define \( f(z) = e^{-1/z^4} \) if \( z \neq 0 \), and set \( f(0) = 0 \). Show that the partial derivatives of the real and imaginary parts of \( f \) exist and satisfy the Cauchy-Riemann equations everywhere on \( \mathbb{R}^2 \), but \( f \) is not complex differentiable, or even continuous, at 0.

(b) (D. Menchoff) Set \( f(z) = \frac{z^5}{|z|^4} \) for \( z \neq 0 \), and \( f(0) = 0 \). Show that \( f \) is continuous and has first-order partials everywhere on \( \mathbb{C} \), and the first-order partials at 0 satisfy the Cauchy-Riemann equations, but \( f \) is not complex differentiable at 0.

X.8.2.2. Let \( D \) be the open unit disk in \( \mathbb{C} \).

(a) Show that the power series \( \sum_{k=1}^{\infty} \frac{z^k}{k^2} \) converges uniformly on \( D \).

(b) Show that the series \( \sum_{k=1}^{\infty} \frac{z^{k-1}}{k} \) of term-by-term derivatives converges u.c. but not uniformly on \( D \).

X.8.2.3. (Another proof of the Fundamental Theorem of Algebra, the “standard” one) Let \( f \) be a polynomial with complex coefficients and no root in \( \mathbb{C} \), and let \( g = \frac{1}{f} \). Then \( g \) is an entire function.

(a) Use Lemma X.1.4.1. to show that \( g \) is bounded.

(b) Apply Liouville’s Theorem () to conclude that \( g \), and hence \( f \), is constant.

X.8.2.4. (Yet another proof of the Fundamental Theorem of Algebra [Boa64]) Suppose \( f \) is a polynomial of degree \( n \geq 1 \) with no root in \( \mathbb{C} \).

(a) Set \( p(z) = f(z)\bar{f}(z) \), where \( \bar{f} \) is the polynomial obtained from \( f \) by replacing each coefficient by its complex conjugate. Then \( p \) is a polynomial of degree \( 2n \) with no root in \( \mathbb{C} \), taking strictly positive values on the real axis.

(b) Set \( I = \int_{-\pi}^{\pi} \frac{1}{p(2\cos \theta)} \, d\theta \). Then \( I > 0 \).

(c) Show that \( I = -i \int_{\gamma} \frac{1}{\zeta p(\zeta + \bar{\zeta})^{-1}} \, d\zeta \), where \( \gamma \) is the unit circle.

(d) Show that \( p(z + \zeta^{-1}) = z^{-2n} q(z) \) for a polynomial \( q \) with no roots in \( \mathbb{C} \).

(e) Conclude from Cauchy’s Theorem that \( I = -i \int_{\gamma} \frac{\zeta^{2n-1}}{q(\zeta)} \, d\zeta = 0 \), contradicting (b).

X.8.2.5. Prove the following complex analog of Rolle’s Theorem for polynomials:

**Theorem.** Let \( f(z) \) be a polynomial with complex coefficients. Then the roots of \( f' \) are contained in the (necessarily closed) convex hull \( K \) of the roots of \( f \).

(a) Since \( K \) is an intersection of closed half planes, it suffices to show that if \( H \) is a closed half plane containing all the roots of \( f \), then \( H \) also contains all the roots of \( f' \). Show that it suffices to prove this if \( H \) is the closed upper half plane.

(b) We may assume \( f \) is monic without loss of generality. Use the Fundamental Theorem of Algebra to write

\[
 f(z) = (z - z_1)^{m_1}(z - z_2)^{m_2} \cdots (z - z_n)^{m_n}
\]
where $z_1, \ldots, z_n \in \mathbb{C}$ and $m_1, \ldots, m_n \in \mathbb{N}$.

(c) Use either the Product Rule or logarithmic differentiation to show that

$$\frac{f'(z)}{f(z)} = \frac{m_1}{z - z_1} + \frac{m_2}{z - z_2} + \cdots + \frac{m_n}{z - z_n}$$

for $z \in \mathbb{C} \setminus \{z_1, \ldots, z_n\}$.

(d) Under the assumption that $\text{Im}(z_k) \geq 0$ for all $k$, show that if $\text{Im}(z) < 0$, then $\text{Im} \left( \frac{f'(z)}{f(z)} \right) > 0$ and hence $f'(z) \neq 0$.

(e) Explain why the theorem is a complex analog of Rolle’s Theorem.

**X.8.2.6.** The aim of this problem is to further justify the definition of the complex exponential function (X.1.1.8.(iii)). Suppose $f$ is a holomorphic function on a horizontal strip $\Omega \subset \mathbb{C}$ with $\mathbb{R} \subset \Omega$, which satisfies $f' = f$ on $\Omega$ and $f(0) = 1$. Let $u$ and $v$ be the real and imaginary parts of $f$, i.e. $f(x + iy) = u(x, y) + iv(x, y)$. From the equation $f' = f$ it follows that $u$ and $v$ are $C^\infty$ on $\Omega$.

(a) Using $f' = f$, show that $\frac{\partial u}{\partial x} = u$, and for fixed $y$ use the Uniqueness Theorem for first-order linear differential equations (IX.1.2.7.) to conclude that $u(x, y) = e^x \phi(y)$ for some real-valued $C^\infty$ function $\phi$ defined in a neighborhood of 0 in $\mathbb{R}$. Similarly, $v(x, y) = e^x \psi(y)$ for some $C^\infty$ $\psi$.

(b) Using the Cauchy-Riemann equations, show that $\phi' = -\psi$ and $\psi' = \phi$.

(c) Use $f(0) = 1$ and the Uniqueness Theorem for solutions to systems of first-order linear differential equations (IX.1.3.3.) to conclude that $\phi(y) = \cos y$ and $\psi(y) = \sin y$ for all $y$. Thus $f$ agrees with the complex exponential function on $\Omega$.

(d) Similarly characterize the complex trigonometric and hyperbolic functions.

In fact, by the Rigidity Theorem, any function on such an $\Omega$ which is holomorphic and agrees with the usual exponential function on the real axis must agree with the complex exponential function everywhere on $\Omega$, and similarly for trigonometric and hyperbolic functions.

**X.8.2.7.** Discuss the Riemann surface for the function $\log \log z$.

**X.8.2.8.** Discuss the validity of the following formulas, where all letters denote complex numbers, and interpret them in terms of Riemann surfaces:

(a) $\log(zw) = \log z + \log w$.

(b) $\log(z^c) = c \log z$.

(c) $ze^{z+d} = ze^{z+d}$.

(d) $(ze^d)^c = ze^{cd}$.

(e) $(zw)^c = ze^{cd}$.

**X.8.2.9.** Develop the argument in the last part of the proof of X.3.4.4. to show that if $\gamma_0$ and $\gamma_1$ are piecewise-smooth contours from $p$ to $q$ which are homotopic in an open set $\Omega$, then they are homotopic in $\Omega$ via a piecewise-smooth homotopy. [Choose partitions $\mathcal{P}$ and $\mathcal{Q}$ as in the proof; for $1 < j < m$ let $H(s_j, t)$ be piecewise-linear in $t$ with $H(s_j, t_k) = h(s_j, t_k)$ for each $k$, and then extend $H$ by making it piecewise-linear in $s$ for fixed $t$.]
X.8.2.10. (a) Let $\Omega$ be a connected open set in $\mathbb{C}$ containing an interval $I$ on the real axis. Show that the complex exponential function is the only function which is holomorphic on $\Omega$ and which agrees with the usual real exponential function on $I$. [Use the Rigidity Theorem (X.5.1.4.).] Do the same for the sine and cosine functions.

(b) Show that the power series
$$\sum_{k=0}^{\infty} \frac{z^k}{k!}$$
converges u.c. on all of $\mathbb{C}$ to the function $e^z$. Similarly, show that the series expansions
$$\cos z = \sum_{k=0}^{\infty} \frac{(-1)^k}{(2k)!} z^{2k}$$
$$\sin z = \sum_{k=0}^{\infty} \frac{(-1)^k}{(2k+1)!} z^{2k+1}$$
are valid for all $z \in \mathbb{C}$. Give similar series representations for $\cosh z$ and $\sinh z$.

Thus the usual power series representations of the real exponential, trigonometric, and hyperbolic functions are valid also for the complex ones. This problem provides additional justification for why the extensions we gave of the exponential function, etc., to $\mathbb{C}$ are reasonable (and indeed are the only reasonable ones.) In fact, in many references these functions are defined using the power series.

X.8.2.11. [?] Here is an example of an improper real integral which can be computed by a more complicated contour integration. Consider the integral
$$\int_0^\infty \frac{x^{-k}}{1 + x} \, dx$$
(where $k$ is a real constant and $x^{-k}$ is interpreted in the usual real sense, i.e. as a positive real number for $x > 0$).

(a) Show that this improper integral converges if and only if $0 < k < 1$.

We make this restriction in the rest of the problem. Define
$$f(z) = \frac{z^{-k}}{1 + z}$$
where $z^{-k}$ is defined using a branch cut along the positive real axis and taking the argument between 0 and $2\pi$. Thus the argument of $z^{-k}$ lies between $-2\pi k$ and 0.

We also consider the contour $\gamma = \gamma_1 + \gamma_2 + \gamma_3 + \gamma_4$:
where $\gamma_1$ and $\gamma_3$ are line segments along the ray of points with argument $\epsilon$ and $2\pi - \epsilon$ respectively, and $\gamma_2$ and $\gamma_4$ are circle arcs of radius $R$ and $r$ respectively.

(b) Show that if $0 < r < 1$, $R > 1$, and $0 < \epsilon < \pi$ we have
$$\int_\gamma f = 2\pi i \text{Res}(f, -1) = 2\pi i e^{-\pi i k}.$$
(c) Show that
\[ \int_{\gamma_2} f \to 0 \]
as \( R \to +\infty \) and
\[ \int_{\gamma_4} f \to 0 \]
as \( r \to 0 \) uniformly in \( \epsilon \).
(d) Show that, for fixed \( r \) and \( R \), as \( \epsilon \to 0+ \) we have
\[ \int_{\gamma_1} f \to \int_r^R \frac{x^{-k}}{1 + x} \, dx \]
and that
\[ \int_{\gamma_3} f \to -e^{-2\pi ik} \int_r^R \frac{x^{-k}}{1 + x} \, dx \]
[The integrals do not approach the same limit because of the branch cut.]
(e) Conclude that
\[ \int_0^\infty \frac{x^{-k}}{1 + x} \, dx = \frac{2\pi i e^{-\pi i k}}{1 - e^{-2\pi i k}} . \]
(f) Show that
\[ 1 - e^{-2\pi ik} = 2ie^{-\pi i k} \sin \pi k \]
so that
\[ \int_0^\infty \frac{x^{-k}}{1 + x} \, dx = \frac{\pi}{\sin \pi k} . \]

**X.8.2.12.** Suppose \( f \) has a singularity at \( z_0 \), and that \( f \) is bounded in a deleted neighborhood of \( z_0 \). Mimic the proof of (iv) \( \Rightarrow \) (i) in **X.5.2.7.** to show that the singularity is removable, by showing directly that for fixed \( z \) near \( z_0 \),
\[ \lim_{\delta \to 0^+} \left[ \int_{\gamma_\delta} \frac{f(\zeta)}{\zeta - z} \, d\zeta \right] = 0 \]
by estimating the size of the integral.

**X.8.2.13.** (a) Show that the implication (ii) \( \Rightarrow \) (i) in **X.5.2.7.** is equivalent to the following:
**Theorem.** Let \( D \) be an open disk in \( \mathbb{C} \) centered at \( z_0 \), and \( f : D \to \mathbb{C} \). If \( f \) is continuous on \( D \) and holomorphic on \( D \setminus \{z_0\} \), then \( f \) is holomorphic on \( D \) (i.e. differentiable at \( z_0 \)).

(b) Prove this theorem by showing that the integral of \( f \) around any triangle in \( D \) is zero and applying Morera’s Theorem.

**X.8.2.14.** Using the Big Picard Theorem (**X.5.2.19.**) and **X.5.3.5.**, prove the Little Picard Theorem (**X.3.3.12.**). Do the case of a polynomial separately using the Fundamental Theorem of Algebra.
X.8.2.15. For \( z \in \mathbb{C} \) set \( f(z) = e^{e^z} (= e^{(e^z)}) \). Then \( f \) is an entire function. What is wrong with the following argument? Since \( e^z \) is never 0, \( f \) never takes either the value 0 or the value 1. Thus \( f \) is a counterexample to the Little Picard Theorem (X.3.3.12.).
X.9. Differential Algebra

Differential algebra is, roughly speaking, the algebraic theory of calculus. Versions appear in quite different contexts. A basic application concerns solutions of differential equations, in particular answering questions about whether antiderivatives or other solutions to differential equations have elementary closed formulas. A quite different context is the study of one-parameter automorphism groups of operator algebras, and in forms of amenability.

X.9.1. Derivations

A derivation on a ring is an algebraic operation which abstracts the essential properties of the derivative, specifically the product rule.

X.9.1.1. Definition. Let $R$ be a ring. A derivation on $R$ is a function $\delta : R \to R$ with the properties

$$\delta(x + y) = \delta(x) + \delta(y)$$

$$\delta(xy) = \delta(x)y + x\delta(y)$$

for all $x, y \in R$. If $R$ is an algebra over a field $\mathbb{F}$, we often (but not always) expand the first condition to require that $\delta$ be $\mathbb{F}$-linear, i.e. we add the requirement

$$\delta(\alpha x) = \alpha \delta(x)$$

for all $\alpha \in \mathbb{F}, x \in R$ (cf. X.9.1.5.(iii)).

A differential subring of a differential ring $(R, \delta)$ is a subring $S$ which is closed under $\delta$; the restriction of $\delta$ to $S$ is thus a derivation on $S$.

X.9.1.2. Note that $R$ need not be commutative; if $R$ is not commutative, it is crucial to respect the order of the factors in the product rule terms (since addition is always commutative, the order of the terms does not matter).

Derivations can be defined more generally from a ring $R$ to an $R$-bimodule $M$ with the same properties; but we will primarily stick to the case of derivations from $R$ to $R$, which are general enough for most purposes.

X.9.1.3. Examples. (i) Let $I$ be an interval in $\mathbb{R}$, and $R$ be a ring of real-valued differentiable functions on $I$ which is closed under differentiation, e.g. $C^\infty(I)$ or the set of polynomials, and set $\delta(f) = f'$. Then $\delta$ is a derivation on $R$. This is the prototype example.

$R$ must be closed under differentiation: a ring such as $C^1(I)$ will not work, since the derivative of a $C^1$ function is not in $C^1$ in general. We could more generally define differentiation as a derivation from $C^p(I)$ to the $C^{p-1}(I)$-bimodule $C^{p-1}(I)$ for any $p \geq 1$.

(ii) Similarly, if $U$ is an open set in $\mathbb{R}^2$ and $R = C^\infty(U)$, set $\delta_x(f) = \frac{\partial f}{\partial x}$ and $\delta_y(f) = \frac{\partial f}{\partial y}$. Then $\delta_x$ and $\delta_y$ are derivations on $R$.

(iii): Let $\mathbb{F}$ be a unital commutative ring, usually a field, and let $X, X_1, X_2, \ldots$ be a sequence of indeterminates. Form the polynomial ring

$$R = \mathbb{F}[X, X_1, X_2, \ldots].$$
We will regard $X_n$ as the “$n$’th derivative” of $X$ (we may think of $X$ as $X_0$). Specifically, we define a derivation $\delta$ on $R$ with $\delta(X_k) = X_{k+1}$ for all $k \geq 0$. Linearity and the product rule then dictates the following formula for $\delta$:

$$
\delta \left( \sum_{k,n} \alpha_{k,n} X_k^n \right) = \sum_{k,n} n \alpha_{k,n} X_k^{n-1} X_{k+1}
$$

(the sum is a finite sum). It is easily checked that $\delta$ is a derivation on $R$. The ring $R$ with this derivation is called the ring of differential polynomials in $X$, over $F$, denoted $\mathbb{F}\{X\}$. We may similarly form rings of differential polynomials in more than one variable, e.g. $\mathbb{F}\{X,Y\}$.

(iv) Here is an important class of derivations of interest only on noncommutative rings. Let $R$ be a ring, and $a \in R$. Set

$$
\delta_a(x) = [a,x] = ax - xa
$$

Then $\delta_a$ is a derivation on $R$, called the inner derivation defined by $a$. It is the zero derivation if and only if $a$ is in the center of $R$ (e.g. if $R$ is commutative).

More generally, if $M$ is an $R$-bimodule and $a \in M$, then $\delta_a$ is a derivation from $R$ to $M$. Amenability is characterized by certain types of derivations always being inner (i).

(v) We illustrate the connection between inner derivations and derivatives with the following example, which is a (very) special case of the theory to be developed in (i). Let $\mathcal{H}$ be a (complex) Hilbert space, and let $H$ be a self-adjoint operator in $\mathcal{B}(\mathcal{H})$. For each $t \in \mathbb{R}$, let $U_t = e^{itH}$. Then $U_t$ is a unitary operator on $\mathcal{H}$, $U_{s+t} = U_s U_t$ for all $s,t$, and $t \mapsto U_t$ is norm-continuous. Consider the inner derivation $\delta = \delta_H$ on $\mathcal{B}(\mathcal{H})$, i.e. $\delta(X) = HX - XH$. Then $\delta$ is a derivation on $\mathcal{B}(\mathcal{H})$, and is also a bounded operator on $\mathcal{B}(\mathcal{H})$, i.e. $\delta \in \mathcal{B}(\mathcal{B}(\mathcal{H}))$. Thus we may form the operator

$$
\alpha_t = e^{i\delta} \in \mathcal{B}(\mathcal{B}(\mathcal{H}))
$$

for any $t \in \mathbb{R}$. Then $\alpha_t$ is a *-automorphism of $\mathcal{B}(\mathcal{H})$ for each $t$, $\alpha_{s+t} = \alpha_s \circ \alpha_t$ for all $s,t$, and $t \mapsto \alpha_t$ is norm-continuous ($\{\alpha_t\}$ is a norm-continuous one-parameter group of automorphisms of $\mathcal{B}(\mathcal{H})$). We have

$$
\alpha_t(X) = U_t UX_t^*
$$

$$
H = \lim_{t \to 0} \frac{U_t - I}{t}
$$

$$
\delta(X) = \lim_{t \to 0} \frac{\alpha_t(X) - X}{t}
$$

for all $X \in \mathcal{B}(\mathcal{H})$. Every norm-continuous one-parameter automorphism group of $\mathcal{B}(\mathcal{H})$ is of this form (i), i.e. every bounded *-derivation on $\mathcal{B}(\mathcal{H})$ is inner.

The formal relation between derivations and one-parameter automorphism groups is quite simple (if convergence questions are ignored): if $(\alpha_t)$ is a one-parameter automorphism group and we define

$$
\delta(X) = \lim_{t \to 0} \frac{\alpha_t(X) - X}{t}
$$

(assuming the limit exists for all $X$), then for any $X$ and $Y$ we have

$$
\delta(XY) = \lim_{t \to 0} \frac{\alpha_t(XY) - I}{t} = \lim_{t \to 0} \frac{\alpha_t(X)\alpha_t(Y) - X\alpha_t(Y) + X\alpha_t(Y) - I}{t}
$$
so $\delta$ is a derivation. Conversely, if $\delta$ is a derivation, a formal power-series calculation (assuming the appropriate series converge) shows that $e^\delta$ is an automorphism. Thus derivations are "derivatives" of one-parameter automorphism groups.

One-parameter groups of automorphisms of $B(\mathcal{H})$ which are only point-norm continuous (strongly continuous) are more important in applications, e.g. in the time evolution of a dynamical system, and have a similar description except that the $\mathcal{H}$ is unbounded and only densely defined in general, as is the derivation $\delta$.

Constants

**X.9.1.4.** Let $\delta$ be a derivation on a ring $R$. An element $x \in R$ is a constant (for $\delta$) if $\delta(x) = 0$. Write $R_0$ for the set of constants for $\delta$.

**X.9.1.5.** **PROPOSITION.** Let $\delta$ be a derivation on a ring $R$, and $R_0$ the set of constants for $\delta$. Then

(i) $R_0$ is a subring of $R$.

(ii) If $R$ is a unital ring, then $1 \in R_0$, i.e. $R_0$ is a unital subring of $R$.

(iii) If $K$ is a subring of $R_0$ which is contained in the center of $R$, and $R$ is regarded as an algebra over $K$, then $\delta$ is $K$-linear, i.e.

$$\delta(\alpha x) = \alpha \delta(x)$$

for all $\alpha \in K$, $x \in R$.

**PROOF:** Parts (i) and (iii) are obvious. For (ii), we have

$$\delta(1) = \delta(1 \cdot 1) = \delta(1)1 + 1\delta(1) = 2\delta(1)$$

so $\delta(1) = 0$.

**X.9.1.6.** If $\delta$ is a derivation on a ring $R$, and $\alpha \in R_0$ is in the center of $R$, then $\alpha \delta$ is also a derivation on $R$, where $(\alpha \delta)(x) = \delta(\alpha x)$:

$$\alpha \delta(xy) = \delta(\alpha xy) = \delta(\alpha) \delta(xy) + \alpha \delta(xy) = \alpha \delta(x)y + \alpha x \delta(y) = \alpha \delta(x)y + x \alpha \delta(y).$$

**X.9.1.7.** **EXAMPLES.** (i) In **X.9.1.3.(i)**, the constants are exactly the constant functions.

(ii) In **X.9.1.3.(ii)**, if $U$ is connected, the constants for $\delta_x$ are just the functions whose value depends only on $y$. But if $U$ is not connected, the constants for the derivation are a little more complicated (functions of only $y$ on each component of $U$).

(iii) In **X.9.1.3.(iii)**, the constants are just the elements of $F$.

(iv) In **X.9.1.3.(iv)**, the constants for the inner derivation $\delta_a$ are exactly the elements of $R$ which commute with $a$.

(v) The ring of constants is not necessarily commutative. In the extreme case, if $\delta$ is the zero derivation on any ring $R$, then $R_0 = R$. 988
X.9.2. Differential Fields

In the subject of differential algebra, derivations on fields are usually considered. In this subsection, all rings will be commutative.

X.9.2.1. Definition. A differential field is a pair \((F, \delta)\), where \(F\) is a field of characteristic zero (III.4.3.2.) and \(\delta\) a derivation on \(F\). (In some references the characteristic zero requirement is omitted.)

The restriction to fields is rather natural, due to the following result:

X.9.2.2. Theorem. Let \(R\) be a unital commutative ring, and \(D\) a subset of \(R\) closed under multiplication, \(1 \in D\), which contains neither 0 nor any zero divisors. If \(\delta\) is a derivation on \(R\), then \(\delta\) extends uniquely to a derivation \(\tilde{\delta}\) on the ring \(D^{-1}R\) of quotients (III.4.3.4.). The extension is given by the “quotient rule”

\[
\tilde{\delta}\left(\frac{x}{y}\right) = \frac{y\delta(x) - x\delta(y)}{y^2}
\]

for all \(x \in R, y \in D\). In particular, if \(R\) is an integral domain and \(\delta\) is a derivation on \(R\), then \(\delta\) extends uniquely to the quotient field of \(R\). If \(x \in R\) and \(y \in D\) are constants for \(\delta\), then \(xy\) is a constant for \(\tilde{\delta}\).

Proof: Recall that elements of \(D^{-1}R\) can be symbolically written as \(\frac{x}{y}\) with \(x \in R, y \in D\), with \(\frac{x}{y} = \frac{z}{w}\) if and only if \(xw = yz\). (We should really write \([\frac{x}{y}]\) or \([x, y]\) instead of \(\frac{x}{y}\).)

To motivate the definition of \(\tilde{\delta}\) and prove uniqueness, suppose \(\tilde{\delta}\) is a derivation on \(D^{-1}R\) extending \(\delta\). For each \(y \in D\), we have, by X.9.1.5.(ii),

\[
0 = \tilde{\delta}(1) = \tilde{\delta}\left(\frac{1}{y}\right) = y\tilde{\delta}\left(\frac{1}{y}\right) = y\tilde{\delta}\left(\frac{1}{y}\right) + \frac{1}{y}\delta(y) = \frac{y\delta(x) - x\delta(y)}{y^2}.
\]

and if \(x \in R\), we have

\[
\tilde{\delta}\left(\frac{x}{y}\right) = \tilde{\delta}\left(\frac{1}{y}\right) = \frac{1}{y}\delta(x) + x\tilde{\delta}\left(\frac{1}{y}\right) = \frac{1}{y}\delta(x) - \frac{x}{y^2}\delta(y) = \frac{y\delta(x) - x\delta(y)}{y^2}.
\]

We now show that \(\tilde{\delta}\) is well defined. We first suppose \(x \in R\) and \(y, z \in D\). Then

\[
\tilde{\delta}\left(\frac{xz}{yz}\right) = \frac{yz\delta(xz) - xz\delta(yz)}{y^2z^2} = \frac{yz(x\delta(z) + z\delta(x)) - xz(y\delta(z) + z\delta(y))}{y^2z^2} = \frac{yz^2\delta(x) - xz^2\delta(y)}{y^2z^2} = \frac{y\delta(x) - x\delta(y)}{y^2} = \tilde{\delta}\left(\frac{x}{y}\right).
\]

Now if \(\frac{z}{y} = \frac{z}{w}\), i.e. \(xw = yz\), we have

\[
\tilde{\delta}\left(\frac{x}{y}\right) = \tilde{\delta}\left(\frac{yw^2}{y^2w^2}\right) = \tilde{\delta}\left(\frac{y^2zw}{y^2w^2}\right) = \tilde{\delta}\left(\frac{z}{w}\right).
\]
The embedding of $R$ into $D^{-1}R$ sends $x$ to $\frac{x}{1}$, and

$$\tilde{\delta}\left(\frac{x}{1}\right) = \frac{1 \cdot \delta(x) - x\delta(1)}{1} = \delta(x)$$

since $\delta(1) = 0$. Thus $\tilde{\delta}$ extends $\delta$.

To show that $\tilde{\delta}$ is a derivation, let $x, z \in R$ and $y, w \in D$. Then

$$\tilde{\delta}\left(\frac{x}{y}, \frac{z}{w}\right) = \frac{yvw\delta(xz) - xz\delta(yw)}{y^2w^2} = \frac{yw(x\delta(z) + z\delta(x)) - xz(y\delta(w) + w\delta(y))}{y^2w^2}$$

$$= \frac{yz\delta(x) - xz\delta(y) + xyw\delta(z) - xzw\delta(y)}{y^2w^2}$$

so $\tilde{\delta}$ is a derivation.

The last statement is obvious from the formula for $\tilde{\delta}$.

A corollary of the first part of the proof is:

**X.9.2.3. COROLLARY.** Let $\delta$ be a derivation on a unital ring $R$. If $y \in R$ is invertible, then

$$\delta(y^{-1}) = -y^{-1}\delta(y)y^{-1}.$$  

In particular, if $y$ is a constant for $\delta$, so is $y^{-1}$. So if $(F, \delta)$ is a differential field, the ring of constants for $\delta$ is a subfield of $F$.

Here are the most important examples of differential fields for our purposes:

**X.9.2.4. EXAMPLES.** (i) Let $F$ be a field of characteristic zero (e.g. $\mathbb{Q}$, $\mathbb{R}$, or $\mathbb{C}$). The polynomial ring $F[X]$ in one variable over $F$ becomes a differential ring under the derivation

$$\delta \left( \sum_{k=0}^{n} a_k X^k \right) = \sum_{k=1}^{n} k a_k X^{k-1}$$

and the quotient field $F(X)$ of rational functions in one variable over $F$ becomes a differential field with the unique extension from **X.9.2.2.** given by the quotient rule.

There is a minor but technically important point about this example and the succeeding ones which is glossed over in many references on differential fields. The elements of $F(X)$ are called “rational functions,” but they are not exactly functions from $F$ (or a fixed subset) to $F$ since functions which agree except at finitely many points are identified. Thus, for example, $f(X) = X + 1$, $g(X) = \frac{X^2-1}{X-1}$, and $h(X) = \frac{X^2-X-2}{X-2}$ all represent the same element of $F(X)$ even though they represent different functions since their domains are different.

It is customary in differential algebra to play a little fast and loose with domains of “functions” since it turns out that the domains and other functional properties are not really relevant to the algebra, but one should be careful in the process.
(ii) Let $\Omega$ be a connected open set in $\mathbb{C}$. Let $\mathcal{M}(\Omega)$ be the set of meromorphic functions on $\Omega$, complex-valued functions which are differentiable on $\Omega$ except for isolated poles (or removable singularities). We again identify two functions if they agree when all removable singularities have been filled in, i.e. if the functions agree on a nonempty open subset of $\Omega$, or more generally on a subset of $\Omega$ with a limit point in $\Omega$. The reciprocal of a meromorphic function on $\Omega$ which is not identically zero is again a meromorphic function on $\Omega$, so $\mathcal{M}(\Omega)$ is a field. The usual complex differentiation is a derivation on $\mathcal{M}(\Omega)$ making it into a differential field.

$\mathbb{C}(X)$ may be regarded as a differential subfield of $\mathcal{M}(\Omega)$ for any $\Omega$. If $\Omega_1 \subseteq \Omega_2$, then restriction gives a natural embedding of $\mathcal{M}(\Omega_2)$ into $\mathcal{M}(\Omega_1)$, so $\mathcal{M}(\Omega_2)$ can be regarded as a subfield of $\mathcal{M}(\Omega_1)$. (It is a proper subfield if $\Omega_2 \neq \Omega_1$: for example, if $z_0 \in \Omega_2 \setminus \Omega_1$, then $f(z) = e^{1/(z-z_0)}$ is in $\mathcal{M}(\Omega_1)$ but not $\mathcal{M}(\Omega_2)$.) The field of constants in these differential fields is $\mathbb{C}$ (i.e. the usual constant functions).

If $\Omega$ is not connected, then $\mathcal{M}(\Omega)$ has zero divisors and is not a field: a function which is identically zero on one component of $\Omega$ but not on all of $\Omega$ is a zero divisor.

Differential Function Fields

These examples lead to a convenient definition of the principal objects of study in elementary differential algebra:

X.9.2.5. Definition. A differential function field or df is a differential subfield of $\mathcal{M}(\Omega)$ containing $\mathbb{C}(X)$, for some nonempty connected open subset $\Omega$ of $\mathbb{C}$.

As mentioned earlier, the exact set $\Omega$ will turn out to be unimportant, and we will feel free to reduce it whenever necessary. The next convenient result illustrates the technique:

X.9.2.6. Proposition. Let $F$ be a differential function field, and $K$ a finite extension of $F$. Then $K$ is isomorphic to a differential function field, and the derivation on $K$ is uniquely determined by the derivation on $F$.

Proof: Identify $F$ with a subfield of $\mathcal{M}(\Omega)$ for some $\Omega \subseteq \mathbb{C}$. Suppose $K = F(\phi)$ for some $\phi \in K$ ($K$ can be constructed from $F$ by finitely many such steps; in fact, it can be done in one step by the Primitive Element Theorem of algebra). Then $\phi$ is a root of an irreducible polynomial $p(Y)$ with coefficients in $F$. Regard $p$ as a function $p(z, w)$ from $\Omega \times \mathbb{C}$ to $\mathbb{C}$ which is analytic except where $z$ is a pole of a coefficient function of $p$. By the Analytic Implicit Function Theorem (VIII.6.8.4.), there is an open set $\Omega' \subseteq \Omega$ and an analytic function $g$ on $\Omega'$ such that $p(z, g(z)) = 0$ for all $z \in \Omega'$. The embedding of $K$ into $\mathcal{M}(\Omega')$ which is restriction on $F$ and which sends $\phi$ to $g$ represents $K$ as a differential function field.

Algebraic Extensions of Derivations

The uniqueness of the derivation follows from a more general version of this result:

X.9.2.7. Proposition. Let $(F, \delta)$ be a differential field, and $K$ an algebraic extension of $F$. Then $\delta$ extends uniquely to a derivation on $K$. 

991
PROOF: [Ros72] Define two derivations $\delta_0$, $\delta_1$ on $\mathbb{F}[X]$ by

$$
\delta_0 \left( \sum_{k=0}^{n} \alpha_k X^k \right) = \sum_{k=0}^{n} \delta(\alpha_k) X^k
$$

$$
\delta_1 \left( \sum_{k=0}^{n} \alpha_k X^k \right) = \sum_{k=1}^{n} k\alpha_k X^{k-1}
$$

(it is routine to check that $\delta_0$ and $\delta_1$ are derivations). Let $\tilde{\delta}$ be a derivation on $\mathbb{K}$ extending $\delta$. If $p(X) = \sum_{k=0}^{n} \alpha_k X^k$, then for any $z \in \mathbb{K}$,

$$
0 = \tilde{\delta}(p(z)) = \sum_{k=0}^{n} \tilde{\delta}(\alpha_k z^k) = \sum_{k=0}^{n} \tilde{\delta}(\alpha_k) z^k + \sum_{k=1}^{n} \alpha_k z^{k-1} \tilde{\delta}(z) = (\delta_0(p))(z) + (\delta_1(p))(z)\tilde{\delta}(z) .
$$

Let $f$ be the irreducible polynomial of $z$ over $\mathbb{F}$. Taking $p = f$, we have

$$
0 = \tilde{\delta}(0) = \tilde{\delta}(f(z)) = (\delta_0(f))(z) + (\delta_1(f))(z)\tilde{\delta}(z)
$$

$$
(\delta_1(f))(z)\tilde{\delta}(z) = -(\delta_0(f))(z) .
$$

But $\delta_1(f)$ is the “derivative” of $f$ in the usual algebraic sense. Since $\mathbb{F}$ has characteristic zero, $z$ is not a root of $\delta_1(f)$, i.e. $(\delta_1(f))(z) \neq 0$, and hence

$$
\tilde{\delta}(z) = -\frac{(\delta_0(f))(z)}{(\delta_1(f))(z)} .
$$

Thus an extension of $\delta$ to $\mathbb{K}$ (if one exists) is unique, and for any $z \in \mathbb{K}$, we have that $\tilde{\delta}(z) \in \mathbb{F}(z)$.

To show existence, we may assume $\mathbb{K} = \mathbb{F}(z)$ for some $z$. We have $\mathbb{K} = \mathbb{F}(z) \cong \mathbb{F}[X]/(f(X))$, where $f(X)$ is the irreducible polynomial of $z$ over $\mathbb{F}$. We need only show that the derivation

$$
\tilde{\delta} = \delta_0 - \frac{(\delta_0(f))(z)}{(\delta_1(f))(z)} \delta_1
$$

of $\mathbb{F}[X]$ drops to a derivation of $\mathbb{F}[X]/(f(X))$ (X.9.4.3.), since this drop will extend $\delta$. Thus we only need to show that $\tilde{\delta}$ maps the ideal $(f(X))$ into itself, i.e. that $\delta(f)$ is a multiple of $f$, or equivalently that $z$ is a root of $\tilde{\delta}(f)$. But

$$
(\tilde{\delta}(f))(z) = (\delta_0(f))(z) - \frac{(\delta_0(f))(z)}{(\delta_1(f))(z)} (\delta_1(f))(z) = 0 .
$$

Exponentials and Logarithms

X.9.2.8. DEFINITION. Let $(\mathbb{F}, \delta)$ be a differential field, and $x, y \in \mathbb{F}$, $y \neq 0$. Then $y$ is an exponential of $x$, and $x$ is a logarithm of $y$, if $\delta(y) = y\delta(x)$, or equivalently $\delta(x) = \frac{\delta(y)}{y}$. 

992
X.9.2.9. **Proposition.** (i) If $y_1$ is an exponential of $x$, then $y_2$ is an exponential of $x$ if and only if $y_2 = cy_1$ for some nonzero constant $c$.

(ii) If $x_1$ is a logarithm for $y$, then $x_2$ is a logarithm for $y$ if and only if $x_2 = x_1 + c$ for some constant $c$.

**Proof:** (ii) is trivial since $(x_2) = (x_1)$ if and only if $y_2 = y_1 + c$.

(i): The following statements are equivalent for $y_2 \neq 0$:

\[ \frac{\delta(y_2)}{y_2} = \frac{\delta(y_1)}{y_1} = \frac{\delta(y_1)}{y_1} \]

\[ y_2 \delta(y_1) = y_1 \delta(y_2) \]

\[ \frac{y_2 \delta(y_1) - y_1 \delta(y_2)}{y_2^2} = \delta \left( \frac{y_1}{y_2} \right) = 0. \]

X.9.2.10. **Example.** Let $f \in M(\Omega)$ for some connected open set $\Omega \subseteq \mathbb{C}$. An exponential for $f$ is a function $g$ of the form $cf^k$ for some nonzero $c \in \mathbb{C}$. The function $g$ is meromorphic (holomorphic) on any subregion $\Omega' \subseteq \Omega$ containing no poles of $f$, i.e. a subset on which $f$ is holomorphic.

If $f$ is not identically zero, a logarithm for $f$ is a function $h$ of the form $c + \log f$ for some $c \in \mathbb{C}$. The function $h$ can be chosen meromorphic (holomorphic) on any simply connected $\Omega' \subseteq \Omega$ not containing any zeroes or poles of $f$.

Thus, if $F$ is any differential function field, and $f \in F$, there is a df $K$ containing $F$ containing an exponential for $f$; if $f$ is nonzero there is also such a $K$ containing a logarithm for $f$. The smallest such df is well defined up to isomorphism, and is called the df obtained from $F$ by adding an exponential [logarithm] of $F$; it is isomorphic to an evident quotient of the universal differential algebra $F\{X\}$ (by the differential ideal generated by $X_1 - fX$ in the exponential case and $fX_1 - f'$ in the logarithm case).

X.9.2.11. **Proposition.** [*Logarithmic Differentiation Formula*] Let $(F, \delta)$ be a differential field, $a_1, \ldots, a_n$ nonzero elements of $F$, and $r_1, \ldots, r_n \in \mathbb{N}$. Set $a = a_1^{r_1} a_2^{r_2} \cdots a_n^{r_n}$. Then

\[ \frac{\delta(a)}{a} = r_1 \frac{\delta(a_1)}{a_1} + r_2 \frac{\delta(a_2)}{a_2} + \cdots + r_n \frac{\delta(a_n)}{a_n}. \]

**Proof:** This is an easy proof by induction on $r_1 + \cdots + r_n$, using the product rule.
X.9.3. Integration in Finite Terms

The name of this section has been the title of at least two important publications on the subject ([?), [Ros72]). The general problem is: if \( \delta \) is a derivation on a ring \( R \), what is the range of \( \delta \), and in particular is \( \delta \) surjective? If \( x \in R \), can \( \delta \) be extended to a well-behaved larger ring with \( x \) in the range of the extended derivation?

Rather than treating the general problem, we will have the much more modest goal of examining the question for differential function fields. In other words, we will determine conditions for when there is, or is not, a differentiable function \( g \) with an elementary formula whose derivative is a given function \( f \) which has an elementary formula, or equivalently whether

\[
\int f(x) \, dx
\]

has a formula in terms of standard functions.

We must first carefully determine what it means for a function to have an “elementary formula.”

Elementary Formulas

X.9.3.1. We will informally say a function has an elementary formula if it can be written in terms of algebraic operations and exponential, logarithm, trigonometric, and inverse trigonometric functions, which are defined on some common interval. (We could include hyperbolic and inverse hyperbolic functions too, but these functions can be written in terms of exponential and logarithm functions so they come for free).

X.9.3.2. It is convenient and useful to pass to complex functions. Each of the “building block” functions (algebraic, exponential, logarithm, trigonometric, inverse trigonometric) can be regarded as a holomorphic function on large regions of the complex plane, and hence any real-valued function defined on a real interval which has an elementary formula in the above sense will be holomorphic on a large region in \( \mathbb{C} \). In addition, when we expand to complex functions, we get the pleasant fact that trigonometric and inverse trigonometric functions can also be written in terms of exponential and logarithm functions () and thus do not have to be separately considered. We can thus reduce the problem to consideration of only functions which can be written with formulas involving only algebraic operations and exponential and logarithm functions.

X.9.3.3. Definition. Let \((F, \delta)\) be a differential field. A differential field \( K \) containing \( F \) is an elementary extension of \( F \) if there is a finite chain

\[
F = F_1 \subseteq F_2 \subseteq \cdots \subseteq F_n = K
\]

of field extensions where, for each \( k \), \( F_{k+1} \) is either a finite extension of \( F_k \) or is obtained by adding to \( F_k \) an exponential or logarithm of an element of \( F_k \).

An elementary function field is an elementary extension of the field \( \mathbb{C}(X) \) of rational functions over \( \mathbb{C} \). A function \( f \) which is meromorphic on a region in \( \mathbb{C} \) is an elementary function if it lies in some elementary function field.

X.9.3.4. By (), an elementary function field is a differential function field. Any elementary extension of an elementary extension of a differential field \( F \) is an elementary extension of \( F \); in particular, an elementary extension of an elementary function field is an elementary function field.
X.9.3.5. Example. A function with a formula like
\[ f(z) = \frac{\sqrt[3]{e^{\cos(z^2+1)} - \log(\sin^{-1} z)}}{z^5 - iz + 1} \]
is an elementary function: it lies in the field extension

The problem of integration in finite terms thus becomes the following specific problem:

X.9.3.6. Question. Let \( f \) be an elementary function. Is there an elementary function \( g \) with \( g' = f \)?

X.9.3.7. It would be clean to take the field of all elementary functions, with its natural derivative (derivation), and ask what the range of this derivation is. However, it is not clear that this version of the question is well defined. (There is certainly no region in \( \mathbb{C} \) on which all elementary functions are meromorphic.) Thus we have to work locally in elementary function fields.

A more general version of the question is thus:

X.9.3.8. Question. Let \((\mathbb{F}, \delta)\) be a differential field, and \( x \in \mathbb{F} \). Under what conditions is there an elementary extension \((\mathbb{K}, \delta)\) of \( \mathbb{F} \) and an element \( y \in \mathbb{K} \) with \( x = \delta(y) \)?

X.9.3.9. In 1835, Liouville gave a necessary and sufficient condition (X.9.3.11.) for elements of elementary function fields, which was abstracted by Ostrowski [?] in 1946 (cf. [Ros72]):

X.9.3.10. Theorem. Let \((\mathbb{F}, \delta)\) be a differential field, and \( x \in \mathbb{F} \). Then there is an elementary extension \((\mathbb{K}, \delta)\) of \((\mathbb{F}, \delta)\) with the same field of constants as \((\mathbb{F}, \delta)\), and an element \( y \in \mathbb{K} \) with \( x = \delta(y) \), if and only if there are constants \( c_1, \ldots, c_n \) and elements \( u_1, \ldots, u_n, v \) of \( \mathbb{F} \) such that
\[
x = \sum_{k=1}^{n} c_k \frac{\delta(u_k)}{u_k} + \delta(v) .
\]

X.9.3.11. Corollary. Let \((\mathbb{F}, \delta)\) be an elementary function field, and \( f \in \mathbb{F} \). Then there is an elementary function \( g \) with \( f = g' \) if and only if there are constants \( c_1, \ldots, c_n \) and functions \( h_1, \ldots, h_n, \phi \) in \( \mathbb{F} \) such that
\[
f = \sum_{k=1}^{n} c_k \frac{h'_k}{h_k} + \phi' .
\]
X.9.3.12. To obtain the corollary from the theorem, it suffices to note that all differential function fields have the same field of constants, namely the constant functions. One direction of the theorem is very easy: if $x$ is of the given form, one only needs to add logarithms $z_1, \ldots, z_n$ of $u_1, \ldots, u_n$ to $\mathbb{F}$, and then

$$y = c_1 z_1 + \cdots + c_n z_n + v$$

is an antiderivative of $x$. Thus the conclusion of the theorem can be strengthened, since $K$ is obtained by just adding logarithms.

The other direction is a more involved argument requiring some elementary field theory, and is omitted. See e.g. [Ros72]. The requirement that $K$ have the same constants as $F$ is necessary: if $F = \mathbb{R}(X)$, and $f(x) = \frac{1}{x^2 + 1}$, then $f$ is not of the given form in $F$ even though it has an elementary antiderivative in an extension of $\mathbb{C}(X)$ (which is a finite, hence elementary, extension of $F$) by a logarithm. (It does have such an expression in $\mathbb{C}(X)$, to which the theorem applies.)

Applications

We now discuss some simple functions which have no elementary antiderivatives.

X.9.3.13. We first examine integrals of the form

$$\int \frac{1}{\sqrt{p(x)}} \, dx$$

where $p$ is a polynomial with complex coefficients of degree $\geq 3$ and with no multiple roots. Integrals of this type include elliptic integrals, which arise in computing the arc length of an ellipse. Of course, what we want is an elementary function $g$ whose derivative is $f(z) = \frac{1}{\sqrt{p(z)}}$ (say, on some subregion of $\mathbb{C}$; it could be the inverse image under $1/p$ of any simply connected region not containing 0).

X.9.3.14. We now examine integrals of the form

$$\int f(x) e^{g(x)} \, dx$$

where $f$ and $g$ are rational functions. Liouville showed:

X.9.3.15. Theorem. Let $f$ and $g$ be in $\mathbb{C}(X)$, with $f \neq 0$ and $g$ not constant. Then there is an elementary function $h$ such that $h'(z) = f(z)e^{g(z)}$ if and only if there is a rational function $r$ such that

$$r'(X) + g'(X)r(X) = f(X)$$

in $\mathbb{C}(X)$. If there is such an $r$, then $h(z) = r(z)e^{g(z)}$ is an elementary antiderivative of $fe^g$.

X.9.3.16. Note that the condition is considerably stronger than simply asserting that the differential equation

$$y' + g'(t)y = f(t)$$

has a solution, which will always be the case from existence theorems for differential equations (at least if $f$ and $g$ have real coefficients); the condition requires that it have a rational solution. A corollary (equivalent version) of the theorem is that if the differential equation does not have a rational solution, it does not have an elementary solution.
X.9.3.17. For example, consider the integral

\[ \int \frac{e^x}{x} \, dx . \]

Applying the theorem with \( f(X) = \frac{1}{X} \) and \( g(X) = X \), this integral has an elementary formula if and only if the differential equation

\[ r'(X) + r(X) = \frac{1}{X} \]

has a rational solution. Suppose \( r(X) = \frac{p(X)}{q(X)} \) is a solution with \( p(X) \), \( q(X) \) polynomials which are relatively prime. We have

\[ \frac{q(X)p'(X) - p(X)q'(X)}{[q(X)]^2} + \frac{p(X)}{q(X)} = \frac{q(X)p'(X) - p(X)q'(X) + p(X)q(X)}{[q(X)]^2} = \frac{1}{X} \]

in \( \mathbb{C}(X) \), and hence \( X \) divides \([q(X)]^2\) and therefore \( q(X) \). Thus

\[ q(X) = X^n \phi(X) \]

for some \( n \geq 1 \) and some polynomial \( \phi(X) \) not divisible by \( X \). Note that \( X \) does not divide \( p(X) \). We have

\[
\begin{align*}
\frac{X^n \phi(X)p'(X) - p(X)[nX^{n-1} \phi(X) + X^n \phi'(X)]}{X^{2n}[\phi(X)]^2} + \frac{p(X)}{X^n \phi(X)} &= \frac{X^n [\phi(X)p'(X) - \phi'(X)p(X) + \phi(X)p(X)] - nX^{n-1} \phi(X)p(X)}{X^{2n}[\phi(X)]^2} \\
&= \frac{X [\phi(X)p'(X) - \phi'(X)p(X) + \phi(X)p(X)] - n \phi(X)p(X)}{X^{n+1}[\phi(X)]^2} = \frac{1}{X}
\end{align*}
\]

in \( \mathbb{C}(X) \). The denominator is divisible by \( X^{n+1} \), so the numerator must be divisible by \( X^n \), and in particular by \( X \). Thus \( n \phi(X)p(X) \) must be divisible by \( X \). But \( X \) does not divide \( p(X) \), so it must divide \( \phi(X) \), a contradiction. Thus there is no rational solution, and no elementary formula for the antiderivative.

The substitution \( x = \log u \) converts this integral into

\[ \int \frac{1}{\log u} \, du \]

which therefore also does not have an elementary formula. This integral arises in the Prime Number Theorem (\( \)).

X.9.3.18. Now we turn to the best-known example of this type:

\[ \int e^{-x^2} \, dx \]

which is important in probability (\( \)). The arguments for

\[ \int e^{x^2} \, dx \]

997
are essentially identical.

Applying the theorem with \( f(X) = 1 \) and \( g(X) = -X^2 \), we need to show that there is no rational function \( r(X) \) satisfying

\[
r'(X) - 2Xr(X) = 1 .
\]

Clearly there is no polynomial satisfying this equation, since if \( r(X) \) is a polynomial of degree \( d \), the left side is a polynomial of degree \( d + 1 \). Thus we may write \( r(X) = \frac{p(X)}{q(X)} \) in lowest terms with \( q \) not constant. Then \( q \) has a root \( z_0 \in \mathbb{C} \), i.e. \( r \) has a pole of some finite order \( n \geq 1 \) at \( z_0 \), so \( r \) can be written

\[
r(X) = \frac{h(X)}{(X - z_0)^n}
\]

with \( h(X) \in \mathbb{C}(X) \) defined and nonzero at \( z_0 \), and \( h \) and \( h' \) are continuous at \( z_0 \). Set

\[
\phi(X) = r'(X) - 2Xr(X) = \frac{(X - z_0)^n h'(X) - n(X - z_0)^{n-1}h(X)}{(X - z_0)^{2n}} - \frac{2Xh(X)}{(X - z_0)^n}
\]

\[
= \frac{(X - z_0)^n[h'(X) - 2Xh(X)] - n(X - z_0)^{n-1}h(X)}{(X - z_0)^{2n}} = \frac{(X - z_0)[h'(X) - 2Xh(X)] - nh(X)}{(X - z_0)^{n+1}}
\]

and thus, if \( \phi \) is regarded as a meromorphic function on \( \mathbb{C} \), we have

\[
\lim_{z \to z_0} (z - z_0)^{n+1} \phi(z) = \lim_{z \to z_0} \left[ (z - z_0)[h'(z) - 2zh(z)] - nh(z) \right] = nh(z_0) \neq 0
\]

which contradicts that \( \phi(X) = 1 \) in \( \mathbb{C}(X) \).

Thus there is no rational solution to the differential equation, and no elementary formula for the antiderivative.

**X.9.4. Exercises**

**X.9.4.1.** Let \((R, \delta)\) and \((\tilde{R}, \tilde{\delta})\) be differential rings. A ring-homomorphism \( \phi : R \to \tilde{R} \) is a **differential homomorphism**, or **diffomorphism**, if \( \phi \) intertwines \( \delta \) and \( \tilde{\delta} \), i.e. \( \tilde{\delta}(\phi(x)) = \phi(\delta(x)) \) for all \( x \in R \). [The term "diffomorphism" is to "diffeomorphism" exactly as "homomorphism" is to "homeomorphism".]

Show that if \((R, \delta)\) is a commutative differential ring and \( z \in R \), there is a unique diffomorphism from the differential polynomial ring \( R_0\{X\} \) (X.9.1.3.(iii)) to \( R \) sending \( X \) to \( z \). Thus \( R_0\{X\} \) is the "universal" differential algebra with one generator over the ring \( R_0 \) of constants.

**X.9.4.2.** Generalize the construction of the differential polynomial ring as follows. Let \((F, \delta)\) be a commutative differential ring, and let \( X, X_1, X_2, \ldots \) be a sequence of indeterminates. Form the polynomial ring

\[
R = F[X, X_1, X_2, \ldots] .
\]

Define a map \( \tilde{\delta} : R \to R \) by

\[
\tilde{\delta} \left( \sum_{k,n} \alpha_{k,n} X_k^n \right) = \sum_{k,n} \delta(\alpha_{k,n}) X_k^n + \sum_{k,n} n\alpha_{k,n} X_k^{n-1} X_{k+1} .
\]
(i) Show that $\hat{\delta}$ is a derivation on $R$ which extends the derivation $\delta$ on the subring $F$ of “constant polynomials” (which is not the ring of constants for $\hat{\delta}$ in general!) Denote the ring $R$ by $F\{X\}$. Note that if $\delta$ is the zero derivation on $F$, then this definition agrees with the previous definition of $F\{X\}$.

(ii) Show that if $(K, \delta)$ is another commutative differential ring and $\phi : F \to K$ is a diffeomorphism, and $z \in K$, then there is a unique extension $\phi$ of $\phi$ to a diffeomorphism from $F\{X\}$ to $K$ sending $X$ to $z$. Thus $F\{X\}$ is the “universal” differential algebra in one variable over the differential ring $(F, \delta)$.

**X.9.4.3.** Let $(R, \delta)$ be a differential ring, and $J$ a closed two-sided ideal of $R$ (i.e., if $\delta(J) \subseteq J$, show that $\delta$ drops to a derivation $\hat{\delta}$ on the quotient ring $R/J$ satisfying $\hat{\delta}(\pi(x)) = \pi(\delta(x))$ for all $x \in R$, where $\pi : R \to R/J$ is the quotient map (i.e. $\pi$ is a diffeomorphism). An ideal of $R$ invariant under $\delta$ is called a **differential ideal**.

**X.9.4.4.** Let $(K, \delta)$ be a differential field, and $F$ a subfield of $K$ closed under $\delta$. If $y \in K \setminus F$ is an exponential or logarithm of an element of $F$, is $y$ necessarily transcendental over $F$? What if $F$ contains all constants of $K$?

**X.9.4.5.** Define a one-parameter automorphism group of $C^\infty_c(\mathbb{R})$ by

$$[\alpha_t(f)](x) = f(x + t).$$

Show that $\alpha_t$ is an automorphism for each $t$, that $\alpha_{t+s} = \alpha_t \circ \alpha_s$ for all $t, s$. Discuss continuity of this one-parameter automorphism group and how the “derivative” in the sense of X.9.1.3.(v) is the derivation given by ordinary differentiation.
Chapter XI

Topology

Topology is a part of mathematics which provides a general setting for the notions of limits and continuity.

Topology is a huge subject, and goes far beyond the parts which form an essential tool for analysis and
other parts of mathematics. Our treatment of topology will mostly just cover the basic tools of the subject,
with an eye to applications in analysis.

In his classic topology book [Kel75], J. Kelley described the contents as “what every young analyst
should know.” While his judgment was of course subjective, it can be taken as a good guide. The topology
covered in this book largely represents my own judgment of What Every Analyst Should Know, but I admit
some idiosyncracies due to my own personal interests.

The idea behind topology is to describe what it means for points of a set to be “close together.” There
are at least four standard and commonly used equivalent ways to define, specify, or think of a topology on
a set $X$ (usually called a space):

(1) Specifying what the neighborhoods of each point of $X$ are, i.e. specifying which subsets of $X$ are open.
(2) Specifying the closure of each subset of $X$.
(3) Specifying which sequences (or generalized sequences) in $X$ converge, and what their limits are.
(4) Specifying which functions into or out of $X$ are continuous.

A good way of doing (1) is to specify a metric on $X$, and hence open balls in $X$, but there are other ways
to do (1) also.

Approach (1) is normally taken as the definition of a topology. We will in due course describe all four
approaches and how to go from each to the others.

Topology as used by topologists (or as presented in most elementary topology classes) has a rather
different emphasis than topology as used by analysts. Topologists by and large consider spaces which have
only one obvious or natural topology (except sometimes for exotic topologies artificially constructed primarily
to provide counterexamples; there are other exceptions too). When a topologist considers convergence of a
sequence or continuity of a function, there is a natural interpretation, and it is not necessary to go back and
worry about “with respect to what topology?” The topology tends to be taken for granted.
An analyst must quickly overcome this mindset. Spaces arising in analysis, notably function spaces, often have more than one *natural* topology, sometimes a great many, with varying properties. Convergence in one sense does not generally imply convergence in another sense, and some properties (e.g. continuity of functions) are preserved under certain kinds of limits but not others. Thus, for example, an analyst should never say of functions that \( f_n \to f \) without carefully specifying what is meant, because such a statement is totally ambiguous otherwise. An analyst needs to be acutely aware of which topology is being considered in a given situation, and that there is usually a multitude of reasonable candidates.

Topology is a subject which is full of definitions; in fact, the density of definitions in topology may be the highest in all the parts of mathematics. This situation arises because of the great generality of the subject and the enormous variety of topological spaces with varied properties. Most definitions in topology are of little direct interest to analysts. We will for the most part stick to those definitions relevant to analysis to try to avoid getting too bogged down in terminology.
Figure XI.1: Rumored original source of topology in Serbia
XI.1. Topological Spaces

The most important tool used in the study of limits and continuity in Euclidean spaces and metric spaces is the notion of “open set.” The idea behind the definition of a topological space is to abstract the notion of open set directly, without working through intermediate structures like metrics. Thus a topological space will just be an abstract set $X$ together with a specified collection of subsets which we arbitrarily call “open” sets in $X$; the term “open” does not have any intrinsic or geometric meaning in this context. We only require that the “open” sets have some simple union and intersection properties which hold for open sets in Euclidean space, and which are necessary to make a reasonable theory of limits and continuity.

XI.1.1. Definitions

XI.1.1.1. Definition. A topology on a set $X$ is a subset $T$ of $\mathcal{P}(X)$ with the following properties:

(i) $\emptyset, X \in T$.

(ii) $T$ is closed under finite intersections.

(iii) $T$ is closed under arbitrary unions.

The sets in $T$ are called the open sets (or $T$-open sets) in $X$.

A topological space is a pair $(X, T)$, where $X$ is a set and $T$ is a topology on $X$.

There is a technical question whether a topological space is required to be nonempty (the pair $(\emptyset, \mathcal{P}(\emptyset))$ satisfies the definition). We will generally assume topological spaces are nonempty, but explicitly state this when it is important.

XI.1.1.2. A set can have many different topologies. For example, the function spaces studied in analysis typically have several different natural topologies, and it is necessary to carefully distinguish between them. In some settings, there is one standard topology which is obvious from the context, so by abuse of language we often make statements like “let $X$ be a topological space.” However, it should be carefully noted and always kept in mind that the specification of a topology is an essential part of the definition of a topological space.

Topological spaces are the natural abstract setting for the notions of limits and continuity. We typically refer to elements of a topological space as “points.” In this connection, it is convenient to think of an open set containing a point as a “neighborhood” of the point. Slightly more generally:

XI.1.1.3. Definition. Let $(X, T)$ be a topological space, and $x \in X$. A neighborhood (or $T$-neighborhood) of $x$ is a set containing an open set which contains $x$.

Note that by this definition, a neighborhood of a point in $X$ is not necessarily an open set. It is sometimes convenient to work with neighborhoods which are not open. But the most important neighborhoods of points are open neighborhoods; every neighborhood of a point $x$ contains an open neighborhood of $x$, which is simply an open set containing $x$. We will try to always specify “open neighborhood” when open sets are required, even though this sometimes becomes a little pedantic.
Topologies and Metrics.

XI.1.1.4. **Examples.**

(i) If $X$ is any set, then $\mathcal{P}(X)$ is a topology on $X$, called the *discrete topology*.

(ii) If $X$ is any set, then $\{\emptyset, X\}$ is a topology on $X$, called the *indiscrete topology*.

(iii) The most important examples of topologies are those defined by metrics. If $(X, \rho)$ is a metric space, as usual define a subset of $X$ to be open (or $\rho$-open) if it contains an open ball around each of its points. The set $\mathcal{T}_{\rho}$ of $\rho$-open sets is a topology on $X$, called the *topology defined by (or underlying topology of)* the metric space $(X, \rho)$. Equivalent metrics define the same topology.

The discrete topology on a set $X$ comes from a metric (the *discrete metric*) $\rho$, where $\rho(x, y) = 1$ if $x \neq y$.

The usual notions of convergence of sequences and closure of a set in a metric space, or of continuity of functions between metric spaces, depend only on the underlying topology and can all be phrased in terms of the topology. See () and Problem () for continuity, and () for the other notions.

XI.1.1.5. There are, however, many examples of topological spaces which do not come from metric spaces (e.g. the indiscrete topology on a set with more than one element), some of which are important in applications. Even a metrizable topological space (one whose topology comes from a metric) need not have any *natural* metric defining the topology, and it is often unnatural to artificially pick one of the many possible metrics defining a topology which is given in another way. Thus it is useful to work directly with topological spaces rather than metric spaces in many situations.

XI.1.1.6. Although topologies, even interesting topologies, do not come from metrics in general, most interesting topologies share some of the properties of metric spaces: there are “enough” open sets that points have “small” neighborhoods, and in particular distinct points have disjoint neighborhoods. There are varying degrees of similarity to metrizable spaces which are useful, described by the separation axioms developed in ()

XI.1.2. **Bases and Subbases**

XI.1.2.1. If $\{\mathcal{T}_\alpha\}$ is a family of topologies on a set $X$, then $\bigcap_{\alpha} \mathcal{T}_\alpha$ is also a topology on $X$ (Exercise XI.1.6.2.). In particular, if $\mathcal{S}$ is any subset of $\mathcal{P}(X)$, there is a smallest topology containing $\mathcal{S}$, called the *topology generated by* $\mathcal{S}$ (there is always at least one topology containing $\mathcal{S}$, the discrete topology).

**Bases**

It is usually convenient to use a smaller collection of “nice” open sets to describe a topology. For example, in a topology defined by a metric, the open balls generate the topology as in XI.1.2.1. We abstract this situation in the notion of base:
XI.1.2.2. DEFINITION. Let \((X, \mathcal{T})\) be a topological space, and \(p \in X\). A subset \(B\) of \(\mathcal{T}\) is a local base for \(\mathcal{T}\) at \(p\) if, whenever \(U \in \mathcal{T}\) and \(p \in U\), there is a \(V \in B\) with \(p \in V\) and \(V \subseteq U\).

A subset \(B\) of \(\mathcal{T}\) is a base for \(\mathcal{T}\) if it is a local base at every point, i.e. whenever \(U \in \mathcal{T}\) and \(x \in U\), there is a \(V \in B\) with \(x \in V\) and \(V \subseteq U\). In other words, \(U = \bigcup_{V \in B} V\), i.e. every open set is a union of sets in \(B\).

In particular, if \(B\) is a base for \(\mathcal{T}\), then \(\mathcal{T}\) is the topology generated by \(B\).

When a base or local base \(B\) is specified, the sets in \(B\) are usually called basic open sets. Some authors use the term basis instead of base, in analogy with the use of “basis” for a vector space; but this is potentially misleading, since a base for a topology does not necessarily have any type of minimality condition like a basis for a vector space: for example, any collection of open sets containing a base for \(\mathcal{T}\) is also a base for \(\mathcal{T}\).

XI.1.2.3. EXAMPLES. (i) If \((X, \rho)\) is a metric space, and \(p \in X\), the open balls centered at \(p\) form a local base for the topology at \(p\). The set of all open balls in \(X\) forms a base for \(\mathcal{T}_\rho\).

(ii) If \(X\) has the discrete topology, and \(p \in X\), then \(\{\{p\}\}\) is a local base for the topology at \(p\). The collection of all singleton subsets of \(X\) is a base for the discrete topology.

(iii) If \(\mathcal{T}\) is a topology on \(X\), then the collection of all sets in \(\mathcal{T}\), or the collection of all nonempty sets in \(\mathcal{T}\), is a (not very interesting) base for \(\mathcal{T}\).

XI.1.2.4. There is nothing unique about a base for a given topology. For example, if \(\rho_1\) and \(\rho_2\) are equivalent metrics on a set \(X\), the open balls from \(\rho_1\) and \(\rho_2\) may be quite different, but the open sets they generate will be the same. See (i) for an example.

It is useful to know when a collection \(B\) of open subsets of \(X\) forms a base for the topology it generates.

XI.1.2.5. PROPOSITION. Let \(X\) be a set and \(\mathcal{B} \subseteq \mathcal{P}(X)\), and let \(\mathcal{T}\) be the topology generated by \(\mathcal{B}\). Then \(\mathcal{B}\) is a base for \(\mathcal{T}\) if and only if

(i) \(\bigcup_{V \in \mathcal{B}} V = X\) and

(ii) If \(V_1, \ldots, V_n \in \mathcal{B}\) and \(x \in \bigcap_{j=1}^n V_j\), there is a \(V \in \mathcal{B}\) with \(x \in V\) and \(V \subseteq \bigcap_{j=1}^n V_j\).

XI.1.2.6. Note that a base for a topology need not be closed under finite intersections. For example, an intersection of open balls with different centers in a metric space is generally not an open ball. (For XI.1.2.5.(ii), it obviously suffices that \(\mathcal{B}\) be closed under finite intersections, as is frequently the case.)

First and Second Countability

Most interesting topological spaces have uncountably many open sets. But frequently there is a countable base for the topology, or at least a countable local base at each point, and if so the topology is more easily describable and tends to behave more nicely.
XI.1.2.7. **Definition.** Let \((X, \mathcal{T})\) be a topological space.

(i) \((X, \mathcal{T})\) satisfies the *first axiom of countability*, or is *first countable*, if there is a countable local base for \(\mathcal{T}\) at each point.

(ii) \((X, \mathcal{T})\) satisfies the *second axiom of countability*, or is *second countable*, if there is a countable base for \(\mathcal{T}\).

The “first” and “second” are used for historical reasons, but the terminology persists because it is both appropriate and useful.

XI.1.2.8. **Examples.**

(i) The discrete topology on a set \(X\) is always first countable; it is second countable if and only if \(X\) is countable.

(ii) The indiscrete topology on a set \(X\) is always second countable.

(iii) The usual topology on \(\mathbb{R}^n\) is second countable: balls with rational radii around points with rational coordinates form a base for the topology. More generally, the topology of a metric space is always first countable (for any point \(p\), balls of rational radius centered at \(p\) form a local base at \(p\)), and is second countable if and only if the metric space is separable (XI.2.3.15.).

(iv) Let \(X\) be a set. The *finite complement topology* on \(X\) is the topology consisting of \(\emptyset\) and all subsets of \(X\) with finite complement. (It is easily checked that this is a topology; cf. Exercise XI.1.6.4.) If \(X\) is countable, then this topology is second countable: in fact, there are only countably many open sets in all. But if \(X\) is uncountable, then the finite complement topology is not first countable, and in fact no point has a countable neighborhood base. For if \(p \in X\) and \(\{U_n : n \in \mathbb{N}\}\) is a countable collection of open neighborhoods of \(p\), set \(E = \cap_{n=1}^{\infty} U_n\). Then \(E\) has countable complement and is therefore uncountable, and in particular contains a point \(q \neq p\). Then \(X \setminus \{q\}\) is an open neighborhood of \(p\) not containing any \(U_n\), so the \(U_n\) cannot form a local base at \(p\).

Topological spaces which are not first countable are rather unusual, but they do arise naturally in analysis; see (). First countability is important since it is precisely in first countable topological spaces that the topology can be entirely described by convergence of sequences; in spaces which are not first countable it is necessary to work with generalizations of sequences called nets.

XI.1.2.9. **Caution:** For a topological space to be first countable, it is not sufficient that every singleton subset be a countable intersection of open sets (which may be assumed to be decreasing since a finite intersection of open sets is open), i.e. that every singleton subset is a \(G_δ\): there are countable topological spaces which are not first countable (Exercise XI.11.12.8.). (The condition that singletons are \(G_δ\)’s is not necessary either: the indiscrete topology on any set is even second countable. In a first countable \(T_1\) space () , every singleton subset is a \(G_δ\) (XI.7.3.3.). In fact, see XI.7.8.1.)

XI.1.2.10. **Proposition.** Let \((X, \mathcal{T})\) be a second countable topological space, and \(\mathcal{B}\) be a base for \(\mathcal{T}\). Then \(\mathcal{B}\) contains a countable base for \(\mathcal{T}\). In particular, every \(U \in \mathcal{T}\) is a countable union of sets in \(\mathcal{B}\).
XI.1.2.11. We can more generally define the weight \( w(X) \) of a topological space \( X \) to be the minimum cardinality of a base for the topology of \( X \) (this is only well defined in general if the AC is assumed). Thus \( X \) is second countable if and only if \( w(X) \leq \aleph_0 \). Weight is an example of a \textit{cardinal invariant} for topological spaces. The simplest cardinal invariant for \( X \) is \( \text{card}(X) \); another cardinal invariant is \( \text{density} \) \( d(X) \) (XI.2.3.16.). There are many other cardinal invariants, such as:

(i) \textit{character} \( \chi(X) \), minimum cardinal \( \kappa \) such that every point of \( X \) has a local base of cardinality \( \leq \kappa \), e.g. \( X \) is first countable if and only if \( \chi(X) \leq \aleph_0 \).

(ii) \textit{Lindelöf number} \( L(X) \), the smallest cardinal \( \kappa \) such that every open cover of \( X \) has a subcover (XI.1.3.3.) of cardinality \( \leq \kappa \), e.g. \( X \) is Lindelöf (XI.1.3.4.) if and only if \( L(X) \leq \aleph_0 \).

(iii) \textit{cellularity} \( c(X) \), minimum cardinal \( \kappa \) such that every family of pairwise disjoint nonempty open subsets of \( X \) has cardinality \( \leq \kappa \) . \( X \) has the \textit{countable chain condition} if \( c(X) \leq \aleph_0 \).

The invariants \( w(X) \), \( d(X) \), \( L(X) \), and \( c(X) \) coincide for metrizable spaces, but differ in general. A thorough discussion of cardinal invariants can be found in [KV84], and there is also extensive discussion in [Eng89].

Subbases

It is sometimes convenient to work with a less restrictive set of generators:

XI.1.2.12. \textbf{Definition.} Let \((X, \mathcal{T})\) be a topological space, and \( S \subseteq \mathcal{T} \). Then \( S \) is a \textit{subbase} for \( \mathcal{T} \) if the collection of finite intersections of sets in \( S \) forms a base for \( \mathcal{T} \).

XI.1.2.13. \textbf{Example.} In \( \mathbb{R}^2 = \mathbb{R} \times \mathbb{R} \), let \( S \) be the collection of all sets of the form \( I \times \mathbb{R} \) or \( \mathbb{R} \times I \), where \( I \) is an open interval in \( \mathbb{R} \). Then \( S \) is a subbase for the usual topology on \( \mathbb{R}^2 \).

More generally, the topology generated by a family of pseudometrics is naturally defined by a subbase. See ( ).

XI.1.2.14. It is sometimes convenient to extend the notion of base to allow sets which are not open. We say that a collection \( \mathcal{B} \) of not necessarily open subsets of \( X \) is a base for the topology \( \mathcal{T} \) if, whenever \( U \in \mathcal{T} \) and \( x \in U \), there is an \( E \in \mathcal{B} \) which is a neighborhood of \( x \) for which \( E \subseteq U \). For example, the set of closed balls of positive radius in a metric space is a base for the topology in this extended sense. We can similarly extend the notion of local base and subbase. Thus, for example, we can in some cases (e.g. in \( \mathbb{R}^n \)) take a base for a topology consisting of compact sets ( ).

If \( \mathcal{B} \) is a base for the topology \( \mathcal{T} \) in this sense, then the interiors (XI.2.3.17.) of the sets in \( \mathcal{B} \) form a base for the topology consisting of open sets. Thus if \( X \) has a countable base in this sense, it is second countable. The same applies to local bases; in particular, if every point of \( X \) has a countable local base in this sense, then \( X \) is first countable.
XI.1.3. Covers and Subcovers

It is often convenient to cover a topological space with “small” subsets, particularly small open sets.

XI.1.3.1. Definition. Let $X$ be a set, and $U = \{U_i : i \in I\}$ a collection of subsets of $X$. If $Y \subseteq X$, then $U$ covers $Y$, or is a cover of $Y$, if $Y \subseteq \bigcup_{i \in I} U_i$. $U$ covers $X$ if $\bigcup_{i \in I} U_i = X$.

If $X$ is a topological space, each $U_i$ is open in $X$, and $U$ covers $X$, then $U$ is an open cover of $X$.

XI.1.3.2. Examples. (i) Any base or subbase for the topology of $X$ is an open cover of $X$.

(ii) If $(X, \rho)$ is a metric space and $\epsilon > 0$ is fixed, then the open balls of radius $\epsilon$ form an open cover of $X$.

XI.1.3.3. Definition. Let $X$ be a set, $Y \subseteq X$, and $U$ a cover of $Y$. A subcover of $U$ is a subcollection of $U$ which also covers $Y$.

Any subcover of an open cover is also an open cover. Although the terminology is imprecise, one must specify the set $Y$ to discuss subcovers; normally one uses “subcover” only for covers of the whole set $X$.

XI.1.3.4. Definition. Let $X$ be a topological space.

(i) $X$ is a Lindelöf space if every open cover of $X$ has a countable subcover.

(ii) $X$ is compact if every open cover of $X$ has a finite subcover.

Compact spaces are discussed in detail in (). Obviously every compact space is Lindelöf; the converse is far from true.

XI.1.3.5. Proposition. Every second countable topological space is Lindelöf.

Proof: Let $\{V_n : n \in \mathbb{N}\}$ be a countable base for the topology of $X$. Let $U$ be an open cover of $X$. Fix a $U_0 \in U$. For each $n \in \mathbb{N}$, if $V_n$ is contained in some $U \in U$, choose $U_n \in U$ with $V_n \subseteq U_n$; if $V_n \not\subseteq U$ for no $U \in U$, set $U_n = U_0$. We claim $\{U_n : n \in \mathbb{N}\}$ is a subcover of $U$ (it is obviously countable). If $p \in X$, then there is a $U \in U$ with $p \in U$ since $U$ is a cover of $X$. Then there is an $n$ such that $p \in V_n$ and $V_n \subseteq U$ since $\{V_n\}$ is a base for the topology. Then $p \in U_n$. Thus $\cup_{n \in \mathbb{N}} U_n = X$. 

Note that this proof requires the Countable AC.

XI.1.3.6. In particular, $\mathbb{R}^n$ is Lindelöf for any $n$ by XI.1.2.8.(iii).

We can sharpen this result:

XI.1.3.7. Definition. A topological space $X$ is locally second countable if every $x \in X$ has an open neighborhood which is second countable in the relative topology.

Since every subspace of a second countable space is second countable, we may eliminate “open” from the definition without changing its meaning.
XI.1.3.8. **Proposition.** Let $X$ be a topological space. Then $X$ is second countable if and only if it is Lindelöf and locally second countable.

**Proof:** If $X$ is second countable, then it is obviously locally second countable, and Lindelöf by XI.1.3.5. Conversely, for each $x \in X$ let $U_x$ be an open neighborhood of $x$ which is second countable. Let $\{U_n : n \in \mathbb{N}\}$ be a countable subcover of $\{U_x : x \in X\}$. For each $n$, let $\mathcal{V}_n = \{V_{n1}, V_{n2}, \ldots\}$ be a countable base for the relative topology on $U_n$. Then $\bigcup_n \mathcal{V}_n$ is a countable base for the topology on $X$. (Note that each $V_{nk}$ is open in $U_n$, and $U_n$ is open in $X$, so $V_{nk}$ is open in $X$.)

This proof uses the Countable AC.

XI.1.4. **Relative Topology on a Subspace**

If $(X, \mathcal{T})$ is a topological space and $Y$ is a subset of $X$, then there is one, and only one, reasonable way to put a topology on $Y$ which is compatible with the topology on $X$:

XI.1.4.1. **Definition.** Let $(X, \mathcal{T})$ and $Y \subseteq X$. The relative topology, or subspace topology, on $Y$ from $\mathcal{T}$ is

$$\mathcal{T}_Y = \{U \cap Y : U \in \mathcal{T}\}$$

i.e. the open sets in $Y$ are the intersections with $Y$ of the open sets in $X$. $Y$ with this topology is called a **subspace** of $X$.

XI.1.4.2. **Proposition.** $\mathcal{T}_Y$ is a topology on $Y$.

Here is the proof as it appears in many standard references:

**Proof:** We have $\emptyset = \emptyset \cap Y$ and $Y = X \cap Y$, so $\emptyset, Y \in \mathcal{T}_Y$. If $V_1, \ldots, V_n \in \mathcal{T}_Y$, then, for each $k$, $V_k = U_k \cap Y$ for some $U_k \in \mathcal{T}$; so

$$V_1 \cap \cdots \cap V_n = (U_1 \cap Y) \cap \cdots \cap (U_n \cap Y) = (U_1 \cap \cdots \cap U_n) \cap Y \in \mathcal{T}_Y$$

since $U_1 \cap \cdots \cap U_n \in \mathcal{T}$. If $\{V_i : i \in I\}$ is a collection of sets in $\mathcal{T}_Y$, then, for each $i$, $V_i = U_i \cap Y$ for some $U_i \in \mathcal{T}$; then

$$\bigcup_{i \in I} V_i = \bigcup_{i \in I}(U_i \cap Y) = \left(\bigcup_{i \in I} U_i\right) \cap Y \in \mathcal{T}_Y$$

since $\bigcup_{i \in I} U_i \in \mathcal{T}$.

**XI.1.4.3.** Note that the AC is used in this proof to choose the $U_i$. (Most standard references seem to overlook this point! See XI.1.6.5.) But the result does not depend on the AC, because there is actually a systematic way to choose the $U_i$: for each $i$ let $U_i$ be the union of all $W \in \mathcal{T}$ such that $V = W \cap Y$ (I am indebted to S. Jabuka for this argument). There is also an alternate approach which does not use the AC (XI.1.4.7.).
XI.1.4.4. If $A \subseteq Y$, the phrase “$A$ is open” is ambiguous since also $A \subseteq X$: does it mean that $A$ is open in $Y$ (i.e. $A \in \mathcal{T}_Y$) or that $A$ is open in $X$ (i.e. that $A \in \mathcal{T}$)? To avoid ambiguity, we use the term relatively open for the first: $A \subseteq Y$ is relatively open in $Y$ if $A \in \mathcal{T}_Y$, i.e. $A = U \cap Y$ for some $U \in \mathcal{T}$. If $Y$ is open in $X$, i.e. $Y \in \mathcal{T}$, there is no ambiguity: a subset of $Y$ is relatively open if and only if it is open in $X$ (the converse holds also).

XI.1.4.5. Since $(X \setminus A) \cap Y = Y \setminus (A \cap Y)$ for any $A \subseteq X$, the closed sets in $(Y, \mathcal{T}_Y)$ are precisely the sets of the form $F \cap Y$ for $F$ closed in $X$. These sets are called the relatively closed subsets of $Y$. If $Y$ is closed in $X$, then a subset of $Y$ is relatively closed if and only if it is closed in $X$.

If $A \subseteq Y$, the phrase “closure of $A$” is also ambiguous: we could mean the closure $\bar{A}$ of $A$ in $(Y, \mathcal{T}_Y)$ or the closure $\bar{A}$ in $(X, \mathcal{T})$. But the situation is well behaved:

XI.1.4.6. Proposition. We have $\bar{A} = \bar{A} \cap Y$ for any $A \subseteq Y$.

Proof: Let $y \in \bar{A}$. Then for any $V \in \mathcal{T}_Y$ with $y \in V$ there is a $z \in A \cap V$. If $U \in \mathcal{T}$ with $y \in U$, set $V = U \cap Y$. If $z \in A \cap V$, then $z \in A \cap U$, so $y \in A$. Conversely, if $y \in A \cap Y$ and $V \in \mathcal{T}_Y$ with $y \in V$, then there is a $U \in \mathcal{T}$ with $V = U \cap Y$. Since $y \in \bar{A}$, there is a $z \in A \cap U$. Since $A \subseteq Y$, $z \in Y \cap U = V$. Thus $y \in \bar{A}$.

The set $\bar{A}$ is called the relative closure of $A$ in $Y$.

In light of this result, we can give an alternate construction of the relative topology:

XI.1.4.7. Proposition. Let $(X, \mathcal{T})$ be a topological space, and $Y \subseteq X$. For $A \subseteq Y$, define $\bar{A} = \bar{A} \cap Y$ (\bar{A} denotes the closure of $A$ in $X$). Then $A \mapsto \bar{A}$ is a Kuratowski closure operator (XI.2.4.1.) on $Y$, and the closed sets in the corresponding topology are precisely the sets of the form $F \cap Y$ for $F$ closed in $X$, i.e. is the relative topology on $Y$.

The proof is very simple and is left to the reader. It does not depend on the AC, and hence gives an alternate proof of XI.1.4.2. not using the AC.

The relative topology also has other properties which make it the only reasonable choice:

XI.1.4.8. Proposition. Let $(X, \mathcal{T})$ be a topological space, $Y \subseteq X$, and $\mathcal{T}_Y$ the relative topology on $Y$. Then

(i) If $(y_i)$ is a net in $Y$ and $y \in Y$, then $y_i \to y$ in $(Y, \mathcal{T}_Y)$ if and only if $y_i \to y$ in $(X, \mathcal{T})$.

(ii) If $Z$ is another topological space and $f : X \to Z$ is continuous, then $f|_Y : Y \to Z$ is also continuous.

(iii) The topology $\mathcal{T}_Y$ is the weakest topology on $Y$ making the inclusion map into $X$ continuous.

(iv) If $(Z, S)$ is a topological space and $f : Z \to Y$ is a function, then $f$ is continuous as a function from $(Z, S)$ to $(Y, \mathcal{T}_Y)$ if and only if it is continuous as a function from $(Z, S)$ to $(X, \mathcal{T})$.

XI.1.4.9. Note that (i) does not say that if a net in $Y$ converges in $X$, then it converges in $Y$. This will only be true if $Y$ is closed in $X$. 

1010
XI.1.4.10. Proposition. Let \((X, \mathcal{T})\) be a topological space, and \(Z \subseteq Y \subseteq X\). Then the relative topology on \(Z\) as a subspace of \((Y, \mathcal{T}_Y)\) is the same as the relative topology as a subspace of \((X, \mathcal{T})\), i.e. \((\mathcal{T}_Y)_Z = \mathcal{T}_Z\).

Bases

XI.1.4.11. If \((X, \mathcal{T})\) is a topological space and \((Y, \mathcal{T}_Y)\) is a subspace, and if \(B\) is a base for \(\mathcal{T}\), then it is easily checked that \(B_Y = \{B \cap Y : B \in B\}\) is a base for \(\mathcal{T}_Y\). Similarly, if \(y \in Y\) and \(B\) is a local base for \(\mathcal{T}\) at \(y\), then \(B_Y\) is a local base for \(\mathcal{T}_Y\) at \(y\). We thus obtain:

XI.1.4.12. Proposition. Let \((X, \mathcal{T})\) be a topological space and \((Y, \mathcal{T}_Y)\) a subspace. Then

(i) If \((X, \mathcal{T})\) is first countable, so is \((Y, \mathcal{T}_Y)\).

(ii) If \((X, \mathcal{T})\) is second countable, so is \((Y, \mathcal{T}_Y)\).

XI.1.4.13. It is not true that if \((X, \mathcal{T})\) is separable, then \((Y, \mathcal{T}_Y)\) is necessarily separable. There are many counterexamples, e.g. XI.7.8.10.(h), XI.7.8.14.(d), XI.11.12.4.

XI.1.5. Separated Union

There are many operations making new topological spaces from old ones. One of the simplest is separated union.

XI.1.5.1. Definition. Let \((X, \mathcal{T})\) be a topological space, and \(\{X_i : i \in I\}\) a collection of pairwise disjoint nonempty subsets of \(X\) whose union is \(X\) (i.e. a partition of \(X\)). Then \(X\) is the separated union of the \(X_i\) if a subset \(U\) of \(X\) is open (i.e. \(U \in \mathcal{T}\)) if and only if \(U \setminus X_i\) is relatively open in \(X_i\) for every \(i \in I\).

XI.1.5.2. If \(U \in \mathcal{T}\), then by definition \(U \cap X_i\) is relatively open in \(X_i\) for each \(i\). So the important condition is the converse, which is not automatic [consider a partition of \(X\) into singleton sets; then \(X\) is the separated union if and only if its topology is the discrete topology.] Some authors call a separated union a disjoint union, but the term “separated union” seems clearer and more descriptive.

A subset \(U\) of a topological space \(X\) is called clopen if both \(U\) and \(X \setminus U\) are open in \(X\). (“Clopen” means “both open and closed”; cf. (.)

XI.1.5.3. Proposition. Let \(\{X_i : i \in I\}\) be a partition of a topological space \(X\). Then \(X\) is the separated union of the \(X_i\) if and only if each \(X_i\) is a clopen subset of \(X\).

Proof: Suppose \(X\) is the separated union of the \(X_i\). For each fixed \(j \in I\), \(X_j \cap X_i\) is either \(X_j\) (if \(i = j\)) or \(\emptyset\) (if \(i \neq j\)). Thus \(X_j \cap X_i\) is relatively open in \(X_i\) for each \(i\); hence \(X_j\) is open in \(X\). So for any \(J \subseteq I\), \(\cup_{j \in J} X_j\) is open in \(X\). In particular, for each \(j\), \(X \setminus X_j = \cup_{i \neq j} X_i\) is open in \(X\), hence \(X_j\) is clopen in \(X\). More generally, if \(J \subseteq I\), \(X \setminus \cup_{j \in J} X_j = \cup_{i \in I \setminus J} X_i\) is open in \(X\); so \(\cup_{j \in J} X_j\) is clopen in \(X\).
Conversely, suppose each $X_i$ is clopen (and in particular open) in $X$. Let $U$ be a subset of $X$ such that $U \cap X_i$ is relatively open in $X_i$ for each $i$. Then, since $X_i$ is open in $X$, $U \cap X_i$ is open in $X$ for each $i$, and hence $U = \bigcup_{i \in I} (U \cap X_i)$ is open in $X$.

XI.1.5.4. We can reverse the process. Suppose we are given a family $\{(X_i, T_i) : i \in I\}$ of topological spaces. Form the set-theoretic disjoint union $X = \bigsqcup_{i \in I} X_i$(). Let $\mathcal{T}$ be the collection of all subsets $U$ of $X$ such that $U \cap X_i \in T_i$ for all $i$. It is easily checked that $\mathcal{T}$ is a topology on $X$ and $(X, \mathcal{T})$ is the separated union of the $(X_i, T_i)$.

XI.1.6. Exercises

XI.1.6.1. Give a logical critique of the following statement which can be found in many books:

“A metric space is a topological space.”

As part of your answer, you might consider, if $\rho$ and $\sigma$ are equivalent metrics on a set $X$, whether the spaces $(X, \rho)$ and $(X, \sigma)$ are the “same” or “different.”

XI.1.6.2. Show that if $\{T_\alpha\}$ is a family of topologies on a set $X$, then $\bigcap_\alpha T_\alpha$ is also a topology on $X$.

XI.1.6.3. Prove Proposition XI.1.2.5.

XI.1.6.4. (a) Show that the finite complement topology (XI.1.2.8.(iv)) on a set $X$ is a topology. Show that it is the discrete topology if and only if $X$ is finite.

(b) Let $X$ be a set. The countable complement topology on $X$ consists of $\emptyset$ and all subsets of $X$ with countable complement. Show that this is a topology on $X$, which is the discrete topology if and only if $X$ is countable. If $X$ is uncountable, show that the countable complement topology is not first countable.

XI.1.6.5. Explain why the following argument (which appears or is implicit in many books and does not use the AC) is not adequate to prove that the set $\mathcal{T}_Y$ defined in XI.1.4.1. is closed under arbitrary unions and is thus a topology:

“Let $\{U_i \cap Y : i \in I, U_i \in \mathcal{T}\}$ be an indexed collection of relatively open sets (sets in $\mathcal{T}_Y$). Then

$$\bigcup_{i \in I} (U_i \cap Y) = \left( \bigcup_{i \in I} U_i \right) \cap Y \in \mathcal{T}_Y$$

since $\bigcup_{i \in I} U_i \in \mathcal{T}$.”
XI.2. Closed Sets and Limit Points

XI.2.1. Closed Sets

Complements of open sets in a topological space are called closed sets:

XI.2.1.1. Definition. Let $(X, \mathcal{T})$ be a topological space. A subset $A$ of $X$ is closed in the topology $\mathcal{T}$, or $\mathcal{T}$-closed, if $A^c = X \setminus A \in \mathcal{T}$.

There is an important alternate description of closed sets (XI.2.3.6.).

XI.2.1.2. Examples. (i) A subset of $\mathbb{R}$ is closed in the usual topology if and only if it is closed in the sense of (i).
(ii) If $X$ has the discrete topology, then every subset of $X$ is closed.
(iii) If $X$ has the indiscrete topology, then the only closed subsets of $X$ are $\emptyset$ and $X$.

XI.2.1.3. It is important to note that being closed is not the opposite of being open: on the one hand, a subset of $X$ can be both open and closed (cf. XI.2.1.2.(ii)), and on the other hand a subset of $X$ need not be either open or closed – in fact typically “most” subsets of a topological space are neither open nor closed.

From de Morgan’s laws we immediately obtain the following properties of closed sets:

XI.2.1.4. Proposition. Let $(X, \mathcal{T})$ be a topological space, and $\mathcal{E}$ the collection of $\mathcal{T}$-closed sets. Then

(i) $\emptyset, X \in \mathcal{E}$.
(ii) $\mathcal{E}$ is closed under finite unions.
(iii) $\mathcal{E}$ is closed under arbitrary intersections.

XI.2.1.5. Conversely, if $X$ is a set and $\mathcal{E}$ is a collection of subsets of $X$ satisfying XI.2.1.4.(i)–(iii), then the complements of the sets in $\mathcal{E}$ form a topology $\mathcal{T}$ for which $\mathcal{E}$ is precisely the collection of closed sets. Thus a topology can be equally well defined by specifying the closed sets instead of the open sets.

XI.2.1.6. There is an asymmetry between unions and intersections for both open sets and closed sets. An arbitrary union of closed sets is not closed in general: for example, in $\mathbb{R}$ with its usual topology, points (singleton subsets) are closed, and every subset of $\mathbb{R}$ is a union of singleton sets. Correspondingly, an arbitrary intersection of open sets is not open in general. In fact, this asymmetry is the crucial underlying feature of topology, and it is what gives the subject its power and usefulness.

XI.2.2. Limit Points of a Set

One of the most fundamental notions in topology is limit point. Roughly speaking, a point $x$ in a topological space $X$ is a limit point of a set $A$ if there are points of $A$ “arbitrarily close” to $x$. More specifically:
XI.2.2.1. Definition. Let $(X, T)$ be a topological space, $A \subseteq X$, and $x \in X$. Then $x$ is a limit point of $A$ (in the topology $T$) if every open neighborhood of $x$ contains at least one point of $A$.

Note that if $x \in A$, then $x$ is trivially a limit point of $A$ since every neighborhood of $x$ contains at least one point of $A$, namely $x$ itself. But the importance of the notion of limit point is that limit points of $A$ are not necessarily in $A$. For example, 0 and 1 are limit points of the open interval $(0, 1)$ in $\mathbb{R}$ with its usual topology. Whether a point $x$ is a limit point of a subset $A$ can depend crucially on the topology used (if $x \notin A$); if there is a possibility of confusion we will use the terminology $T$-limit point.

There is a closely related but distinct notion:

XI.2.2.2. Definition. Let $(X, T)$ be a topological space, $A \subseteq X$, and $x \in X$. Then $x$ is an accumulation point of $A$ (in the topology $T$) if every deleted open neighborhood of $x$ contains at least one point of $A$, i.e. if every open neighborhood of $x$ contains at least one point of $A$ other than $x$.

Accumulation points are called cluster points by some authors, but for clarity we will only use the term “cluster point” in reference to sequences or nets (where the meaning is somewhat different, cf. XI.3.1.7.), not subspaces.

XI.2.2.3. Unlike for limit points, a point in $A$ is not necessarily an accumulation point of $A$; a point of $A$ which is not an accumulation point of $A$ is called an isolated point of $A$. A point of $X$ which is not in $A$ is a limit point of $A$ if and only if it is an accumulation point of $A$. There is some nonuniformity of terminology in the literature: some authors take “limit point” to mean what we call “accumulation point.” It will sometimes be convenient to have separate terms for the two notions, and for the purposes of this section limit points are more important. See XI.2.5. for a discussion of accumulation points and isolated points.

XI.2.3. Closure of a Set

XI.2.3.1. If $(X, T)$ is a topological space and $A \subseteq X$, then there is a smallest closed subset of $X$ containing $A$, namely the intersection of all closed subsets of $X$ containing $A$ (there is at least one such set, $X$; recall that any intersection of closed sets is closed).

XI.2.3.2. Definition. Let $(X, T)$ be a topological space and $A \subseteq X$. The smallest $T$-closed subset of $X$ containing $A$ is called the closure of $A$ in $X$ (or $T$-closure of $A$).

The standard notation for the closure of $A$ is $\overline{A}$; the notation $Cl(A)$ is also common. The closure of $A$ depends on $X$ and $T$; when this needs to be made explicit we will use the notation $Cl_X(A)$, $Cl_T(A)$, or $Cl_{(X, T)}(A)$.

Here are some elementary properties of closure:

XI.2.3.3. Proposition. Let $(X, T)$ be a topological space and $A, B \subseteq X$. Then

(i) $A \subseteq \overline{A}$.

(ii) $A$ is closed if and only if $A = \overline{A}$.

(iii) $\overline{A} = \overline{\overline{A}}$.
(iv) If \( A \subseteq B \), then \( \bar{A} \subseteq \bar{B} \).
(v) \( \bar{A \cup B} = \bar{A} \cup \bar{B} \).
(vi) \( \emptyset = \emptyset \) and \( \bar{X} = X \).

Proof: (i) and (ii) are trivial from the definition, and (iii) and (vi) follow immediately from (ii). (iv) is also immediate from the definition [\( B \) is a closed set containing \( A \)]. For (v), note that \( \bar{A} \cup \bar{B} \) is a union of two closed sets, hence closed, and contains \( A \cup B \), so \( \bar{A \cup B} \subseteq \bar{A} \cup \bar{B} \). On the other hand, \( A \subseteq A \cup B \), so \( \bar{A} \subseteq \bar{A \cup B} \) by (iv), and similarly \( \bar{B} \subseteq \bar{A \cup B} \). 

XI.2.3.4. If \( A, B \subseteq X \), it is not generally true that \( \bar{A \cap B} = \bar{A} \cap \bar{B} \). For example, if \( A = (0, 1) \) and \( B = (1, 2) \) in \( \mathbb{R} \) (with its usual topology), then \( \bar{A} \cap \bar{B} = \{ 1 \} \). But \( A \cap B = \emptyset \), so \( \bar{A \cap B} = \emptyset \).

However, we do always have \( \bar{A \cap B} \subseteq \bar{A} \cap \bar{B} \), since the set on the right is a closed set containing \( A \cap B \). More generally, for any collection \( \{ A_i : i \in I \} \) of subsets of \( X \), we have \( \bigcap_{i \in I} \bar{A_i} \subseteq \bigcap_{i \in I} \bar{A_i} \) by the same argument. A similar argument shows that \( \bigcup_{i \in I} \bar{A_i} \subseteq \bigcup_{i \in I} \bar{A_i} \), but we do not have equality in general if \( I \) is infinite.

The definition of closure is precise but often hard to apply directly. There is a more generally useful characterization of closure:

XI.2.3.5. Theorem. Let \((X, T)\) be a topological space and \( A \subseteq X \). Then the closure of \( A \) is exactly the set of all limit points (XI.2.2.1.) of \( A \).

Proof: Let \( U \) be the complement of \( \bar{A} \); then \( U \) is open. Suppose \( x \) is a limit point of \( A \). If \( x \notin \bar{A} \), then \( U \) is an open neighborhood of \( x \) containing no points of \( A \), contradicting that \( x \) is a limit point of \( A \). Thus \( x \in \bar{A} \).

Now suppose \( x \) is not a limit point of \( A \). Then there is an open neighborhood \( V \) of \( x \) containing no point of \( A \). So \( V^c \) is a closed set with \( A \subseteq V^c \), and hence \( \bar{A} \subseteq V^c \), \( x \notin \bar{A} \).

XI.2.3.6. Corollary. Let \((X, T)\) be a topological space. A subset of \( X \) is closed if and only if it contains all its limit points.

Dense Sets and Separability

XI.2.3.7. Definition. Let \((X, T)\) be a topological space, and \( D \subseteq X \). Then \( D \) is dense in \( X \) if \( \bar{D} = X \).

XI.2.3.8. Proposition. Let \( X \) be a topological space, and \( D \subseteq X \). Then \( D \) is dense in \( X \) if and only if every nonempty open subset of \( X \) contains a point of \( D \).

An intersection of two dense subsets is not necessarily dense, or even nonempty: both \( \mathbb{Q} \) and \( \mathbb{J} \) are dense in \( \mathbb{R} \). But if at least one of the sets is open, the intersection is dense:
XI.2.3.9. **Proposition.** Let $X$ be a topological space, and $U$ and $V$ dense subsets of $X$. If $U$ is open, then $U \cap V$ is dense in $X$.

**Proof:** Let $W$ be a nonempty open set in $X$. Then $U \cap W$ is an open set in $X$, which is nonempty since $U$ is dense. Then $W \cap (U \cap V) = (U \cap W) \cap V$ is nonempty since $V$ is dense. \[\Box\]

XI.2.3.10. **Corollary.** Let $X$ be a topological space. The intersection of any finite number of dense open subsets of $X$ is a dense open subset of $X$.

In some, but not all, topological spaces, an intersection of a countable number of dense open sets is always dense (but not necessarily open). See XI.2.11.

Some topological spaces have “small” dense subsets, which can cause better behavior:

XI.2.3.11. **Definition.** A topological space is separable if it has a countable dense subset.

Note that separability in this sense has nothing to do with the separation axioms of XI.71. The coincidence of terminology is regrettable, but well established.

XI.2.3.12. **Examples.** (i) If $X$ has the indiscrete topology, then any nonempty subset of $X$ is dense. Thus $X$ is separable.

(ii) If $X$ has the discrete topology, no proper subset of $X$ is dense in $X$. Thus $X$ is separable if and only if it is countable. In fact, a countable set with any topology is separable.

(iii) If $X$ is an infinite set with the finite complement topology, any infinite subset of $X$ is dense. Thus $X$ is separable if and only if it contains a countably infinite subset (this will always be true if the Countable AC is assumed).

(iv) If $\mathbb{R}$ has the usual topology, $\mathbb{Q}$ is a countable dense subset, so $\mathbb{R}$ is separable. More generally, the points of $\mathbb{R}^n$ with rational coordinates form a countable dense set (for the usual topology), so $\mathbb{R}^n$ is separable.

XI.2.3.13. Separability seems to be related to first or (especially) second countability. There are some connections, as the next two results show. But a topological space can be separable without being first countable (an uncountable set with the finite complement topology; cf. also () and ()), first countable without being separable (an uncountable set with the discrete topology), and both first countable and separable without being second countable ()

XI.2.3.14. **Proposition.** A second countable topological space is separable.

**Proof:** If $\{U_n : n \in \mathbb{N}\}$ is a countable base for the topology consisting of nonempty sets, choose $x_n \in U_n$ for each $n$. Then $\{x_n : n \in \mathbb{N}\}$ is a countable dense set in $X$. \[\Box\]

This proof requires the Countable AC, and the result cannot be proved in ZF.
XI.2.3.15. **Theorem.** A metrizable topological space is second countable if and only if it is separable.

**Proof:** Let \((X, \rho)\) be a metric space. If \(X\) is second countable, it is separable by XI.2.3.14.. Conversely, suppose \(X\) has a countable dense set \(D = \{x_n : n \in \mathbb{N}\}\). Let \(\mathcal{B}\) be the collection of all open balls of the form \(B_r(x_n)\), where \(x_n \in D\) and \(r \in \mathbb{Q}\). Then \(\mathcal{B}\) is a countable collection of open sets in \(X\). We claim \(\mathcal{B}\) is a base for the topology. To show this, we need only show that if \(x \in X\) and \(\epsilon > 0\), there is an \(n\) and \(r\) such that \(x \in B_r(x_n)\) and \(B_r(x_n) \subseteq B_\epsilon(x)\). Choose \(n\) such that \(\rho(x, x_n) < \frac{\epsilon}{3}\) and \(r \in \mathbb{Q}\) such that \(\frac{\epsilon}{3} < r < \frac{2\epsilon}{3}\). Then \(x \in B_r(x_n)\), and \(B_r(x_n) \subseteq B_\epsilon(x)\) by the triangle inequality.

The implication proved in this proof does not require any form of Choice, since only finitely many choices must be made.

XI.2.3.16. More generally, we can define the density \(d(X)\) of a topological space \(X\) to be the minimum cardinality of a dense subset of \(X\) (this is only well defined in general if the AC is assumed). \(X\) is separable if and only if \(d(X) \leq \aleph_0\). A slight variation of the proof of XI.2.3.14. shows that \(d(X) \leq w(X)\) (XI.1.2.11.) for any \(X\). We can have \(d(X) < w(X)\) (a separable space is not necessarily second countable), but if \(X\) is regular we have \(w(X) \leq 2^{d(X)}\) (XI.7.8.6.).

**Interior of a Set**

There is a dual notion to closure:

XI.2.3.17. **Definition.** Let \((X, \mathcal{T})\) be a topological space, and \(A \subseteq X\). The interior of \(A\) (in \(X\), in the topology \(\mathcal{T}\)) is the largest open (\(\mathcal{T}\)-open) subset of \(X\) contained in \(A\).

There is a largest such open set, the union of all open sets contained in \(A\); there is always one such set, the empty set. The interior of \(A\) can very well be empty. The standard notation for the interior of \(A\) is \(A^\circ\); the notation \(\text{Int}(A)\) is also used.

XI.2.3.18. Note that the interior of a subset \(A\) of \(X\) is a relative notion, not intrinsic to \(A\) (if \(A\) is given the relative topology, the interior of \(A\) with respect to \(A\) is all of \(A\)! The interior of \(A\) is also dependent on the topology \(\mathcal{T}\), although the notation \(A^\circ\) does not reflect this; the notation \(\text{Int}(A)\) is thus more flexible, since it can be embellished as \(\text{Int}_X(A)\), \(\text{Int}_\mathcal{T}(A)\), or \(\text{Int}_{(X, \mathcal{T})}(A)\) when necessary.

XI.2.3.19. **Example.** Let \(X = \mathbb{R}\) with its usual topology, \(A = [0, 1]\). Then \(A^\circ = (0, 1)\). If, however, \(X = \mathbb{R}^2\) and \(A\) is the interval \([0, 1]\) on the \(x\)-axis, then \(A^\circ = \emptyset\).

The relation between interior and closure is:

XI.2.3.20. **Proposition.** Let \(X\) be a topological space, and \(A \subseteq X\). Then \((A^\circ)^c = (A^c)^-\), i.e. \(A^\circ = [(A^c)^-]^c\).

From this, de Morgan’s laws, and XI.2.3.3. we obtain the basic properties of interior:
XI.2.3.21. \textbf{Proposition.} Let \((X, T)\) be a topological space and \(A, B \subseteq X\). Then

(i) \(A^o \subseteq A\).

(ii) \(A\) is open if and only if \(A^o = A\).

(iii) \((A^o)^o = A^o\).

(iv) If \(A \subseteq B\), then \(A^o \subseteq B^o\).

(v) \((A \cap B)^o = A^o \cap B^o\).

(vi) \(\emptyset^o = \emptyset\) and \(X^o = X\).

XI.2.3.22. We always have \(A^o \cup B^o \subseteq (A \cup B)^o\), but equality does not hold in general. A dramatic example is to take \(X = \mathbb{R}\), \(A = \mathbb{Q}\), and \(B = \mathbb{J}\); then \(A^o = B^o = \emptyset\) but \((A \cup B)^o = X\).

\textbf{Boundary of a Subset}

XI.2.4. \textbf{Specification of a Topology via Closure}

Instead of defining a topology by specifying the open sets, we can define it by specifying the closure of each set (this will determine the closed sets). This procedure can be axiomatized by a list of properties of the closure operation. This approach to topology is generally attributed to Kuratowski, although he himself in \((\text{Kur66})\) credited the procedure to F. Riesz.

XI.2.4.1. \textbf{Definition.} Let \(X\) be a set. A \textit{Kuratowski closure operation} on \(X\) is an assignment to each subset \(A\) of \(X\) a subset \(\overline{A}\) of \(X\), called the \textit{closure} of \(A\), with the following properties:

(i) \(\overline{\emptyset} = \emptyset\).

(ii) \(A \subseteq \overline{A}\) for all \(A \subseteq X\).

(iii) \(\overline{\overline{A}} = \overline{A}\) for all \(A \subseteq X\).

(iv) \(\overline{A \cup B} = \overline{A} \cup \overline{B}\) for all \(A, B \subseteq X\).

XI.2.4.2. \textbf{Examples.} (i) Let \((X, T)\) be a topological space. For \(A \subseteq X\), let \(\overline{A}\) be the closure of \(A\) in the topological sense (XI.2.3.2). Then \(A \mapsto \overline{A}\) is a Kuratowski closure operation (XI.2.3.3). We will show the converse: if \(A \mapsto \overline{A}\) is a Kuratowski closure operation on \(X\), then there is a unique topology on \(X\) such that the closure operation is closure with respect to the topology (XI.2.4.4).

(ii) If \(X\) is a nonempty set, set \(\overline{A} = X\) for every \(A \subseteq X\). Then this operation satisfies XI.2.4.1.(ii), (iii), and (iv), but not (i).

(iii) If \(X\) is a nonempty set, set \(\overline{A} = \emptyset\) for all \(A \subseteq X\). Then this operation satisfies XI.2.4.1.(i), (iii), and (iv), but not (ii).

(iv) Let \(X = \{1, 2, 3\}\). Set \(\overline{\emptyset} = \emptyset\), \(\overline{\{1\}} = \{1, 2\}\), and \(\overline{A} = X\) for every other \(A\). Then this operation satisfies XI.2.4.1.(i), (ii), and (iv), but not (iii).
(v) Let \(X = \{1, 2, 3\}\). Set \(\emptyset = \emptyset, \{1, 2\} = \{1, 2\}\), and \(A = X\) for every other \(A\). Then this operation satisfies XI.2.4.1.(i), (ii), and (iii), but not (iv).

(ii)–(v) show that the axioms in XI.2.4.1. are independent, and hence all are necessary to specify a topology.

The most powerful of the axioms is (iv):

**XI.2.4.3. Proposition.** Let \(A \mapsto \bar{A}\) be an operation on \(X\) satisfying (iv). Then

(i) If \(A \subseteq B \subseteq X\), then \(\bar{A} \subseteq \bar{B}\).

(ii) If \(\{A_i : i \in I\}\) is a collection of subsets of \(X\), then \(\bigcup_{i \in I} \bar{A}_i \subseteq \bigcup_{i \in I} \bar{A}_i\).

(iii) If \(\{A_i : i \in I\}\) is a collection of subsets of \(X\), then \(\bigcap_{i \in I} \bar{A}_i \subseteq \bigcap_{i \in I} \bar{A}_i\).

**Proof:** (i): If \(A \subseteq B\), then \(\bar{B} = \bar{A} \cup B = \bar{A} \cup \bar{B}\) which implies that \(\bar{A} \subseteq \bar{B}\).

(ii): For each \(j \in I\), \(A_j \subseteq \bigcup_{i \in I} A_i\), so \(\bar{A}_j \subseteq \bigcup_{i \in I} \bar{A}_i\) by (i).

(iii): For each \(j \in I\), \(\bigcap_{i \in I} A_i \subseteq A_j\), so \(\bigcap_{i \in I} \bar{A}_i \subseteq \bar{A}_j\) by (i).

**XI.2.4.4. Theorem.** Let \(A \mapsto \bar{A}\) be a Kuratowski closure operation on a set \(X\). Then there is a unique topology \(T\) on \(X\) such that the closure operation is precisely closure in the topology \(T\).

**Proof:** If there is such a topology, then the closed sets for the topology must be precisely the sets \(A\) for which \(A = \bar{A}\) by axiom (ii), so there is at most one such topology. So we must show that the collection of such sets defines a topology (i.e. the complements of such sets form a topology on \(X\)). Call such sets closed.

By XI.2.1.5., we must show that \(\emptyset\) and \(X\) are closed, and that the collection of closed sets is closed under finite unions and arbitrary intersections.

We have \(\emptyset = \emptyset\) by axiom (i), and \(X \subseteq \bar{X}\) by axiom (ii), hence \(X = \bar{X}\).

Suppose \(A = \bar{A}\) and \(B = \bar{B}\). Then \(\overline{A \cup B} = \overline{A} \cup \overline{B} = \overline{A} \cup \overline{B}\) by axiom (iv), so \(A \cup B\) is closed. By iteration (or induction), the collection of closed sets is closed under finite unions.

Suppose \(A_i = \overline{A}_i\) for each \(i \in I\). Then \(\bigcap_{i \in I} \overline{A}_i \subseteq \bigcap_{i \in I} \bar{A}_i = \bigcap_{i \in I} A_i\) by XI.2.4.3.(iii), and the opposite inclusion follows from axiom (ii). Thus the collection of closed sets is closed under arbitrary intersections.

**XI.2.4.5.** Suppose \(A \mapsto \bar{A}\) is an operation on a set \(X\) satisfying axiom (iv) and also

(v) \(\{p\} = \{p\}\) for every \(p \in X\).

Then the operation satisfies axiom (ii) by XI.2.4.3.(ii) since any subset of \(X\) is a union of singleton subsets. If \(X\) has two distinct points \(p\) and \(q\), then \(\emptyset \subseteq \{p\} \subseteq \{p\}\) by XI.2.4.3.(i), and similarly \(\emptyset \subseteq \{q\}\), so the operation also satisfies axiom (i). Thus if it also satisfies axiom (iii), it is a Kuratowski closure operation. A Kuratowski closure operation satisfies axiom (v) if and only if the corresponding topology is \(T_1()\).
XI.2.5. Isolated Points and Derived Sets

We now look at isolated points and accumulation points (XI.2.2.2.) in more detail. In order to avoid some cardinal-theoretic difficulties, we will assume the AC.

XI.2.5.1. A point \( p \) in a topological space \( X \) is an isolated point of \( X \) if it is not in the closure of \( X \setminus \{p\} \), i.e. if \( \{p\} \) is an open set in \( X \). (In some references, an isolated point is also required to be closed, which is automatic in a \( T_1 \) space; but we will not make this restriction.) A topological space is dense-in-itself if it contains no isolated points. A topological space \( X \) is scattered if every nonempty subset of \( X \) contains an isolated point in the relative topology, i.e. if no (nonempty) subset of \( X \) is dense-in-itself.

Any subset of a scattered space is scattered. A subset of a space which is dense-in-itself is not necessarily dense-in-itself (it could even be scattered); but an open subset of a space which is dense-in-itself must also be dense-in-itself.

XI.2.5.2. If \( A \) is a subset of a topological space \( X \), denote by \( A' \) the set of accumulation points of \( A \) in \( X \). \( A' \) is called the derived set of \( A \) in \( X \). A subset \( A \) of \( X \) is closed if and only if \( A' \subseteq A \). We say \( A \) is a perfect subset of \( X \) if \( A' = A \). \( A \) is perfect in \( X \) if and only if it is closed and dense-in-itself.

Note that the properties of being scattered or dense-in-itself are intrinsic properties of a space (or subspace), but being perfect is a relative property.

The next theorem, the main result of this section, is often stated in references in much less generality than necessary (the proof does not even become simpler for these special cases!) Recall (XI.1.2.11.) that the weight \( w(X) \) of a topological space \( X \) is the smallest cardinality of a base for the topology of \( X \).

XI.2.5.3. Theorem. [General Cantor-Bendixson Theorem] Let \( X \) be a topological space. Then there is a unique decomposition of \( X \) as a disjoint union of a perfect subset \( X^p \) and a (necessarily open) scattered subset \( X^s \). We have \( \text{card}(X^s) \leq \min(\text{card}(X), w(X)) \).

Note that \( X^p \) or \( X^s \) can be empty: \( X^s = \emptyset \) if (and only if) \( X \) is dense-in-itself, and \( X^p = \emptyset \) if (and only if) \( X \) is scattered.

Proof: The proof will actually show more than the stated result; the additional conclusions will be formalized at the end of the proof.

Define a decreasing collection of closed subsets of \( X \) by transfinite induction as follows. Set \( X^{(0)} = X \). For any ordinal \( \alpha \), if \( X^{(\alpha)} \) has been defined, set \( X^{(\alpha+1)} = (X^{(\alpha)})' \). If \( \alpha \) is a limit ordinal, set \( X^{(\alpha)} = \bigcap_{\beta < \alpha} X^{(\beta)} \). We have \( X^{(\alpha)} \subseteq X^{(\beta)} \) if \( \beta < \alpha \). Note that \( X^{(1)} \) is \( X \) with the isolated points removed; since each isolated point is open, \( X^{(1)} \) is closed in \( X \). By the same argument, \( X^{(\alpha+1)} \) is relatively closed in \( X^{(\alpha)} \); thus by transfinite induction \( X^{(\alpha)} \) is a closed subset of \( X \) for all \( \alpha \).

The \( X^{(\alpha)} \) cannot continue to strictly decrease (it will stabilize before \( \text{card}(\alpha) > \text{card}(X) \)); there must be a smallest \( \alpha \) for which \( X^{(\alpha+1)} = X^{(\alpha)} \). If \( X^p = X^{(\alpha)} \) for this \( \alpha \), then \( X^p \) is a perfect subset of \( X \).

Set \( X^s = X \setminus X^p \); then \( X^s \) is open in \( X \). Suppose \( Y \) is a subset of \( X \) which is dense-in-itself. If \( Y \cap X^s \neq \emptyset \), then there is a largest \( \beta \) such that \( Y \subseteq X^{(\beta)} \), and \( \beta < \alpha \). Thus there is a \( y \in Y \cap (X^{(\beta)} \setminus X^{(\beta+1)}) \). But then \( y \) is an isolated point of \( X^{(\beta)} \) and hence an isolated point of \( Y \), a contradiction. Thus every dense-in-itself subset of \( X \) is contained in \( X^p \), and \( X^s \) is scattered.
For uniqueness, suppose $X = Z \cup W$, where $Z$ is perfect and $W$ scattered. We have seen that $Z \subseteq X^p$. If $X^p \cap W \neq \emptyset$, it is a relatively open subset of $X^p$ which contains an isolated point, a contradiction.

For the cardinality assertion, let $\mathcal{B}$ be a base for the topology of $X$ with $\text{card}(\mathcal{B}) = w(X)$. First note that if $p$ is an isolated point of $X$, then $\{p\} \in \mathcal{B}$. By a similar argument, for each $x \in X^{(\alpha)} \setminus X^{(\alpha+1)}$ there is an open set $U_x \in \mathcal{B}$ with $U_x \cap X^{(\alpha)} = \{x\}$. It is clear that $x \mapsto U_x$ is an injective map from $X^s$ to $\mathcal{B}$, so $\text{card}(X^s) \leq w(X)$. The assertion $\text{card}(X^s) \leq \text{card}(X)$ is trivial.

The next corollary, or special cases of it, is usually called the “Cantor-Bendixson Theorem.” Actually Cantor and Bendixson (who worked independently) only stated the result for subsets of $\mathbb{R}^n$ since the formalism of general topology had not yet been developed.

**XI.2.5.4. Corollary. [Cantor-Bendixson Theorem]** Let $X$ be a second countable topological space. Then $X$ can be written uniquely as a disjoint union of a perfect subset $X^p$ and a (necessarily open) scattered subset $X^s$. In addition, $X^s$ is countable.

**XI.2.5.5.** The set $X^{(\alpha)}$ is called the $\alpha$'th derived set of $X$, and the smallest $\alpha$ for which $X^{(\alpha+1)} = X^{(\alpha)} = X^p$ is called the (Cantor-Bendixson) height $ht(X)$ of $X$. The chain of derived subsets and the height are homeomorphism invariants of $X$. The height is an ordinal invariant of $X$, not a cardinal invariant; if $X$ is second countable, then $ht(X)$ is a countable ordinal, but it is not always a finite ordinal or even $\omega$. In fact, every countable ordinal $\alpha$ occurs as the height of a compact subset $X_\alpha$ of $\mathbb{R}$. More generally, every ordinal occurs as the height of a compact Hausdorff space.

**XI.2.6. Exercises**

**XI.2.6.1.** (cf. [Dug78, III.5]) (a) Define a notion of “interior operation” on a set in analogy with the definition of a Kuratowski closure operation, using the properties from XI.2.3.21., and prove the analog of XI.2.4.4. that a topology can be specified by such an interior operation.

(b) Do the same for “boundary operation,” using the properties of ().

(c) Do the same for the “derived set” operation $A \mapsto A'$ (XI.2.5.2.).

**XI.2.6.2.** (a) Show that if $X$ is a $T_1$ topological space and $A \subseteq X$, then $A'$ is closed in $X$.

(b) Show by example that if $X$ is just $T_0$, $A'$ need not be closed in $X$.  

1021
XI.3. Convergence

One of the most important uses of a metric is to define limits of sequences. Limits of sequences can be defined nicely in any topological space, although not all properties of limits of sequences in metric spaces carry over to this case. And it turns out that for (most – cf. XI.3.5.1.) topological spaces which are not first countable, the theory of limits of sequences is not adequate to fully describe convergence and continuity in the space, and one must use a generalized version of sequences known as nets. An alternate equivalent point of view with some technical advantages uses filters in place of nets.

XI.3.1. Limits of Sequences

Limits of sequences in topological spaces are defined just as in metric spaces, replacing open balls by open neighborhoods:

XI.3.1.1. Definition. Let \((X, T)\) be a topological space, and let \((x_n)\) be a sequence in \(X\), and \(x \in X\). Then \((x_n)\) converges to \(x\) in \((X, T)\), denoted \(x_n \to x\) or \(\lim_{n \to \infty} x_n = x\), if for every open neighborhood \(U\) of \(x\) there is an \(N\) such that \(x_n \in U\) for all \(n \geq N\). (We say that \(x_n\) is eventually in \(U\).)

If there is any possible ambiguity about which topology is used on \(X\), we write \(x_n \to_T x\) or \(\lim_{n \to \infty} x_n = x\).

XI.3.1.2. The word “open” can be deleted from this definition without changing its meaning, since every neighborhood of \(x\) contains an open neighborhood. Similarly, the existence of an \(N\) need only be shown for \(U\)’s in a fixed local base for the topology at \(x\).

XI.3.1.3. Unlike in metric spaces, limits of sequences need not be unique: for example, in a space with the indiscrete topology every sequence converges to every point. This undesirable situation does not occur in Hausdorff spaces (XI.7.4.1.).

Subsequences and Tails

Subsequences and tails of sequences are defined just as in \((X, T)\). Convergence of a sequence depends only on the tails of the sequence, and implies convergence of each subsequence, just as in the metric case (the proof is essentially identical):

XI.3.1.4. Proposition. Let \(X\) be a topological space, and \((x_n)\) a sequence in \(X\), \(x \in X\).

(i) \(x_n \to x\) if and only if some tail of \((x_n)\) converges to \(x\).

(ii) If \(x_n \to x\), then every subsequence of \((x_n)\) converges to \(x\). In particular, every tail of \((x_n)\) converges to \(x\).

There is a sort of converse to (ii), which is almost harder to state than to prove:
XI.3.1.5. PROPOSITION. Let $X$ be a topological space, and $(x_n)$ a sequence in $X$, $x \in X$. If $(x_n)$ does not converge to $x$, then there is a subsequence of $(x_n)$, no subsequence of which converges to $x$.

**Proof:** If $(x_n)$ does not converge to $x$, then there is an open neighborhood $U$ of $x$ such that $x_n \notin U$ for infinitely many $n$. These $x_n$ form a subsequence with no terms in $U$, so no subsequence of it can converge to $x$. The result is often stated in the contrapositive:

XI.3.1.6. COROLLARY. Let $X$ be a topological space, and $(x_n)$ a sequence in $X$, $x \in X$. If every subsequence of $(x_n)$ has a subsequence which converges to $x$, then $x_n \not\rightarrow x$.

Cluster Points of Sequences

XI.3.1.7. DEFINITION. Let $X$ be a topological space, and $(x_n)$ a sequence in $X$, $x \in X$. Then $x$ is a cluster point of $(x_n)$ if every open neighborhood $U$ of $x$ contains $x_n$ for infinitely many $n$ (we say $x_n$ is frequently in $U$).

The proof of the next Proposition is essentially identical to the proof of ().

XI.3.1.8. PROPOSITION. Let $X$ be a topological space, and $(x_n)$ a sequence in $X$. For each $n$, let $F_n$ be the closure in $X$ of $\{x_k : k \geq n\}$. Then $\bigcap_n F_n$ is exactly the set of cluster points of $(x_n)$. In particular, the set of cluster points of a sequence is a closed set.

If $x_n \rightarrow x$, or more generally if there is a subsequence of $(x_n)$ which converges to $x$, then $x$ is a cluster point of $(x_n)$. The converse is not true in general (), but is true if the topological space is first countable:

XI.3.1.9. PROPOSITION. Let $X$ be a topological space, $(x_n)$ a sequence in $X$, and $x \in X$. If $x$ is a cluster point of $(x_n)$, and there is a countable local base for the topology at $x$ (in particular, if $X$ is first countable), then there is a subsequence of $(x_n)$ which converges to $x$.

**Proof:** Let $(U_n)$ be a decreasing sequence of open neighborhoods of $x$ forming a local base (). Let $x_{k_1} \in U_1$, and inductively choose $k_{n+1} > k_n$ with $x_{k_{n+1}} \in U_{n+1}$; this is possible since $x_k \in U_{n+1}$ for infinitely many $k$. (For definiteness and to avoid use of the Countable AC, choose $k_{n+1}$ to be the smallest $k > k_n$ for which $x_k \in U_{n+1}$.) Then $(x_{k_n})$ is a subsequence of $(x_n)$, and $x_{k_n} \in U_m$ for $n \geq m$. If $V$ is any neighborhood of $x$, then $U_m \subseteq V$ for some $m$, so $x_{k_n} \in V$ for all $n \geq m$. Thus $x_{k_n} \rightarrow x$.

XI.3.1.10. If $A$ is a subset of a topological space $X$, $x \in X$, and there is a sequence $(x_n)$ in $A$ with $x_n \rightarrow x$, then $x$ is obviously a limit point of $A$, so $x \in \bar{A}$. The converse is not true in general (), but is true if the topological space is first countable:
XI.3.1.11. Proposition. Let $A$ be a subset of a topological space $X$ and $x \in X$. If there is a countable local base for the topology at $x$ (in particular, if $X$ is first countable), then $x \in A$ if and only if there is a sequence $(x_n)$ of points of $A$ which converges to $x$.

Proof: The proof is very similar to the proof of XI.3.1.9. One direction is noted above, and does not require a countable local base. Conversely, suppose $x \in A$. Let $(U_n)$ be a decreasing sequence of open neighborhoods of $x$ forming a local base. Then $A \cap U_n$ is nonempty for every $n$. Choose $x_n \in A \cap U_n$ for each $n$. If $V$ is any neighborhood of $x$, then $U_m \subseteq V$ for some $m$, so $x_n \in V$ for all $n \geq m$. Thus $x_n \to x$.

Note that the Countable AC is needed for this proof.

XI.3.1.12. Thus, if $X$ is a first countable topological space, then (assuming the Countable AC) convergence of sequences tells the whole story about the topology.

Iterated Limits

There is another property of convergent sequences in first countable topological spaces:

XI.3.1.13. Proposition. Let $(X, T)$ be a topological space and $\{x_{k,n} : k, n \in \mathbb{N}\}$ be a doubly indexed set of points in $X$. Suppose $\lim_{n \to \infty} x_{k,n} = x_k$ for each $k$ and $\lim_{k \to \infty} x_k = x$. If $x$ has a countable local base (in particular, if $X$ is first countable), then there are strictly increasing sequences $(k_m), (n_m) \in \mathbb{N}$ such that $\lim_{m \to \infty} x_{k_m,n_m} = x$.

The sequence $(x_{k_m,n_m})$ is a sort of “diagonal” sequence, and this property of limits is sometimes called the diagonal property.

Proof: Let $(U_m)$ be a countable decreasing local neighborhood base at $x$. Then for each $m$ there is a $K_m$ such that $x_k \in U_m$ for all $k \geq K_m$. Then for each $k \geq K_m$ there is an $N_{k,m}$ such that $x_{k,n} \in U_m$ for all $n \geq N_{k,m}$. Inductively choose $k_1 = n_1 = 1$ and $k_m = \max(k_{m-1} + 1, K_m)$ and $n_m = \max(n_{m-1} + 1, N_{k_m,m})$ for $m > 1$. It is routine to check that $x_{k_m,n_m} \to x$.

XI.3.1.14. This result can fail if $x$ does not have a countable local base (). But the net version holds in general ()

XI.3.2. Nets and Limits

In a topological space which is not first countable, sequences are generally inadequate to completely describe the behavior of the topology and convergence. But there is a deceptively simple way to generalize sequences, which in complete analogy does fully describe the topology. These generalized sequences are called nets. On the surface, the results of the preceding subsection work for general topological spaces by simply substituting “net” for “sequence” and “subnet” for “subsequence”; however, below the surface there are some subtleties involved, especially with the notion of a subnet.
XI.3.2.1. Definition. Let $X$ be a topological space (or just a set). A net in $X$ is a function from a directed set $(I, \leq)$ to $X$. The set $I$ is called the index set of the net.

A sequence is just a net whose index set is $\mathbb{N}$. If $\phi : I \to X$ is a net with index set $I$, we usually denote the net by $(x_i)_{i \in I}$ or just by $(x_i)$ if $I$ is understood, where $x_i = \phi(i)$. This notation is a simple extension of sequence notation. However, this notation does not reflect the direction on $I$, which is part of the definition of the net.

XI.3.2.2. Note that the index set of a net does not have to be partially ordered. One can in principle restrict to partially ordered index sets in the theory of nets (cf. XI.3.2.4., XI.3.2.5., II.4.4.11.). However, it is often convenient to use nets whose index sets are not partially ordered.

XI.3.2.3. Definition. Let $X$ be a topological space, $(x_i)$ a net in $X$, and $x \in X$. Then $(x_i)$ converges to $x$, denoted $x_i \to x$ or $\lim_{i \to x} x_i = x$, if for every open neighborhood $U$ of $x$ there is an $i_0 \in I$ such that $x_i \in U$ whenever $i_0 \leq i$. (We say the net $(x_i)$ is eventually in $U$.)

As for sequences, the word "open" can be deleted, and it suffices to let the $U$ range over a local base at $x$.

XI.3.2.4. If the index set of a net is not properly directed (i.e. has a largest element), convergence of the net is pretty trivial: if there is exactly one largest element $i_1$ in $I$, then the net automatically converges to $x_{i_1}$. If there is more than one largest element in $I$, then the net rarely converges (only if every neighborhood of $x_i$ for each largest element $i$ contains $x_j$ for all the other largest $j$; this cannot happen in a $T_0$-space unless $x_i = x_j$ for all largest $i$ and $j$, in which case the net converges to this element). The theory of convergence of nets is only interesting if the index set is properly directed.

The convergence of a net depends on the ordering (direction) of $I$ only up to equivalence, i.e. only on the "cofinal behavior" of the direction:

XI.3.2.5. Proposition. Let $(I, \leq)$ be a directed set, $X$ a topological space, and $(x_i)_{i \in I}$ a net in $X$ with index set $I$. Let $\preceq$ be another direction on $I$ which is equivalent to $\leq$. If $x \in X$, then $x_i \to x$ using the direction $\leq$ on $I$ if and only if $x_i \to x$ using the direction $\preceq$ on $I$.

This is obvious using the definition of equivalence of directions ().

Subnets

The definition of a subnet is not an obvious one. Experience has shown that the following definition is appropriate, and flexible enough to be useful:

XI.3.2.6. Definition. Let $X$ be a topological space, $(I, \leq)$ a directed set, and $\phi : I \to X$ a net in $X$. A subnet of $\phi$ is a net $\phi \circ f$, where $f$ is a directed function from a directed set $(J, \preceq)$ to $(I, \leq)$. The index set of the subnet is $(J, \preceq)$.

Thus the index set of a subnet of a net is not necessarily the same as the index set of the net.
Proof: We give the proof of (ii), leaving the simpler proof of (i) to the reader. Suppose $(x_{f(j)})_{j \in J}$ is a subnet of $(x_i)$, and let $U$ be an open neighborhood of $x$. There is an $i_0$ such that $x_i \in U$ for all $i \geq i_0$. Fix $j_0 \in J$ so that $f(j) \geq i_0$ for all $j \geq j_0$. Then $x_{f(j)} \in U$ for all $j \geq j_0$, so the subnet converges to $x$. \hfill \Diamond

The net version of XI.3.1.5. is the hard-to-state “converse” to (ii):

XI.3.2.11. Proposition. Let $X$ be a topological space, and $(x_i)$ a net in $X$, $x \in X$.

(i) $x_i \to x$ if and only if some tail of $(x_i)$ converges to $x$.

(ii) If $x_i \to x$, then every subnet of $(x_i)$ converges to $x$. In particular, every tail of $(x_i)$ converges to $x$. 

Proof: We give the proof of (ii), leaving the simpler proof of (i) to the reader. Suppose $(x_{f(j)})_{j \in J}$ is a subnet of $(x_i)$, and let $U$ be an open neighborhood of $x$. There is an $i_0$ such that $x_i \in U$ for all $i \geq i_0$. Fix $j_0 \in J$ so that $f(j) \geq i_0$ for all $j \geq j_0$. Then $x_{f(j)} \in U$ for all $j \geq j_0$, so the subnet converges to $x$. \hfill \Diamond

The proofs of the next two results are almost identical to the sequence versions:

XI.3.2.9. The most obvious subnets of a net $(x_i)$ are formed by letting $J$ be a cofinal subset () of $I$ and $f$ the inclusion of $J$ into $I$. We will call a subnet of this kind a subtail (a nonstandard name; there appears to be no standard one). A tail of a net is a subtail where $J$ is of the form $\{i \in I : i_0 \leq i\}$ for a fixed $i_0 \in I$. A subtail of a sequence is exactly just a subsequence, and a tail of a sequence in this sense is the same as a tail as previously defined.

For purposes of describing topologies and convergence, subtails are inadequate in general, just as in the sequence case. Thus it is necessary to use the more complicated but more general and flexible notion of subnet as we have defined it.

XI.3.10. Proposition. Let $X$ be a topological space and $(x_i)$ a net in $X$. Any subnet of a subnet of $(x_i)$ is a subnet of $(x_i)$. Any subtail of a subtail of $(x_i)$ is a subtail, and any tail of a tail is a tail.
XI.3.2.12. PROPOSITION. Let $X$ be a topological space, and $(x_i)$ a net in $X$, $x \in X$. If $(x_i)$ does not converge to $x$, then there is a subnet of $(x_i)$ (in fact a subtail), no subnet of which converges to $x$.

PROOF: If $(x_i)$ does not converge to $x$, then there is an open neighborhood $U$ of $x$ such that $J = \{i \in I : x_i \notin U\}$ is cofinal in $I$. This $J$ gives a subtail with no terms in $U$, so no subnet of it can converge to $x$. ⋄

The result is often stated in the contrapositive:

XI.3.2.13. COROLLARY. Let $X$ be a topological space, and $(x_i)$ a net in $X$, $x \in X$. If every subnet of $(x_i)$ has a subnet which converges to $x$, then $x_i \rightarrow x$.

Weak Subnets
We can extend XI.3.2.12. in an interesting way.

XI.3.2.14. DEFINITION. Let $(x_i)$ be a net in $X$ with index set $I$ defined by $\phi : I \rightarrow X$. A weak subnet of $(x_i)$ is a net defined by $\phi \circ f$, where $f$ is a not necessarily directed function from a directed set $J$ to $I$.

XI.3.2.15. Any subnet is a weak subnet, but there are many weak subnets which are not subnets: for example, $f$ could be a constant function. Even if $f$ is strictly increasing, the weak subnet is not necessarily a subnet since the range of $f$ may not be cofinal in $I$ (this cannot happen for sequences).

The proof of XI.3.2.12. actually shows the following considerably stronger result:

XI.3.2.16. PROPOSITION. Let $X$ be a topological space, and $(x_i)$ a net in $X$, $x \in X$. If $(x_i)$ does not converge to $x$, then there is a subnet of $(x_i)$ (in fact a subtail), no weak subnet of which converges to $x$.

XI.3.2.17. COROLLARY. Let $X$ be a topological space, and $(x_i)$ a net in $X$, $x \in X$. If every subnet of $(x_i)$ has a weak subnet which converges to $x$, then $x_i \rightarrow x$.

Cluster Points of Nets

XI.3.2.18. DEFINITION. Let $X$ be a topological space, and $(x_i)$ a net in $X$, $x \in X$. Then $x$ is a cluster point of $(x_i)$ if every open neighborhood $U$ of $x$ contains $x_i$ for a cofinal set of $i$ (we say $x_i$ is frequently in $U$).

The proof of the next Proposition is essentially identical to the proof of (). This result motivates the theory of convergence via filters ( ).
XI.3.2.19. **Proposition.** Let \((x_i)_{i \in I}\) be a net in a topological space \(X\). For each \(i \in I\), set

\[ T_i = \{ x_j : j \geq i \}. \]

Then \(\cap_{i \in I} T_i\) is precisely the set of cluster points of the net \((x_i)\). In particular, the set of cluster points of a net is closed.

The set \(T_i\) is called the *tail set* of the net \((x_i)\) corresponding to \(i\). Thus the convergence of a net depends only weakly on the actual directed set \(I\) but only on the collection of tail sets of the net.

**Proof:** If \(x\) is a cluster point of \((x_i)\), then any neighborhood of \(x\) contains point of \(T_i\) for arbitrarily large \(i\), hence \(x \in \cap_{i \in I} T_i\). Conversely, if \(x \in \cap_{i \in I} T_i\) and \(U\) is an open neighborhood of \(x\), then for each \(i\) we have \(T_i \cap U \neq \emptyset\), and any element of this intersection is of the form \(x_j\) for some \(j \geq i\). Thus \(x\) is a cluster point of \((x_i)\).

If \(x_i \to x\), or more generally if there is a subnet of \((x_i)\) which converges to \(x\), then \(x\) is a cluster point of \((x_i)\). Unlike in the sequence case, the converse is true in general, showing the universal applicability of nets to convergence. The proof is a good example of how nets are used in practice, and beautifully and graphically demonstrates the utility of the subnet definition.

XI.3.2.20. **Theorem.** Let \(X\) be a topological space, \((x_i)\) a net in \(X\), and \(x \in X\). If \(x\) is a cluster point of \((x_i)\), then there is a subnet of \((x_i)\) which converges to \(x\).

**Proof:** Let \(J\) be the set of all pairs \((U, i)\), where \(U\) is an open neighborhood of \(x, i \in I\), and \(x_i \in U\). Put a preorder \(\preceq\) on \(J\) by setting \((U_1, i_1) \preceq (U_2, i_2)\) if \(U_2 \subseteq U_1\) and \(i_1 \leq i_2\).

We show that \((J, \preceq)\) is directed. Suppose \((U_1, i_1)\) and \((U_2, i_2)\) are in \(J\). Set \(V = U_1 \cap U_2\) and let \(i_3\) be an upper bound for \(\{i_1, i_2\}\) in \(I\). Then since \(x\) is a cluster point of \((x_i)\), there is an \(i \geq i_3\) with \(x_i \in V\). Then \((V, i) \in J\) and \((V, i)\) is an upper bound for \(\{(U_1, i_1), (U_2, i_2)\}\).

Define \(f : J \to I\) by \(f(U, i) = i\). We show that \(f\) is directed. Let \(i_0 \in I\). We must find \((U_1, i_1) \in J\) such that \((V, i) \in J\), \((U_1, i_1) \preceq (V, i)\) implies \(i \geq i_0\). Just take \(U_1 = X\) and \(i_1 = i_0\). (Note that \(f\) is in fact order-preserving.)

Finally, we show that the subnet \((x(U, i))\) converges to \(x\). Let \(V\) be an open neighborhood of \(x\), and fix \(i_0\) such that \(x_{i_0} \in V\). Then \((V, i_0) \in J\) and \(x_{(U, i)} \in V\) whenever \((V, i_0) \preceq (U, i)\). Similarly, we get a net version of XI.3.1.11. which is valid in complete generality. The proof shows the utility of considering directed sets which are not partially ordered.

XI.3.2.21. **Theorem.** Let \(A\) be a subset of a topological space \(X\) and \(x \in X\). Then \(x \in \bar{A}\) if and only if there is a net \((x_i)\) of points of \(A\) which converges to \(x\).

**Proof:** If there is a net in \(A\) converging to \(x\), then every neighborhood of \(x\) contains a term of the net, hence a point of \(A\). Thus \(x \in \bar{A}\). Conversely, suppose \(x \in \bar{A}\). Let \(I\) be the set of all pairs \((U, y)\), where \(U\) is an open neighborhood of \(x\) and \(y \in U \cap A\). (We have \(U \cap A \neq \emptyset\) for all \(U\).) Put a preorder \(\leq\) on \(I\) by \((U, y) \leq (V, z)\) if \(V \subseteq U\). (Note that this is rarely a partial order.)

1028
We show that \((I,\leq)\) is directed. If \((U_1,y_1)\) and \((U_2,y_2)\) are in \(I\), set \(V = U_1 \cap U_2\), and let \(z \in V \cap A\). Then \((V,z)\) is an upper bound for \(\{(U_1,y_1),(U_2,y_2)\}\).

Define a net \((x_i)_{i \in I}\) by setting \(x_i(U,y) = y\). Then \(x_i \in A\) for all \(i\). If \(U\) is any open neighborhood of \(x\), let \(y \in U \cap A\), and set \(i_0 = (U,y) \in I\). Then for any \((V,z) \geq (U,y)\) in \(I\), \(x_i(U,z) = z \in V \subseteq U\), i.e. if \(i \geq i_0\), \(x_i \in U\). Thus \(x_i \to x\).

Note that unlike in the sequence case, no form of Choice is needed for this result. This again shows the versatility of the theory of nets and subnets.

**Interleaving Nets**

**XI.3.2.22.** It is technically useful to be able to “interleave” or “intertwine” two nets into a single net. This is easily done for sequences: if \((x_n)\) and \((y_n)\) are sequences in \(X\), simply alternate the terms to form the sequence

\[
(x_1,y_1,x_2,y_2,\ldots,x_n,y_n,\ldots)
\]

which will converge to a limit \(x\) if and only if \(x_n \to x\) and \(y_n \to x\) (cf. (i)).

It is unclear how to do this in the case of nets. There are two technical difficulties:

(i) The two nets need not even have the same index set.

(ii) Even if the index sets are the same, it is not obvious what “alternating” terms means.

The difficulty is in the generality of the indexing for nets, but the generality and flexibility of indexing is also the key to the solution.

**XI.3.2.23.** We first show how to modify two nets to new nets with the same index set. Suppose \((x_i)\) is a net in \(X\) with index set \(I\), and suppose \(J\) is another directed set; we will use \(\prec\) for the direction in both \(I\) and \(J\). Set \(K = I \times J\), and give \(K\) the product ordering: \((i_1,j_1) \prec (i_2,j_2)\) if and only if \(i_1 \prec i_2\) and \(j_1 \prec j_2\) (cf. (i)). For \(k = (i,j)\), set \(x_k = x_i\).

**XI.3.2.24.** **Proposition.** The net \((x_k)\) converges to \(x \in X\) if and only if \(x_i \to x\).

**Proof:** Let \(U\) be a neighborhood of \(x\). If \(x_k \to x\), there is an \(k_0 = (i_0,j_0)\) such that \(x_k \in U\) whenever \(k_0 \prec k\); then \(x_i \in U\) whenever \(i_0 \prec i\). Conversely, if \(x_i \to x\), there is an \(i_0\) such that \(x_i \in U\) whenever \(i_0 \prec i\); if \(j_0\) is any fixed element of \(J\), then \(x_k \in U\) whenever \(k_0 = (i_0,j_0) \prec k\). \(\Box\)

In fact, the modified net \((x_k)\) is a subnet of \((x_i)\) via the projection from \(I \times J\) onto \(I\).

**XI.3.2.25.** If \((x_i)\) and \((y_j)\) are nets in \(X\) with index sets \(I\) and \(J\) respectively, both can be modified to nets with index set \(K = I \times J\); convergence of the nets is unaffected by the reindexing.

**XI.3.2.26.** Now suppose \((x_k)\) and \((y_k)\) are nets with the same index set \(K\). Define a new net \((z_{k,n})\) with index set \(K \times \{1,2\}\) with ordering \((k_1,n_1) \prec (k_2,n_2)\) if and only if \(k_1 \prec k_2\), by taking \(z_{k,1} = x_k\) and \(z_{k,2} = y_k\) for all \(k\) (cf. (i)). The net \((z_{k,n})\) is called the *interleaving* of \((x_k)\) and \((y_k)\). We have:
XI.3.2.27. **Proposition.** The interleaved net \((z_{k,n})\) converges to \(x \in X\) if and only if \(x_k \to x\) and \(y_k \to x\).

The simple proof is almost identical to the proof of XI.3.2.24., and is left to the reader (Exercise ()). Note that \((x_k)\) and \((y_k)\) are subnets of \((z_{k,n})\) via the maps \(k \mapsto (k, 1)\) and \(k \mapsto (k, 2)\) respectively, giving one direction.

**Moore-Smith Convergence**

XI.3.2.28. The theory of convergence of nets is often called the theory of *Moore-Smith convergence*, since it was originated in [?]. The term “net” was coined by *Kelley*.

The Moore of Moore-Smith was E. H. Moore, not R. L. Moore. Both Moores (who were not related) were very important and influential in American mathematics. Both were first-rate mathematicians, but their importance went far beyond their own mathematical work. Both served as presidents of the American Mathematical Society and were instrumental in the development of the AMS.

E. H. Moore was probably more responsible than any other individual for the rise of American mathematics in general, and the University of Chicago in particular, to world-class status. A considerable percentage of current American mathematicians, including the author, are mathematical descendents of his (the Mathematics Genealogy Project [http://www.genealogy.ams.org/] lists at least 18,359 mathematical descendents of E. H. Moore).

R. L. Moore, in addition to being one of the principal founders of the American school of topology, was a gifted and energetic teacher who trained a large percentage of the leading American topologists of the mid-twentieth century. He also developed the “Moore method” of pedagogy (cf. I.5.7.), which is much admired and emulated, although it is not without its detractors. Unfortunately, he was also a virulent racist.

There have been a number of other mathematicians named Moore, including the author’s advisor, C. C. Moore, who is apparently unrelated to either E. H. or R. L.

**XI.3.3. Specification of a Topology via Convergence**

It is often desirable to define a topology by specifying which sequences or nets converge. This is particularly convenient when considering function spaces, where we often want to discuss the “topology of pointwise convergence,” the “topology of uniform convergence,” etc. This can be done rather cleanly, although there are some subtleties.

This approach to topology was developed by Fréchet [], Aleksandrov [] and Urysohn [], and Birkhoff [Bir37]. See [Kur66, §20] and [Kel75] for details.

XI.3.3.1. It is clear that a topology cannot be completely determined by convergence of sequences in general in the non-first-countable case; in fact, two distinct topologies on a set can have the same convergent sequences, such as the usual topology and the discrete topology on \(\beta\mathbb{N}\) (XI.11.9.16.(v); see also () for a natural and important example, and Exercise XI.7.8.12. for a simple one). We have a much better chance of success working with nets, but we will use sequences as much as possible since in applications it is very convenient to use sequences.
XI.3.3.2.  The general setup is: $X$ is a set, and $\mathcal{C}$ a collection of sequences (or nets) in $X$ which we will declare to converge, each with a specified limit. More precisely, $\mathcal{C}$ will be a set of pairs $(s, x)$, where $s$ is a sequence or net in $X$ and $x \in X$; we will declare that the sequence $s$ converges to $x$. We want a topology $\mathcal{T}$ on $X$ such that $s \to x$ in the topology $\mathcal{T}$ for every pair $(s, x)$ in $\mathcal{C}$; ideally, we want $\mathcal{C}$ to be the complete set of convergent sequences (or nets) with respect to $\mathcal{T}$.

We will be primarily interested in the case where a sequence cannot have more than one limit (this was an explicit assumption in [1], [2], [3], [4], [5]), but we will not make this a blanket assumption.

XI.3.3.3.  To make the process work, we make the modest assumption on $\mathcal{C}$ that any subsequence of a sequence in $\mathcal{C}$ is also in $\mathcal{C}$, with the same limit, i.e. that if $(s, x) \in \mathcal{C}$ and $s'$ is a subsequence of $s$, then $(s', x) \in \mathcal{C}$. This subsequence property must be satisfied for $\mathcal{C}$ to have any claim to completeness. (“Sequence” and “subsequence” can be replaced by “net” and “subnet” here.)

XI.3.3.4.  There are two possible approaches to defining $\mathcal{T}$:

(1) We could declare a subset $E$ of $X$ closed if, whenever $(s, x) \in \mathcal{C}$ and $s$ is a sequence in $E$, then $x \in E$. (If $\mathcal{T}$ is a topology on $X$ under which the sequences in $\mathcal{C}$ converge, then any $\mathcal{T}$-closed set has this property.)

(2) We could define a closure operation on $X$ by saying that if $A \subseteq X$, then $\bar{A}$ consists of all $x \in X$ such that there exists $(s, x) \in \mathcal{C}$ with $s$ a sequence in $A$. (If $\mathcal{T}$ is a topology on $X$ under which the sequences in $\mathcal{C}$ converge, then any such $x$ must be a limit point of $A$.) If $A \mapsto \bar{A}$ is a Kuratowski closure operator ( ), it defines a suitable topology $\mathcal{T}$.

Procedure (2) is more constructive. It turns out that procedure (1) works quite nicely, but procedure (2) is more problematic.

First consider procedure (1). Half the answer is almost immediate:

XI.3.3.5.  **Proposition.**  Let $X$ be a set and $\mathcal{C}$ a set of sequences as above, with the subsequence property. Let $\mathcal{E}$ be the collection of closed subsets of $X$ as defined in (1). Then $\mathcal{E}$ is the collection of closed sets in a topology $\mathcal{T}$ which is the strongest topology on $X$ for which $s \to x$ for every $(s, x) \in \mathcal{C}$.

**Proof:** We need to show that $\mathcal{E}$ satisfies the conditions of XI.2.1.4. It is obvious that $\emptyset$ and $X$ are in $\mathcal{E}$, and that $\mathcal{E}$ is closed under arbitrary intersections. So suppose $A$ and $B$ are in $\mathcal{E}$ and $(s, x) \in \mathcal{C}$ with $s$ a sequence in $A \cup B$. Then $s$ either has a subsequence $s'$ in $A$ or a subsequence $s''$ in $B$. In the first case $(s', x) \in \mathcal{C}$, so $x \in A \subseteq A \cup B$ since $A \in \mathcal{E}$, and similarly in the second case $x \in B \subseteq A \cup B$. Thus $A \cup B \in \mathcal{E}$ and $\mathcal{E}$ is closed under finite unions. It is clear from the last observation in (1) that the topology defined by $\mathcal{E}$ is the strongest possible topology on $X$ giving the desired convergence.

XI.3.3.6.  This result and its proof hold if “sequence” is replaced by “net” and “subsequence” by “subnet” throughout (i.e. the subsequence property is replaced by the subnet property, and the definition of “closed” in (1) uses nets).

1031
XI.3.3.7. However, it will rarely be true that $\mathcal{C}$ is the complete set of sequences which converge with respect to $T$. For one thing, for $\mathcal{C}$ to be complete it must have the following property (cf. XI.3.1.6.):

If $s$ is a sequence in $X$, $x \in X$, and every subsequence $s'$ of $s$ has a subsequence $s''$ such that $(s'', x) \in \mathcal{C}$, then $(s, x) \in \mathcal{C}$.

$\mathcal{C}$ must also contain all constant sequences (with limit equal to the constant term).

Even these additional assumptions on $\mathcal{C}$ are not enough in general. Before discussing this further, we will examine procedure (2), beginning with the net version.

XI.3.3.8. So, given a collection $\mathcal{C}$ of nets, let us define a closure operation on $X$ as in (2). If $\mathcal{C}$ is to be the set of convergent nets for a topology, we must have the diagonal property:

It turns out this property along with the previous ones is sufficient to obtain a Kuratowski closure operation:

XI.3.3.9. Proposition. Let $X$ be a set and $\mathcal{C}$ a collection of pairs $(s, x)$ where $s$ is a net in $X$ and $x \in X$. Suppose $\mathcal{C}$ has the following properties:

(i) If $x \in X$ and $s$ is a constant net with all terms $x$, then $(s, x) \in \mathcal{C}$.

(ii) If $(s, x) \in \mathcal{C}$ and $s'$ is a subnet of $s$, then $(s', x) \in \mathcal{C}$.

(iii) Diagonal property

For $A \subseteq X$, let $\bar{A}$ be the set of all $x \in X$ such that there exists a pair $(s, x) \in \mathcal{C}$ with $s$ a net in $A$. Then $A \mapsto \bar{A}$ is a Kuratowski closure operation on $X$. The corresponding topology on $X$ is the strongest topology $T$ on $X$ with the property that $s \rightarrow x$ in $T$ for every $(s, x) \in \mathcal{C}$, and coincides with the topology defined in XI.3.3.5..

Proof: Obviously $\emptyset = \emptyset$, and $X = X$ since $\mathcal{C}$ contains all constant nets. If $A \subseteq X$, then $A \subseteq \bar{A}$ by the same argument, and $\bar{A}$ by (iii). Now suppose $A, B \subseteq X$, and $x \in X$. If $x \in A$ or $x \in B$, then obviously $x \in \bar{A} \cup \bar{B}$. Conversely, if $x \in \bar{A} \cup \bar{B}$, let $s = (x_i)$ be a net in $A \cup B$ with $(s, x) \in S$. Then $s$ is a subnet of $x$ in $A$ or a subnet of $s''$ in $B$. In the first case $(s'', x) \in \mathcal{C}$, so $x \in \bar{A}$, and in the second case $x \in \bar{B}$. In either case, $x \in \bar{A} \cup \bar{B}$. Thus $\bar{A} \cup \bar{B} = \bar{A} \cup \bar{B}$.

XI.3.3.10. From either XI.3.3.5. or XI.3.3.9. we are left with two questions:

1. Is the topology $T$ so defined the unique topology on $X$ for which $s \rightarrow x$ for all $(s, x) \in \mathcal{C}$?

2. Is $\mathcal{C}$ the collection of all convergent sequences or nets with respect to $T$?

The answer to (1) is clearly no in general: we have $s \rightarrow x$ for all $(x, s) \in \mathcal{C}$ for any weaker topology too, e.g. the indiscrete topology.

For question (2) to have a positive answer, it is necessary that $\mathcal{C}$ have the net version of the property of XI.3.3.7., as well as (i)–(iii) of XI.3.3.9.. This suffices:
XI.3.3.11. Theorem. (cf. [Bir37]) Let \( X \) be a set and \( C \) a collection of pairs \((s, x)\) where \( s \) is a net in \( X \) and \( x \in X \). Suppose \( C \) has the following properties:

(i) If \( x \in X \) and \( s \) is a constant net with all terms \( x \), then \((s, x) \in C\).

(ii) If \((s, x) \in C \) and \( s' \) is a subnet of \( s \), then \((s', x) \in C\).

(iii) Diagonal property

(iv) If \( s \) is a net in \( X \), \( x \in X \), and every subnet \( s' \) of \( s \) has a weak subnet \( s'' \) with \((s'', x) \in C \), then \((s, x) \in C\).

Let \( T \) be the topology defined by \( C \) as in XI.3.3.7. or XI.3.3.9. Then \( C \) is precisely the set of nets in \( X \) which converge in \( T \).

Proof: We need only to show that if \( s \) is a net in \( X \) with \( s \to x \), then \((s, x) \in C\). Suppose \((s, x) \notin C\). Then by (iv) there is a subnet \( s' \) of \( s \) such that \((s'', x) \notin C \) for all weak subnets \( s'' \) of \( s' \). Set

\[ E = \{ y \in X | (s'', y) \in C \text{ for some weak subnet } s'' \text{ of } s' \} \, .\]

The set \( E \) is exactly the closure of the set of terms in \( s' \), hence is a closed subset of \( X \). Since all terms of \( s' \) are in \( E \), we cannot have \( s' \to x \) and hence \( s \) does not converge to \( x \).

XI.3.3.12. Hypotheses (iii) and (iv) may be somewhat difficult to check in some cases, but they are indeed necessary conditions for the conclusion (). By a somewhat more complicated argument (cf. [Kel75, p. 74]), it can be shown that hypothesis (iv) can be slightly weakened by replacing “weak subnet” with “subnet.” The proof of this in [Kel75] (implicitly) uses the AC (note that the proof of XI.3.3.11. above does not use any Choice). A class of nets satisfying (i)–(iii) and this version of (iv) is called a convergence class.

XI.3.3.13. It is suggested in [?], p. 19] that hypothesis (iv) is redundant. However, at least some weak version of (iv) is necessary; otherwise, we could take \( C \) to be the class of constant nets. The topology on \( X \) determined by this \( C \) is the discrete topology, but if \( X \) has more than one element \( C \) is not the entire class of convergent nets in \( X \) (the class of eventually constant nets).

The following weak version of (iv) might suffice:

(iv') If \( s \) is a net in \( X \), \( x \in X \), and there is a tail \( s' \) of \( s \) with \((s', x) \in C \), then \((s, x) \in C\).

XI.3.3.14. There is also a set-theoretic problem: the collection of all subnets of a net does not form a set. One might be able to get around this problem by only considering nets whose index set is a subset of some fixed set whose cardinality is large compared to \( |X| \), although construction of diagonal nets may cause difficulty. One really needs a notion of equivalence of nets and that every net on \( X \) is equivalent to a net with an index set of bounded cardinality. This is effectively accomplished using the theory of filter convergence (), which avoids these set-theoretic difficulties.

XI.3.3.15. Unfortunately, there is no simple version of XI.3.3.11. for sequences. The sequence version of (iii) does not hold in general (). If the generated topology is assumed to be first countable, the theorem holds with sequences in place of nets; but there is no simple criterion in terms of convergence of sequences which will characterize when the generated topology is first countable.
XI.3.4. Convergence via Filters

There is another approach to convergence in a topological space which uses filters instead of nets. This approach is somewhat more complicated and less familiar at first, but has some technical advantages once set up. The theories of convergence via nets and filters are entirely equivalent logically, and there is a way of translating directly from one to the other, and it is largely a matter of taste (and, unfortunately, sometimes of national pride, since the theory of net convergence was developed in the United States and the theory of filter convergence in France) which approach is used; but some things are done more easily or efficiently from one of the points of view instead of the other, so it is valuable to be familiar with both approaches.

The theory of convergence via filters was developed by H. Cartan for Bourbaki around 1940. More details can be found in [?], [Dug78].

XI.3.4.1. Recall (XII.1.6.1.) that a filter on X is a nonempty collection $\mathcal{F}$ of subsets of X such that

(i) $\mathcal{F}$ is closed under finite intersections.

(ii) $\mathcal{F}$ has the superset property: if $A \in \mathcal{F}$ and $A \subseteq B \subseteq X$, then $B \in \mathcal{F}$.

(iii) $\emptyset \notin \mathcal{F}$.

XI.3.4.2. Definition. A collection of nonempty subsets of a set X is centered if, for every $A, B \in \mathcal{D}$ there is a $C \in \mathcal{D}$ with $C \subseteq A \cap B$. A centered collection of subsets of X is called a filterbase in X.

XI.3.4.3. A collection of nonempty subsets of a set X is centered if and only if it is directed by inverse inclusion, i.e. $A \leq B$ if $B \subseteq A$. A filterbase $\mathcal{D}$ has the finite intersection property (XII.1.6.9.), and hence is contained in a unique smallest filter $\mathcal{F}$ (XII.1.6.10.) called the filter generated by $\mathcal{D}$; $\mathcal{D}$ is called a filterbase for $\mathcal{F}$. In fact, $\mathcal{F}$ consists precisely of all subsets of X which contain a subset in $\mathcal{D}$.

Here are the most important examples of filterbases for topology:

XI.3.4.4. Examples. (i) Let $(X, \mathcal{T})$ be a topological space and $p \in X$. The set of all $\mathcal{T}$-neighborhoods of $p$ is a filter, called the neighborhood filter, or $\mathcal{T}$-neighborhood filter, of $p$ in X, denoted $\mathcal{N}_p$. The collection of open neighborhoods of $p$ is a filterbase for $\mathcal{N}_p$; more generally, any local base for $\mathcal{T}$ at $p$ is a filterbase for $\mathcal{N}_p$.

(ii) Let X be a set, and $(x_i)_{i \in I}$ a net in X. The tail set $\{T_i : i \in I\}$ (XI.3.2.19.) is a filterbase in X.

XI.3.4.5. Example XI.3.4.4.(ii) is actually universal: if $\mathcal{D}$ is a filterbase in X, let $I$ be the set of pairs $(A, x)$, where $A \in \mathcal{D}$ and $x \in A$. Set $(A, x) \leq (B, y)$ if $B \subseteq A$. Then $I$ is a directed set since $\mathcal{D}$ is centered. If $x_{(A, z)} = z$, then $(x_{(A, z)})$ is a net in X with index set $I$, with $T_{(A, z)} = A$ for each $(A, z)$. There is thus a one-one correspondence between filterbases in X and equivalence classes of nets in X, where two nets are regarded as equivalent if their corresponding filterbases are identical (see Exercise XI.3.5.2.; cf. XI.3.3.14.).

Convergence of Filters

The definition of convergence of a filter is very simple:
XI.3.4.6. Definition. Let \((X, \mathcal{T})\) be a topological space. A filter \(\mathcal{F}\) in \(X\) converges to a point \(p \in X\) if \(\mathcal{N}_p \subseteq \mathcal{F}\).

XI.3.4.7. Because of the superset property of filters, a filter \(\mathcal{F}\) converges to a point \(p\) if and only if, whenever \(U\) is a neighborhood of \(p\), there is an \(A \in \mathcal{F}\) with \(A \subseteq U\). Thus we extend the notion of filter convergence to filterbases:

XI.3.4.8. Definition. Let \((X, \mathcal{T})\) be a topological space. A filterbase \(\mathcal{D}\) in \(X\) converges to a point \(p \in X\) if whenever \(U\) is a neighborhood of \(p\), there is an \(A \in \mathcal{D}\) with \(A \subseteq U\).

Thus a filterbase converges to \(p\) if and only if the filter it generates converges to \(p\).

XI.3.4.9. This is consistent with convergence of nets: a net \((x_i)_{i \in I}\) converges to \(p\) if and only if the corresponding filterbase \(\{T_i : i \in I\}\) converges to \(p\).

Closure via Filters

We can give a characterization of the closure of a set using filters. It is cleanest to express it in terms of filterbases, since if \(A\) is a subset of \(X\) and \(\mathcal{D}\) is a filterbase in \(A\), \(\mathcal{D}\) is also a filterbase in \(X\) (this is false for filters).

XI.3.4.10. Proposition. Let \((X, \mathcal{T})\) be a topological space and \(A \subseteq X\). The \(\mathcal{T}\)-closure of \(A\) in \(X\) consists precisely of all points \(x\) with the property that there is a filterbase \(\mathcal{D}\) in \(A\) converging to \(x\). In particular, \(A\) is \(\mathcal{T}\)-closed if and only if, whenever \(\mathcal{D}\) is a filterbase in \(A\) converging to \(x \in X\), then \(x \in A\).

XI.3.4.11. To state the result using filters, we make the following definition. We say a filter \(\mathcal{F}\) in a set \(X\) is eventually in \(A \subseteq X\) if \(A \subseteq \mathcal{F}\) (or, equivalently, some subset of \(A\) is in \(\mathcal{F}\)). We can then state:

XI.3.4.12. Proposition. Let \((X, \mathcal{T})\) be a topological space and \(A \subseteq X\). The \(\mathcal{T}\)-closure of \(A\) in \(X\) consists precisely of all points \(x\) with the property that there is a filter \(\mathcal{F}\) which is eventually in \(A\) and converges to \(x\). In particular, \(A\) is \(\mathcal{T}\)-closed if and only if, whenever \(\mathcal{F}\) is a filter in \(X\) which is eventually in \(A\) and converges to \(x \in X\), then \(x \in A\).

XI.3.4.13. Similarly, we say a filterbase \(\mathcal{D}\) in \(X\) is eventually in \(A \subseteq X\) if there is a \(D \in \mathcal{D}\) with \(D \subseteq A\).

Cluster Points of Filters

XI.3.4.14. Definition. Let \(\mathcal{D}\) be a filterbase in a set \(X\) and \(A \subseteq X\). We say \(\mathcal{D}\) is frequently in \(A\) if \(A \cap D \neq \emptyset\) for all \(D \in \mathcal{D}\). A point \(x\) is a cluster point for a filterbase \(\mathcal{D}\) in \(X\) if \(\mathcal{D}\) is frequently in every neighborhood of \(x\).

This terminology is consistent with the corresponding definition for nets (). There is no modification needed to replace “filterbase” by “filter” (in fact, the statement for filters is a special case since every filter is a filterbase).
XI.3.4.15. If a filter or filterbase converges to \( x \), then \( x \) is a cluster point. We have the following filter version of XI.3.2.19:

XI.3.4.16. Proposition. Let \( (X, \mathcal{T}) \) be a topological space, and let \( D \) be a filterbase in \( X \). A point \( x \in X \) is a cluster point of \( D \) if and only if \( x \in \bigcap_{D \in \mathcal{D}} D \).

Subfilters

What is the right filter or filterbase analog of a subnet? The following definition is reasonable:

XI.3.4.17. Definition. Let \( \mathcal{D} \) and \( \mathcal{D}' \) be filterbases in a set \( X \). Then \( \mathcal{D}' \) is subordinate to \( \mathcal{D} \), written \( \mathcal{D}' \vdash \mathcal{D} \), if for every \( A \in \mathcal{D} \) there is a \( B \in \mathcal{D}' \) with \( B \subseteq A \).

XI.3.4.18. It is easily seen that if \( \mathcal{F} \) and \( \mathcal{F}' \) are the filters generated by \( \mathcal{D} \) and \( \mathcal{D}' \) respectively, then \( \mathcal{D}' \vdash \mathcal{D} \) if and only if \( \mathcal{F} \subseteq \mathcal{F}' \), i.e. the subordinate filter is larger. If \( \mathcal{F} \subseteq \mathcal{F}' \), we say the filter \( \mathcal{F}' \) is finer than \( \mathcal{F} \). Thus it is not appropriate to call \( \mathcal{D}' \) a “subfilterbase” of \( \mathcal{D} \) (which is a mouthful anyway.) However, if \( (x_i)_{i \in I} \) is a net in \( X \) and \( (y_j)_{j \in J} \) is a subnet, then the tail filterbase of \( (y_j) \) is subordinate to the tail filterbase of \( (x_i) \) (the converse is false).

We have:

XI.3.4.19. Proposition. Let \( (X, \mathcal{T}) \) be a topological space, and let \( \mathcal{D}, \mathcal{D}' \) be filterbases in \( X \), with \( \mathcal{D}' \vdash \mathcal{D} \).

(i) If \( \mathcal{D} \) converges to \( x \in X \), then \( \mathcal{D}' \) converges to \( x \).

(ii) If \( x \in X \) is a cluster point of \( \mathcal{D}' \), it is a cluster point of \( \mathcal{D} \).

We next obtain a generalization of XI.3.2.20:

XI.3.4.20. Proposition. Let \( \mathcal{D} \) be a filterbase in a set \( X \), and \( (x_i)_{i \in I} \) a net in \( X \) which is frequently in \( D \) for every \( D \in \mathcal{D} \). Then there is a subnet of \( (x_i) \) which is eventually in every \( D \in \mathcal{D} \).

Proof: Let \( J \) be the set of all pairs \( (D, i) \) where \( D \in \mathcal{D} \), \( i \in I \), and \( x_i \in D \). Set \( (D_1, i_1) \leq (D_2, i_2) \) if \( D_2 \subseteq D_1 \) and \( i_1 \leq i_2 \). Then \( J \) is directed: if \( (D_1, i_1), (D_2, i_2) \in J \), there is a \( D_3 \in \mathcal{D} \), \( D_3 \subseteq D_1 \cap D_2 \), and an \( i_0 \in I \) with \( i_1, i_2 \leq i_0 \), and an \( i_3 \geq i_0 \) such that \( x_{i_3} \in D_3 \) since \( (x_i) \) is frequently in \( D_3 \), so \( (D_3, i_3) \in J \) and \( (D_1, i_1), (D_2, i_2) \leq (D_3, i_3) \). Define \( f : J \to I \) by \( f(D, i) = i \). Then \( f \) is directed: if \( i_0 \in I \), fix \( D_1 \in \mathcal{D} \) and \( i_1 \geq i_0 \) with \( x_{i_1} \in D_1 \); then \( f(D, i) \geq i_0 \) whenever \( (D, i) \geq (D_1, i_1) \). If \( \phi : I \to X \) gives \( \phi(i) = x_i \), then \( \phi \circ f \) defines a subnet \( (x_{f(j)}) \). If \( D_0 \in \mathcal{D} \), then there is an \( i_0 \in I \) with \( (D_0, i_0) \in J \). If \( (D_0, i_0) \leq (D, i) = (D, j) \), then \( x_{f(j)} \in D \subseteq D_0 \), so the subnet \( (x_{f(j)}) \) is eventually in \( D_0 \).

Rephrasing, we get:

1036
XI.3.4.21. COROLLARY. Let $D$ be a filterbase in a set $X$, and $(x_i)_{i \in I}$ a net in $X$. If the tail set filterbase $D'$ of $(x_i)$ satisfies $D \vdash D'$, then there is a subnet of $(x_i)$ whose tail set filterbase $D''$ satisfies $D'' \vdash D$.

We also have the following analog of XI.3.2.12.:

XI.3.4.22. PROPOSITION. Let $(X, T)$ be a topological space, $D$ a filterbase in $X$, and $x \in X$. If $D$ does not converge to $x$, then there is a filterbase $D' \vdash D$ such that no filterbase $D'' \vdash D'$ converges to $x$.

Ultrafilters and Maximal Filterbases

XI.3.4.23. By XI.3.4.18., larger means “finer” for filters. The largest filters are ultrafilters (XII.1.6.1.), which are therefore the “finest” filters. By XII.1.6.15. (which uses AC), every filter is contained in an ultrafilter. By XII.1.6.12., a filter $F$ in a set $X$ is an ultrafilter if and only if for every $A \subseteq X$, either $A \in F$ or $A^c \in F$, i.e. $F$ is either eventually in $A$ or eventually in $A^c$.

XI.3.4.24. A filterbase which generates an ultrafilter is called a maximal filterbase; “ultrafilterbase” would be a better name but too cumbersome (“maximal filterbase” is an abuse of language since a maximal filterbase is not maximal among all filterbases under inclusion unless it is already an ultrafilter; but see Exercise XI.3.5.4.). A filterbase $D$ in $X$ is maximal if and only if for each $A \subseteq X$, there is a $D \in D$ such that either $D \subseteq A$ or $D \subseteq A^c$.

XI.3.4.25. PROPOSITION. Let $(X, T)$ be a topological space, $D$ a maximal filterbase in $X$, and $x \in X$. If $x$ is a cluster point of $D$, then $D$ converges to $x$.

Proof: Let $U$ be a neighborhood of $x$. Then there is a $D \in D$ with either $D \subseteq U$ or $D \subseteq U^c$. But $D \cap U \neq \emptyset$ since $x$ is a cluster point of $D$, so $D \subseteq U^c$ is impossible and $D \subseteq U$.

XI.3.4.26. PROPOSITION. Let $X$ and $Y$ be sets, $f : X \rightarrow Y$ any function, and $D$ a maximal filterbase in $X$. Then $f(D) = \{f(D) : D \in D\}$ is a maximal filterbase in $Y$.

Proof: It is clear that $f(D)$ is a filterbase in $Y$. If $B \subseteq Y$ and $A = f^{-1}(B)$, then $A^c = f^{-1}(B^c)$. Since $D$ is maximal, there is a $D \in D$ such that either $D \subseteq f^{-1}(B)$ or $D \subseteq f^{-1}(B^c)$, hence either $f(D) \subseteq B$ or $f(D) \subseteq B^c$. Thus $f(D)$ is maximal.

Universal Nets

XI.3.4.27. DEFINITION. A net $(x_i)$ in a set $X$ is a universal net if its tail set filterbase is maximal.

The simple verification of the next proposition is left to the reader.

XI.3.4.28. PROPOSITION. A net $(x_i)$ in a set $X$ is universal if and only if, for every subset $A$ of $X$, either $(x_i)$ is eventually in $A$ or $(x_i)$ is eventually in $A^c$. 1037
XI.3.4.29. The existence of universal nets is an immediate consequence of the existence of ultrafilters. But we can do better:

XI.3.4.30. **Theorem.** Let \( X \) be a set, and \( (x_i) \) a net in \( X \). Then \( (x_i) \) has a universal subnet.

**Proof:** Let \( D \) be the tail set filterbase corresponding to \( (x_i) \). Let \( F \) be an ultrafilter containing \( D \) (i.e. containing the filter generated by \( D \)). Since \( D \subseteq F \), if \( F \in F \) we have \( F \cap D \neq \emptyset \) for all \( D \in D \), and it follows that \( (x_i) \) is frequently in \( F \). Since \( F \) is itself a filterbase, by XI.3.4.20., there is a subnet \( (x_{f(j)}) \) of \( (x_i) \) which is eventually in \( F \) for any \( F \in F \). If \( A \subseteq X \), then either \( A \in F \) or \( A^c \in F \), so \( (x_{f(j)}) \) is either eventually in \( A \) or eventually in \( A^c \). Thus \( (x_{f(j)}) \) is a universal net.

This result requires some version of Choice, and is not a theorem of ZF. In fact, it is equivalent to the fact that every filter on a set is contained in an ultrafilter, hence to BPI ().

XI.3.5. **Exercises**

XI.3.5.1. Let \( X \) be a topological space. Make the following definitions:

(i) A subset \( A \) of \( X \) is **sequentially closed** if, whenever \( (x_n) \) is a sequence in \( A \) with \( x_n \to x \in X \), then \( x \in A \).

(ii) If \( A \) is a subset of \( X \), then the **sequential closure** of \( A \) is the set of all \( x \in X \) for which there is a sequence \( (x_n) \) in \( A \) with \( x_n \to x \).

These definitions, from [Fra65], are standard, but somewhat inconsistent: the sequential closure of a set is not sequentially closed in general. Sequential closure can be applied repeatedly, even transfinitely.

(iii) The space \( X \) is **sequential** if every sequentially closed subset of \( X \) is closed.

(iv) The space \( X \) is a **Fréchet-Urysohn space** if the sequential closure of every subset of \( X \) equals its closure (i.e. is closed).

(a) Show that every first countable topological space is Fréchet-Urysohn, and every Fréchet-Urysohn space is sequential. The simplest example of a Fréchet-Urysohn space which is not first countable is the one-point compactification of an uncountable discrete space (so even a compact Hausdorff Fréchet-Urysohn space need not be first countable). See XI.9.5.7. for another example, and [Eng89, 1.6.19] for a sequential space which is not Fréchet-Urysohn.

(b) Show that the space in XI.11.12.8. is not sequential, even though every singleton subset is a \( G_\delta \). (In fact, “most” topological spaces which are not first countable fail to be sequential.)

(c) Show that every quotient of a sequential space is sequential. In particular, every quotient of a first countable space is sequential.

(d) Show that every sequential Hausdorff space is a quotient of a locally compact metrizable space. [Consider the separated union of the space consisting of all convergent sequences in the space and their limits, i.e. a disjoint union of copies of \( \mathbb{N}^1 \).] This is a strong converse to (c).

(e) Show that a topological space \( X \) is sequential if and only if the sequential criterion for continuity holds for functions from \( X \), i.e. if \( Y \) is any topological space and \( f : X \to Y \) is a function, then \( f \) is continuous if and only if, whenever \( x_n \to x \) in \( X \), we have \( f(x_n) \to f(x) \).
(f) If $X$ is a Fréchet-Urysohn space, $(x_n)$ is a sequence in $X$, and $x \in X$, then $x$ is a cluster point of $(x_n)$ if and only if there is a subsequence of $(x_n)$ converging to $X$. Show that this property characterizes Fréchet-Urysohn spaces among sequential spaces (but not among all topological spaces).

(g) Show that a topological space $X$ is Fréchet-Urysohn if and only if every subspace of $X$ is sequential in the relative topology.

For more on these spaces, see [Eng89] (where Fréchet-Urysohn spaces are called Fréchet spaces). Both notions (sequential and Fréchet-Urysohn) are reasonable precise versions of the condition “the topology of $X$ is completely determined by convergence of sequences.”

**XI.3.5.2.** Let $(x_i)_{i \in I}$ and $(y_j)_{j \in J}$ be two nets in a set $X$. Here are various possible notions of equivalence for the nets. Show each is an equivalence relation and compare them.

(a) The nets generate the same filterbase (XI.3.4.5.).

(b) The corresponding filterbases generate the same filter.

(c) Each net is a subnet of the other.

(d) Every subnet of each net has a subnet which is also a subnet of the other net.

[To compare (a) with (c) and (d), consider constant nets with index sets $\mathbb{N}$ and the first uncountable ordinal.]

**XI.3.5.3.** In what sense is XI.3.4.20. a generalization of XI.3.2.20.?

**XI.3.5.4.** Let $X$ be a set, and $\mathcal{D}, \mathcal{D}'$ filterbases in $X$.

(a) Show that we can have $\mathcal{D}' \Vdash \mathcal{D}$ and $\mathcal{D} \Vdash \mathcal{D}'$ even if $\mathcal{D} \neq \mathcal{D}'$. Thus $\Vdash$ is only a preorder and not a partial order on filterbases.

(b) If $\mathcal{D}$ is a maximal filterbase and $\mathcal{D}' \Vdash \mathcal{D}$, then also $\mathcal{D} \Vdash \mathcal{D}'$, and any $\mathcal{D}$ with this property is maximal.
XI.4. Continuous Functions

XI.4.1. Definition and Properties

XI.4.2. Topological Continuity vs. Metric Continuity
XI.5. Comparison of Topologies

XI.5.1. Stronger and Weaker Topologies

XI.5.1.1. Definition. Let $\mathcal{T}$ and $\mathcal{S}$ be topologies on the same set $X$. Then $\mathcal{S}$ is stronger (larger, finer) than $\mathcal{T}$, and $\mathcal{T}$ is weaker (smaller, coarser) than $\mathcal{S}$, if $\mathcal{T} \subseteq \mathcal{S}$, i.e. if every $\mathcal{T}$-open set is also $\mathcal{S}$-open.

The philosophy behind the names reflects the intuitive idea that a topology gives a notion of “closeness” for points, and a stronger or finer topology gives a more discriminating notion of “closeness” than a weaker or coarser one, i.e. makes it easier to distinguish between points using open sets.

A topology is stronger than itself, and also weaker than itself. In fact, a common and useful way to prove that two potentially different topologies are the same is to show that each is stronger than the other. We sometimes use the terms strictly stronger, strictly weaker, etc., when we mean to specify that the topologies are distinct.

XI.5.1.2. It can happen, and often does, that if $\mathcal{T}$ and $\mathcal{S}$ are topologies on a set $X$, then neither topology is stronger than the other. In this case the topologies are said to be incomparable.

XI.5.1.3. Examples. (i) On every set $X$, the discrete topology is the strongest topology: every topology on $X$ is weaker than the discrete topology. Similarly, every topology on $X$ is stronger than the indiscrete topology, so the indiscrete topology on $X$ is the weakest topology on $X$.

(ii) The finite complement topology (XI.1.2.8.(iv)) on a set $X$ is the weakest $T_1$ topology () on $X$. For in any $T_1$ topology on $X$, the singleton subsets are closed, hence finite sets are closed, so complements of finite subsets must be open. In particular, the finite complement topology on $\mathbb{R}$ is weaker than the ordinary topology.

(iii) Let $X = \{a, b\}$, and let $\mathcal{T} = \{\emptyset, \{a\}, X\}$, $\mathcal{S} = \{\emptyset, \{b\}, X\}$. Then $\mathcal{T}$ and $\mathcal{S}$ are incomparable.

(iv) On $C([0, 1])$, the topology of pointwise convergence () is strictly weaker than the topology of uniform convergence (). The topology of mean convergence () is strictly weaker than uniform convergence but incomparable with pointwise convergence. In fact, for every $p$, $0 < p \leq \infty$, there is an $L^p$ topology on $C([0, 1]) ()$, with $p = 1$ giving mean convergence and $p = \infty$ uniform convergence; the $L^p$ topology is weaker than the $L^r$ topology if and only if $p \leq r ()$. So there is an uncountable family of natural topologies on $C([0, 1])$, all distinct and all comparable; only the strongest of these (uniform convergence) is comparable with pointwise convergence. (There are very many other topologies on $C([0, 1])$ too, most of which are incomparable to these.)

(v) On $C_c(\mathbb{R})$, the set of real-valued continuous functions on $\mathbb{R}$ of compact support, i.e. zero outside a finite interval, there is also an $L^p$ topology for $0 < p \leq \infty ()$. In this case no two of the topologies are comparable ()

XI.5.1.4. When the topology is changed, all the ancillary things associated with a topological space potentially change. If the topology on a space $X$ is made stronger, i.e. with more open sets, then

Since closed sets are complements of open sets, there are more closed sets. (Recall that being closed is not the opposite of being open!) Thus it is easier for a subset of $X$ to be closed.
It is harder for a point \( x \) to be a limit point of a subset \( E \), since there are more open neighborhoods of \( x \) which must have nonempty intersection with \( E \). Thus \( E \) has fewer limit points and the closure of \( E \) is smaller.

Similarly, it is harder for a point \( x \) to be the limit of a sequence or net \((x_i)\), since there are more open neighborhoods of \( x \) which must eventually contain the sequence or net. Thus there are fewer convergent sequences and nets. Similarly, a sequence or net has fewer cluster points.

It is harder for a subset \( F \) of \( X \) to be compact, since there are more open covers of \( F \) which must each have finite subcovers.

It is easier for \( X \) to be \( T_0 \), \( T_1 \), or Hausdorff, since there are more open sets to choose from.

However, it is unclear whether regularity or normality becomes easier when the topology becomes stronger, since on the one hand for a given point \( p \) and closed set \( F \) it is easier to find disjoint neighborhoods, but on the other hand there are more pairs \((p,F)\) to consider. Similarly, normality does not obviously become easier. In fact, regularity and normality are not preserved under making the topology stronger or weaker (cf. XI.7.8.13.; for the other direction, consider weakening the discrete topology). In a similar way, one might expect paracompactness, like compactness, to be preserved when weakening a topology, since there are fewer open covers to consider; but on the other hand an open cover has fewer refinements. Paracompactness is in fact not preserved under either strengthening or weakening the topology (XI.7.8.13. and weakening the discrete topology are again counterexamples).

It is harder for a subset of \( X \) to be connected, since there are more potential separations.

If \( Y \) is another space and \( f : X \to Y \), and the topology on \( Y \) is kept fixed and the topology on \( X \) strengthened, it is easier for \( f \) to be continuous since it is easier for \( f^{-1}(V) \) to be open for any given open set \( V \subseteq Y \). However, if the topology on \( X \) is kept fixed and the topology on \( Y \) is strengthened, it is harder for \( f \) to be continuous since the inverse images of more open sets must be considered. If the topologies on both \( X \) and \( Y \) are strengthened, it may be neither easier nor harder for \( f \) to be continuous. In particular, if the topology on \( X \) is strengthened, functions from \( X \) to \( Y \) may change from continuous to discontinuous or vice versa; the set of continuous functions from \( X \) to \( Y \) will normally be different, although neither larger nor smaller (cf. Exercise XI.7.8.11.).

Of course, there are analogous statements if the topology on \( X \) is weakened.

### XI.5.1.5

The following chart summarizes the main features of stronger and weaker topologies:

<table>
<thead>
<tr>
<th>Stronger (larger, finer) topology</th>
<th>Weaker (smaller, coarser) topology</th>
</tr>
</thead>
<tbody>
<tr>
<td>More open sets</td>
<td>Fewer open sets</td>
</tr>
<tr>
<td>More closed sets</td>
<td>Fewer closed sets</td>
</tr>
<tr>
<td>Fewer limit points</td>
<td>More limit points</td>
</tr>
<tr>
<td>Smaller closures</td>
<td>Larger closures</td>
</tr>
<tr>
<td>Fewer compact subsets</td>
<td>More compact subsets</td>
</tr>
<tr>
<td>Fewer connected subsets</td>
<td>More connected subsets</td>
</tr>
<tr>
<td>Fewer convergent sequences (nets)</td>
<td>More convergent sequences (nets)</td>
</tr>
<tr>
<td>More continuous functions out</td>
<td>Fewer continuous functions out</td>
</tr>
<tr>
<td>Fewer continuous functions in</td>
<td>More continuous functions in</td>
</tr>
</tbody>
</table>
The easiest way to remember what happens under strengthening or weakening of the topology is to think of the extreme cases of the discrete or indiscrete topology. (In fact, one good way to analyze many mathematical situations and guess what happens is to pass to the most extreme case.)

XI.5.1.6. Our use of “stronger” and “weaker” in comparing topologies is the standard one, especially in analysis, particularly functional analysis (weak and weak-* topologies), strong and weak operator topologies. However, it should be noted that a few topology references use these terms in the opposite sense.

XI.5.1.7. Another sometimes convenient way to describe stronger and weaker topologies is: if $S$ and $T$ are topologies on a set $X$, then $S$ is stronger than $T$ if and only if the identity map from $(X; S)$ to $(X; T)$ is continuous.

Strongest and Weakest Topologies Defined by a Family of Functions

XI.5.1.8. If $X$ is a set, and $(Y, S)$ is a topological space, and $f : X \to Y$ is a function, then there is a weakest topology on $X$ such that $f$ is continuous. In fact,

$$T = \{f^{-1}(V) : V \in S\}$$

is a topology on $X$, as is easily checked since inverse images respect unions and intersections, and $T$ is obviously the weakest topology on $X$ making $f$ continuous.

XI.5.1.9. More generally, if $X$ is a set, $\{(Y_j, S_j) : j \in J\}$ is a family of topological spaces (not necessarily distinct), and $f_j : X \to Y_j$ is a function for each $j \in J$, then there is a weakest topology on $X$ making all the $f_j$ continuous. The set

$$\{f_j^{-1}(V) : j \in J, V \in S_j\}$$

is not usually a topology on $X$; however, it is a subbase for a topology $T$ which is obviously the weakest topology on $X$ making all the $f_j$ continuous.

XI.5.1.10. The topology $T$ can also be characterized as the intersection of all topologies on $X$ making each $f_j$ continuous (there is always at least one such topology, the discrete topology). However, it is usually better to describe $T$ constructively as in XI.5.1.9.

XI.5.1.11. The topology $T$ can be described in terms of convergence: a net $(x_i)$ in $X$ converges to $x$ in $(X, T)$ if and only if $f_j(x_i) \to f_j(x)$ in $(Y_j, S_j)$ for every $j \in J$. Thus $T$ is often called the weak topology on $X$ defined by the $f_j$.

XI.5.1.12. One of the most important examples of a weak topology defined by a family of functions is the product topology, i.e. the case where $X = \prod j Y_j$ and the $f_j$ are the coordinate projections. The general situation can also be reduced to the case of one target space using the product topology: if $X$ is a set, $\{(Y_j, S_j) : j \in J\}$ is a family of topological spaces (not necessarily distinct), and $f_j : X \to Y_j$ is a function for each $j \in J$, let $Y = \prod j Y_j$ and $f : X \to Y$ the induced map, i.e. $(f(x))_j = f_j(x)$ for all $j$. Give $Y$ the product topology. Then the weak topology on $X$ from the $f_j$ is the weak topology on $X$ from $f$.
XI.5.1.13. If all the $Y_j$ are Hausdorff and the $f_j$ separate points of $X$, then the weak topology on $X$ defined by the $f_j$ is also Hausdorff: if $p, q \in X$, $p \neq q$, choose $j$ with $f_j(p) \neq f_j(q)$, and choose disjoint neighborhoods $U$ and $V$ of $f_j(p)$ and $f_j(q)$ in $Y_j$; then $f_j^{-1}(U)$ and $f_j^{-1}(V)$ are disjoint neighborhoods of $p$ and $q$. The same statement is true if all the $Y_j$ are regular or completely regular ($\star$).

XI.5.1.14. Similarly, if $Y$ is a set, $\{(X_j, T_j) : j \in J\}$ is a set of topological spaces, and $f_j : X_j \to Y$ is a function for each $j$, then there is a strongest topology on $Y$ making all the $f_j$ continuous:

$$S = \{ V \subseteq Y : f_j^{-1}(V) \in T_j \text{ for all } j \} .$$

It is easy to verify that $S$ is a topology on $Y$, and it is obviously the strongest one making all the $f_j$ continuous. However, this topology is often very weak (frequently even the indiscrete topology). The quotient topology (XI.8.1.1.) is an example of this construction, probably the most important example.
XI.6. Products and the Product Topology

XI.6.1. Exercises

XI.6.1.1. Let \( I \) be an uncountable index set, and \( \{ X_i : i \in I \} \) a collection of topological spaces. Suppose for each \( i \) there is a point \( p_i \in X_i \) which has an open neighborhood \( U_i \) which is not all of \( X_i \) (there will be such a \( p_i \) unless \( X_i \) has the indiscrete topology). Let \( X = \prod_{i \in I} X_i \) with the product topology, and \( p = (\cdots p_i \cdots) \in X \). Show that \( p \) does not have a countable neighborhood base, and hence \( X \) is not first countable. [If \( \{ V_n : n \in \mathbb{N} \} \) is a sequence of open neighborhoods of \( p \), then for each \( n \) there is a finite subset \( F_n \) of \( I \) and nonempty open sets \( W_{n_i} \) such that \( V_n \) contains \( \prod_{i \in F_n} W_{n_i} \times \prod_{i \notin F_n} X_i \). If \( j \in I \setminus (\cup_{n=1}^{\infty} F_n) \), then \( U_j \times \prod_{i \neq j} X_i \) does not contain any \( V_n \).]

XI.6.1.2. Let \( \{ X_i : i \in I \} \) be a collection of topological spaces, and let \( X = \prod_{i \in I} X_i \) with the product topology. Suppose each \( X_i \) is separable and \( \text{card}(I) \leq 2^\mathfrak{c} \). Show that \( X \) is separable. [Let \( \{ p_{in} : n \in \mathbb{N} \} \) be a countable dense set in \( X_i \) for each \( i \). Identify \( I \) with a subset of \( \mathbb{R} \). For each finite set \( S = \{(a_1, b_1), \ldots, (a_m, b_m)\} \) of disjoint open intervals in \( \mathbb{R} \) with rational endpoints, and every corresponding tuple \( N = (n_1, \ldots, n_m) \) of natural numbers, let \( p_{(S,N)} \) be the point of \( x \) whose \( i \)'th coordinate is \( p_{in_k} \) if \( i \in (a_k, b_k) \) and \( p_{i1} \) otherwise. Show that the set of all \( p_{(S,N)} \) is a countable dense set in \( X \).]

This result requires the \( \text{AC} \) for index sets of cardinality \( 2^\mathfrak{c} \).

XI.6.1.3. Let \( D \) be a countable dense set in \([0,1]^\mathfrak{c}\). Then \( D \), with the relative topology, is a countable normal topological space in which no point has a countable local base.

XI.6.1.4. Let \( \{ X_i : i \in I \} \) be a collection of topological spaces, and let \( X = \prod_{i \in I} X_i \) with the product topology. Suppose each \( X_i \) has two disjoint nonempty open sets \( U_i \) and \( V_i \) (this will happen if \( X_i \) is Hausdorff and has more than one point), and that \( X \) is separable. Show that \( \text{card}(I) \leq 2^\mathfrak{c} \). [If \( \{ p_n : n \in \mathbb{N} \} \) is dense in \( X \), for each \( i \) let \( S(i) \) be the set of all \( n \) such that the \( i \)'th coordinate of \( p_n \) is in \( U_i \). Show that \( S(i) \) and \( S(j) \) are distinct subsets of \( \mathbb{N} \) for \( i \neq j \).]

XI.6.1.5. Let \( X \) be an arbitrary product of copies of \( \mathbb{N} \) with the finite complement topology. Show that \( X \) is separable in the product topology. [For each \( n \in \mathbb{N} \) let \( p_n \) be the point of \( X \) with all coordinates \( n \).]

XI.6.1.6. \((a)\) \((\text{Sto}48; \text{cf. Eng}89, 2.3.E)\) Show that \( \mathbb{N}^\mathfrak{c} \) is not normal. [For \( j = 1, 2 \) let \( A_j \) be the set of all points for which, for each \( k \neq j \), at most one coordinate is \( k \). Show that \( A_1 \) and \( A_2 \) are closed and disjoint, but do not have disjoint neighborhoods.]

(b) Conclude from XI.11.12.9. that if \( I \) is an index set with \( \text{card}(I) \geq \aleph_1 \), and, for each \( i \in I \), \( X_i \) is a topological space which is not countably compact, then \( \prod_{i \in I} X_i \) is not normal. In particular, if \( X \) is a topological space which is not countably compact, then \( X^\mathfrak{c} \) is not normal.
XI.7. Separation Axioms

The notion of topological space is so general that practically nothing can be said about all topological spaces. All nontrivial results in topology require additional restrictions, usually including separation axioms. Separation axioms roughly insure that there are “enough” open sets in the topology. There are several important separation axioms of varying strength, described in this section. Virtually all topological spaces arising in applications, particularly in analysis, including any metrizable space, satisfy all these separation axioms.

Note that the separation axioms have nothing to do with separability in the sense of XI.2.3.11.

XI.7.1. The $T$-Axioms

The first five separation axioms first appeared together in [AH74], where they were called $T_0–T_4$ ($T$ for Trennungaxiom); the authors attributed each property to someone else (Kolmogorov, Fréchet, Hausdorff, Vietoris, and Tietze respectively). Alternate names for $T_2–T_4$ are usually used today. There are also a $T_{3rac{1}{2}}$ (XI.7.7.3.), and a $T_5$, discussed in XI.10.1.2.; some add $T_{2rac{1}{2}}$ (XI.7.8.17.) and $T_6$ (XI.10.4.10.).

XI.7.1.1. Definition. Let $X$ be a topological space. Then

(o) $X$ is $T_0$ if, whenever $p$ and $q$ are distinct points of $X$, there is an open neighborhood of at least one of the points not containing the other.

(i) $X$ is $T_1$ if each singleton subset of $X$ is closed.

(ii) $X$ is $T_2$ if any two distinct points of $X$ have disjoint open neighborhoods.

(iii) $X$ is $T_3$ if whenever $E$ is a closed set in $X$ and $p$ a point of $X$ not in $E$, then $p$ and $E$ have disjoint open neighborhoods.

(iv) $X$ is $T_4$ if disjoint closed sets in $X$ have disjoint open neighborhoods.

$X$ is Hausdorff if it is $T_2$.

$X$ is regular if it is $T_3$ and Hausdorff.

$X$ is normal if it is $T_4$ and Hausdorff.

Each of these separation axioms is discussed in more detail below.

XI.7.1.2. There is some nonuniformity of use of the terminology in this definition. Some references define “regular” and “normal” to mean what we have called $T_3$ and $T_4$, and define $T_3$ to mean “$T_2$ and regular”, and similarly for $T_4$. We will regard “$T_3$” and “regular” as essentially synonymous (since they differ only in the case of spaces which are not $T_0$ (XI.7.5.2.)), and similarly “$T_4$” and “normal” are essentially equivalent.

Some references use the term separated as a synonym for “Hausdorff.” But this term is too easily confused with “separable” as defined in XI.2.3.11.
XI.7.2.   $T_0$-Spaces

XI.7.2.1.   PROPOSITION. Let $X$ be a topological space, and $p$ and $q$ distinct points of $X$. The following are equivalent:

(i) $\{p\}$ and $\{q\}$ have identical closures.

(ii) $p$ is in the closure of $\{q\}$ and $q$ is in the closure of $\{p\}$.

(iii) Any open set containing $p$ also contains $q$, and vice versa.

$X$ is $T_0$ if and only if none of these occur for any distinct $p$ and $q$.

PROOF: (i) $\Rightarrow$ (iii): if $U$ is an open set containing $p$ but not $q$, then $U^c$ is a closed set containing $q$ and hence containing the closure of $\{q\}$, so the closure of $\{q\}$ is not the same as the closure of $\{p\}$ (in fact, does not contain $p$). The same argument works with $p$ and $q$ interchanged.

(iii) $\Rightarrow$ (ii): If $p$ is not in the closure of $\{q\}$, the complement of the closure of $\{q\}$ is an open set containing $p$ but not $q$. The same argument works if $p$ and $q$ are interchanged.

(ii) $\Rightarrow$ (i) is trivial.

It is obvious that the $T_0$ condition is precisely the negation of (iii).

XI.7.2.2.   COROLLARY. A $T_1$ topological space is $T_0$.

There are $T_0$ spaces which are not $T_1$, e.g. the Sierpiński space.

The $T_0$ property is a local property. Say that a topological space $X$ is locally $T_0$ if every point of $X$ has an open neighborhood which is $T_0$ in the relative topology. Every $T_0$ space is obviously locally $T_0$. The converse is also true:

XI.7.2.3.   PROPOSITION. A locally $T_0$ space is $T_0$.

PROOF: Let $X$ be a locally $T_0$ space, and $p, q$ distinct points of $X$. We must find an open set containing one of $p$ and $q$ and not the other. Let $U$ be an open neighborhood of $p$ which is $T_0$ in the relative topology. If $q \notin U$, then $U$ is the desired set. If $q \in U$, there is a relatively open subset $V$ of $U$ containing one of $p$ and $q$ but not the other. Since $U$ is open in $X$, $V$ is also open in $X$ (.), and is the desired subset.

XI.7.2.4.   Every topological space has a maximal $T_0$ quotient, which captures all the topological information of the space (XI.8.3.10.).
XI.7.2.5. There is really no reason to consider topological spaces which are not at least $T_0$ (especially in light of XI.8.3.10.). Many authors feel the same about restricting to $T_1$ or $T_2$ spaces; indeed, topological spaces which are not Hausdorff are rather bizarre and are rarely encountered. In analysis almost all spaces encountered are even completely regular. However, there are topological spaces arising in applications in algebra and logic, such as spectra of rings (XI.7.8.16., XV.14.4.39.), which are $T_0$ but not necessarily even $T_1$, so such spaces cannot be completely ignored.

But there is one situation in analysis where spaces which are not $T_0$ arise naturally: certain natural topological groups () and topological vector spaces () are not $T_0$. In this case, taking the maximal $T_0$ quotient amounts to dividing out by the closure of the identity (), hence the $T_0$ quotient is also naturally a topological group or topological vector space.

XI.7.3. $T_1$-Spaces

The $T_1$ property has an alternate characterization, which was actually the original definition:

XI.7.3.1. Proposition. A topological space $X$ is $T_1$ if and only if, whenever $p$ and $q$ are distinct points of $X$, each of $p$ and $q$ has an open neighborhood not containing the other.

Proof: If $X$ is $T_1$ and $p$ and $q$ are distinct points of $X$, then $X \setminus \{q\}$ and $X \setminus \{p\}$ are the desired neighborhoods of $p$ and $q$. Conversely, let $p \in X$. For each $q \in X \setminus \{p\}$, there is an open neighborhood $U_q$ of $q$ not containing $p$. The union of the $U_q$ is open, and equals $X \setminus \{p\}$, so $\{p\}$ is closed.

This characterization gives a simpler proof that a $T_1$ space is $T_0$, and also immediately implies that a Hausdorff space is $T_1$. We used the definition we did for $T_1$ since it is the version which is usually verified and used in applications.

XI.7.3.2. Note that the condition in XI.7.3.1. can be rephrased: whenever $p$ and $q$ are distinct points of $X$, then $p$ has an open neighborhood not containing $q$. For if this statement is true for any $p$ and $q$ (in that order), it is also true for $q$ and $p$, i.e. each of $p$ and $q$ has a neighborhood not containing the other.

XI.7.3.3. Corollary. A topological space $X$ is $T_1$ if and only if every singleton subset of $X$ is an intersection of open sets.

XI.7.3.4. Like the $T_0$ property, the $T_1$ property is a local property. Say that a topological space $X$ is locally $T_1$ if every point of $X$ has an open neighborhood which is $T_1$ in the relative topology. Every $T_1$ space is obviously locally $T_1$. The converse is also true:

XI.7.3.5. Proposition. A locally $T_1$ space is $T_1$.

The proof is a slightly simplified version of the argument in the proof of XI.7.2.3., and is left to the reader.
XI.7.4. Hausdorff Spaces

The Hausdorff property is probably the most widely used separation axiom. Here is one of the main reasons. One of the most basic facts about limits in $\mathbb{R}$ or $\mathbb{R}^n$, or in general metric spaces, is that limits are unique (\textit{\textendash}). This property only holds in Hausdorff spaces:

**XI.7.4.1. Proposition.** Let $X$ be a topological space. Then $X$ is Hausdorff if and only if every convergent net in $X$ has a unique limit.

**Proof:** Suppose $X$ is Hausdorff, and $(x_i)$ is a net in $X$ with $x_i \to x$ and $x_i \to y$ with $x \neq y$. Let $U$ and $V$ be disjoint neighborhoods of $x$ and $y$ respectively. Then there is an $i_1$ such that $x_i \in U$ for all $i \geq i_1$, and there is an $i_2$ such that $x_i \in V$ for all $i \geq i_2$. If $i \geq i_1$ and $i \geq i_2$ (there is such an $i$ since the index set is directed), then $x_i \in U \cap V$, a contradiction. Thus the limit of a convergent net is unique.

Conversely, suppose $X$ is not Hausdorff, and let $x$ and $y$ be distinct points which do not have disjoint neighborhoods. Let $I = \{(U, V, z)\}$, where $U$ is a neighborhood of $x$, $V$ is a neighborhood of $y$, and $z \in U \cap V$. Put a preorder on $I$ by setting $(U_1, V_1, z_1) \leq (U_2, V_2, z_2)$ if $U_2 \subseteq U_1$ and $V_2 \subseteq V_1$. Then $I$ is a directed set. Set $x_{(U, V, z)} = z$; this defines a net with index set $I$, and this net converges to both $x$ and $y$. So limits of convergent nets are not unique.

**XI.7.4.2.** Note that the “if” part can be false if “net” is replaced by “sequence” if the space is not first countable (Exercise XI.7.8.12.). In a first countable space, the sequence version is true (\textit{\textendash}).

**XI.7.4.3.** Unlike the $T_0$ and $T_1$ properties, the Hausdorff property is not a local property. Say that a topological space $X$ is \textit{locally Hausdorff} if every point of $X$ has an open neighborhood which is Hausdorff in the relative topology. A Hausdorff space is obviously locally Hausdorff. But a locally Hausdorff space need not be Hausdorff (XI.19.1.3.(v)), although it is $T_1$ (XI.7.3.5.). However, see XI.7.8.4.

XI.7.5. Regular Spaces

The $T_3$ separation axiom has a simple reformulation which reinforces the utility of the axiom:

**XI.7.5.1. Proposition.** Let $X$ be a topological space. Then $X$ is a $T_3$ space if and only if, whenever $p$ is a point of $X$ and $U$ is an open neighborhood of $p$, there is an open neighborhood $V$ of $p$ with $\overline{V} \subseteq U$.

**Proof:** Suppose $X$ is $T_3$, and $U$ is an open neighborhood of $p$. Then $U^c$ is a closed set not containing $p$, so $p$ and $U^c$ have disjoint open neighborhoods $V$ and $W$. Then $\overline{V}$ is contained in the closed set $W^c$, hence in $U$. Conversely, suppose $X$ has the property in the statement, and $E$ is a closed set in $X$ and $p$ is a point of $X$ not in $E$. Then $U = E^c$ is an open neighborhood of $p$, so there is an open neighborhood $V$ of $p$ with $\overline{V} \subseteq U$. Then $V$ and $(\overline{V})^c$ are disjoint open neighborhoods of $p$ and $E$, so $X$ is a $T_3$ space.

In the presence of $T_3$, only the $T_0$ axiom is needed to give the Hausdorff property and thus regularity:
XI.7.5.2. **Proposition.** Let $X$ be a topological space which is $T_3$ and $T_0$. Then $X$ is Hausdorff, and thus regular.

**Proof:** Let $p$ and $q$ be distinct points of $X$. Suppose $p$ is not in the closure $E$ of $\{q\}$. Then $p$ and $E$ have disjoint open neighborhoods, which are disjoint open neighborhoods of $p$ and $q$. The same proof works if $q$ is not in the closure of $\{p\}$. Apply XI.7.2.1.

A set with the indiscrete topology and more than one point is an example of a $T_3$ space which is not $T_0$.

XI.7.6. **Normal Spaces**

XI.7.6.1. In the presence of $T_4$, the $T_1$ condition gives $T_2$, hence normality, as is obvious. However, unlike with regularity, $T_0$ is not enough: the Sierpiński space is $T_0$ and vacuously $T_4$, but not $T_1$. It is also obvious that normality implies regularity, although $T_4$ does not imply $T_3$ in the absence of $T_1$ (the Sierpiński space is again a counterexample).

There is an analog of XI.7.5.1. for normal spaces. The proof is virtually identical.

XI.7.6.2. **Proposition.** Let $X$ be a topological space. Then $X$ is a $T_4$ space if and only if, whenever $E$ is a closed set in $X$ and $U$ is an open neighborhood of $E$, there is an open neighborhood $V$ of $E$ with $V \subseteq U$.

XI.7.6.3. **Proposition.** A closed subspace of a $T_4$ space is $T_4$. Hence a closed subspace of a normal space is normal.

**Proof:** If $A$ is a closed subspace of a $T_4$ space $X$, and $Y, Z$ are (relatively) closed subsets of $A$, then $Y$ and $Z$ are closed in $X$, hence have disjoint neighborhoods $U, V$ in $X$. Then $A \cap U$ and $A \cap V$ are disjoint neighborhoods in $A$.

A general subspace of a normal space is not necessarily normal (XI.11.12.6.). However, an $F_\sigma$ in a normal space is normal (XI.7.8.7.).

An alternate way of phrasing normality is using partitions:

XI.7.6.4. **Definition.** Let $X$ be a topological space, and $Y, Z$ disjoint closed subsets of $X$. A partition between $Y$ and $Z$ in $X$ is a (necessarily closed) subset $P$ of $X$ such that there are open sets $U, V \subseteq X$ with $Y \subseteq U, Z \subseteq V, U \cap V = \emptyset$, and $X \setminus (U \cup V) = P$.

Note that there can be many partitions between disjoint subsets. A partition can be empty: $\emptyset$ is a partition between $Y$ and $Z$ in $X$ if (and only if) there is a clopen set $U$ in $X$ with $Y \subseteq U$ and $Z \subseteq (X \setminus U)$. 1050
XI.7.6.5. **Proposition.** Let $X$ be a topological space. Then $X$ is $T_4$ if and only if every pair of disjoint closed subsets of $X$ has a partition in $X$.

**Proof:** If every pair of disjoint closed subsets of $X$ has a partition in $X$, and $Y, Z$ are disjoint closed subsets of $X$, let $P$ be a partition between $Y$ and $Z$ in $X$; the associated $U$ and $V$ are disjoint neighborhoods of $Y$ and $Z$. Thus $X$ is $T_4$. Conversely, suppose $X$ is $T_4$ and $Y$ and $Z$ are disjoint closed subsets of $X$. Let $U$ and $V$ be disjoint neighborhoods of $Y$ and $Z$ in $X$; then $P = X \setminus (U \cup V)$ is a partition between $Y$ and $Z$ in $X$. \(\Box\)

XI.7.6.6. **Proposition.** A metrizable topological space is normal.

In fact, a metrizable space has a stronger property called *complete normality*. See XI.10.1.1. for a definition and proof. In particular, a metrizable space is regular and Hausdorff.

Every compact Hausdorff space is also normal (XI.11.4.3.).

Here is a useful refinement of the definition of normality:

XI.7.6.7. **Definition.** Let $X$ be a topological space, and $\mathcal{U} = \{U_i : i \in I\}$ a cover of $X$. A *shrinking* of $\mathcal{U}$ is a cover $\mathcal{V} = \{V_i : i \in I\}$ (same index set) with $V_i \subseteq U_i$ for all $i$. An *open [closed] shrinking* is a shrinking in which $\mathcal{V}$ is an open [closed] cover.

XI.7.6.8. **Proposition.** Let $X$ be a topological space. Then $X$ is $T_4$ if and only if every finite open cover of $X$ has a closed shrinking.

**Proof:** If $X$ is not $T_4$, let $Y$ and $Z$ be disjoint closed sets in $X$ which do not have disjoint neighborhoods. Then the open cover $\{X \setminus Y, X \setminus Z\}$ does not have a closed shrinking.

Conversely, suppose $X$ is $T_4$. We show by induction on the number of sets in the cover that every finite open cover of $X$ has a closed shrinking. First suppose $\mathcal{U} = \{U_1, U_2\}$ is an open cover of $X$. Then $X \setminus U_1$ and $X \setminus U_2$ are disjoint closed sets in $X$, and so have disjoint open neighborhoods $V_1, V_2$. Then $\{X \setminus V_1, X \setminus V_2\}$ is a closed shrinking of $\mathcal{U}$.

Now suppose every open cover with $n$ sets has a closed shrinking, and let $\mathcal{U} = \{U_1, \ldots, U_{n+1}\}$ be an open cover of $X$. There is a closed shrinking $\{E_1, \ldots, E_{n-1}, F\}$ for the open cover $\{U_1, \ldots, U_{n-1}, U_n \cup U_{n+1}\}$. Then $F$ is a closed subset of $X$, hence $T_4$, so the open cover $\{F \cap U_n, F \cap U_{n+1}\}$ of $F$ has a closed shrinking $\{E_n, E_{n+1}\}$. Then $\{E_1, \ldots, E_{n+1}\}$ is a closed shrinking of $\mathcal{U}$. \(\Box\)

There is a nice “dual” fact about normal spaces. We first make a definition:

XI.7.6.9. **Definition.** Let $X$ be a topological space, and $A_1, \ldots, A_n$ closed subsets of $X$. A *swelling* of $\{A_1, \ldots, A_n\}$ is a collection $\{U_1, \ldots, U_n\}$ of open sets in $X$ with $A_k \subseteq U_k$ for each $k$ and $U_{k_1} \cap U_{k_2} \cap \cdots \cap U_{k_m} = \emptyset$ for any $k_1, \ldots, k_m$ with $A_{k_1} \cap A_{k_2} \cap \cdots \cap A_{k_m} = \emptyset$. 1051
XI.7.6.10. PROPOSITION. Let \( X \) be a \( T_4 \) topological space, and \( A_1, \ldots, A_n \) closed subsets of \( X \). Then \( \{A_1, \ldots, A_n\} \) has a swelling.

PROOF: Let \( B_1 \) be the union of all sets of the form \( A_{k_1} \cap A_{k_2} \cap \cdots \cap A_{k_m} \) for which
\[
A_1 \cap A_{k_1} \cap A_{k_2} \cap \cdots \cap A_{k_m} = \emptyset .
\]

Since this is a finite union, \( B_1 \) is closed; and \( A_1 \) and \( B_1 \) are disjoint. By normality there are disjoint open neighborhoods \( U_1 \) and \( V_1 \) of \( A_1 \) and \( B_1 \), so that \( U_1 \) is disjoint from \( B_1 \).

Now repeat the process with \( A_2 \), with \( A_1 \) replaced by \( U_1 \): let \( B_2 \) be the union of all finite intersections of \( \{U_1, A_3, \ldots, A_n\} \) which are disjoint from \( A_2 \), and obtain an open neighborhood \( U_2 \) of \( A_2 \) with \( U_2 \) disjoint from \( B_2 \). Repeating the process \( n \) times (at the \( k \)'th step \( A_j \) is replaced by \( U_j \) for all \( j < k \)), we obtain a swelling \( \{U_1, \ldots, U_n\} \).

There are two important theorems about normality with nontrivial proofs. The first is due to ():

XI.7.6.11. THEOREM. A \( T_3 \) Lindelöf space is \( T_4 \). Thus a regular Lindelöf space is normal.

In fact, a stronger result holds: every regular Lindelöf space is paracompact (), and every paracompact space is normal (). But we give a straightforward proof of XI.7.6.11. which is simpler than the proofs of these two stronger results.

PROOF: Let \( X \) be a \( T_3 \) Lindelöf space, and \( E \) and \( F \) disjoint closed sets in \( X \). For each \( p \in E \), there is an open neighborhood \( W_p \) of \( p \) such that \( W_p \cap F = \emptyset \) (XI.7.5.1.). Then \( \{W_p : p \in E\} \cup \{E^c\} \) is an open cover of \( X \), so has a countable subcover \( \{E^c, W_1, W_2, \ldots\} \). Similarly, there is a countable cover \( \{F^c, Z_1, Z_2, \ldots\} \) of \( X \) with \( Z_n \cap E = \emptyset \) for all \( n \). We have \( E \subseteq \bigcup_n W_n \) and \( F \subseteq \bigcup_n Z_n \). Inductively define \( U_1 = W_1 \), \( V_1 = Z_1 \setminus U_1 \), \( U_2 = W_2 \setminus V_1 \), \( V_2 = Z_2 \setminus (U_1 \cup U_2) \), \( U_3 = W_3 \setminus (V_1 \cup V_2) \), etc. Each \( U_n \) and \( V_n \) is open, and \( U_n \cap V_n = \emptyset \) for all \( n \) and \( m \). If \( p \in E \), then \( p \in W_n \) for some \( n \), hence \( p \in U_n \) since \( p \notin V_m \subseteq Z_m \) for any \( m \). Similarly, if \( q \in F \), then \( q \in V_m \) for some \( m \). Thus \( U = \bigcup_n U_n \) and \( V = \bigcup_n V_n \) are disjoint neighborhoods of \( E \) and \( F \).

The second theorem is a key result showing that normal spaces can be completely studied by analytic methods (specifically, real-valued continuous functions):

XI.7.6.12. THEOREM. [URYSOHN’S LEMMA] Let \( X \) be a normal topological space. If \( E_0 \) and \( E_1 \) are disjoint closed sets in \( X \), then there is a continuous function \( f : X \to [0, 1] \) with \( f(x) = 0 \) for all \( x \in E_0 \) and \( f(x) = 1 \) for all \( x \in E_1 \).

This result is a special case of the Tietze Extension Theorem (), but we give a direct proof which is somewhat simpler.

PROOF: We will make repeated use of XI.7.6.2. Let \( U_0 = E_0^c \). Then \( U_0 \) is an open neighborhood of \( E_1 \). Let \( U_{1/2} \) be an open neighborhood of \( E_1 \) with \( U_{1/2} \subseteq U_0 \). Let \( U_{3/4} \) be an open neighborhood of \( E_1 \) with \( U_{3/4} \subseteq U_{1/2} \). \( U_0 \) is an open neighborhood of \( U_{1/2} \); let \( U_{1/4} \) be an open neighborhood of \( U_{1/2} \) with \( U_{1/4} \subseteq U_0 \). Continuing in this way, for each dyadic rational \( t \) with \( 0 \leq t < 1 \) choose an open neighborhood \( U_t \) of \( E_1 \) such that \( U_s \subseteq U_t \) if \( s < t \).
For $x \in X$ define $f(x) = \sup \{t : x \in U_t\}$ if $x \in U_0$ and $f(x) = 0$ if $x \in E_0$. Then $0 \leq f(x) \leq 1$ for all $x \in X$, and $f(x) = 1$ if $x \in E_1$. We show $f$ is continuous. If $(x_i)$ is a net in $X$ with $x_i \to x$, we show that $f(x_i) \to f(x)$. Let $t = f(x)$. If $t > 0$, then for any dyadic rational $s$, $0 \leq s < t$, we have $x \in U_s$; since $U_s$ is open, $x_i \in U_s$ for sufficiently large $i$, i.e. $f(x_i) \geq s$ for sufficiently large $i$. This shows that $f(x_i) \to f(x)$ if $t = 1$. Now suppose $t < 1$. If $s$ is any dyadic rational with $t < s < 1$, choose a dyadic rational $r$ with $t < r < s$. Then $x \notin U_r$. Since $\bar{U}_s \subseteq U_r$, $x$ is in the open set $(\bar{U}_s)^c$, so $x_i \in (\bar{U}_s)^c$ for sufficiently large $i$, i.e. $f(x_i) \leq s$ for sufficiently large $i$. Thus $f(x_i) \to f(x).$  

The Countable AC is used in this proof.

\textbf{XI.7.6.13.} Normality is a nice separation condition to have, but it is somewhat more delicate than the other conditions: for example, unlike all the other separation axioms it does not pass to subspaces or products in general (see XI.11.12.6. and XI.7.8.10. for counterexamples; cf. XI.10.1.2.).

\textbf{XI.7.7. Completely Regular Spaces}

Another separation axiom is commonly added to the hierarchy:

\textbf{XI.7.7.1. Definition.} Let $X$ be a topological space. Then $X$ is \textit{completely regular} if it is $T_0$ and, whenever $E$ is a closed set in $X$ and $p$ a point of $X$ not in $E$, there is a continuous function $f : X \to [0, 1]$ such that $f(p) = 1$ and $f(x) = 0$ for all $x \in E$.

\textbf{XI.7.7.2. Proposition.} A completely regular space is regular (and in particular Hausdorff).

\textbf{Proof:} Suppose $X$ is completely regular. If $E$ is a closed set in $X$ and $p$ a point of $X$ not in $E$, and $f$ is a continuous function from $X$ to $[0, 1]$ as in XI.7.7.1., then $f^{-1}((1/2, 1])$ and $f^{-1}([0, 1/2))$ are disjoint open neighborhoods of $p$ and $E$, so $X$ is $T_3$. Since $X$ is $T_0$, it is regular. 

\textbf{XI.7.7.3.} A normal space is completely regular by Urysohn’s Lemma. Thus the completely regular condition is a separation axiom between $T_3$ and $T_4$, and is sometimes called $T_{3 \frac{1}{2}}$ (with the usual ambiguity about whether the space is required to be Hausdorff). A completely regular space is also sometimes called a \textit{Tikhonov space}.

There are regular spaces which are not completely regular (see [SS95]), and completely regular spaces which are not normal, e.g. XI.19.5.8.

\textbf{XI.7.7.4. Theorem.} Let $X$ be a topological space. Then $X$ is homeomorphic to a subset of a compact Hausdorff space if and only if $X$ is completely regular.

\textbf{Proof:} Since compact Hausdorff spaces are normal (XI.11.4.3.) and hence completely regular, and complete regularity obviously passes to subspaces, the complete regularity condition is necessary. Conversely, let $X$ be completely regular. Let $\mathcal{C}$ be a set of continuous functions from $X$ to $[0, 1]$ such that for every closed set $E$ in $X$ and $p \in X \setminus E$, there is an $f \in \mathcal{C}$ with $f(p) = 1$ and $f = 0$ on $E$, and form the space $Y = [0, 1]^\mathcal{C}$ with the product topology. $Y$ is Hausdorff, and compact by Tikhonov’s theorem. Define a function $\phi : X \to Y$ by
letting ϕ(x) be the point whose f’th coordinate is f(x), for each f ∈ C. ϕ is continuous since its composition with each coordinate projection is continuous. We need only show that it is a homeomorphism, e.g. if (x_i) is a net in X, and x ∈ X with ϕ(x_i) → ϕ(x), then x_i → x. We have ϕ(x_i) → ϕ(x) if and only if f(x_i) → f(x) for every f ∈ C. If x_i ≠ x, there is a neighborhood U of x and a subnet (x_j) such that x_j ∉ U for all j. There is an f ∈ C such that f(x) = 1 and f(y) = 0 for all y ∈ U^c; for this f, f(x_j) = 0 for all j, so f(x_i) ≠ f(x), a contradiction.

XI.7.7.5. A good case can be made that complete regularity is the most natural restriction for topological spaces, and that completely regular spaces form the proper class of spaces to consider, especially for applications in analysis. This is the general thesis of [GJ76], for example. Completely regular spaces are precisely the spaces characterized by each of the following conditions:

(i) Spaces which can be embedded in compact Hausdorff spaces.
(ii) Spaces with a topology arising from a uniform structure.
(iii) Spaces whose topology is defined by a (separating) family of pseudometrics.
(iv) Spaces whose structure can be completely analyzed by study of real-valued continuous functions (i.e. analytic methods).

XI.7.8. Exercises

XI.7.8.1. Let X be a topological space. Show that the following are equivalent:

(i) Every singleton subset of X is an intersection of open sets.
(ii) Every subset of X is an intersection of open sets.
(iii) X is T_1.

XI.7.8.2. Let X = {a, b}, and let T = {∅, {a}, X}.

(a) Show that T is a topology on X.
(b) {b} is closed, but {a} is not closed; {a} is open, and the closure of {a} is X (i.e. {a} is dense in X).
(c) (X, T) satisfies T_0 and T_4, but not T_1, T_2, or T_3.
(d) If x_n = a for all n, then x_n → a and x_n → b.
(e) X is compact () and connected (). In fact, X is path-connected ()

(X, T) is called the Sierpiński space.

XI.7.8.3. (a) Let X be a T_0 space, and U a finite nonempty open subset of X. Show that U contains an open singleton subset of X. [Consider a minimal nonempty open subset of U.]
(b) Let X be a T_1 space, and U a finite nonempty open subset of X. Show that every point of U is an isolated point of X. In particular, a finite T_1 space has the discrete topology.

A T_0 space containing a nonempty finite open set need not have any isolated points, and not every singleton subset of a finite open set is open in general. The Sierpiński space is a counterexample to both.
XI.7.8.4. Let $X$ be a topological space.

(a) If each point of $X$ has a closed neighborhood which is Hausdorff in the relative topology, show that $X$ is Hausdorff.

(b) If each point of $X$ has a closed neighborhood which is $T_3$ in the relative topology, show that $X$ is $T_3$.

(c) (cf. [Eng89, 3.3.1]) If each point of $X$ has a closed neighborhood which is $T_{3\frac{1}{2}}$ in the relative topology, show that $X$ is $T_{3\frac{1}{2}}$.

(d) If each point of $X$ has a closed neighborhood which is [completely] regular in the relative topology, show that $X$ is [completely] regular.

Example XI.19.1.3.(v) shows that the word “closed” cannot be removed from any of the statements. Since there are locally compact Hausdorff spaces which are not normal (XI.11.12.6.), the corresponding statements with “$T_4$” or “normal” do not hold.

XI.7.8.5. (a) Let $X$ be a Hausdorff space. Suppose $X$ has a dense subspace $D$ of cardinality $\kappa$. Show that $\text{card}(X) \leq 2^{2^\kappa}$. Thus $\text{card}(X) \leq 2^{2^{|X|}}$ (XI.2.3.16.). [For each $p \in X$, let $\mathcal{A}_p = \{U \cap D : U$ an open neighborhood of $p\} \in \mathcal{P}(\mathcal{P}(D))\). Show that $\mathcal{A}_p \neq \mathcal{A}_q$ if $p \neq q$. In particular, a separable Hausdorff space has cardinality $\leq 2^{2^{\aleph_0}}$.

There are separable Hausdorff spaces of cardinality $2^{2^{\aleph_0}}$, even compact ones, e.g. $\beta\mathbb{N}$ and $[0,1]^\mathbb{C}$.

(b) Show that if $X$ is any set with the finite complement topology ($\mathcal{O}$), then any infinite subset of $X$ is dense, and hence $X$ is separable if $\text{card}(X) \geq \aleph_0$. Thus the conclusion of (a) fails in general for compact $T_1$ spaces, and there is no bound at all on the cardinality of such spaces.

(c) If $X$ is a separable, first countable Hausdorff space, show that $X$ has cardinality $\leq 2^{\aleph_0}$. [If $D$ is a countable dense set in $X$, for each $x \in X$ choose a sequence in $D$ converging to $x$.] In general, if $X$ is Hausdorff, we have $\text{card}(X) \leq d(X)^{\chi(X)}$ (XI.1.2.11., XI.2.3.16.).

Note that unlike for (a), the Axiom of Choice is needed for (c).

XI.7.8.6. (a) Let $X$ be a regular space. Suppose $X$ has a dense subspace $D$ of cardinality $\kappa$. Show there is a base for the topology of cardinality $\leq 2^\kappa$. Thus $\mathcal{W}(X) \leq 2^{d(X)}$ (XI.1.2.11., XI.2.3.16.). [If $\{U_i : i \in I\}$ is a base, for each $i$ set $V_i = [(U_i \cap D)^-]^{\mathcal{O}}$. Note that $U_i \subseteq V_i \subseteq \bar{U}_i$. Show that $\{V_i : i \in I\}$ is a base of cardinality $\leq 2^\kappa$.]

(b) If $X$ is a $T_0$-space, and there is a base for the topology of cardinality $\kappa$, then $\text{card}(X) \leq 2^\kappa$. Thus $\text{card}(X) \leq 2^{d(X)}$ (XI.1.2.11.). [If $\mathcal{U}$ is the base, associate to each $p$ the collection $\mathcal{U}_p$ of all elements of $\mathcal{U}$ containing $p$.]

(c) Combine (a) and (b) to give an alternate proof of XI.7.8.5.(a) for regular spaces.

XI.7.8.7. (a) Let $X$ be a $T_1$ topological space. Show that $X$ is normal if and only if, whenever $E$ is a closed set in $X$ and $U$ an open set in $X$ containing $E$, there is a sequence $(V_n)$ of open sets in $X$ with $V_n \subseteq U$ for all $n$ and $E \subseteq \bigcup_{n=1}^{\infty} V_n$. If $A$ and $B$ are disjoint closed subsets of $X$, choose such sequences $(V_n)$ for $A$ in $X \setminus B$ and $(W_n)$ for $B$ in $X \setminus A$. Then

$$\bigcup_{n=1}^{\infty} \left( V_n \setminus \left[ \bigcup_{k \leq n} \bar{W}_k \right] \right) \quad \text{and} \quad \bigcup_{n=1}^{\infty} \left( W_n \setminus \left[ \bigcup_{k \leq n} \bar{V}_k \right] \right)$$
are disjoint neighborhoods of $A$ and $B$.]
(b) Use (a) to show that every $F_{\sigma}$ in a normal space is normal.

**XI.7.8.8.** [Pea75] Make the following definitions:

**Definition.** Let $X$ be a topological space.

A subset $Y$ of $X$ is a *generalized $F_{\sigma}$* in $X$ if, whenever $U$ is an open neighborhood of $Y$ in $X$, there is an $F$ which is an $F_{\sigma}$ in $X$ with $Y \subseteq F \subseteq U$.

A subset $Y$ of $X$ is *normally situated* in $X$ if, whenever $U$ is an open neighborhood of $Y$ in $X$, there is a locally finite cover $\{V_i : i \in I\}$ of $Y$ with each $V_i$ an open $F_{\sigma}$ in $X$ contained in $U$.

$X$ is *totally normal* if $X$ is normal and every subset of $X$ is normally situated in $X$.

(a) Show that if $X$ is normal, then every generalized $F_{\sigma}$ in $X$ is normally situated in $X$. [Use (a).]

(b) Show that if $X$ is normal and $Y$ is normally situated in $X$, then $Y$ is normal.

(c) Show that every subspace of a totally normal space is totally normal.

(d) Show that every totally normal space is completely normal (XI.10.1.2.).

(e) Show that the space of ordinals less than or equal to the first uncountable ordinal (which is completely normal by XI.16.1.1.) is not totally normal (cf. XI.11.12.10.).

(f) Show that every perfectly normal space (XI.10.4.10.) is totally normal. Give an example of a totally normal space which is not perfectly normal.

(g) What is the relationship between total normality and (hereditary) paracompactness (XI.11.10.3.)?

**XI.7.8.9.** Show that a separable normal space cannot have a closed discrete subspace of cardinality $2^{\aleph_0}$. [Count the number of real-valued continuous functions and apply Urysohn’s Lemma.] More generally, if $X$ is normal and has a dense set of cardinality $\kappa$, and a closed discrete subspace of cardinality $\lambda$, then $2^\lambda \leq 2^\kappa$; in particular, $X$ cannot have a closed discrete subspace of cardinality $2^\kappa$ (Jones’s Lemma).

**XI.7.8.10.** The Sorgenfrey Line. Put a topology $S$ on $\mathbb{R}$ by taking $\{(a,b) : a, b \in \mathbb{R}, a < b\}$ as a base.

(Many references use base sets of the form $[a,b)$, which gives a different but homeomorphic topology.) $(\mathbb{R}, S)$ is called the Sorgenfrey line, denoted $S$.

(a) Show that $S$ is stronger than the usual topology on $\mathbb{R}$, and thus is Hausdorff.

(b) Show that $S$ is zero-dimensional, hence normal. [Show that $(a,b)$ is clopen for all $a < b$.]

(c) Show that any bounded nondecreasing sequence in $\mathbb{R}$ converges in $S$ to its limit in $\mathbb{R}$, but that no strictly decreasing sequence converges in $S$.

(d) Show that $S$ is first countable and separable.

(e) Show that every subset $A$ of $S$ is separable and Lindelöf. [Show that $\{x \in A : (x - \epsilon, x) \cap A = \emptyset \text{ for some } \epsilon > 0\}$ is countable. Then show that if $U$ is an open cover of $A$, and $V$ is the union of all intervals $(a,b)$ for which $(a,b)$ is contained in some element of $U$, then $A \setminus V$ is countable.] In particular, $S$ is (hereditarily) paracompact.

(f) Show that every closed subset of $S$ is a $G_\delta$. Thus $S$ is perfectly normal (XI.10.4.10.), hence completely normal.
(g) Show that a subset of $S$ is compact if and only if it is closed in the usual topology of $\mathbb{R}$, bounded above, and has no strictly decreasing sequences (i.e. is well ordered in the usual ordering). Conclude that every compact subset of $S$ is countable (cf. ()). In particular, $S$ is not locally compact or $\sigma$-compact.

(h) Show that $S \times S$ is not normal. [The set \{(x, -x) : x \in S\} is a closed discrete subset of $S \times S$ of cardinality $2^{\aleph_0}$. Apply Exercise XI.7.8.9. Alternatively, show using the Baire Category Theorem that \{(x, -x) : x \in \mathbb{Q}\} and \{(x, -x) : x \in \mathbb{I}\} do not have disjoint neighborhoods.] So $S \times S$ is not paracompact or Lindelöf. Note that $S \times S$ is separable, first countable, and completely regular.

(i) Show that $S$ is not second countable. [If it were, it would be metrizable, so $S \times S$ would also be metrizable. There is also a simple direct proof.]

(j) Show that $S$ is a Baire space ().

(k) Give $\mathbb{R} \times \{0, 1\}$ the lexicographic ordering and the order topology. Show that $S$ is homeomorphic to the subspace $\mathbb{R} \times \{0\}$ with the relative topology. Thus $S$ is a suborderable space (XI.1.6.4), and hence completely collectionwise normal (XI.16.1.1). But $S$ is not an orderable space.

The Sorgenfrey line provides a simple counterexample for many seemingly plausible statements, particularly about product spaces. If $T$ is the subset of $S$ consisting of irrational numbers, with the relative topology, it is plausible that $T$ is homeomorphic to $S$ since $S$ is zero-dimensional; but in fact $T$ is not homeomorphic to $S$ [?].

XI.7.8.11. Let $\mathcal{T}$ be the usual topology on $\mathbb{R}$ and $S$ the Sorgenfrey topology (XI.7.8.10.).

(a) Which functions from $\mathbb{R}$ to $\mathbb{R}$ are continuous from $(\mathbb{R}, S)$ to $(\mathbb{R}, T)$?

(b) Which functions from $\mathbb{R}$ to $\mathbb{R}$ are continuous from $(\mathbb{R}, T)$ to $(\mathbb{R}, S)$?

(c) Which functions from $\mathbb{R}$ to $\mathbb{R}$ are continuous from $(\mathbb{R}, S)$ to $(\mathbb{R}, S)$?

XI.7.8.12. Let $X$ be an uncountable set with the countable complement topology (XI.1.6.4.).

(a) Show that $X$ is $T_1$ but not Hausdorff.

(b) Show that a sequence in $X$ converges if and only if it is eventually constant. Thus the convergent sequences in this topology are the same as the convergent sequences in the discrete topology.

(c) Every convergent sequence in $X$ has a unique limit. Contrast with XI.7.4.1..

XI.7.8.13. Smirnov’s Deleted Sequence Topology [SS95, #64]. Let $A = \{\frac{1}{n} : n \in \mathbb{N}\} \subseteq \mathbb{R}$. Let $\mathcal{T}$ be the usual topology on $\mathbb{R}$. Define a topology $\mathcal{S}$ on $\mathbb{R}$ by

$$\mathcal{S} = \{U \setminus B : U \in \mathcal{T}, B \subseteq A\} .$$

(a) Show that $\mathcal{S}$ is a topology on $\mathbb{R}$ which is stronger than $\mathcal{T}$.

(b) Show that $(\mathbb{R}, \mathcal{S})$ is Hausdorff.

(c) Show that $(\mathbb{R}, \mathcal{S})$ is not regular. [$A$ is a closed set, $0 \notin A$, but $0$ and $A$ do not have disjoint neighborhoods.]

(d) Repeat the construction with $A$ replaced by any nonclosed set with dense complement, e.g. $\mathbb{Q}$. 1057
XI.7.8.14. **The Tangent Disk Space** [SS95, Example 82]. Let $X$ be the closed upper half plane in $\mathbb{R}^2$. Let $\mathcal{T}$ be the collection of all unions of subsets of $X$ of the following types:

(i) Any subset of the open upper half plane which is open in the ordinary topology.

(ii) The union of $\{(a,0)\}$ and an open disk of radius $r$ ($r > 0$) centered at $(a, r)$, for some $a \in \mathbb{R}$ (an open disk in the upper half plane tangent to the $x$-axis at $a$).

(a) Show that $\mathcal{T}$ is a topology on $X$ which is stronger than the relative Euclidean topology.

(b) Show that $(X, \mathcal{T})$ is separable and first countable.

(c) Show that $(X, \mathcal{T})$ is completely regular.

(d) Show that $(X, \mathcal{T})$ is not normal. [Show that the relative topology on the $x$-axis is the discrete topology, and apply XI.7.8.9.]

This example is due to Niemytzki [] and is called the Niemytzki tangent disk space or Niemytzki plane. Some references call it the Moore plane, which is not historically accurate and can be confused with the Moore manifold XI.19.5.8., which is not the same (to make matters worse, the Moore manifold has been occasionally called the Niemytzki plane!)

XI.7.8.15. Show that every infinite Hausdorff space contains a sequence of pairwise disjoint nonempty open sets. (There is a simple argument using DC. Some form of Choice is needed; cf. II.9.4.11.)

XI.7.8.16. Let $R$ be a unital ring (III.3.6.3.). Let $\text{Spec}(R)$ be the set of prime ideals (II.6.4.12.) in $R$. Put a topology on $\text{Spec}(R)$ as follows. If $E \subseteq \text{Spec}(R)$, set

$$\ker(E) = \bigcap_{P \in E} P$$

and define

$$\widehat{E} = \{ P \in \text{Spec}(R) : \ker(E) \subseteq P \}.$$

More generally, if $A \subseteq R$, define

$$\text{hull}(A) = \{ P \in \text{Spec}(R) : A \subseteq P \}$$

so that $\widehat{E} = \text{hull}(\ker(E))$.

(a) Show that $E \mapsto \widehat{E}$ is a Kuratowski closure operator (XI.2.4.1.), hence defines a topology on $\text{Spec}(R)$, called the hull-kernel or Jacobson topology on $\text{Spec}(R)$ (if $R$ is commutative, it is also called the Zariski topology).

(b) Show that the hull-kernel topology is always $T_0$.

(c) Show that the hull-kernel topology on $\text{Spec}(\mathbb{Z})$ is not $T_1$.

(d) Show that $\text{Spec}(R)$ is compact in the hull-kernel topology.

(e) Let Maxspec($R$) be the subset of $\text{Spec}(R)$ consisting of the maximal ideals (II.6.4.12.) of $R$, with the hull-kernel topology (which is the relative topology). Show that Maxspec($R$) is closed in $\text{Spec}(R)$, hence also compact, and always $T_1$. Show that Maxspec($\mathbb{Z}$) is not Hausdorff.

(f) Explain why prime ideals must be used, i.e. what goes wrong if we try to take $\text{Spec}(R)$ to be the set of all (proper) ideals in $R$?

$\text{Spec}(R)$, or certain natural subsets like Maxspec($R$), with the hull-kernel topology, is a fundamental object of study in several parts of mathematics, including Operator Algebras () and Algebraic Geometry ().
XI.7.8.17. **Other Separation Axioms.** Several other separation axioms have been considered. Here are two of them.

**Definition.** Let $X$ be a topological space. $X$ is **completely Hausdorff**, or $T_{2^{1/2}}$, if distinct points of $X$ have disjoint closed neighborhoods.

$X$ is **Urysohn** if, whenever $p, q \in X$, $p \neq q$, there is a continuous function $f : X \to [0, 1]$ with $f(p) = 0$ and $f(q) = 1$ (equivalently, there is a continuous $g : X \to \mathbb{R}$ with $g(p) \neq g(q)$).

(a) Show that the two conditions in the definition of an Urysohn space are equivalent.

(b) Show that a regular space is completely Hausdorff (use XI.7.5.1.).

(c) Show that an Urysohn space is completely Hausdorff.

(d) Show that any topology stronger than a completely Hausdorff topology [resp. Urysohn topology] is completely Hausdorff [resp. Urysohn].

A completely Hausdorff space is obviously Hausdorff, and a completely regular space is Urysohn. There are Hausdorff spaces which are not completely Hausdorff (XI.7.8.18.), in fact in which no two points have disjoint closed neighborhoods [SS95, Example 75]. There are Urysohn spaces which are not regular, hence not completely regular (XI.7.8.13.), completely Hausdorff spaces which are neither regular nor Urysohn [SS95, Example 80], and regular spaces which are not Urysohn [SS95, Example 90].

There has been a bizarre reversal in terminology concerning these two axioms. Our definitions are the ones from [SS95], which were apparently universally used until that time (see e.g. [Bou98]). For unknown reasons, the definitions were reversed in [Wil04]: what we call “completely Hausdorff” is called “Urysohn” there, and vice versa. Since the publication of [Wil04], usage of the terms has been inconsistent but has tended to follow [Wil04]. The earlier definitions make more sense to me since “Urysohn functions” separating points or points and closed sets are standard terminology (although using “completely Hausdorff” in WILLARD’S sense would be in analogy with the term “completely regular,” note that the “completely” in “completely normal” means something completely different). My guess is that WILLARD simply made a mistake, which has been perpetuated since; if he had deliberately changed established terminology he probably would have said so and given a reason, and I find it hard to believe he would worry about doing so in such a relatively minor side thread of topology. I have thus reverted to the historical definitions. It would be good if topologists would definitively decide what these definitions should be. There is one additional term sometimes used: spaces which are Urysohn according to our definition are sometimes called **functionally Hausdorff**. (In analogy, completely regular spaces could be called **functionally regular**; “functionally normal” is the same as normal by Urysohn’s Lemma.)

XI.7.8.18. **Double Origin Topology** (ALEKSANDROV and URYSOHN, cf. [SS95, Example 74]). Let $X = \mathbb{R}^2 \cup \{0\}$. Give $X$ a topology $\mathcal{T}$ consisting of all unions of the following types of sets: any subset of $X \setminus \{0, 0'\}$ which is open in $\mathbb{R}^2 \setminus \{0\}$ in the usual topology; the union of $\{0\}$ and an open half-disk in the upper half plane centered at $0$; the union of $\{0'\}$ and an open half-disk in the lower half plane centered at $0$.

(a) Show that $\mathcal{T}$ is a topology on $X$.

(b) Show that $(X, \mathcal{T})$ is Hausdorff.

(c) Show that $0$ and $0'$ do not have disjoint closed neighborhoods. Thus $(X, \mathcal{T})$ is not completely Hausdorff.

(d) Show that $(X, \mathcal{T})$ is path-connected.
XI.8. Quotient Spaces and the Quotient Topology

In this section, we will examine what happens when we take a topological space $X$ and “collapse” various subsets of $X$ to points.

Recall (II.3.3.9.) that there are three equivalent points of view for identifying subsets of a set $X$:

(i) Equivalence relations on $X$.

(ii) Partitions of $X$.

(iii) Functions from $X$ onto another set $Y$.

We suppose the set $X$ has a given topology, and want to topologize the set of equivalence classes, or the set $Y$, in an appropriate way. This topological space will be called the quotient space of $X$ by the relation.

Many constructions in topology amount to forming a quotient space.

XI.8.1. The Quotient Topology

We first take the point of view of having a function $f$ from our set $X$ onto another set $Y$. If $X$ has a specified topology $T$, we want to put a topology $T_f$ on $Y$ which makes $f$ continuous, and which is “universal”, i.e. the strongest possible. There is an obvious way to do this, since for $f$ to be continuous $f^{-1}(V)$ must be in $T$ for every $V \in T_f$ (cf. XI.5.1.14.).

XI.8.1.1. Definition. Let $(X, T)$ be a topological space, and $f : X \to Y$ a surjective function. The quotient topology on $Y$ from $f$ is the topology

$$T_f = \{ V \subseteq Y : f^{-1}(V) \in T \}.$$ 

In other words, a subset of $Y$ is open in the quotient topology if and only if its preimage in $X$ is open. Equivalently, a subset of $Y$ is closed in the quotient topology if and only if its preimage in $X$ is closed.

It is easily checked () that the quotient topology is indeed a topology. The quotient topology on $Y$ has a universal property. If $g$ is a function from $X$ to a set $Z$, and $g(x_1) = g(x_2)$ whenever $x_1, x_2 \in X$ and $f(x_1) = f(x_2)$, then there is an induced function $\tilde{g} : Y \to Z$ with $g = \tilde{g} \circ f$. The next result is obvious from the definition of the quotient topology.

XI.8.1.2. Proposition. Let $X$ be a topological space, and $f$ a surjective function from $X$ to $Y$. Give $Y$ the quotient topology. If $Z$ is a topological space and $g : X \to Z$ factors through $f$, i.e. $g = \tilde{g} \circ f$, then $g$ is continuous if and only if $\tilde{g}$ is continuous.
XI.8.1.3. **Examples.** (i) Let $\pi_1$ be the projection of $\mathbb{R}^2$ onto the $x$-axis, regarded as $\mathbb{R}$, i.e. $\pi_1(x, y) = x$. It is easily seen that the quotient topology on $\mathbb{R}$ is the ordinary topology (inverse images of sets in $\mathbb{R}$ are unions of vertical lines through points of the set). More generally, if $X$ and $Y$ are topological spaces, the projection from $X \times Y$ onto $X$ (or onto $Y$) is a quotient map, i.e. the quotient topology on $X$ is the given topology.

(ii) Let $X = [0, 1]$, $Y$ the unit circle in $\mathbb{R}^2$, and $f(t) = (\cos 2\pi t, \sin 2\pi t)$. Then $f$ is surjective, and one-to-one except at the endpoints. It is easy to check that the quotient topology on $Y$ is the usual topology (relative topology from $\mathbb{R}^2$). Thus we can regard a circle as the quotient of a closed interval with the endpoints identified.

Not all quotient spaces are this nice (cf. XI.8.1.11).

XI.8.1.4. The quotient topology is not the only topology on $Y$ making $f$ continuous in general; any weaker topology (e.g. the indiscrete topology) also will. But by XI.8.1.2. (taking $Z = Y$ and $g = f$), the quotient topology is the strongest topology on $Y$ making $f$ continuous. For example, if $f : X \to X$ is the identity function, the quotient topology on $X$ from $f$ is precisely the original topology on $X$.

**Quotients by Equivalence Relations**

XI.8.1.5. Now switch to the equivalent point of view of an equivalence relation $\sim$ on $X$. The set $Y$ can be identified with the set of equivalence classes, and the function $f : X \to Y$ is the function $f(x) = [x]$. We will write $X/\sim$ for $Y$ from this point of view, and call $f$ the projection, quotient map, or identification map, of $X$ onto $X/\sim$, which is called the quotient space or identification space of $X$ by $\sim$. We give $X/\sim$ the quotient topology.

XI.8.1.6. **Definition.** Let $\sim$ be an equivalence relation on a set $X$.

(i) A subset $A$ of $X$ is saturated if it is closed under $\sim$, i.e. if $x \in A$ and $y \sim x$, then $y \in A$.

(ii) If $A \subseteq X$, the saturation of $A$ is the set of all elements of $X$ equivalent to an element of $A$.

XI.8.1.7. It is obvious that the saturation of a subset of $X$ is saturated, and is the smallest saturated set containing $A$. If $f : X \to X/\sim$ is the projection from $X$ to $X/\sim$, the saturation of $A$ is precisely $f^{-1}(f(A))$. More generally, a subset $A$ of $X$ is saturated if and only if $A = f^{-1}(B)$ for some subset $B$ of $X/\sim$. In fact, $A = f^{-1}(f(A))$ if $A$ is saturated.

A saturated set is just a union of equivalence classes. An arbitrary union, intersection, or complement of saturated sets is saturated.

XI.8.1.8. The quotient map $f : X \to X/\sim$, besides being continuous, has the additional property that if $U$ is a saturated open set in $X$, then $f(U)$ is open in $X/\sim$, or equivalently (since the complement of a saturated open set is a saturated closed set, and vice versa) if $E$ is a saturated closed set in $X$, then $f(E)$ is closed in $X/\sim$. A surjective continuous map from a topological space $X$ to $Y$ with the quotient topology has this property for the equivalence relation defined by $x_1 \sim x_2$ if $f(x_1) = f(x_2)$.

It would be natural to give this type of function a name. Three names have been proposed and used in various references: (1) strongly continuous, first used in [AH74]; (2) bicontinuous, first used in [Kur66];
(3) quasi-compact, first used in [Why50]. None of the names have become generally established, and none is satisfactory since, among other reasons, they are all also sometimes used to mean other things. The term quasi-compact is the most unsatisfactory, since this term is sometimes used for spaces which are compact but not necessarily Hausdorff, and a mapping of the above type has nothing to do with quasi-compactness, and anyway the term quasi-compact mapping is commonly used to mean something else in algebraic geometry (more appropriately related to quasi-compactness). The term strongly continuous is also not appropriate, since it is too easily confused with the common use of “strongly continuous” in functional analysis (), and anyway it does not have the right intuitive connotation: a better term (which we do not seriously advocate) would be barely continuous, since the topology on Y is “just barely” weak enough to make the function continuous. The term bicontinuous is the least objectionable and we will use it, although it is also used to refer to simultaneous continuity with respect to two pairs of topologies (cf. [Kel63]). The term “bicontinuous” is especially appropriate in our context in the case where f is also injective: f is then bicontinuous if and only if both f and f⁻¹ are continuous (i.e. f is a homeomorphism).

It is easily seen that, conversely, if X and Y are topological spaces and f is a surjective continuous map which is bicontinuous in the above sense, then the topology on Y is necessarily the quotient topology. Thus we obtain:

XI.8.9.  PROPOSITION. Let X and Y be topological spaces and f a surjective function from X to Y. Then the topology on Y is the quotient topology from f (i.e. f is a quotient map) if and only if f is bicontinuous.

XI.8.10. This proposition characterizes when a surjective continuous function is a quotient map. Since it is obvious that a surjective continuous function which is either open or closed is bicontinuous, it follows that any such map is a quotient map. But a bicontinuous map need not be either open or closed (XI.8.11).

A quotient space can be badly behaved:

XI.8.11.  EXAMPLE. Let ~ be the equivalence relation on R defined by x ~ y if x − y ∈ Q (). Then each equivalence class is dense in R. Let f : R → R/~ be the projection. If E is a nonempty closed set in R/~, then f⁻¹(E) is a saturated closed subset of R. Since each equivalence class is dense, f⁻¹(E) is dense in R, hence f⁻¹(E) = R, E = R/~. Thus the quotient topology on R/~ is the indiscrete topology.

The same argument works for any X and ~ if all equivalence classes are dense in X.

XI.8.2.  Semicontinuous Decompositions

We want some conditions on ~ which will give that the quotient map f is closed or open. These are easily describable:

XI.8.2.1.  PROPOSITION. Let (X, T) be a topological space, ~ an equivalence relation on X, and f : X → X/~ the quotient map. The following are equivalent:

(i) The saturation of every closed set in X is closed.
(ii) If \( p \) is any point of \( X \), and \( U \) is an open neighborhood of \([p]\), then there is a saturated open set \( V \subseteq X \) with \([p] \subseteq V \subseteq U\).

(iii) If \( A \) is any saturated subset of \( X \), and \( U \) is an open neighborhood of \( A \), then there is a saturated open set \( V \subseteq X \) with \( A \subseteq V \subseteq U\).

(iv) If \( U \) is an open set in \( X \), the union of all saturated subsets of \( U \) is also open.

(v) \( f \) is a closed mapping.

An equivalence relation or partition of \( X \) satisfying these conditions is called an upper semicontinuous (usc) decomposition of \( X \).

**Proof:** (iii) \( \Rightarrow \) (ii) is trivial, and for the converse, suppose \( A \) is saturated and \( U \) is an open neighborhood of \( A \). For each \( p \in A \) let \( V_p \) be a saturated open neighborhood of \([p]\) contained in \( U \). Then \( V = \cup_p V_p \) is a saturated open neighborhood of \( A \) contained in \( U \).

(i) \( \Rightarrow \) (ii): Let \( p \in X \) and \( U \) an open neighborhood of \([p]\). Then \( U^c \) is closed, so the saturation \( B \) of \( U^c \) is closed. If \( p \in B \), then there is a \( q \in X \), \( q \sim p \), with \( q \in U^c \), contradicting that \([p] \subseteq U \). Thus \( V = B^c \) is a saturated open set containing \([p]\) and contained in \( U \).

(iii) \( \Rightarrow \) (i): Let \( E \) be a closed subset of \( X \), and \( B \) its saturation. Then \( U = E^c \) is an open neighborhood of the saturated set \( A = B^c \), so there is a saturated open neighborhood \( V \) of \( A \) contained in \( U \). The saturated closed set \( V^c \) contains \( U^c = E \) and is contained in \( A^c = B \); since \( B \) is the saturation of \( E \), we have \( V^c = B \) and \( B \) is closed.

(i) \( \iff \) (iv): Let \( U \) be open. Then the saturation of \( U^c \) is precisely the complement of the union of all saturated subsets of \( U \).

(i) \( \iff \) (v): If \( E \) is a closed set in \( X \), and \( B \) is the saturation of \( E \), then \( B \) is closed if and only if \( f(B) = f(E) \) is closed.

There is a similar characterization of when a quotient map is open, although there does not appear to be a clean analog of conditions (ii)–(iv).

**XI.8.2.2. Proposition.** Let \((X, T)\) be a topological space, \(\sim\) an equivalence relation on \(X\), and \(f : X \to X/\sim\) the quotient map. Then \(f\) is an open mapping if and only if the saturation of every open set in \(X\) is open.

An equivalence relation or partition of \(X\) satisfying these conditions is called a lower semicontinuous (lsc) decomposition of \(X\).

**XI.8.2.3.** More generally, if \(X\) and \(Y\) are topological spaces and \(2^X\) is given the topology of \((\cdot)\), a similar definition can be made for a function from \(Y\) to \(2^X\) to be upper or lower semicontinuous. There is a (somewhat tenuous) connection with upper and lower semicontinuous functions from \(\mathbb{R}\) to \(\mathbb{R}\) \((\cdot)\), which may have motivated the terminology for decompositions. See [Kur66, p. 174].

A decomposition which is both upper and lower semicontinuous is called continuous. A decomposition is continuous if and only if the quotient map is both open and closed.

Combining these characterizations with **XI.8.1.10.**, we obtain:
XI.8.2.4. Proposition. Let X and Y be topological spaces, and \( f : X \to Y \) a continuous surjection. If \( f \) is closed [open], then \( f \) is a quotient map and the corresponding decomposition of \( X \) isusc [lsc].

XI.8.2.5. Examples. (i) The decomposition of XI.8.1.3.(i) is lower semicontinuous but not upper semicontinuous: if \( E \) is the closed set \( \{ (x, y) : xy = 1 \} \) of \( \mathbb{R}^2 \), the saturation of \( E \) is \( \mathbb{R}^2 \) with the y-axis removed, and \( \pi_1(E) = \mathbb{R} \setminus \{0\} \), which are not closed. The projection \( \pi_1 \) is open ()

(ii) The decomposition of XI.8.1.3.(ii) is upper semicontinuous but not lower semicontinuous. Upper semicontinuity is obvious since only one equivalence class has more than one point. But the saturation and image of the open set \( [0, \frac{1}{2}) \) is not open.

(iii) Let \( \pi_1 \) be projection of \( [0, 1]^2 \) onto the first coordinate. Then the corresponding decomposition of \( [0, 1]^2 \) into vertical line segments is continuous (), ()

(iv) The decomposition of XI.8.1.11. is neither upper nor lower semicontinuous.

XI.8.3. Separation Axioms for Quotient Spaces

Since a primary use of quotient spaces is to construct new topological spaces, it is important to know how properties of \( X \), especially separation properties, pass to \( X/\sim \). Example XI.8.1.11. shows that nothing is preserved in general; however, under reasonable and verifiable conditions separation properties do pass to quotients.

We begin with a simple observation:

XI.8.3.1. Proposition. Let \( \sim \) be an equivalence relation on a topological space \( X \). Then \( X/\sim \) is a \( T_1 \) space if and only if each equivalence class is closed.

XI.8.3.2. Corollary. Let \( \sim \) be an equivalence relation on a \( T_1 \) topological space \( X \), and \( f : X \to X/\sim \) the quotient map. If \( f \) is closed (i.e. if the decomposition is usc), then \( X/\sim \) is \( T_1 \).

Proof: If \( p \in X \), then \( \{p\} \) is closed in \( X \), and hence its saturation \( [p] \) is also closed. 

An important variation is that the equivalence relation is closed:

XI.8.3.3. Definition. Let \( X \) be a topological space. A relation \( R \) on \( X \) is closed if it is a closed subset of \( X \times X \) with the product topology.

More generally, we can define closed relations from one topological space to another.
XI.8.3.4. If is an equivalence relation, the condition that is closed implies that each equivalence class is closed. But the conditions are not equivalent: for example, if is a $T_1$ space which is not Hausdorff, the equality relation on $X$ has closed equivalence classes (singletons) but is not a closed relation (i.e. the diagonal is not closed in $X \times X$, cf. (ii)).

This example shows that for an equivalence relation, being closed is not closely related to being upper or lower semicontinuous: the equality relation on a topological space is always both upper and lower semicontinuous, but only closed if the space is Hausdorff. Conversely, the equivalence relations of XI.8.2.5.(i)-(ii) are closed, but the decompositions fail to be lsc and usc respectively.

XI.8.3.5. Proposition. Let be an equivalence relation on a topological space $X$. If $X/ \sim$ is Hausdorff, then $\sim$ is closed.

Proof: Suppose $\sim$ is not closed. Then there is a net $((x_i, y_i))$ in $X \times X$ converging to an $(x, y) \in X \times X$ with $x_i \sim y_i$ for all $i$ but $x \not{\sim} y$. If $f : X \to X/ \sim$ is the quotient map, then the net $(f(x_i)) = (f(y_i))$ in $X/ \sim$ in $X/ \sim$ converges to both $f(x)$ and $f(y)$, so $X/ \sim$ is not Hausdorff.

The converse of XI.8.3.5. is not true in general. But we have:

XI.8.3.6. Proposition. Let be an equivalence relation on a topological space $X$, and $f : X \to X/ \sim$ the quotient map. If $f$ is open (i.e. the decomposition is lsc) and $\sim$ is closed, then $X/ \sim$ is Hausdorff.

Proof: Let $y_1, y_2 \in X/ \sim$ and $x_1, x_2 \in X$ with $f(x_1) = y_1, f(x_2) = y_2$. Then $x_1 \not{\sim} x_2$, so, since $\sim$ is closed, there are open neighborhoods $V$ and $W$ of $x_1$ and $x_2$ such that $V \times W$ is disjoint from the relation $\sim$. Then $f(V)$ and $f(W)$ are disjoint open neighborhoods of $y_1$ and $y_2$.

XI.8.3.7. The converse of XI.8.3.6. is also false in general: in XI.8.2.5.(ii), the quotient space is Hausdorff but the decomposition is not lsc. We also have:

XI.8.3.8. Proposition. Let be an equivalence relation on a $T_4$ topological space $X$, and $f : X \to X/ \sim$ the quotient map. If $f$ is closed (i.e. if the decomposition is usc), then $X/ \sim$ is $T_4$.

Proof: Let $E_1$ and $E_2$ be disjoint closed subsets of $X/ \sim$. Then $f^{-1}(E_1)$ and $f^{-1}(E_2)$ are disjoint closed subsets of $X$, so they have disjoint open neighborhoods $V$ and $W$. We have that $V^c$ and $W^c$ are closed and $V^c \cup W^c = X$, so $f(V^c)$ and $f(W^c)$ are closed in $X/ \sim$ and $f(V^c) \cup f(W^c) = X/ \sim$. Thus $U_1 = [f(V^c)]^c$ and $U_2 = [f(W^c)]^c$ are disjoint open sets. Since $f^{-1}(E_1) \subseteq V, f(V^c)$ is disjoint from $E_1$ and $E_1 \subseteq U_1$. Similarly, $E_2 \subseteq U_2$.

XI.8.3.9. Corollary. Let be an equivalence relation on a normal topological space $X$, and $f : X \to X/ \sim$ the quotient map. If $f$ is closed (i.e. if the decomposition is usc), then $X/ \sim$ is normal and $\sim$ is closed.

Proof: Combine XI.8.3.8. and XI.8.3.2. to conclude that $X/ \sim$ is normal. Since $X/ \sim$ is Hausdorff, $\sim$ is closed by XI.8.3.5.
The Maximal $T_0$ Quotient

We have so far skipped the $T_0$ condition. There is an important result here:

**XI.8.3.10. Theorem.** Let $X$ be a topological space. Then there is a maximal $T_0$ quotient $\tilde{X}$, a quotient space of $X$, such that:

(i) $\tilde{X}$ is $T_0$.

(ii) If $Y$ is any $T_0$ space and $f : X \to Y$ a continuous function, then there is a unique continuous function $\tilde{f} : \tilde{X} \to Y$ such that $f = \tilde{f} \circ \pi_0$, where $\pi_0 : X \to \tilde{X}$ is the quotient map.

(iii) The quotient map $\pi_0$ is open and closed, i.e. the partition of $X$ is continuous.

(iv) If $A$ is any subset of $X$ and $B = \pi_0^{-1}(\pi_0(A))$ is the saturation of $A$, then

$$\tilde{A} = \tilde{B} = \pi_0^{-1}(\overline{\pi_0(A)}) = \pi_0^{-1}(\overline{\pi_0(A)})$$

and $\overline{\pi_0(A)} = \pi_0(\tilde{A})$. Every closed set and every open set in $X$ is saturated.

The quotient space $\tilde{X}$ is uniquely determined up to bijective equivalence by conditions (i) and (ii). The space $\tilde{X}$ is $X/\sim$, where $\sim$ is the equivalence relation on $X$ defined by $x \sim y$ if $\{x\} = \{y\}$.

**Proof:** We verify that the quotient by the given equivalence relation has properties (i)–(iv). Let $A \subseteq X$, and $B = \pi_0^{-1}(\pi_0(A))$. Let $p \in B$. If $U$ is any open neighborhood of $p$, then there is a $y \in U \cap B$. Then $y \sim x$ for some $x \in A$, so $y \in \{x\}$. Thus any neighborhood of $y$ contains $x$, and in particular $x \in U$. Thus every neighborhood of $p$ contains a point of $A$, so $p \in A$, i.e. $B \subseteq A$, and the opposite inclusion is trivial. Thus $\tilde{A} = \tilde{B}$.

If $A$ is closed, then we have $A = \tilde{A} = \tilde{B}$, so $B \subseteq A$, and the opposite inclusion is trivial, so $A$ is saturated. Since the complement of a saturated set is saturated, every open set is saturated. Thus (iii) is an immediate consequence.

If $A$ is again a general subset of $X$, then $\pi_0(\tilde{A})$ is a closed set containing $\pi_0(A)$, so $\overline{\pi_0(\tilde{A})} \subseteq \pi_0(\tilde{A})$, and the opposite inclusion holds by continuity. Since $\tilde{A}$ is saturated, $\tilde{A} = \pi_0^{-1}(\pi_0(\tilde{A}))$. Thus (iv) is proved.

We then easily obtain (i): if $x, y \in X$ and $\{\pi_0(x)\} = \{\pi_0(y)\}$, we have $\{x\} = \pi_0^{-1}(\{\pi_0(x)\}) = \pi_0^{-1}(\{\pi_0(y)\}) = \{y\}$

so $x \sim y$ and $\pi_0(x) = \pi_0(y)$. Apply XI.7.2.1.

To show (ii), suppose $f$ is a continuous function from $X$ to a $T_0$ space $Y$. It suffices to show that if $x_1, x_2 \in X$ and $x_1 \sim x_2$, then $f(x_1) = f(x_2)$. Suppose $f(x_1) \neq f(x_2)$. Since $Y$ is $T_0$, we may assume without loss of generality that $f(x_1)$ has an open neighborhood $V$ not containing $f(x_2)$. But then $f^{-1}(V)$ is an open neighborhood of $x_1$ not containing $x_2$, so $x_1 \not\sim x_2$.

Finally, we verify uniqueness; in fact, we show slightly more. We use the standard uniqueness argument for universal properties (i). Let $\tilde{X}$ be a $T_0$ space, and $\tilde{f} : X \to \tilde{X}$ a continuous function with the universal property of (ii). Then there is a (unique) $f : X \to \tilde{X}$ such that $\tilde{f} = f \circ \pi_0$, and a (unique) $g : \tilde{X} \to \tilde{X}$ such that $\pi_0 = g \circ \tilde{f}$. But then $(g \circ f) \circ \pi_0 = \pi_0$, so $g \circ f$ is the unique $h : X \to \tilde{X}$ such that $\pi_0 = h \circ \pi_0$. But the identity map $\iota_{\tilde{X}}$ also has this property, so $g \circ f = \iota_{\tilde{X}}$. Similarly, $f \circ g = \iota_{\tilde{X}}$, so $g = f^{-1}$ is a homeomorphism.

This result is due to KOLMOGOROV, and the maximal $T_0$ quotient is sometimes called the Kolmogorov quotient. There is also a maximal Hausdorff quotient (XI.8.5.6.).
Other Properties Preserved in Quotients

We now discuss some properties other than separation properties.

XI.8.3.11. Any property preserved under all surjective continuous maps, e.g. separability and compactness, is of course preserved under arbitrary quotient maps.

For first and second countability, we need the decomposition to be lsc, i.e. the quotient map is open:

XI.8.3.12. Proposition. Let \( f : X \to X/\sim \) be an equivalence relation on a topological space \( X \), and \( f : X \to X/\sim \) the quotient map. If \( f \) is open (i.e. the decomposition is lsc) and \( X \) is first countable \( \) or second countable, then \( X/\sim \) is also first countable \( \) or second countable. \( \square \)

Proof: Let \( p \in X \), and \( \{ U_n : n \in \mathbb{N} \} \) a countable base at \( p \). Then \( \{ f(U_n) \} \) is a collection of open neighborhoods of \( f(p) \). If \( V \) is an open neighborhood of \( f(p) \), then \( f^{-1}(V) \) is an open neighborhood of \( p \), so there is an \( n \) such that \( U_n \subseteq f^{-1}(V) \). Then \( f(U_n) \subseteq V \) and \( \{ f(U_n) : n \in \mathbb{N} \} \) is a countable base at \( f(p) \).

If \( \{ U_n : n \in \mathbb{N} \} \) is a countable base for the topology of \( X \), then by a nearly identical argument \( \{ f(U_n) : n \in \mathbb{N} \} \) is a countable base for the topology of \( X/\sim \).

Compactness and Local Compactness

XI.8.3.13. If \( X \) is compact and \( Y \) is Hausdorff, and \( f : X \to Y \) is continuous, then \( f \) is automatically a closed mapping \( \); so if \( f \) is surjective it is a quotient map and \( Y \) is also compact.

XI.8.4. Quotient Metrics

A construction related to, but not in general identical to, the quotient space construction is the construction of a quotient (pseudo)metric.

XI.8.4.1. Let \( (X, \rho) \) be a metric space and \( \sim \) an equivalence relation on \( X \), and let \( Y = X/\sim \) be the set-theoretic quotient. We want to put a “quotient metric” \( \bar{\rho} \) on \( Y \). As a first try, we could consider setting

\[
\bar{\rho}([x],[y]) = \inf \{ \rho(x',y') : x' \in [x], y' \in [y] \}.
\]

This function is well-defined, nonnegative, and symmetric, but easy examples (e.g. \( \)) show that \( \bar{\rho} \) defined this way usually does not satisfy the triangle inequality (and it is not definite in general, i.e. could only be a pseudometric).

There is a way to modify this definition to give a pseudometric (Exercise XI.8.5.15.), but there is a very slick way to define what is obviously the right candidate for the quotient metric:

XI.8.4.2. Definition. Let \( (X, \rho) \) be a metric space, and \( \sim \) an equivalence relation on \( X \). Define \( \beta : X \times X \to [0, +\infty) \) by

\[
\beta(x,y) = \begin{cases} 
\rho(x,y) & \text{if } x \not\sim y \\
0 & \text{if } x \sim y
\end{cases}
\]

Let \( \rho_\beta \) be the maximum pseudometric of \( \beta \) (VI.2.4.7.), and set \( \bar{\rho}([x],[y]) = \rho_\beta(x,y) \). Then \( \bar{\rho} \) is the quotient pseudometric on \( X/\sim \).

It is not hard to see that \( \bar{\rho} \) is well defined (Exercise XI.8.5.16.), and it is then obviously a pseudometric.
XI.8.4.3. Examples. (i) Let \( X = [0, 1] \) with the usual metric, and \( \sim \) the equivalence relation obtained by identifying 0 and 1 (i.e. 0 \sim 1 \) and the other equivalence classes are singletons). Then \( X/ \sim \) is a circle of circumference 1, and the quotient pseudometric is the arc length metric.

(ii) Let \( X = [0, +\infty) \) with the usual metric \( \rho \), and \( \sim \) the equivalence relation obtained by identifying \( \mathbb{N} \cup \{0\} \) to a point, i.e. the equivalence classes are \( \mathbb{N} \cup \{0\} \) and singletons. \( (X/ \sim, \tilde{\rho}) \) is homeomorphic to the space of XI.18.4.7.

(iii) Let \( X = (0, 1) \) with the usual metric \( \rho \), and \( \sim \) the equivalence relation obtained by identifying \( \frac{1}{n} \) for each \( n \in \mathbb{N} \). Then each equivalence class is closed, but we still have that \( \tilde{\rho} \) is the zero pseudometric.

(iv) Let \( X = \mathbb{R} \) with the usual metric \( \rho \), and \( \sim \) the equivalence relation whose classes are the cosets of \( \mathbb{Q} \). Every equivalence class is dense, so \( \tilde{\rho} \) is the zero pseudometric.

(v) Let \( X = (0, 1) \) with the usual metric \( \rho \). Let \( \sim \) be the equivalence relation obtained by identifying \( x \) with \( x^2 \) for each \( x \in (0, 1) \). Then each equivalence class is closed, but we still have that \( \tilde{\rho} \) is the zero pseudometric.

XI.8.4.4. Examples (iv) and (v) show that \( \tilde{\rho} \) is not always a metric if \( \rho \) is, even if all equivalence classes are closed. Since \( \tilde{\rho}(x, y) \leq \rho(x, y) \) for all \( x, y \in X \), the quotient map from \( (X, \rho) \) to \( (X/ \sim, \tilde{\rho}) \) is continuous, i.e. the \( \tilde{\rho} \) topology on \( X/ \sim \) is weaker than the quotient topology. It is the quotient topology in good cases (e.g. in (i)), but strictly weaker in general (e.g. in (ii), (iii), (v)). The \( \tilde{\rho} \) topology can depend on the exact metric and not just on the topology: examples (ii) and (iii) are homeomorphic respecting the equivalence relation, but the quotient metric topologies are not the same.

XI.8.4.5. But if \( X \) is metrizable and \( X/ \sim \) is also metrizable in the quotient topology (cf. (iv)), there is a metric on \( X \) giving its topology such that the quotient metric gives the quotient topology. For if \( \sigma \) is a metric on \( X \) giving its topology and \( \tau \) a metric on \( X/ \sim \) giving its topology, and \( \pi : X \to X/ \sim \) is the quotient map, then \( \hat{\rho} = \sigma + (\tau \circ \pi) \) is a metric on \( X \) which is equivalent to \( \sigma \), and the \( \hat{\rho} \)-topology on \( X/ \sim \) is stronger than than the \( \tau \)-topology and weaker than the quotient topology, hence they all coincide, i.e. \( \hat{\rho} \) is equivalent to \( \tau \).

XI.8.5. Exercises

XI.8.5.1. Let \( X, Y, Z \) be topological spaces, and \( f : X \to Y \) and \( g : Y \to Z \) surjective continuous functions. Set \( h = g \circ f : X \to Z \).

(a) Show that if \( f \) and \( g \) are quotient maps, then \( h \) is also a quotient map.

(b) Show that if \( h \) is a quotient map, then \( g \) is also a quotient map. Is \( f \) necessarily a quotient map?

XI.8.5.2. (a) Let \( X \) and \( Y \) be topological spaces, and let \( \pi_1 \) be projection of \( X \times Y \) onto \( X \). Show that \( \pi_1 \) is a quotient map and that the corresponding decomposition of \( X \times Y \) is lsc.

(a) Let \( \{X_i : i \in I\} \) be a family of topological spaces, and let \( X = \prod_{i \in I} X_i \). For \( j \in I \), let \( \pi_j \) be projection of \( X \) onto \( X_j \). Show that \( \pi_j \) is a quotient map and that the corresponding decomposition of \( X \) is lsc.
XI.8.5.3. Let \( \sim \) be an equivalence relation on a topological space \( X \), and \( f : X \to X/ \sim \) the quotient map. If \( Z \subseteq X \), let \( \sim_Z \) be the restriction of \( \sim \) to \( Z \). Is \( Z/ \sim_Z \) homeomorphic to \( f(Z) \) in general? What if \( Z \) is open or closed in \( X \)? What if the decomposition is usc or lsc?

XI.8.5.4. Let \( X_1, X_2, Y_1, Y_2 \) be topological spaces, and \( f : X_1 \to Y_1 \) and \( g : X_2 \to Y_2 \) be quotient maps. Define \( h : X_1 \times X_2 \to Y_1 \times Y_2 \) by \( h(x_1, x_2) = (f(x_1), g(x_2)) \). Is \( h \) necessarily a quotient map? What if \( f \) and \( g \) are open or closed? (cf. [Mun75, p. 141-143].)

XI.8.5.5. Show that the maximal \( T_0 \) quotient of a topological space \( X \) can be described alternately as follows.

(a) Define an equivalence relation \( \approx \) on \( X \) by \( x_1 \approx x_2 \) if \( f(x_1) = f(x_2) \) for every continuous function \( f \) from \( X \) to a \( T_0 \) space \( Y_f \) (which can depend on \( f \)). Show that \( X/ \approx \) is \( T_0 \). Conclude that \( \approx = \sim \).

(b) Describe \( \tilde{X} \) explicitly by considering the map \( \pi \) from \( X \) to \( \prod_f Y_f \) by \( (\pi(x))_f = f(x) \) (show that this can be done without set-theoretic difficulties by choosing a suitable representative set of functions). Set \( Y = \pi(X) \). Show that \( Y \cong \tilde{X} \) and that \( \pi_0 \) can be identified with \( \pi \), regarded as a map from \( X \) to \( Y \).

XI.8.5.6. The Maximal Hausdorff Quotient. Let \( X \) be a topological space. Prove the following theorem:

**Theorem.** Let \( X \) be a topological space. Then there is a maximal Hausdorff quotient \( \tilde{X} \), a quotient space of \( X \), such that:

(i) \( \tilde{X} \) is Hausdorff.

(ii) If \( Y \) is any Hausdorff space and \( f : X \to Y \) a continuous function, then there is a unique continuous function \( \tilde{f} : \tilde{X} \to Y \) such that \( f = \tilde{f} \circ \pi_2 \), where \( \pi_2 : X \to \tilde{X} \) is the quotient map.

The quotient space \( \tilde{X} \) is uniquely determined up to bijective equivalence by conditions (i) and (ii).

(a) Define an equivalence relation \( \approx \) on \( X \) by \( x_1 \approx x_2 \) if \( f(x_1) = f(x_2) \) for every continuous function \( f \) from \( X \) to a Hausdorff space \( Y_f \) (which can depend on \( f \)). Show that \( \tilde{X} = X/ \approx \) is Hausdorff. Describe \( \tilde{X} \) as in XI.8.5.5.(b). Give the standard proof of uniqueness.

(b) It is not easy to explicitly describe the equivalence relation \( \approx \). As a first approximation, define \( \sim \) on \( X \) by \( x \sim y \) if \( x \) and \( y \) do not have disjoint neighborhoods. Is \( \sim \) an equivalence relation?

(c) Extend \( \sim \) to an equivalence relation by taking its transitive closure. Is \( X/ \sim \) necessarily Hausdorff? If it is, it must be (up to bijective equivalence) the \( \tilde{X} \) of (a).

(d) If \( X/ \sim \) is not Hausdorff, iterate the construction. Let \( \sim' \) be the relation on \( X/ \sim \) defined in the same way as \( \sim \). Write \( \sim_1 = \sim \) on \( X \), and let \( \sim_2 \) be the equivalence relation on \( X \) corresponding to the relation \( \sim' \) on \( X/ \sim_1 \). Describe \( \sim_2 \) explicitly.

(e) Transfinitely define an increasing collection \( \sim_\alpha \) of equivalence relations on \( X \) in this way. Show that this collection stabilizes at some \( \beta \), and that \( X/ \sim_\beta \) is Hausdorff and is bijectively equivalent to \( \tilde{X} \).

The smallest such \( \beta \) is called the **Hausdorff height** of \( X \) and is an ordinal invariant of \( X \).

The maximal Hausdorff quotient of \( X \) is sometimes called the **Hausdorffization** or **Hausdorffification** of \( X \). See () for details.
XI.8.5.7.  
(a) Is there a maximal $T_1$ quotient of a topological space $X$ along the same lines as the maximal $T_0$ quotient and the maximal Hausdorff quotient?
(b) Show there is no maximal regular, completely regular, normal, or completely normal quotient in general. [There are nonregular topologies on $\mathbb{R}$ which are stronger than the usual topology (e.g. XI.7.8.13.).]

XI.8.5.8.  
There are $2^{\aleph_0}$ pairwise disjoint dense subsets of $\mathbb{R}$ [this can be proved without any form of choice, e.g. by taking rational translates of the von Neumann numbers (III.8.4.13.). See also XI.8.5.9..] Let $\{A_t : t \in \mathbb{R}\}$ be such a collection. We may assume $\bigcup_t A_t = \mathbb{R}$ by expanding one of the sets if necessary. Set

$$X = \{(t, y) \in \mathbb{R}^2 : y \in A_t\} \subseteq \mathbb{R}^2.$$ 

Then projection $\pi_2$ of $X$ onto the second coordinate is a bijection from $X$ onto $\mathbb{R}$. The projection $\pi_1$ is a surjective but not injective function from $X$ to $\mathbb{R}$. Let $\mathcal{E}$ denote the usual topology on $\mathbb{R}$.

(a) Let $\mathcal{T}$ be any topology on $\mathbb{R}$. Let $\mathcal{T}_X$ be the relative topology on $X$ of the product topology $\mathcal{T} \otimes \mathcal{E}$ on $\mathbb{R} \times \mathbb{R}$. Show that $\mathcal{T}_X$ is a Hausdorff topology on $X$. [Distinct points of $X$ have distinct second coordinates.]

(b) If $\mathcal{T}$ is any topology on $\mathbb{R}$, let $\mathcal{H}(\mathcal{T})$ be the topology on $\mathbb{R}$ obtained by transferring $\mathcal{T}_X$ to $\mathbb{R}$ via the bijection $\pi_2$. Then $\mathcal{H}(\mathcal{T})$ is a Hausdorff topology on $\mathbb{R}$ which is stronger than $\mathcal{E}$. If $\mathcal{T}_1$ and $\mathcal{T}_2$ are different topologies on $\mathbb{R}$, then $\mathcal{H}(\mathcal{T}_1)$ and $\mathcal{H}(\mathcal{T}_2)$ are different topologies on $\mathbb{R}$. Thus there are enormously many distinct (Hausdorff) topologies on $\mathbb{R}$ stronger than $\mathcal{E}$.

(c) The surjective map $\pi_1 \circ \pi_2^{-1}$ is continuous and open from $(\mathbb{R}, \mathcal{H}(\mathcal{T}))$ to $(\mathbb{R}, \mathcal{T})$.

(d) Show that $(\mathbb{R}, \mathcal{T})$ has the quotient topology from $(\mathbb{R}, \mathcal{H}(\mathcal{T}))$ under this map.

(e) If $Y$ is any topological space of cardinality $\leq 2^{\aleph_0}$, then $Y$ can be identified as a subset of $\mathbb{R}$ with some relative topology. Thus $Y$ is a continuous open image of a Hausdorff space.

This can be extended to topological spaces of arbitrary cardinality (XI.8.5.9.).

XI.8.5.9.  
(a) Let $\kappa$ be a cardinal. Then there is a compact Hausdorff space $Z$ which has a collection of $\kappa$ pairwise disjoint dense subsets. [Let $Z = \{0, 1\}^\kappa$, and consider the equivalence relation on $Z$ where two points are equivalent if they differ in only finitely many coordinates. Use II.9.7.14.]

(b) If $Y$ is any topological space of cardinality $\leq 2^{\aleph_0}$, then $Y$ can be identified as a subset of $\mathbb{R}$ with some relative topology. Thus $Y$ is a continuous open image of a Hausdorff space.

Repeat problem XI.8.5.8. with this $X$ to show that $Y$ is a continuous open image (quotient) of a Hausdorff space.

XI.8.5.10.  
Let $Y$ be the Sierpiński space. Define $f : [0, 1] \to Y$ by $f(t) = a$ if $t < 1$ and $f(1) = b$. Show that $f$ is a quotient map. However, $f$ is neither open nor closed. Use XI.8.5.8. to write $Y$ as a quotient of a Hausdorff space by an open map; see XI.7.8.13.(d). (It cannot be done by a closed map since the quotient of a $T_1$ space by a closed map is $T_1$.)
XI.8.5.11. Let $X$ and $Y$ be topological spaces, and $f : X \to Y$ a surjective continuous map. Say $f$ is \textit{semiclosed} if the image of the closure of every saturated set in $X$ is closed in $Y$.

(a) Show that $f$ is semiclosed if and only if, for every subset $B$ of $Y$, we have

$$B = f(f^{-1}(B)).$$

(b) Show that every semiclosed map is a quotient map. In fact, $f$ is semiclosed if and only if, for every subset $B$ of $Y$, $f|_{f^{-1}(B)}$ is a quotient map from $f^{-1}(B)$ onto $B$. Thus a semiclosed map is also called a \textit{hereditary quotient map}.

(c) Show that every (surjective) closed map is semiclosed.

(d) Show that all the examples of quotient maps in this section (except XI.8.5.12.) are semiclosed. In particular, a semiclosed map need not be closed.

(e) If $f : X \to Y$ is a quotient map and $Y$ is Hausdorff and first countable, then $f$ is semiclosed.

(f) Not every quotient map is semiclosed (XI.8.5.12.).

(g) Show that if $X$ and $Y$ are first countable and $Y$ is $T_1$, $f : X \to Y$ is semiclosed, $(y_n)$ is a sequence in $Y$, and $y \in Y$, then $y_n \to y$ if and only if for every subsequence of $(y_n)$ there is a subsequence $(y_{n_k})$ for which there is a sequence $(x_{n_k})$ in $X$ and an $x \in X$ with $x_{n_k} \to x$, $f(x_{n_k}) = y_{n_k}$ for all $n$, and $f(x) = y$. In other words, convergent sequences in $Y$ have subsequences which can be lifted to convergent sequences in $X$.

This result is quite useful in identifying and describing quotient topologies. The restriction that $Y$ be $T_1$, or something like it, is necessary (XI.8.5.13.). And even if $X$ and $Y$ are compact metrizable spaces (where the result in (g) is almost trivial), and $f$ is closed, passage to subsequences is necessary in general (XI.8.5.14.).

XI.8.5.12. Let $X = \{a_1, a_2, b_1, b_2, c_1, c_2, x_1, x_2\}$, $Y = \{a, b, c, y\}$, and $f : X \to Y$ with $f(a_j) = a$, $f(b_j) = b$, $f(c_j) = c$, $f(x_j) = y$ for $j = 1, 2$. Give $X$ the topology generated by $\{b_1, x_1\}$ and $\{c_2, x_2\}$.

(a) Show that the quotient topology on $Y$ is the indiscrete topology.

(b) Show that $y$ is in the closure of $\{a\}$ in $Y$, but neither $x_1$ nor $x_2$ is in the closure in $X$ of $f^{-1}(\{a\}) = \{a_1, a_2\}$. Thus $f$ is not semiclosed.

XI.8.5.13. Let $X = \{x_n, z_n : n \in \mathbb{N}\}$, $Y = \{y\} \cup \{y_n : n \in \mathbb{N}\}$, $f : X \to Y$ with $f(x_n) = y_n$ and $f(z_n) = y$ for all $n$. Give $X$ the topology generated by $\{\{x_n\}, \{x_n, z_n\} : n \in \mathbb{N}\}$, and give $Y$ the quotient topology.

(a) Show that $X$ and $Y$ are first countable but not $T_1$, and that the quotient map $f$ is semiclosed.

(b) Show that $y_n \to y$ in $Y$, but no subsequence of $(y_n)$ lifts to a convergent sequence in $X$.

XI.8.5.14. Let $X$ be the compact subset

$$\left\{ \left( \frac{1}{n}, 1 \right) : n \in \mathbb{N} \text{ odd} \right\} \cup \left\{ \left( \frac{1}{n}, 0 \right) : n \in \mathbb{N} \text{ even} \right\} \cup \{(0,0),(0,1)\}$$

of $\mathbb{R}^2$, and $Y = \{0\} \cup \{\frac{1}{n} : n \in \mathbb{N}\} \subseteq \mathbb{R}$. Define $f : X \to Y$ by $f(x, y) = x$.

(a) Show that $f$ is a quotient map which is closed, hence semiclosed.

(b) Show that the convergent sequence $y_n = \frac{1}{n}$ in $Y$ does not lift to a convergent sequence in $X$. 1071
XI.8.5.15. Let $(X, \rho)$ be a metric space, and $\sim$ an equivalence relation on $X$. Show that the quotient metric $\bar{\rho}$ can be explicitly described as

$$\bar{\rho}(a, b) = \inf \sum_{k=1}^{n} \rho(x_k, y_k)$$

where the infimum is over all finite sets \{x_1, \ldots, x_{n+1}, y_1, \ldots, y_n\}, where $x_1 = a$, $x_{n+1} = b$, and $y_k \sim x_{k+1}$ for $1 \leq k \leq n$ ($n$ may vary). The definition does not change if we only require that $x_1 \sim a$, along with the other conditions.

XI.8.5.16. Let $X, \rho, \sim, \beta$ be as in XI.8.4.2. Use the triangle inequality to show that if $\sigma$ is a pseudometric on $X$ with $\sigma \leq \rho_\beta$, then $\sigma$ drops to a well-defined pseudometric on $X/\sim$. In particular, $\bar{\rho}$ is well defined.
XI.9. Identification Spaces

Perhaps the most important method of construction of topological spaces is by identification or “gluing.” There are a few variations, which all fall under the quotient space construction.

XI.9.1. Collapsing a Subset to a Point

XI.9.1.1. Let \( X \) be a topological space, and \( A \) a subset. We can “collapse \( A \) to a point” by taking the equivalence relation ~ for which \( A \) is one equivalence class and all other equivalence classes are single points. Then the space \( X/\sim \) with the quotient topology is usually denoted \( X/A \) and is called the identification space of \( X \) by \( A \), or with \( A \) collapsed to a point. (This notation \( X/A \) is common, but sometimes conflicts with other common notation. For example, if \( X \) is a topological group and \( A \) a subgroup, then \( X/A \) usually denotes the quotient group \( (\cdot) \), which is not the same thing. See also XI.9.3.6.) We may identify \( X/A \) with \((X \setminus A) \cup \{a\}\), where \( a = \{A\} \).

In order to obtain a \( T_1 \) quotient, \( A \) must be closed in \( X \), and the collapsing construction is almost exclusively used in this situation.

More generally, we may take a finite or infinite collection of pairwise disjoint subsets of \( X \) and collapse each one to a point. If \( A \) and \( B \) are disjoint subsets of \( X \) (usually closed), write \( X/(A,B) \) for the space obtained from \( X \) by collapsing \( A \) and \( B \) to (separate) points. The collapsing can be done consecutively, i.e. by forming \((X/A)/B \) or \((X/B)/A \), or simultaneously. Note that \( X/(A,B) \not\cong X/(A \cup B) \).

XI.9.1.2. Proposition. Let \( X \) be a topological space and \( A \) a closed subset of \( X \), and \( f : X \to X/A \) the quotient map. Then \( f \) is closed, i.e. the decomposition is usc, and the restriction of \( f \) to \( X \setminus A \) is a homeomorphism onto the open set \((X/A) \setminus \{a\}\).

Proof: \( X \setminus A \) is open in \( X \), \( W = (X/A) \setminus \{a\} \) is open in \( X/A \), and \( f \) is a bijection of \( X \setminus A \) to \( W \). Identifying \( W \) with \( X \setminus A \), a subset \( V \) of \( W \) is open in \( X/A \) if and only if the corresponding subset of \( X \setminus A \) is open in \( X \), i.e. \( V \) is relatively open in \( W \) if and only if \( f^{-1}(V) \) is relatively open in \( X \setminus A \). Thus \( f|_{X \setminus A} \) is a homeomorphism.

If \( E \) is a subset of \( X \), then \( f^{-1}(f(E)) = E \) if \( E \cap A = \emptyset \), and \( f^{-1}(f(E)) = E \cup A \) if \( E \cap A \neq \emptyset \). In any case, if \( E \) is closed, \( f^{-1}(f(E)) \) is closed, so \( f \) is closed.

All the results can fail if \( A \) is not closed (Exercise XI.9.5.1.).

XI.9.1.3. Conversely, if \( f : X \to Y \) is a quotient map and every point of \( Y \) but one has a singleton preimage, then \( Y = X/f^{-1}\{q\} \), where \( q \) is the exceptional point. If \( \{q\} \) is closed in \( Y \) (e.g. if \( Y \) is \( T_1 \)), then \( f \) is closed and \( f|_{X \setminus f^{-1}(\{q\})} \) is a homeomorphism onto \( Y \setminus \{q\} \).

XI.9.1.4. Examples. (i) Let \( f \) be the map from \([0,1] \) to \( \mathbb{T} \cong S^1 \) from XI.8.1.3.(ii). We have \( S^1 \cong [0,1]/\{0,1\} \), i.e. a circle is a closed interval with endpoints identified.

(ii) More generally, let \( B^n \) be the closed unit ball in \( \mathbb{R}^n \). The boundary is the \((n-1)\)-sphere \( S^{n-1} \). We have that \( B^n/S^{n-1} \cong S^n \), as is easily checked (e.g. via XI.9.1.8.). For another construction of \( S^n \) by collapsing, see XI.9.1.12.(iii).
XI.9.1.5. Proposition. Let $X$ be a Hausdorff topological space, and $A \subseteq X$. Then $X/A$ is Hausdorff if and only if, for each $p \in X \setminus A$, $A$ and $p$ have disjoint neighborhoods. (This entails that $A$ must be a closed subset of $X$.) In particular, if $X$ is regular and $A$ is closed, then $X/A$ is Hausdorff.

XI.9.1.6. An identification space from a regular space need not be regular. For example, if $X$ is regular but not normal, and $A$ and $B$ are disjoint closed sets in $X$ which do not have disjoint neighborhoods, then $X/A$ is not regular. However, we have the following special case of XI.8.3.9:

XI.9.1.7. Proposition. Let $X$ be a normal space and $A$ a closed subset of $X$. Then $X/A$ is normal.

A particularly important special case is:

XI.9.1.8. Proposition. Let $X$ be a compact Hausdorff space, and $A$ a closed subset of $X$. Then $X/A$ is homeomorphic to the one-point compactification (XI.11.8.3.) of $X \setminus A$.

Proof: Combine XI.9.1.3. and XI.11.8.5.

Cones and Suspensions

We can define a cone over any topological space $X$ by forming a cylinder with base $X$ and collapsing the top edge to a point:

XI.9.1.9. Definition. Let $X$ be a topological space. The space $CX = ([0,1] \times X)/(\{1\} \times X)$ is called the cone over $X$.

This construction is primarily used when $X$ is a compact Hausdorff space. In this case, $CX$ is homeomorphic to the one-point compactification of $[0,1) \times X$ (XI.9.1.8).

XI.9.1.10. Examples. (i) The cone over $[0,1]$ is (homeomorphic to) a solid triangle.

(ii) The cone over $S^1$ is an ordinary cone, which is homeomorphic to a closed disk.

(iii) More generally, for any $n$ the cone over $S^n$ is homeomorphic to $B^{n+1}$ (note that $B^{n+1} \setminus \{0\}$ is homeomorphic to $[0,1) \times S^n$).

(iv) The cone $CK$ over the Cantor set $K$ can be identified with the union of all line segments in $\mathbb{R}^2$ between $(1,1)$ and points of $K$, regarded as a subset of the $x$-axis. The point $(\frac{1}{2},1)$ can be replaced by any point of $\mathbb{R}^2$ not on the $x$-axis. This is a good example of a space which is path-connected but not locally path connected. ($CX$ is path-connected for any topological space $X$.)

We can similarly form the “suspension” of $X$ by collapsing each end of the cylinder over $X$ to (separate) points:
**XI.9.1.11. Definition.** Let \( X \) be a topological space. The *suspension* of \( X \) is

\[
SX = ([0,1] \times X)/\{(0) \times X, (1) \times X\}.
\]

This is also primarily used in the case where \( X \) is a compact Hausdorff space, and gives a “two-point compactification” of \((0,1) \times X \cong \mathbb{R} \times X\) in this case. In general, the suspension of \( X \) is formed by collapsing the base of \( CX \) to a point.

The suspension of \( X \) can be thought of as two copies of \( CX \) joined base-to-base (\(\cdot\)).

**XI.9.1.12. Examples.** (i) The suspension of \([0,1]\) can be pictured as a (solid) diamond in \(\mathbb{R}^2\).

(ii) The suspension of \(S^1\) can be pictured as the union of two cones joined along their base circles (\(\cdot\)). This space is homeomorphic to \(S^2\).

(iii) More generally, the suspension of \(S^n\) is homeomorphic to \(S^{n+1}\). This can be seen by first forming \(CS^n \cong B^{n+1}\), and then collapsing the base, which is the boundary \(S^n\), to a point (cf. XI.9.1.4(ii)).

**Wedge Sums**

**XI.9.1.13.** Let \( \{X_i : i \in I\} \) be a collection of topological spaces, and for each \( i \) let \(*_i\) be a designated point of \(X_i\). The *wedge sum* of \( \{(X_i, *_i) : i \in I\} \) is the space \( X \) obtained from the separated union of the \(X_i\) with all the \(*_i\) identified together to one point \(*\). (The homeomorphism class of \( X \) depends in general on the choice of the \(*_i\).) If each \( X_i \) is a circle, the space \( X \) is called a *wedge of circles* or *bouquet of circles*.

If \( I \) is a finite set with \( n \) elements and each \( X_i \) is a circle, the space \( X \) is the bouquet of \( n \) circles, resembling a flower with \( n \) petals. A bouquet of two circles is homeomorphic to a figure 8.

A wedge sum of infinitely many nontrivial spaces is rarely metrizable. For example, a wedge or bouquet of infinitely many circles is not first countable (XI.9.5.7., XI.9.5.8.).

**XI.9.2. Gluing and Attaching**

Gluing and attaching are perhaps the most extensively used constructions in topology.

**XI.9.2.1.** Let \( X \) be a topological space, and \( A \) and \( B \) disjoint subsets of \( X \) (with care, the disjointness can be relaxed). Let \( f : A \to B \) be a homeomorphism, or more generally a quotient map. We take the quotient of \( X \) obtained by identifying \( x \) with \( f(x) \) for all \( x \in A \). More precisely, we define an equivalence relation \( \sim \) on \( X \) by taking

\[
[x] = \{y \in A : f(y) = f(x)\} \cup \{f(x)\}
\]

if \( x \in A \), \( [x] = \{x\} \cup f^{-1}(\{x\}) \) if \( x \in B \), and \( [x] = \{x\} \) if \( x \notin A \cup B \). The space \( X/\sim \) is called the *identification space* of \( X \) with \( A \) identified with \( B \) via \( f \), or with \( A \) glued (or sewed) to \( B \) via \( f \). Note that if \( f \) is a homeomorphism, the equivalence classes just consist of \( \{x, f(x)\} \) for \( x \in A \) and \( \{x\} \) for \( x \notin A \cup B \).

We may more generally do more than one gluing, gluing \( A_1 \) to \( B_1 \) and \( A_2 \) to \( B_2 \), etc. We need that \( A_j \) and \( B_j \) are disjoint for each \( j \), but \( A_j \) and \( A_k \), \( B_j \) and \( B_k \), and \( A_j \) and \( B_k \) need not be disjoint for \( j \neq k \), but the gluings have to be consistent on the overlaps. The gluing can be done consecutively or simultaneously. See e.g. XI.9.2.3(v).
XI.9.2.2. In the gluing construction, to obtain a nice quotient space it is not necessary that \(A\) and \(B\) be closed (XI.9.2.3(ii)); however, the case where they are not closed is rather delicate. The construction is more robust if they are closed.

XI.9.2.3. Examples. (i) Let \(X = [0, 1]\), \(A = \{0\}\), \(B = \{1\}\), \(f\) the obvious homeomorphism. Then the identification space with \(A\) glued to \(B\) is \(S^1\), as in XI.8.1.3.(ii) or XI.9.1.4.

(ii) Let \(X = (0, 1)\), \(A = (0, \frac{1}{3})\), \(B = (\frac{2}{3}, 1)\), \(f(x) = x + \frac{2}{3}\) for \(x \in A\). Then the identification space is homeomorphic to \(S^1\).

The identification space depends crucially on the choice of homeomorphism. If instead we take \(f(x) = 1 - x\) for \(x \in A\), the identification space is not Hausdorff.

(iii) Let \(X = [0, 1]^2\), \(A = [0, 1] \times \{0\}\), \(B = [0, 1] \times \{1\}\). Define \(f : A \to B\) by \(f(t, 0) = (t, 1)\). Then the identification space is a cylinder (Figure XI.2). Informally, we take a rectangle and glue the ends together with no twist.

(iv) Let \(X = [0, 1]^2\), \(A = [0, 1] \times \{0\}\), \(B = [0, 1] \times \{1\}\). Define \(f : A \to B\) by \(f(t, 0) = (1 - t, 1)\). Then the identification space is a Möbius strip (Figure XI.3, from https://upload.wikimedia.org/wikipedia/commons/d/d9/M%C3%B6bius_strip.jpg). Informally, we take a rectangle and glue the ends together with a twist.

Figure XI.2: A cylinder.

Figure XI.3: A Möbius strip.
Figure XI.3: A Möbius strip.
(v) Let $X = [0, 1]^2$, $A_1 = [0, 1] \times \{0\}$, $B_1 = [0, 1] \times \{1\}$, $A_2 = \{0\} \times [0, 1]$, $B_2 = \{1\} \times [0, 1]$. Define $f_1 : A_1 \rightarrow B_1$ by $f(t,0) = (t,1)$ and $f_2 : A_2 \rightarrow B_2$ by $f_2(0,t) = (1,t)$. The identification space is homeomorphic to a 2-torus $T^2 \cong S^1 \times S^1$. It can be made from a rectangle by first gluing the top and bottom edges to form a cylinder, and then gluing the end circles (with no twist); see Figure XI.4, from http://bakingandmath.com/tag/torus/. (See this website, or https://en.wikipedia.org/wiki/Homotopy, for an animation of the topological equivalence of a torus and a coffee cup; the old joke is that a topologist is a mathematician who cannot tell the difference between a doughnut and a coffee cup.)

![Figure XI.4: Construction of a torus.](image)

(vi) Let $X = [0, 1]^2$, $A_1 = [0, 1] \times \{0\}$, $B_1 = [0, 1] \times \{1\}$, $A_2 = \{0\} \times [0, 1]$, $B_2 = \{1\} \times [0, 1]$. Define $f_1 : A_1 \rightarrow B_1$ by $f(t,0) = (t,1)$ and $f_2 : A_2 \rightarrow B_2$ by $f_2(0,t) = (1,1-t)$. The identification space is called a **Klein bottle** (actually in German it is *Kleinsche Fläche*, not *Kleinsche Flasche*; the English name may be a mistranslation). It can be made from a rectangle by first gluing the top and bottom edges to form a cylinder, and then gluing the end circles with an orientation-reversing map; see Figure XI.5 (from https://en.wikipedia.org/wiki/Klein_bottle) or, for an animated version, https://www.youtube.com/watch?v=E8rifKlq5hc; note that the apparent self-intersection is only an artifact of trying to depict the Klein bottle as a subset of $\mathbb{R}^3$ – the picture is really a higher-dimensional version of a knot diagram in $\mathbb{R}^2$. A Klein bottle cannot be topologically embedded in $\mathbb{R}^3$, but it can be embedded in $\mathbb{R}^4$. A Klein bottle can also be constructed from a Möbius strip by suitably identifying points on the boundary circle (Figure XI.6, from http://squareone-learning.com/blog/2014/09/around-and-round-and-never-off-the-surface/), or by gluing two Möbius strips together along their boundary circle. There are many nice pictures and videos of the Klein bottle on the internet, e.g. https://www.youtube.com/watch?v=sRTKSzA0Br4.
Figure XI.5: Construction of a Klein bottle.

Figure XI.6: Construction of a Klein bottle from a Möbius strip.
(vii) Let $X = [0, 1]^2$, $A_1 = [0, 1] 	imes \{0\}$, $B_1 = [0, 1] \times \{1\}$, $A_2 = \{0\} \times [0, 1]$, $B_2 = \{1\} \times [0, 1]$. Define $f_1 : A_1 \to B_1$ by $f(t, 0) = (1 - t, 1)$ and $f_2 : A_2 \to B_2$ by $f_2(0, t) = (1, 1 - t)$. The identification space is called the projective plane. It can be made from a rectangle by first gluing the top and bottom edges with a twist to form a Möbius strip, and then suitably identifying points on the boundary circle (not in the same way as for a Klein bottle). A better way is to take $A$ as the union of the top and left edges, and $B$ the union of the right and bottom edges (these sets are not quite disjoint), and then gluing $A$ to $B$. This amounts to gluing the top semicircle of the closed unit disk in $\mathbb{R}^2$ to the bottom semicircle by a $180^\circ$ rotation, or identifying $x$ with $-x$ for each $x$ of norm 1. See Figure XI.7, from http://www.math.cornell.edu/~mec/Winter2009/Victor/part3.htm.

A projective plane is harder to picture than a Klein bottle, but there are many ways to do it; see Figure XI.8, from http://xahlee.info/math/riemann_sphere__real_projective_plane.html for one way. Unlike this picture which has a pinch point, there is a (nonobvious – HILBERT thought it was impossible!) way to immerse the projective plane in $\mathbb{R}^3$ called Boy’s surface [Boy03]; see https://www.youtube.com/watch?v=9gRx66xXXek for a nice animation. Note again that the apparent self-intersection is only an artifact of trying to depict the projective plane as a subset of $\mathbb{R}^3$. A projective plane cannot be topologically embedded in $\mathbb{R}^3$, but it can be embedded in $\mathbb{R}^4$. There are several other standard ways to construct the projective plane (XI.9.3.7.). The projective plane is denoted $\mathbb{R}P^2$; there are generalizations (real projective spaces) $\mathbb{R}P^n$ for each $n$ (XI.9.3.7.(iii)), as well as complex projective spaces $\mathbb{C}P^n$ (XI.9.3.7.(iv)).

(viii) Every closed surface (closed 2-manifold) (including $S^2$!) can be obtained by starting with a regular $(2n)$-gon for some $n$ and identifying pairs of edges in an appropriate way (XI.9.5.4.).
Attaching

XI.9.2.4. A variation of gluing is to have two spaces $X$ and $Y$, subsets $A$ of $X$ and $B$ of $Y$, and a homeomorphism (or quotient map) $f: A \to B$. This can be put into the previous setting by considering the disjoint union of $X$ and $Y$. The glued identification space is usually denoted $X \cup_f Y$; we say $X$ is attached to $Y$ via $f$.

XI.9.2.5. There are two especially important examples of attaching: CW complexes and surgery.

Handles and Surgery

Surgery is a method of creating new manifolds from known ones. The general setup of surgery in topology is based on the following important fact:

XI.9.2.6. Proposition. Let $M$ and $N$ be $n$-manifolds with boundary, and let $f: \partial M \to \partial N$ be a homeomorphism. Then $M \cup_f N$ is an $n$-manifold without boundary.
XI.9.2.7. The general idea of surgery is to remove from a (usually closed) $n$-manifold $M$ an open submanifold and glue in another $n$-manifold $N$ whose boundary is homeomorphic to the boundary of the removed piece to obtain a new closed $n$-manifold. The simplest interesting example is:

XI.9.2.8. Let $M$ be a closed surface, e.g. $S^2$. Cut two disjoint open disks out of a larger disk in $M$. What is left is a compact 2-manifold with boundary $M_0$ whose boundary consists of a disjoint union of two circles, which may be given a consistent orientation. The cylinder $N = [0, 1] \times S^1$ is also a closed manifold with boundary, whose boundary consists of two circles. Glue $N$ to $M_0$ along the boundary circles, giving them the same orientation. The result is called $M$ with a handle attached. See Figure XI.9, from http://www.uff.br/cdme/pdp/pdp-html/pdp-en.html. It is easy to see that $S^2$ with a handle attached is homeomorphic to $T^2$, and $T^2$ with a handle attached is a two-holed torus. An $n$-holed torus is obtained by adding $n$ handles to $S^1$ (Figure XI.10, from https://upload.wikimedia.org/wikipedia/commons/a/ac/Sphere_with_three_handles.png). It turns out that every closed surface is homeomorphic to either $S^2$ (if orientable) or $\mathbb{R}P^2$ or a Klein bottle (if nonorientable) with some finite number of handles attached. In the orientable case, the number of handles is called the genus and is a topological invariant. Genus can also be defined in the nonorientable case (XI.9.2.12.).

![Figure XI.9: Attaching a handle to a sphere.](image)

If $N$ is attached to $S^2$ with the end circles given opposite orientations, the surface obtained is the Klein bottle, not the torus.

XI.9.2.9. A variation is to take closed surfaces $M$ and $N$, cut out small disks from both of them, and glue the remainders together along the boundary circles (see Figure XI.11, from https://upload.wikimedia.org/wikipedia/commons/thumb/5/52/Connected_sum.svg/1280px-Connected_sum.svg). The resulting surface is called the connected sum of $M$ and $N$, denoted $M \# N$. The connected sum of an $m$-holed torus and an $n$-holed torus is an $(m + n)$-holed torus. Connected sum with a torus is topologically the same thing as adding a handle.
Figure XI.10: Sphere with three handles.

Figure XI.11: Connected sum.
Connected sum can be done for $n$-manifolds by cutting out a small ball $B^n$ from both and gluing the remainders along the boundary $S^{n-1}$'s. In general, the orientation chosen for the identification of the boundaries affects the homeomorphism class of the connected sum ( ).

XI.9.2.10. In higher dimensions, there is more flexibility in surgery. A key observation is that for any $p$ and $q$, the boundary of $S^p \times B^q$ is homeomorphic to $S^p \times S^{q-1}$, as is the boundary of $B^{p+1} \times S^{q-1}$. (We used this for handles with $p = 0$ and $q = 2$). Thus, if $M$ is an $n$-manifold, we can take any $p$ and $q$ with $p + q = n$, cut out an open submanifold whose closure is homeomorphic to $S^p \times B^q$, and glue in a copy of $B^{p+1} \times S^{q-1}$.

If $n = 3$, the only possibility of this type is to add a “three-dimensional handle,” cutting out two 3-balls (a copy of $S^0 \times B^3$) and replacing it by a copy of $B^1 \times S^2 \cong [0,1] \times S^2$. But if $n = 4$, there is another interesting possibility: cutting out a copy of $S^1 \times B^3$ and replacing it with a copy of $B^2 \times S^2$. See ( ).

XI.9.2.11. Actually, even in three dimensions, there is another interesting possibility: the removed manifold with boundary can be glued back in, but with a different homeomorphism on the boundary. (It may be hard to believe this could make a different manifold, but such a self-homeomorphism of the boundary does not generally extend to a self-homeomorphism of the removed manifold.) This can be done also in two dimensions by removing a handle and gluing it back on reversing the orientation of one of the boundary circles, but the three-dimensional case is more interesting since if the removed piece is a solid torus, there are many essentially different ways of gluing it back in ( ), none of which affect orientability. The removed solid torus may be knotted or unknotted, and this type of surgery is called surgery on a knot. More generally, we can do surgery on a link. It is known (Lickorish-Wallace theorem) that every closed orientable 3-manifold can be obtained from $S^3$ by surgery on a link ([Wal60], [Lic62]).

XI.9.2.12. Other types of surgery are possible. For example, the boundary of a Möbius strip is a circle, so if $M$ is a 2-manifold, we may cut a disk out of $M$ and glue in a Möbius strip (called a cross-cap). A 2-sphere with a cross-cap added is a projective plane (Figure XI.8). Adding a cross-cap is the same thing as taking connected sum with a projective plane. Every nonorientable closed surface is obtained by adding a number of cross-caps to a sphere; this number is the genus ( ). Similar things can be done in higher dimensions.

XI.9.3. Group Actions on Spaces

XI.9.3.1. Another important source of quotients arises from group actions. A group of homeomorphisms of a topological space $X$ is a set $G$ of homeomorphisms of $X$ such that

(i) $G$ is closed under composition: if $g, h \in G$, then $g \circ h$ (usually written $gh$) is also in $G$.

(ii) $G$ is closed under inversion: if $g \in G$, then $g^{-1} \in G$.

(recall that compositions and inverses of homeomorphisms are homeomorphisms). It follows that the identity map on $X$ is in $G$.

It turns out to be convenient to change point of view slightly:
XI.9.3.2. **Definition.** Let \( G \) be a group and \( X \) a topological space. An *action* of \( G \) on \( X \) is a homomorphism \( \sigma : G \to \text{Homeo}(X) \) from \( G \) to the homeomorphism group of \( X \).

We usually write \( \sigma_g \) in place of \( \sigma(g) \), and often just write \( g \cdot x \) for \( \sigma_g(x) \). The homomorphism property of \( \sigma \) is that \( \sigma_{gh} = \sigma_g \circ \sigma_h \) (written \( \sigma_g \sigma_h \)), or \( (gh) \cdot x = g \cdot (h \cdot x) \), for \( g, h \in G \), \( x \in X \); we have \( \sigma_{e^{-1}} = \sigma_e^{-1} \) for \( e \in G \), and \( \sigma_e \) is the identity homeomorphism if \( e \) is the identity of \( G \).

XI.9.3.3. The group action picture includes the group of homeomorphisms picture: if \( G \) is a group of homeomorphisms of \( X \), the inclusion map of \( G \) into \( \text{Homeo}(X) \) is an action of \( G \) on \( X \). Conversely, if \( \sigma \) is an injective homeomorphism from \( G \) to \( \text{Homeo}(X) \) (we say \( \sigma \) is a *faithful* action of \( G \) on \( X \)), then \( G \) can be identified with the group \( \sigma(G) \) of homeomorphisms of \( X \). The group action picture is slightly more general since group actions need not be faithful (in the theory of group representations () it turns out to be important to allow nonfaithful representations). The conceptual importance of the group action picture is that the group \( G \) can be considered abstractly and is not *a priori* tied to homeomorphisms of a particular space, and it is useful to let the same abstract group act on many different spaces.

Group actions of groups on sets can be similarly defined with no relation to topology: just consider homomorphisms from a group to the group of bijections (permutations) of the set. This can be regarded as a special case of group actions of groups on topological spaces where the space has the discrete topology.

Actions of topological groups on topological spaces are also considered (). In this section, we will not consider the case of topological groups (or, alternatively, we will give all groups the discrete topology).

**Orbits**

XI.9.3.4. **Definition.** Let \( \sigma \) be an action of a group \( G \) on a topological space \( X \), and \( x \in X \). The *orbit* of \( x \) under \( G \) (or \( \sigma \)) is the set

\[
[x] = \{ g \cdot x : g \in G \} = \{ \sigma_g(x) : g \in G \}.
\]

Of course, \( x \in [x] \) since \( x = e \cdot x \). The crucial fact about orbits is that they form a partition of the space:

XI.9.3.5. **Proposition.** Let \( \sigma \) be an action of a group \( G \) on a topological space \( X \). If \( x, y \in X \), then either \( [x] = [y] \) or \( [x] \) and \( [y] \) are disjoint. Equivalently, the relation \( x \sim y \) if \( [x] = [y] \) is an equivalence relation on \( X \).

**Proof:** Suppose \( z \in [x] \cap [y] \). Then there are \( g, h \in G \) with \( z = g \cdot x \) and \( z = h \cdot y \). Then \( y = h^{-1} \cdot z = (h^{-1} g) \cdot x \), and similarly \( x = (g^{-1} h) \cdot y \), so \( [x] = [y] \).

XI.9.3.6. Thus, if \( \sigma \) is an action of a group \( G \) on a topological space \( X \), we may form the quotient space \( X/\sigma \) of orbits, called the *orbit space* of the action, and give it the quotient topology. The orbit space is also often written \( X/G \), especially if \( G \) is given concretely as a group of homeomorphisms of \( X \), although this notation conflicts with the notation for identification spaces (XI.9.1.1.).

Many interesting topological spaces can be constructed as orbit spaces of group actions:
XI.9.3.7. Examples. (i) Let $X$ be the unit circle in $\mathbb{R}^2$. The set consisting of the identity and reflection across the $x$-axis is a group of homeomorphisms of $X$. Each orbit consists of two points except for $[(1,0)]$ and $[(-1,0)]$, which are singletons. The orbit space is homeomorphic to the closed interval $[-1,1]$, and the quotient map can be identified with projection onto the $x$-axis.

(ii) Let $\mathbb{Z}$ act on $\mathbb{R}$ by translation: $n \cdot x = x + n$. Each orbit contains a unique point in the interval $(0,1]$. But the quotient topology is not the subspace topology on $(0,1]$; for example, we have $\left[\frac{1}{n}\right] \to [0] = [1]$. In fact, the quotient space $\mathbb{R}/\mathbb{Z}$ is homeomorphic to the circle obtained from $[0,1]$ by identifying 0 and 1.

(iii) Let $X$ be the unit sphere $S^{n-1}$ in $\mathbb{R}^n$. The set consisting of the identity and the antipodal map $x \mapsto -x$ is a group of homeomorphisms of $S^{n-1}$. Every orbit has two points. The quotient space consists of $S^{n-1}$ with antipodal points identified, and is called real projective $(n-1)$-space, denoted $\mathbb{R}P^{n-1}$. If $n = 3$, we obtain the (real) projective plane (XI.9.2.3). If $n = 2$, we obtain the quotient of the circle by the antipodal map, which is a smaller circle. Note that this action of $\mathbb{Z}_2$ on the circle is very different from the action in (i).

(iv) We may also define complex projective space. Let $T$ be the multiplicative group of complex numbers of absolute value 1. Regard $S^{2n-1}$ as the unit sphere in $\mathbb{C}^n$. Then $T$ acts on $S^{2n-1}$ by $\lambda \cdot x = \lambda x$. The quotient $S^{2n-1}/T$ is called complex projective $n$-space, denoted $\mathbb{C}P^{n-1}$. It is a $(2n-2)$-dimensional manifold.

Projective spaces can also be described in other ways. $\mathbb{R}P^n$ can be described as the set of lines through the origin in $\mathbb{R}^{n+1}$, the quotient of $\mathbb{R}^{n+1} \setminus \{0\}$ by identifying two points if they lie on the same line through $0$. Each such line contains exactly two points on the unit sphere, which are identified; this leads to the picture of $\mathbb{R}P^n$ as the closed upper hemisphere of $S^n$ with antipodal points on the “equator” identified, the higher-dimension analog of the picture in XI.9.2.3.(vii). Similarly, $\mathbb{C}P^n$ is the set of complex “lines” through the origin (one-dimensional complex subspaces) in $\mathbb{C}^{n+1}$.

$\mathbb{R}P^n$ can also be described as $\mathbb{R}^n$ with certain points at infinity added: identify $x \in \mathbb{R}^n$ with the line through the origin and the point $(x,1) \in \mathbb{R}^{n+1}$ (or, equivalently, the equivalent point of norm 1 on the upper hemisphere of $S^n$). The points at infinity added to make $\mathbb{R}P^n$ can be regarded as “lines at infinity,” which form a copy of $\mathbb{R}P^{n-1}$. There is a similar description for $\mathbb{C}P^n$ as $\mathbb{C}^n$ with “complex lines at infinity” added (a copy of $\mathbb{C}P^{n-1}$). These pictures are the origin of the name “projective space.”

(v) The 3-sphere $S^3$ can be regarded as the unit sphere in $\mathbb{C}^2$:

$$S^3 = \{(z,w) \in \mathbb{C}^2: |z|^2 + |w|^2 = 1\}.$$

Fix $p > 1$ and let $\lambda = e^{2\pi i/p}$. Then $\lambda$ is a complex number of absolute value 1, and $\lambda^p = 1$. Define a faithful action of $\mathbb{Z}_p$ (or a nonfaithful action of $\mathbb{Z}$) on $S^3$ by

$$k \cdot (z,w) = (\lambda^k z, \lambda^k w).$$

The quotient space $S^3/\mathbb{Z}_p$ is called a lens space. If $p = 2$, we obtain $\mathbb{R}P^3$. More generally, if $q$ is an integer relatively prime to $p$ (we may restrict to $0 < q < p$), we can define the action by

$$k \cdot (z,w) = (\lambda^k z, \lambda^{qk} w).$$

The lens spaces obtained, denoted $L(p,q)$, $L(p:q)$, or $L_{q/p}$, depend rather subtly on $p$ and $q$: they can be homotopy equivalent without being homeomorphic, and, although orientable, can fail to have orientation-reversing homeomorphisms. Lens spaces can also be constructed by gluing two solid tori along their boundary (); see [Mun84] for another construction of lens spaces by identifying points on the boundary of $B^3$, or [Thu97] for more constructions and an explanation of why these are called “lens spaces.”
Homogeneous Spaces

XI.9.3.8. A simple but particularly important example of a group action is when the space \( X \) is a topological group and \( G \) is a subgroup of \( X \). A topological group acts on itself by (right) translation \((\cdot)\), and so does any subgroup, i.e. \( g \cdot x = xg^{-1} \) for \( g \in G, x \in X \) (this formula with the inverse is needed to make \((gh) \cdot x = g \cdot (h \cdot x)\) for \( g, h \in G, x \in X \)). The orbit space \( X/G \), which is the space of left cosets \((\cdot)\) of \( G \) in \( X \), with the quotient topology is called a homogeneous space. (There is additional structure here: the group \( X \) acts on \( X/G \) by left translation. If \( G \) is a normal subgroup of \( X \), then \( X/G \) is also a topological group.) The quotient space has reasonable properties, e.g. is Hausdorff, only when \( G \) is a closed subgroup of \( X \) (cf. Exercise XI.9.5.1.). The simplest case is when \( G \) is a closed discrete subgroup.

Example XI.9.3.7.(ii) is a basic example of this construction. A closely related example is to take \( X = \mathbb{R}^n \) and \( G = \mathbb{Z}^n \) the additive subgroup of integer points; the quotient is the \( n \)-torus \( T^n \), which is a product of \( n \) circles. In the case \( n = 2 \) we obtain the ordinary torus (XI.9.2.3.(v)); higher-dimensional tori can be similarly constructed by identifying opposite faces of an \( n \)-cube.

XI.9.3.9. The lens spaces \( L(p, 1) \) (XI.9.3.7.(v)) are another example. The topological group \( SU(2) \) (also isomorphic to \( \text{Sp}(1) \) and to the multiplicative group of unit quaternions) is homeomorphic to \( S^3 \), and we can take the quotient by the cyclic subgroup generated by \( \text{diag}(\lambda, \lambda) \). Other lens spaces do not arise as homogeneous spaces of \( SU(2) \).

\( SU(2) \) has other interesting finite subgroups, perhaps the most interesting of which is the binary icosahedral group, which covers the group of rigid motions of a regular icosahedron centered at the origin (a subgroup of \( SO(3) \), which is a quotient of \( SU(2) \)); the quotient of \( SU(2) \cong S^3 \) by this group is called the Poincaré homology sphere, a closed 3-manifold with the same homology as \( S^3 \) but not homeomorphic to \( S^3 \) (it is not simply connected; its fundamental group is the binary icosahedral group, a group of order 120 with no nontrivial abelian quotients). The Poincaré homology sphere can also be constructed from a regular dodecahedron by identifying opposite faces with an appropriate twist \((\cdot)\). See [Thu97] and [Wee02] for a nice description and for many other examples of 3-manifolds obtained from polyhedra by gluing faces (cf. XI.9.5.6.).

Stabilizers and Freeness

XI.9.4. Local Homeomorphisms and Covering Maps

XI.9.5. Exercises

XI.9.5.1. (a) Let \( X = \mathbb{R} \) and \( A = \mathbb{Q} \), and consider the identification space \( X/A \). Show that all the conclusions of XI.9.1.2. fail, and \( X/A \) is not \( T_1 \). Is \( X/A \ T_0 \)?

(b) Let \( \mathbb{R}/\mathbb{Q} \) be the homogeneous space (XI.9.3.8.) considering \( \mathbb{Q} \) as an additive subgroup of \( \mathbb{R} \). Show that \( \mathbb{R}/\mathbb{Q} \) is the space of XI.8.1.11., and thus has the indiscrete topology.

Note that, although the notation \( \mathbb{R}/\mathbb{Q} \) is used in both (a) and (b), the spaces are quite different.

XI.9.5.2. Figures XI.12 and XI.13 show orientable closed surfaces. By the classification, each is homeomorphic to \( S^2 \) with some number of handles. Find the number of handles (genus), and describe a homeomorphism. (There are not only homeomorphisms, but even isotopies; cf. https://www.youtube.com/watch?v=k8Rxep2Mkp8.)

1087
Figure XI.12: An orientable closed surface.

Figure XI.13: Another orientable closed surface.
XI.9.5.3. (a) Show that $\mathbb{R}P^2 \# \mathbb{R}P^2$ is homeomorphic to the Klein bottle $K$.

(b) Show that $\mathbb{R}P^2 \# K$ is homeomorphic to $\mathbb{R}P^2 \# T^2$, and hence $\mathbb{R}P^2 \# T^2$ is homeomorphic to $\mathbb{R}P^2 \# \mathbb{R}P^2 \# \mathbb{R}P^2$.

(c) Show that $\mathbb{R}P^2$ with $n$ handles attached is homeomorphic to the connected sum of $2n + 1$ copies of $\mathbb{R}P^2$, and that $K$ with $n$ handles attached is homeomorphic to the connected sum of $2n + 2$ copies of $\mathbb{R}P^2$.

XI.9.5.4. Let $P$ be a polygon with $2n$ sides, which we may take to be a regular polygon. A gluing scheme on $P$ consists of a choice of an orientation and a labeling of each edge of $P$, such that each label names exactly two edges. A gluing scheme defines a gluing of $P$ by gluing each pair of edges with the same label according to the designated orientation. For example, the gluing scheme of Figure XI.5 gives a Klein bottle when glued.

(a) Show that the gluing scheme of Figure XI.14 gives a two-holed torus.

(b) Show that the gluing schemes of Figure XI.15 both give $S^2$ when glued.
(c) Show that in any gluing scheme, two consecutive edges with the same label and opposite orientations can be eliminated. [Fold them into the interior of the polygon.]

(d) Show that if a gluing scheme contains a labeled pair of edges with the same orientation (with respect to the boundary circle), then the glued space contains a Möbius strip. [See Figure XI.16.] Thus the glued space is not orientable.

(e) Show that if all pairs of glued edges have opposite orientations, a sphere with some number of handles (perhaps none) is obtained from the gluing.

(f) In the situation of (d), show that the glued space consists of adding a cross-cap to a glued space from a polygon with fewer sides. Conclude by induction that the glued space is a connected sum of projective planes, or, equivalently, a sphere with a number of cross-caps added (cf. Exercise XI.9.5.3.).

(g) Conclude from (e) and (f) that the glued space is always a closed surface which is either a sphere with handles attached if orientable, or a sphere with cross-caps attached (a connected sum of projective planes) if nonorientable. Show that every such surface can be obtained this way (although the polygon and gluing scheme are not unique).

(h) Show that if a connected closed surface can be triangulated, it can be represented as the gluing of a polygon by a gluing scheme. Since every 2-manifold can be triangulated, every connected closed surface (2-manifold) is of the form of (g).

(i) Show that no two of the surfaces of (g) with different numbers of handles or projective planes are homeomorphic. Thus (g) gives a complete classification of closed 2-manifolds.

See [Mas77] (or [Mas91]), or [Blo97] (from which the above pictures are taken), for a nice almost complete discussion of the classification of closed 2-manifolds. See [Tho92] for a different approach, and [FW99] (or [Wee02] for a modern proof due to J. Conway. (Note that these proofs are all incomplete since they use the nontrivial fact that every surface can be triangulated, first proved by T. Radó in 1925 [?], cf. [AS60]. For a short proof of triangulability see [DM68] or [Tho92], and http://arxiv.org/pdf/1312.3518.pdf for a different argument not using the Jordan-Schönflies Theorem. See [Ber03, p. 139] for a simple approach to triangulating a compact surface using Riemannian geometry.) For a complete classification of connected noncompact (triangulable) surfaces, see [Ric63].

XI.9.5.5. (a) Let \(X = [0, 1], n \in \mathbb{N}, A_n = \{\frac{k}{n} : 0 \leq k \leq n\}\). Show that \(X/A_n\) is a bouquet of \(n\) circles. In particular, \(X/A_2\) is a figure 8. Show that \(X/A_n\) is the one-point compactification of the disjoint union of \(n\) open intervals (copies of \(\mathbb{R}\)).

(b) Let \(X = [0, 1], A_\omega = \{0\} \cup \{\frac{1}{n} : n \in \mathbb{N}\}\). Show that \(X/A_\omega\) is homeomorphic to the Hawaiian earring (XI.18.4.6.). Show that \(X/A_\omega\) is the one-point compactification of the disjoint union of \(\mathbb{R}_0\) open intervals (copies of \(\mathbb{R}\)).

(c) Let \(K\) be the Cantor set. Show that the quotient \([0, 1]/K\) is also homeomorphic to the Hawaiian earring. [The complement is a countable disjoint union of open intervals.] What about the quotient by identifying other compact subsets of \([0, 1]\)?

XI.9.5.6. [Thu97] Identify the faces of two solid tetrahedra as in Figure XI.16 (there is a unique identification consistent with the picture). Note that the six thick edges are all identified together, as are the six thin edges and all eight vertices.

(a) Show that every point of the identification space \(X\) has a neighborhood homeomorphic to \(\mathbb{R}^3\) except the point \(v\) coming from the vertices. Thus, if \(Y = X \setminus \{v\}\), then \(Y\) is a (noncompact) 3-manifold. If \(Z\) is \(X\)
with a suitable small open neighborhood of \( v \) removed, then \( Z \subseteq Y \) is a compact 3-manifold with boundary homeomorphic to a 2-torus, and there is a deformation retraction of \( Y \) onto \( Z \).

(b) Show that \( Y \) is homeomorphic to the complement in \( S^3 \) of a figure 8 knot \((\cdot)\), and \( Z \) is the complement of a tubular neighborhood of the knot.

(c) [Thu97, p. 129-132] Show similarly that there are two gluing schemes on a pair of octahedra with vertices removed, which respectively give the complement in \( S^3 \) of the Whitehead link (XI.18.5.8.) and the Borromean rings (XI.18.5.4.). Generalize.

**XI.9.5.7.** [Eng89, 1.6.18] Consider the quotient space \( X \) obtained from \( \mathbb{R} \) by collapsing \( Z \) to a point \( z \) (in the notation of XI.9.1.1., this is \( \mathbb{R} / Z \), but this notation is generally reserved for the quotient group \( T \) as in XI.9.3.8., quite a different space.)

(a) Show that \( X \) is perfectly normal (XI.10.4.10.). In particular, \( \{ z \} \) is a \( G_\delta \).

(b) Show that \( z \) does not have a countable local base. Thus \( X \) is not first countable.

(c) Show that \( X \) is a Fréchet-Urysohn space (XI.3.5.1.).

(d) Describe the topological differences, if any, between this space, the Hawaiian earring (XI.18.4.6.), the space of XI.18.4.7., an infinite wedge of circles \((\cdot)\), and the one-point compactification of a countable separated union of copies of \( \mathbb{R} \) (cf. XI.9.5.8.).

**XI.9.5.8.** (a) As a special case of XI.8.5.1.(a), show that collapsing subsets of a space can be done in two or more steps: if \( (A_j) \) and \( (B_k) \) respectively are families of pairwise disjoint subsets of a topological space \( X \) and each \( A_j \) is a union of \( B_k \)'s, the quotient space of \( X \) obtained by collapsing each \( A_j \) to a (separate) point can be obtained by first collapsing the \( B_k \) to (separate) points and then collapsing the set of points corresponding to each \( A_j \) to a point.

(b) As a special case, let \( X \) be a countable separated union of copies of \([0,1]\), indexed by \( \mathbb{Z} \). First identify the endpoints of the \( n \)'th interval to a single point \( *_n \) to obtain a separated union of circles with distinguished
point. Then identify all the $*_{n}$ to a single point. Show that an infinite wedge of circles is obtained.

(c) On the other hand, first identify the right endpoint of the $n$'th interval with the left endpoint of the $(n + 1)$'st interval for each $n$. Show that the quotient space is homeomorphic to $\mathbb{R}$ with the identified points corresponding to $\mathbb{Z}$. Then identify these points together to obtain the space from XI.9.5.7.

(c) Conclude that both the space of XI.9.5.7. and a (countably) infinite wedge of circles are homeomorphic to the quotient of $X$ obtained by identifying all endpoints of all the intervals together to one point, and, in particular, the first two spaces are homeomorphic.
XI.10. Metrizable Spaces

Although the notion of topological space was designed to abstract the concept of a metric space in order to take specific reference to a metric out of the picture, metrizable spaces (topological spaces whose topology comes from a metric) have some nice properties not shared by more general topological spaces, and it is useful to know which topological spaces are metrizable. In this section we give (partial) answers to this question and pursue some of the special properties of metrizable spaces. Completely metrizable spaces (ones whose topology comes from a complete metric) are especially important and also have intrinsic characterizations.

Note that a metrizable space is not the same thing as a metric space: a metrizable space is a topological space for which there exists a metric (which is highly non-unique) giving the topology. A metric space can be regarded as a (metrizable) topological space with a specified metric giving its topology.

XI.10.1. Metrizability

It is a nontrivial problem to determine exactly when a topology comes from a metric, i.e. when a topological space is metrizable. Necessary conditions are that the space be first countable and completely normal (XI.10.1.2.), but these are not sufficient (>). (Note that any subspace of a metrizable space is metrizable).

The first observation is that a metric space \((X, \rho)\) is Hausdorff: if \(x, y \in X \ x \neq y\), and \(\epsilon = \frac{\rho(x,y)}{3}\), then \(B_\epsilon(x)\) and \(B_\epsilon(y)\) are disjoint neighborhoods of \(x\) and \(y\). We also have the following strengthening of \(T_4\):

\[
\text{XI.10.1.1. Proposition. Let } X \text{ be a metrizable space, } A, B \subseteq X \text{ with } \bar{A} \cap B = A \cap \bar{B} = \emptyset \text{ (such } A \text{ and } B \text{ are said to be separated). Then } A \text{ and } B \text{ have disjoint open neighborhoods in } X. \\
\text{Proof: Let } \rho \text{ be a metric on } X \text{ defining the given topology. The conditions on } A \text{ and } B \text{ are equivalent to: } \\
\rho(x, B) > 0 \text{ for all } x \in A \text{ and } \rho(x, A) > 0 \text{ for all } x \in B. \text{ Set } \\
U = \{x \in X : \rho(x, A) < \rho(x, B)\} \\
V = \{x \in X : \rho(x, B) < \rho(x, A)\} \\
\text{and note that } A \subseteq U, B \subseteq V. \text{ An easy application of the triangle inequality shows that } U \text{ and } V \text{ are open, and they are obviously disjoint.}
\]

\[
\text{XI.10.1.2. A } T_1 \text{ topological space satisfying the conclusion of this proposition is called } \text{completely normal. A completely normal space is obviously normal. A topological space } X \text{ is completely normal if and only if every subspace of } X \text{ is normal (XI.10.4.10.), and thus a completely normal space is sometimes called } \text{hereditarily normal. This property is also sometimes called } T_5. \\
\text{The first metrization theorem, and still probably the most useful, was due to Urysohn in (>):}
\]
XI.10.1.3. **Theorem.** [Urysohn Metrization Theorem] Every second countable regular topological space is metrizable.

**Proof:** A second countable regular space is Lindelöf (XI.1.3.5.), hence normal (XI.7.6.11.). Let $X$ be a second countable regular (hence normal) space, and let $U$ be a countable base for the topology of $X$. For each pair $(U, V)$ of sets in $U$ with $V \subseteq U$, let $f_{UV}$ be a continuous function from $X$ to $[0, 1]$ which is 1 on $V$ and 0 on $U^c$; such a function exists by Urysohn’s Lemma (XI.7.6.12.). Let $C$ be the set of all the $f_{UV}$. Then $C$ is countable. If $E$ is a closed set in $X$ and $x \in X \setminus E$, then $E^c$ is an open neighborhood of $x$, so there is a $U \in U$ with $x \in U \subseteq E^c$. There is an open neighborhood $W$ of $x$ with $W \subseteq U$ (XI.7.5.1.), and there is a $V \in U$ with $x \in V \subseteq W$. Then $V \subseteq U$, and $f_{UV}$ satisfies $f_{UV}(x) = 1$ and $f_{UV} = 0$ on $E$. Thus by the proof of XI.7.7.4., $X$ embeds into the cube $[0, 1]^C$. Since $C$ is countable, this cube is metrizable ().

Note that the proof shows slightly more than the statement of the theorem: any second countable regular space embeds in the Hilbert cube ().

XI.10.1.4. There are many other metrization theorems, some of which are quite recent, and there are now various known necessary and sufficient conditions for metrizability. We will state only one of these results here since too many additional definitions are required for the others, and the results are of limited use in analysis. See [SS95] for a survey. There is one version which can be easily stated (cf. [Dug78, p. 207]):

XI.10.1.5. **Theorem.** Let $(X, T)$ be a topological space. Then $X$ is metrizable if and only if it is regular and has a sequence $(U_n)$ of open covers such that if $V$ is any finite open cover of $X$, $U_n$ refines $V$ for some $n$.

**Metrization of Products and Separated Unions**

It is fairly obvious that a finite product of metrizable spaces is metrizable (). It is not true that an arbitrary product of metrizable spaces is metrizable; an uncountable product of nontrivial Hausdorff spaces is not even first countable (XI.6.1.1.). But a *countable* product of metrizable spaces is metrizable. And an arbitrary separated union of metrizable spaces is metrizable.

The technical device giving a simple proof of both facts is:

XI.10.1.6. **Proposition.** Let $\rho$ be a metric on a set $X$. Then there is a uniformly equivalent metric $\tilde{\rho}$ on $X$ with $\tilde{\rho}(x, y) \leq 1$ for all $x, y \in X$. If $\rho$ is complete, then $\tilde{\rho}$ is complete.

**Proof:** There are two standard ways to construct such a metric. One way to do it is to set

$$\tilde{\rho}(x, y) = \frac{\rho(x, y)}{1 + \rho(x, y)} .$$

The triangle inequality needs proof for this metric, which is nontrivial but not difficult (see below). There is, however, a different low-tech way to define $\tilde{\rho}$ which is perhaps less elegant but does the trick more simply: let

$$\tilde{\rho}(x, y) = \min(\rho(x, y), 1) .$$
Proving the triangle inequality for this version of \( \tilde{\rho} \) is just a trivial case-by-case verification. For either definition, we have \( \tilde{\rho}(x, y) \leq \rho(x, y) \) for all \( x, y \in X \) and \( \rho(x, y) \leq 2\tilde{\rho}(x, y) \) if \( \rho(x, y) \leq 1 \), from which it follows easily that \( \rho \) and \( \tilde{\rho} \) are uniformly equivalent. Since uniformly equivalent metrics have the same Cauchy sequences, the completeness statement follows.

For the reader’s edification, we give a proof of the triangle inequality for the metric

\[
\tilde{\rho}(x, y) = \frac{\rho(x, y)}{1 + \rho(x, y)}.
\]

The proof is not difficult, but requires a little trick. Let \( x, y, z \in X \). We may assume \( x \neq z \). Then

\[
\tilde{\rho}(x, z) = \frac{\rho(x, z)}{1 + \rho(x, z)} = \frac{1}{\rho(x, z) + 1} \leq \frac{1}{\rho(x, y) + \rho(y, z) + 1}.
\]

\[
= \frac{\rho(x, y) + \rho(y, z)}{1 + \rho(x, y) + \rho(y, z)} + \frac{\rho(y, z)}{1 + \rho(x, y) + \rho(y, z)}.
\]

\[
\leq \frac{\rho(x, y)}{1 + \rho(x, y)} + \frac{\rho(y, z)}{1 + \rho(y, z)} = \tilde{\rho}(x, y) + \tilde{\rho}(y, z).
\]

\[
\tilde{\rho}(x, z) \leq \tilde{\rho}(x, y) + \tilde{\rho}(y, z) \leq \tilde{\rho}(x, z) + \tilde{\rho}(x, y).
\]

\[
\tilde{\rho}(x, y) = \frac{\rho(x, y)}{1 + \rho(x, y)}.
\]

XI.10.1.7. **Theorem.** A countable product of metrizable spaces is metrizable in the product topology. A countable product of completely metrizable spaces is completely metrizable.

**Proof:** Let \((X_k)\) be a sequence of metrizable spaces, and for each \( k \) let \( \rho_k \) be a metric on \( X_k \) giving the topology on \( X_k \), with the property that \( \rho_k(x, y) \leq 1 \) for all \( x, y \in X_k \), with \( \rho_k \) complete if \( X_k \) is completely metrizable (XI.10.1.6.).

On \( X = \prod_{k \in \mathbb{N}} X_k \), define

\[
\rho(x, y) = \sum_{k=1}^{\infty} 2^{-k} \rho_k(x_k, y_k)
\]

for \( x = (x_1, x_2, \ldots) \) and \( y = (y_1, y_2, \ldots) \) in \( X \). Note that the infinite series converges absolutely for any \( x, y \). It is simple and routine to verify that \( \rho \) is a metric on \( X \). So we need to show that \( \rho \) defines the product topology. It suffices to show that, for fixed \( x = (x_1, x_2, \ldots) \in X \), every \( \rho \)-ball around \( x \) contains an open rectangle around \( x \), and conversely.

Let \( \epsilon > 0 \). Fix \( n \) with \( 2^{-n+1} < \epsilon \). Then

\[
B_{\epsilon/2}^{\rho_1}(x_1) \times B_{\epsilon/2}^{\rho_2}(x_2) \times \cdots \times B_{\epsilon/2}^{\rho_n}(x_n) \times \prod_{k=n+1} B_{\epsilon/2}^{\rho_k}(x_k)
\]

is an open rectangle in \( X \) containing \( x \) and contained in \( B_{\epsilon}^{\rho}(x) \): if \( y = (y_1, y_2, \ldots) \in X \) with \( \rho_k(x_k, y_k) < \frac{\epsilon}{2^n} \) for \( 1 \leq k \leq n \), then

\[
\sum_{k=1}^{\infty} 2^{-k} \rho_k(x_k, y_k) = \sum_{k=1}^{n} 2^{-k} \rho_k(x_k, y_k) + \sum_{k=n+1}^{\infty} 2^{-k} \rho_k(x_k, y_k) < \frac{\epsilon}{2} \sum_{k=1}^{n} 2^{-k} + \sum_{k=n+1}^{\infty} 2^{-k} < \frac{\epsilon}{2} + 2^{-n} = \epsilon.
\]

1095
Conversely, if
\[ V = U_1 \times U_2 \times \cdots \times U_m \times \prod_{k=n+1}^{\infty} X_k \]
is an open rectangle containing \( x \), for \( 1 \leq k \leq m \) there is an \( \epsilon_k \) such that \( B_{\epsilon_k}^m(x_k) \subseteq U_k \). Set
\[ \epsilon = \min(\epsilon_1/2, \epsilon_2/4, \ldots, 2^{-m} \epsilon_m) . \]
If \( y = (y_1, y_2, \ldots) \in X \) with \( \rho(x, y) < \epsilon \), then, for \( 1 \leq k \leq m \)
\[ \rho_k(x_k, y_k) < 2^k \rho(x, y) < 2^k \epsilon \leq \epsilon_k \]
so \( y \in V \), i.e. \( B_{\epsilon}^m(x) \subseteq V \).

If \( (x^{(n)}) = ((x_k^{(n)}) \) is a Cauchy sequence in \( (X, \rho) \), the last inequality shows that \( (x_k^{(n)}) \) is a Cauchy sequence in \( (X_k, \rho_k) \) for each \( k \). If each \( \rho_k \) is complete, then these sequences all converge, and hence \( (x^{(n)}) \) also converges, so \( \rho \) is complete.

This proof requires the Countable AC.

**XI.10.1.8. Proposition.** An arbitrary separated union \( \bigcup \) of metrizable spaces is metrizable. An arbitrary separated union of completely metrizable spaces is completely metrizable.

**Proof:** Let \( \{X_i : i \in I\} \) be a collection of metrizable spaces. Fix a metric \( \rho_i \) on \( X_i \) for each \( i \) giving the topology on \( X_i \), with the property that \( \rho_i(x, y) \leq 1 \) for all \( x, y \in X_i \), with \( \rho_i \) complete if \( X_i \) is completely metrizable (XI.10.1.6.). Let \( X \) be the separated union of the \( X_i \). For \( x, y \in X \), set \( \rho(x, y) = \rho_i(x, y) \) if \( x \) and \( y \) are both in the same \( X_i \), and \( \rho(x, y) = 1 \) otherwise. It is easily checked that \( \rho \) is a metric giving the topology of \( X \), and that \( \rho \) is complete if each \( \rho_i \) is.

This proof uses the AC; the case of \( I \) countable requires the Countable AC.

**Metrizability of Compact Hausdorff Spaces**

**XI.10.1.9. Theorem.** Let \( X \) be a compact Hausdorff space. The following are equivalent:

(i) \( X \) is metrizable.

(ii) \( X \) is second countable.

(iii) \( X \) embeds in the Hilbert cube.

(iv) \( \mathcal{C}_R(X) \) is separable (for the uniform norm).

**Proof:** (i) \( \Rightarrow \) (ii): Let \( d \) be a metric on \( X \). \( (X, d) \) is totally bounded, hence separable, and a separable metric space is second countable.

(ii) \( \Rightarrow \) (iii): Let \( \{U_n : n \in \mathbb{N}\} \) be a countable base for the topology. For each \( n, m \) with \( U_n \subseteq U_m \), let \( f_{n,m} \) be a continuous function from \( X \) to \([0, 1]\) with \( f = 1 \) on \( U_n \) and \( f = 0 \) on \( U_m^c \) (there is such an \( f_{n,m} \) by Urysohn’s
Lemma since $X$ is normal). Set $I = \{(n, m) : \tilde{U}_n \subseteq U_m\} \subset \mathbb{N}^2$ and $Y = [0, 1]^I$ with the product topology. Then $Y$ is homeomorphic to the Hilbert cube (unless $f$ is finite). Define $\phi : X \to Y$ by $\phi(x)_{(n,m)} = f_{n,m}(x)$. Then $\phi$ is continuous by the coordinatewise criterion since each $f_{n,m}$ is continuous. If $x_1, x_2 \in X$, $x_1 \neq x_2$, let $V$ be a neighborhood of $x_1$ not containing $x_2$, $U_m$ a basic neighborhood of $x_1$ contained in $V$, and $U_n$ a basic neighborhood of $x_1$ with $\tilde{U}_n \subseteq U_m$ (there is such an $U_n$ since $X$ is regular). Then $f_{n,m}(x_1) = 1$ and $f_{n,m}(x_2) = 0$, so $\phi(x_1) \neq \phi(x_2)$ and thus $\phi$ is one-to-one. To show $\phi$ is a homeomorphism onto its image, suppose $(x_i)$ is a net in $X$ and $\phi(x_i) \to \phi(x)$ for some $x \in X$. If $x_i \to x$, then there is a neighborhood $V$ of $x$ which does not contain any $x_i$ for a cofinal set of $i$. As in the previous part of the proof, there are $n,m$ such that $x \in U_n \subseteq \tilde{U}_n \subseteq U_m \subseteq V$; then $f_{n,m}(x) = 1$ but $f_{n,m}(x_i) = 0$ for $i$ in a cofinal set, contradicting that $\phi(x_i) \to \phi(x)$. Thus $x_i \to x$.

(iii) $\Rightarrow$ (i) since the Hilbert cube is metrizable.

(iii) $\Rightarrow$ (iv): note first that $C_\mathbb{R}(\mathbb{H})$ is separable: polynomials in the coordinates with rational coefficients are dense by the Stone-Weierstrass Theorem. $C_\mathbb{R}(X)$ is a quotient of $C_\mathbb{R}(\mathbb{H})$ by restriction of functions (this map is surjective by the Tietze Extension Theorem), so $C_\mathbb{R}(X)$ is also separable.

(iv) $\Rightarrow$ (iii): if $C_\mathbb{R}(X)$ is separable, the set $\mathcal{G}$ of continuous functions from $X$ to $[0, 1]$ is also separable in the topology of uniform convergence. Let $\mathcal{F}$ be a countable dense subset of $\mathcal{G}$, and let $Y = [0, 1]^\mathcal{F}$. Then $Y$ is homeomorphic to the Hilbert cube. Define $\phi : X \to Y$ by $\phi(x)_{f} = f(x)$. If $x \in X$ and $V$ is any neighborhood of $x$, there is a $g \in \mathcal{G}$ with $g(x) = 1$ and $g = 0$ on $V'$ since $X$ is completely regular, and $g$ can be uniformly approximated arbitrarily closely by an $f \in \mathcal{F}$. The proof that $\phi$ is a homeomorphism onto its image is then almost identical to the proof of (ii) $\Rightarrow$ (iii).

**XI.10.1.10.** **Corollary.** Let $X$ and $Y$ be compact Hausdorff spaces. If $X$ is metrizable and there is a continuous function from $X$ onto $Y$, then $Y$ is also metrizable.

**Proof:** Let $\phi : X \to Y$ be surjective. Then $f \mapsto f \circ \phi$ embeds $C_\mathbb{R}(Y)$ as a subspace of $C_\mathbb{R}(X)$. Since $C_\mathbb{R}(X)$ is separable and metrizable, so is $C_\mathbb{R}(Y)$.

**XI.10.1.11.** Note that the normed algebra $C(X)$ of complex-valued continuous functions on $X$ is separable if and only if $C_\mathbb{R}(X)$ is separable. Thus, if $X$ is a compact Hausdorff space, $C(X)$ is separable if and only if $X$ is metrizable.

**XI.10.1.12.** Compactness is essential in this result: it fails in general even if $X$ is locally compact and second countable, and $Y$ is perfectly normal. There is a countable perfectly normal space $Y$ which is not first countable (.), hence not metrizable, and $Y$ is a continuous image of $\mathbb{N}$ with the discrete topology. There is even a counterexample if $f$ is a closed map (XI.9.5.7.). The problem seems to be that a single point can be a $G_\delta$ even if the point does not have a countable neighborhood base, which cannot happen in a compact space (XI.11.4.5.).

**XI.10.2. A Universal Space**

We describe a “universal” separable complete metric space:
XI.10.2.1. Definition. Let \( \mathcal{N} = \mathbb{N}^\mathbb{N} \) with the product topology, taking the discrete topology on \( \mathbb{N} \).

\( \mathcal{N} \) consists of all sequences of natural numbers. If \( (a_n) \) is a sequence in \( \mathcal{N} \), say \( a_n = (a_{n,1}, a_{n,2}, \ldots) \), then \( a_n \to b = (b_1, b_2, \ldots) \) if and only if, for each \( k \), there is an \( n_k \) such that \( a_{n,k} = b_k \) for all \( n \geq n_k \).

Recall that set theorists typically write \( \omega \) for \( \mathbb{N} \) (actually \( \mathbb{N} \setminus \{0\} \)), and in set theory \( \mathcal{N} \) is often denoted \( \omega^\omega \).

A notation we will use repeatedly: if \( s = (s_1, s_2, \ldots) \in \mathcal{N} \), write \( s|n = (s_1, \ldots, s_n) \in \mathbb{N}^n \). These are called initial segments of \( s \). Take \( s|0 \) to be the “empty string.”

XI.10.2.2. Proposition. \( \mathcal{N} \) is separable.

Proof: The set of sequences which are eventually 1 is countable and dense in \( \mathcal{N} \).

\[ \mathbb{N} \text{ is a complete metric space under the discrete metric } \delta(a,b) = 1 \text{ if } a \neq b. \]

This is a special case of ( ).

XI.10.2.3. Proposition. The function \( \rho(a,b) = \sum_{k=1}^{\infty} 2^{-k} \delta(a_k, b_k) \) for \( a = (a_k) \) and \( b = (b_k) \) in \( \mathcal{N} \) is a complete metric on \( \mathcal{N} \) giving the product topology.

XI.10.2.4. Proposition. (i) \( \mathcal{N} \) is homeomorphic to \( \mathbb{N} \times \mathcal{N} \), and to \( \{1,\ldots,n\} \times \mathcal{N} \) for any \( n \in \mathbb{N} \). \( \mathcal{N} \) is a disjoint union of a finite or countable sequence of closed subsets, each homeomorphic to \( \mathcal{N} \).

(ii) \( \mathcal{N} \) is homeomorphic to \( \mathbb{N}^n \times \mathcal{N} \) for any \( n \in \mathbb{N} \), and to \( \mathcal{N}^{\mathbb{N}} \).

Proof: (i): The map \( (n, (a_1, a_2, \ldots)) \mapsto (n, a_1, a_2, \ldots) \) is a homeomorphism from \( \mathbb{N} \times \mathcal{N} \) onto \( \mathcal{N} \). If \( n \in \mathbb{N} \),

\[ \{1,\ldots,n\} \times \mathcal{N} \cong \{1,\ldots,n\} \times \mathbb{N} \cong \mathbb{N} \times \mathcal{N} \cong \mathcal{N} \]

taking a one-one correspondence between \( \{1,\ldots,n\} \times \mathbb{N} \) and \( \mathbb{N} \). To obtain an explicit sequence of disjoint closed subsets homeomorphic to \( \mathcal{N} \) partitioning \( \mathcal{N} \), for each \( n \in \mathbb{N} \) let \( \mathcal{N}_n = \{a = (a_k) : a_1 = n\} \).

(ii): If \( n \in \mathbb{N} \), then \( \mathcal{N}^n \cong \mathbb{N}^n \times \{1,\ldots,n\} \), and similarly \( \mathcal{N}^{\mathbb{N}} \cong \mathbb{N}^{\mathbb{N} \times \mathbb{N}} \). Fix one-one correspondences between \( \mathbb{N} \times \{1,\ldots,n\} \) and \( \mathbb{N} \), and between \( \mathbb{N} \times \mathbb{N} \) and \( \mathbb{N} \).

XI.10.2.5. Remark. Note that this proposition does not depend on any form of the Axiom of Choice, since explicit one-one correspondences can be specified (cf. ( ).)

It follows from XI.10.2.2. and XI.10.2.3. that \( \mathcal{N} \) is second countable. An explicit countable base for the topology for \( \mathcal{N} \) can be given:
XI.10.2.6. Proposition. For each \( m \in \mathbb{N} \) and each \((k_1, \ldots, k_m, n_1, \ldots, n_m) \in \mathbb{N}^{2m}\) with \( k_1 < k_2 < \cdots < k_m \), set
\[ U(k_1, \ldots, k_m, n_1, \ldots, n_m) = \{ a = (a_k) : a_{k_j} = n_j \text{ for } 1 \leq j \leq m \}. \]
Then the \( U(k_1, \ldots, k_m, n_1, \ldots, n_m) \) form a base for the topology of \( \mathcal{N} \).

The sets \( U(k_1, \ldots, k_m, n_1, \ldots, n_m) \) can be explicitly arranged in a sequence without using any form of the Axiom of Choice (Exercise (i)).

The space \( \mathcal{N} \) is universal among separable complete metric spaces in the following sense:

XI.10.2.7. Theorem. Let \((X, \sigma)\) be a nonempty separable complete metric space. Then there is a locally contractive (hence continuous) map from \( \mathcal{N} \) onto \( X \).

Proof: By induction on \( n \), choose nonempty closed sets \( F_{s_1, \ldots, s_n} \) for each finite sequence \((s_1, \ldots, s_n) \in \mathbb{N} \) by choosing a sequence \( F_k \) of nonempty closed sets (not necessarily distinct) of diameter \( \leq 1 \) with \( \cup_k F_k = X \), and if sets for sequences of length \( n \) have been chosen, choose nonempty closed sets \( F_{s_1, \ldots, s_n, k} \) for each \((s_1, \ldots, s_n, k) \) of diameter \( \leq 2^{-n} \) such that \( \cup_k F_{s_1, \ldots, s_n, k} = F_{s_1, \ldots, s_n} \) for each \((s_1, \ldots, s_n) \). (Such a collection of subsets is called a Luzin scheme in \( X \).)

The \( F_{s_1, \ldots, s_n} \) can be chosen without any form of choice: fix a dense sequence \((x_k)\) in \( X \), let \( F_k \) be the closed ball of radius \( 2^{-1} \) around \( x_k \), and at the \( n + 1 \)'st stage let \( F_{s_1, \ldots, s_n, k} \) be the intersection of \( F_{s_1, \ldots, s_n} \) with the closed ball of radius \( 2^{-n-1} \) around \( x_k \) if this intersection has nonempty interior, and otherwise the intersection of \( F_{s_1, \ldots, s_n} \) with the closed ball of radius \( 2^{-n-1} \) around \( x_j \) for the first \( j \) for which the intersection has nonempty interior. It is easily checked that these sets have the desired properties.

If \( s = (s_1, s_2, \ldots) \in \mathcal{N} \), there is a unique point in \( \cap_n F_{s_1, \ldots, s_n} \) by completeness; call this point \( f(s) \). Then \( f \) is a map from \( \mathcal{N} \) onto \( X \). If \( s, t \in \mathcal{N} \) with \( \rho(s, t) < 1 \), choose \( n \) so that \( 2^{-n} \leq \rho(s, t) < 2^{-n+1} \); then \( s_j = t_j \) for \( 1 \leq j \leq n \), so \( f(s), f(t) \in F_{s_1, \ldots, s_n} \), \( \sigma(f(s), f(t)) \leq 2^{-n} \), and \( f \) is locally contractive.

Such a map can be explicitly described in some cases:

XI.10.2.8. Examples. (i) Define \( \phi : \mathbb{N} \to \{0, 1\} \) by \( \phi(1) = 1 \) and \( \phi(n) = 0 \) for \( n > 1 \). Applying \( \phi \) coordinatewise, we obtain a map from \( \mathcal{N} \) onto \( \{0, 1\}^\mathbb{N} \) which is a contraction. Since there is a uniform homeomorphism between \( \{0, 1\}^\mathbb{N} \) and the Cantor set \( K \), we obtain a Lipschitz function from \( \mathcal{N} \) onto \( K \). Also, there is a contractive mapping from \( \{0, 1\}^\mathbb{N} \) onto \( [0, 1] \) ( ), hence a contractive mapping from \( \mathcal{N} \) onto \([0, 1] \). Writing \( \mathcal{N} \) as a disjoint union of closed sets \( \mathcal{N}_n \) as in () and taking the corresponding Lipschitz map from \( \mathcal{N}_n \) onto \([n, n + 1] \), we obtain a locally Lipschitz map from \( \mathcal{N} \) onto \([0, +\infty) \). By taking a one-one correspondence between \( \mathbb{N} \) and \( \mathbb{Z} \), we obtain a similar map from \( \mathcal{N} \) onto \( \mathbb{R} \).

(ii) There is a homeomorphism from \( \mathcal{N} \) onto the set \( J \) of irrational numbers given by continued fractions (): the sequence \((n_1, n_2, \ldots)\) corresponds to the number with continued fraction \((n_1, n_2, \ldots)\), i.e.
\[
(n_1, n_2, \ldots) \mapsto n_1 + \frac{1}{n_2 + \frac{1}{n_3 + \cdots}}
\]
(this actually maps to the irrational numbers greater than 1; use a homeomorphism between \( \mathcal{N} \) and \( \mathcal{N} \times \{0, 1\} \) to get a map onto all of \( J \)).
XI.10.2.9. There is an important extension of this result. Recall that if \( X \) is a topological space and \( Y \subseteq X \), a retract of \( X \) onto \( Y \) is a continuous function \( f : X \to Y \) such that \( f(y) = y \) for all \( y \in Y \). \( Y \) is called a retract of \( X \) if there is a retraction from \( X \) onto \( Y \). If \( X \) is Hausdorff, then a retract of \( X \) is necessarily a closed subset of \( X \). It is relatively rare to have a retraction onto a general closed subset of a topological space; however, \( \mathcal{N} \) has the following remarkable property:

XI.10.2.10. Theorem. Let \( Y \) be a nonempty closed subset of \( \mathcal{N} \). Then there is a contractive retraction from \( \mathcal{N} \) onto \( Y \).

The proof is a slight refinement of the proof of XI.10.2.7., and is left to the reader (Exercise ()). Alternatively, an easy proof can be given using the language of trees.

Trees

Trees can be described in various ways. For our purposes, we will take the following definition:

XI.10.2.11. Definition. A tree is a directed graph \( T \) for which:

(i) Every vertex (node) has a rank in \( \mathbb{N} \cup \{0\} \).

(ii) Every edge goes from a node of rank \( n \) to a node of rank \( n + 1 \) for some \( n \).

(iii) There is a unique node of rank 0, called the root.

(iv) For every node \( x \), there is a unique path (necessarily of length equal to the rank of \( x \)) from the root to \( x \). In particular, every node of rank \( n \geq 1 \) has a unique predecessor of rank \( n - 1 \).

A tree \( T \) is pruned if every node has at least one successor.

A subtree of a tree \( T \) is a subgraph which is itself a tree. A subtree is a pruned subtree if it is itself a pruned tree. (We also regard the empty subgraph as a subtree, which is a pruned subtree.)

XI.10.2.12. Example. Take the nodes of rank \( n \) to be \( \{s|n : s \in \mathcal{N}\} \), and take an edge from \( s|n \) to \( s|(n + 1) \) for each \( s \in \mathcal{N} \) and \( n \in \mathbb{N} \cup \{0\} \). This is a pruned tree, called the tree over \( \mathbb{N} \), denoted \( T_{\mathbb{N}} \). The root is the empty string, and \( \mathcal{N} \) can be naturally identified with the infinite paths in \( T_{\mathbb{N}} \).

The proof of the next proposition is a simple exercise which is left to the reader.

XI.10.2.13. Proposition. When \( \mathcal{N} \) is identified with the set of infinite paths in \( T_{\mathbb{N}} \), there is a natural one-one correspondence between the closed subsets of \( \mathcal{N} \) and the pruned subtrees of \( T_{\mathbb{N}} \), where the subset of \( \mathcal{N} \) corresponding to a pruned subtree \( S \) is the set of infinite paths in \( S \).
XI.10.2.14. Proof of Theorem XI.10.2.10.: In light of XI.10.2.13., we need only show that if $S$ is a nonempty pruned subtree of $T_N$, there is a retraction $\phi$ of $T_N$ onto $S$ which preserves rank and edges. Define $\phi$ by induction on rank as follows. Let $\phi(s|0) = s|0$. Suppose $\phi(s|n)$ has been defined for each $s \in \mathcal{N}$. For each node $s|(n + 1)$ (there are countably many distinct nodes of this type), if $s|(n + 1) \in S$, set $\phi(s|(n + 1)) = s|(n + 1)$, and otherwise let $\phi(s|(n + 1))$ be any successor of $\phi(s|n)$ in $S$ (to make it definite and avoid using AC, let it be the successor node in $S$ with smallest possible $(n + 1)'st$ coordinate). It is easily checked that this $\phi$ has the desired properties. □

XI.10.3. Polish Spaces

XI.10.3.1. Definition. A topological space is a Polish space if it is homeomorphic to a separable complete metric space.

Note that a Polish space is a topological space, not a metric space: it does not come with a specified metric, and even if it is given as a metric space, the given metric may not be complete – there need only be an equivalent complete metric (cf. XI.10.3.3.). Any topological space homeomorphic to a Polish space is a Polish space.

XI.10.3.2. Examples. (i) $\mathbb{R}^n$, or more generally any separable Banach space regarded as a topological space. An open ball in $\mathbb{R}^n$ is homeomorphic to $\mathbb{R}^n$, hence a Polish space.

(ii) Any (nonempty) closed subset of a Polish space; in particular, any closed subset of $\mathbb{R}^n$.

(iii) Any second countable compact Hausdorff space ().

(iv) The space $\mathcal{N}$ (XI.10.2.1.). More generally, a finite or countable Cartesian product of Polish spaces is Polish with the product topology (XI.10.1.7.).

(v) A countable separated union of Polish spaces is a Polish space (XI.10.1.8.).

A Polish space is second countable, Hausdorff, and normal, and is a Baire space (satisfies the conclusion of the Baire Category Theorem).

XI.10.3.3. Theorem. A subset of a Polish space is a Polish space if and only if it is a $G_\delta$.

Proof: Let $X$ be a Polish space, and fix a complete metric $\rho$ on $X$. Suppose $E$ is a $G_\delta$ in $X$. We could simply write down an explicit formula for a complete metric on $E$ giving the relative topology, but the formula is somewhat complicated and deserves some motivation.

Let $U$ be an open subset of $X$, and for $x \in U$ define $g(x) = \frac{1}{\rho(x,U^c)}$. Then $g$ is a continuous function from $U$ to $\mathbb{R}$, and the graph

$$\Gamma = \{(x,g(x)) : x \in U\} \subseteq X \times \mathbb{R}$$

is a closed subset of $X \times \mathbb{R}$ which is homeomorphic to $U$ via projection onto the first coordinate. $X \times \mathbb{R}$ is a complete metric space under the metric

$$\sigma((x,s),(y,t)) = \rho(x,y) + \min(|s| - |t|, 1) .$$

Hence the restriction of $\sigma$ to $\Gamma$ transfers to a complete metric on $U$, also denoted $\sigma$:

$$\sigma(x,y) = \rho(x,y) + \min(|g(x) - g(y)|, 1) .$$
Now write $E = \cap_n U_n$ with $U_n$ open, and let $g_n$ and $\sigma_n$ be the corresponding function and metric for $U_n$. For $x, y \in E$, set
\[
\tau(x, y) = \sum_{n=1}^{\infty} 2^{-n} \sigma_n(x, y) = \rho(x, y) + \sum_{n=1}^{\infty} 2^{-n} \min(|g_n(x) - g_n(y)|, 1).
\]

Then $\tau$ is a metric on $E$, and it is easily shown (Exercise () that $\tau$ induces the relative topology on $E$. If $(x_k)$ is a $\tau$-Cauchy sequence, then $(x_k)$ is a $\rho$-Cauchy sequence, hence $\rho$-converges to some $x \in X$. Since $(x_k)$ is also a $\sigma_n$-Cauchy sequence for each $n$, it $\sigma_n$-converges to some $x^{(n)} \in U_n$. But the $\sigma_n$-topology on $U_n$ is the relative topology, so $x_k \to x^{(n)}$ in $X$ and hence $x^{(n)} = x$, i.e. $x \in U_n$ for all $n$, so $x \in E$ and $x_k$ $\tau$-converges to $x$; thus $(E, \tau)$ is complete. Since every subset of a separable metric space is separable, $E$ is a Polish space.

For the converse, suppose $E \subset X$ is a complete metric space under a metric $\tau$ giving the relative topology. We may assume that $E$ is dense in $X$, since if $Y$ is the closure of $E$, then $Y$ is a $G_\delta$ in $X$, so every $G_\delta$ in $Y$ is a $G_\delta$ in $X$. For $n \in \mathbb{N}$, let $U_n$ be the set of all $x \in X$ such that there is a neighborhood $V^{(n)}_x$ of $x$ with the $\tau$-diameter of $E \cap V^{(n)}_x$ less than $\frac{1}{n}$. Then $U_n$ is open in $X$. Set $F = \cap_n U_n$; then $F$ is a $G_\delta$ containing $E$. If $x \in F$, choose a sequence $x_n \in E \cap V^{(n)}_x$. Then $(x_n)$ is a $\tau$-Cauchy sequence in $E$, hence converges to an element of $E$ we call $f(x)$. The element $f(x)$ is independent of the choice of the $x_n$ and even the $V^{(n)}_x$ (any neighborhood of $x$ has nonempty intersection with $E$). Then $f : F \to E$ is continuous, and if $x \in E$, we have $f(x) = x$. Thus $E = \{x \in F : f(x) = x\}$, so $E$ is (relatively) closed in $F$. Since $E$ is dense in $F$, $E = F$ is a $G_\delta$ in $X$.

**XI.10.3.4.** Note that separability is not used in the proof (except in the last sentence of the first part), so this result also holds for topological spaces homeomorphic to complete metric spaces, not necessarily separable; such spaces are sometimes called absolute $G_\delta$‘s.

We have the following result of Kuratowski [], which is a sharpening of XI.10.2.7. The proof is rather involved, although fairly elementary, and we omit it; see, for example, [?, 2.4.1].

**XI.10.3.5.** **Theorem.** Let $X$ be an uncountable Polish space which is dense in itself. Then there is an injective continuous function from $\mathcal{N}$ onto $X$ such that the image of every open set is an $F_\sigma$.

Since by the Cantor-Bendixson Theorem (XI.2.5.4.) every Polish space is a disjoint union of a countable open subset and a closed subset which is dense-in-itself, we obtain:

**XI.10.3.6.** **Corollary.** Every uncountable Polish space has cardinality $2^{\aleph_0}$.

**How Many Polish Spaces Are There?**

**XI.10.3.7.** **Theorem.** There are exactly $2^{\aleph_0}$ Polish spaces up to homeomorphism.

**Proof:** Let $\mathcal{P}$ be the set of homeomorphism classes of infinite Polish spaces (there are countably many finite Polish spaces, which are just finite discrete spaces). There are $2^{\aleph_0}$ pairwise nonhomeomorphic compact
subsets of $\mathbb{R}^2$ (XI.18.4.1.), each of which is a Polish space, so $\text{card}(\mathcal{P}) \geq 2^{\aleph_0}$. On the other hand, if $X$ is an infinite Polish space, $\rho$ is a complete metric on $X$, and $D$ is a countable dense set in $X$, then $(X, \rho)$ is the completion of $(D, \rho|_D)$. If $D$ is identified with $\mathbb{N}$, the metric $\rho|_D$ can be transferred to $\mathbb{N}$; thus $X$ is homeomorphic to the completion of $\mathbb{N}$ with respect to some metric. So if $\mathcal{M}$ is the set of all metrics on $\mathbb{N}$, $\text{card}(\mathcal{M}) = 2^{\aleph_0}$ and there is a function from $\mathcal{M}$ onto $\mathcal{P}$. Therefore $\text{card}(\mathcal{P}) \leq 2^{\aleph_0}$.

**XI.10.3.8.** The above proof uses the AC (how?). The full AC is not needed: it suffices to assume that $\mathbb{R}$ can be well ordered, i.e. that $2^{\aleph_0}$ is an aleph. For the best that can be proved in ZF, see Exercise XI.10.4.9.

**XI.10.4. Exercises**

**XI.10.4.1.** Arrange the tuples occurring as indexes in () into an explicit sequence, as follows:

(a) The set of pairs $((n_1, \ldots, n_m), (k_1, \ldots, k_m))$ ($m = 0$ is allowed, giving the “empty pair”), with the $n_j$ strictly increasing in $\mathbb{N}$ and the $k_j \in \mathbb{N}$, is in natural one-one correspondence with the set $\mathcal{C}$ of sequences in $\mathbb{N} \cup \{0\}$ which are eventually 0: the pair $((n_1, \ldots, n_m), (k_1, \ldots, k_m))$ corresponds to the sequence with $k_j$ in the $n_j$th place and zeroes elsewhere.

(b) The set $\mathcal{C}$ is in one-one correspondence with $\mathbb{N}$:

$$(t_1, t_2, \ldots) \longleftrightarrow \prod_j p_j^{t_j}$$

where $p_j$ is the $j$th prime.

**XI.10.4.2.** In the proof of XI.10.3.3., show that $\tau$ gives the relative topology on $E$. [Hint: Suppose $(x_m) \subseteq E$ $\rho$-converges to $x \in E$. Given $\epsilon > 0$, fix $n$ so that $2^{-n} < \epsilon/3$, and find $M$ so that $\rho(x_m, x) < \epsilon/3$ and $|g_k(x_m) - g_k(x)| < \epsilon/3$ for all $m \geq M$ and $1 \leq k \leq n$.]

**XI.10.4.3.** (a) Show that if $K$ is a compact subset of $\mathcal{N}$, then for each $n \in \mathbb{N}$ there is a $k_n \in \mathbb{N}$ such that $s_n \leq k_n$ whenever $s = (s_1, s_2, \ldots) \in K$. [Consider the image of $K$ under the $n$th coordinate map $\pi_n : \mathcal{N} \to \mathbb{N}$.]

(b) Show that if $K \subseteq \mathcal{N}$ is compact, then $\mathcal{N} \setminus K$ is dense in $\mathcal{N}$.

(c) Conclude from the Baire Category Theorem that $\mathcal{N}$ is not $\sigma$-compact.

(d) Prove a similar result about an infinite product of copies of $\mathbb{R}$. Thus no infinite-dimensional Banach space is $\sigma$-compact in the norm topology. (Every infinite-dimensional separable Banach space is homeomorphic as a topological space to a product of a countable number of copies of $\mathbb{R}$ [].)

**XI.10.4.4.** If $(X, \rho)$ is a separable metric space, show that $X$ is homeomorphic to a subspace of the Hilbert cube $[0, 1]^\mathbb{N}$, as follows.

(a) Let $\sigma = \min(\rho, 1)$ be a $[0, 1]$-valued metric equivalent to $\rho$, and let $(y_n)$ be a dense sequence in $X$. Define $f_n : X \to [0, 1]$ by $f_n(x) = \sigma(x, y_n)$. Define $f : X \to [0, 1]^\mathbb{N}$ by $f(x) = (f_1(x), f_2(x), \ldots)$. Show that $f$ is continuous.

(b) Show that $f$ is a homeomorphism from $X$ onto $f(X)$. [If $f(x_n) \to f(x)$, for $\epsilon > 0$ choose $m$ so that $\sigma(x, y_m) < \epsilon/2$. Since $f_n(x_m) = \sigma(x, y_m) \to f_m(x) = \sigma(x, y_m) < \epsilon/2$, there is an $N$ such that $f_m(x_n) < \epsilon/2$ for $n \geq N$, so $\sigma(x_n, x) < \epsilon$ for $n \geq N$.]

1103
XI.10.4.5. Show that every metrizable space is homeomorphic to a closed subspace of a product of completely metrizable spaces. If $X$ is metrizable with metric $\rho$, let $\tilde{X}$ be the completion of $X$ with respect to $\rho$, and consider

$$\prod_{y \in X \setminus \{y\}} (\tilde{X} \setminus \{y\}).$$

XI.10.4.6. [Wil04, 23.2] Give a direct proof of XI.10.1.10. as follows. Let $X$ and $Y$ be compact Hausdorff spaces, and $f : X \to Y$ a surjective continuous function. Suppose $X$ is second countable. Let $\mathcal{B}$ be a countable base for the topology of $X$ which is closed under finite unions. Set

$$D = \{Y \setminus f(X \setminus B) : B \in \mathcal{B}\}.$$ 

Show that $D$ is a countable base for the topology of $Y$.

XI.10.4.7. The Hausdorff Metric. Let $(X, \rho)$ be a metric space, and let $\mathcal{K}(X)$ be the set of nonempty compact subsets of $X$. For $x \in X$ and $F \in \mathcal{K}(X)$, set

$$\rho(x, F) = \inf_{y \in F} \rho(x, y) = \min_{y \in F} \rho(x, y).$$

For $E, F \in \mathcal{K}(X)$, set

$$\rho_1(E, F) = \sup_{x \in E} \rho(x, F) = \max_{x \in E} \rho(x, F)$$

and

$$\rho_h(E, F) = \max(\rho_1(E, F), \rho_1(F, E)).$$

This $\rho_h$ is called the Hausdorff metric (or Hausdorff distance) on $\mathcal{K}(X)$. (It can be defined more generally on the space of closed bounded subsets of $X$, but not all of the same properties hold in this space. Such spaces of subsets are often called hyperspaces.)

(a) Show that $\rho_h$ is a metric on $\mathcal{K}(X)$.

(b) Show that if $\rho$ is complete, then $\rho_h$ is also complete. [It suffices to show that every $\rho_h$-Cauchy sequence has a convergent subsequence. Let $(E_n)$ be a sequence in $\mathcal{K}(X)$ with $\rho_h(E_n, E_{n+1}) < 2^{-n}$. If

$$D = \{x \in X : \exists x_n \in E_n \text{ with } x_n \to x \text{ and } \rho(x_n, x_{n+1}) < 2^{-n}\}$$

then $E = \overline{D}$ is nonempty and compact (totally bounded), and $E_n \to E$.]

(c) Show that if $(X, \rho)$ is separable, then $(\mathcal{K}(X), \rho_h)$ is also separable. [Consider finite subsets of a countable dense set in $X$.]

(d) Show that if $(X, \rho)$ is totally bounded, so is $(\mathcal{K}(X), \rho_h)$. [If $D$ is a $\delta$-cover of $X$, then $\mathcal{P}(D)$ is a $\delta$-cover of $\mathcal{K}(X)$.] Conclude from (b) and (c) that if $(X, \rho)$ is compact, so is $(\mathcal{K}(X), \rho_h)$.

(e) The map $x \mapsto \{x\}$ is an isometry from $(X, \rho)$ onto a closed subset of $(\mathcal{K}(X), \rho_h)$. Deduce the converses of the statements in (b), (c), and (d).

(f) If $E, E_1, E_2, \cdots \in \mathcal{K}(X)$ and $E_n \to E$, then $\cap_{n} E_n \subseteq E \subseteq \cup_{n} E_n$. If $Y$ is a closed subset of $X$, then $\mathcal{K}(Y)$ is a closed subset of $\mathcal{K}(X)$. If $Y$ is compact and $\mathcal{K}(X)_Y = \{E \in \mathcal{K}(X) : Y \subseteq E\}$, then $\mathcal{K}(X)_Y$ is also a closed subset of $\mathcal{K}(X)$. In particular, if $p \in X$, then

$$\mathcal{K}(X)_p = \mathcal{K}(X)_{\{p\}} = \{E \in \mathcal{K}(X) : p \in E\}$$

1104
is a closed subset of \( \mathcal{K}(X) \).

(g) Let \( X = \{ \frac{1}{n} : n \in \mathbb{N} \} \cup \{ 0 \} \subseteq [0,1] \) with the metric \( \rho(x,y) = |x-y| \). Show that \( \mathcal{K}(X)_0 \) is homeomorphic to the Cantor set. [A compact subset of \( X \) containing 0 is of the form \( E_S = \{ \frac{1}{n} : n \in S \} \cup \{ 0 \} \) for a subset \( S \) of \( \mathbb{N} \). Send \( E_S \) to the usual sequence in \( \{0,1\}^\mathbb{N} \) associated to \( S \) as in (i).] The complement of \( \mathcal{K}(X)_0 \) in \( \mathcal{K}(X) \) is countable. Describe the topological space \( \mathcal{K}(X) \).

(h) \( \mathcal{K}([0,1]) \) is topologically infinite-dimensional. [If \( n \in \mathbb{N} \) and \( x_1, \ldots, x_n \) are distinct numbers in \( (0,1) \), then there is a neighborhood \( U \) of \( (x_1, \ldots, x_n) \) in \( \mathbb{R}^n \) such that \( (y_1, \ldots, y_n) \mapsto \{y_1, \ldots, y_n\} \) is a homeomorphism from \( U \) into \( \mathcal{K}([0,1]) \).] In fact, \( \mathcal{K}([0,1]) \) is homeomorphic to the Hilbert cube \([?)\), as is \( \mathcal{K}(X) \) for any compact, connected, locally connected metric space \( X \) [CS78].

(i) Show that \( (\mathcal{K}(X), \rho_h) \) is connected [resp. totally disconnected] if and only if \( (X, \rho) \) is connected [resp. totally disconnected].

### XI.10.4.8. The Hausdorff Metric Continued

[ Mic51 ] Use the notation of Exercise XI.10.4.7. Let \( (X, \rho) \) be a metric space.

(a) Show that if \( E, E_1, E_2, \cdots \in \mathcal{K}(X) \), then \( E_n \to E \) if and only if, for every finite set \( \{U_1, \ldots, U_n\} \) of open subsets of \( X \) with \( E \subseteq \bigcup_k U_k \) and \( E \cap U_k \neq \emptyset \) for all \( k \), we have, for all sufficiently large \( n \), \( E_n \subseteq \bigcup_k U_k \) and \( E_n \cap U_k \neq \emptyset \) for all \( k \). (A topology can be defined on \( \mathcal{K}(X) \) in this way for any topological space \( X \); this topology is called the finite topology or Vietoris topology on \( \mathcal{K}(X) \).)

(b) Let \( (Y, \sigma) \) be another metric space, and \( f : X \to Y \) a continuous function. Define \( f_* : \mathcal{K}(X) \to \mathcal{K}(Y) \) by setting \( f_*(E) = f(E) \) for \( E \in \mathcal{K}(X) \) (recall (i) that \( f(E) \) is compact). Show that \( f_* : (\mathcal{K}(X), \rho_h) \to (\mathcal{K}(Y), \sigma_h) \) is continuous.

(c) Show that if \( \sigma \) is another metric on \( X \) which is equivalent to \( \rho \), then \( \sigma_h \) is equivalent to \( \rho_h \). So the topology on \( \mathcal{K}(X) \) depends only on the topology of \( X \), not on the choice of metric.

(d) Show that if \( E_n \to E \) in \( \mathcal{K}(X) \), then \( F = E \cup \bigcup_{n=1}^\infty E_n \) is compact in \( X \). [If \( \mathcal{U} \) is an open cover of \( F \), let \( \{U_1, \ldots, U_m\} \) be a finite subcover of \( E \). Then \( E_n \subseteq \bigcup_{k=1}^m U_k \) for all but finitely many \( n \).] More generally, if \( \mathcal{E} \) is an open cover of \( \mathcal{K}(X) \), then \( \bigcup_{E \in \mathcal{E}} E \) is an open cover of \( \mathcal{K}(X) \) [Mic51, 2.5.1].

### XI.10.4.9. Let \( \mathcal{P} \) be the set of homeomorphism classes of Polish spaces, and \( \kappa = \text{card}(\mathcal{P}) \). Show that the following weak version of XI.10.3.7. is the best which can be proved in ZF [recall (II.9.7.9.) that it cannot be proved in ZF that \( \aleph_1 \) and \( 2^{\aleph_0} \) are comparable.]

**THEOREM.**

(i) \( \kappa \geq \aleph_1 + 2^{\aleph_0} \).

(ii) \( \kappa \lesssim 2^{\aleph_0} \) (II.9.4.2.).

(iii) \( \kappa < 2^{2^{\aleph_0}} \).

The arguments are the ones from the proof of XI.10.3.7. For (i), note that by XI.18.4.2. there are also \( \aleph_1 \) pairwise nonhomeomorphic compact subsets of \( \mathbb{R} \), none of which are homeomorphic to the ones of XI.18.4.1.. For (iii), use II.9.7.7. and II.5.3.3..
XI.10.4.10. Prove the following theorem:

**Theorem.** Let $X$ be a (necessarily $T_1$) topological space. The following are equivalent:

(i) $X$ is completely normal (XI.10.1.2.).

(ii) Every open subspace of $X$ is normal.

(iii) Every subspace of $X$ is normal.

(iv) Every subspace of $X$ is completely normal.

(a) Show that (i) $\Rightarrow$ (iv).

(b) For (ii) $\Rightarrow$ (i), suppose $X$ is normal, $A, B \subseteq X$ with $A \cap \overline{B} = \overline{A} \cap B = \emptyset$ and $W = X \setminus (\overline{A} \cap \overline{B})$ normal. Show $A$ and $B$ have disjoint neighborhoods in $W$, hence in $X$.

(c) A topological space $X$ is **perfectly normal** if it is normal and every closed set in $X$ is a $G_\delta$ (equivalently, every closed set in $X$ is a zero set $\emptyset$), or that every open set in $X$ is an $F_\sigma$. Use the theorem and XI.7.8.7.(b) to show that every perfectly normal space is completely normal. Show that every metrizable space is perfectly normal. There are completely normal spaces which are not perfectly normal, e.g. the one-point compactification of an uncountable discrete space. A space which is perfectly normal is sometimes called $T_6$. 

1106
XI.11. Compactness

Compactness is one of the most important notions in topology, and especially for its applications in analysis. Compact sets behave roughly like finite sets. Compactness is used in applications to insure boundedness, the existence of limits, and the achievement of extrema, among other things.

Use of the Axiom of Choice is pervasive in the theory of compactness, and we will freely employ it; we will usually point out which results depend on it and which do not. Use of the Axiom of Choice can be almost entirely avoided if one sticks only to second countable topological spaces.

XI.11.1. Basic Definitions

XI.11.1.1. Definition. Let \((X, T)\) be a topological space. An open cover (\(T\)-open cover) is a set \(U = \{U_i : i \in I\}\) of \(T\)-open sets with \(\cup_{i \in I} U_i = X\). The open cover \(U\) is finite if \(I\) is finite. A subset \(V\) of an open cover \(U\) is a subcover if it is itself an open cover. If \(Y \subseteq X\) and \(U = \{U_i : i \in I\} \subseteq T\), then \(U\) is an open cover of \(Y\) in \(X\) if \(Y \subseteq \cup_{i \in I} U_i\). Subcovers of \(Y\) in \(X\) are defined similarly.

XI.11.1.2. Definition. Let \((X, T)\) be a topological space. \((X, T)\) is compact if every open cover of \(X\) has a finite subcover. If \(Y \subseteq X\), then \(Y\) is a compact subspace of \(X\) if every open cover of \(Y\) in \(X\) has a finite subcover in \(X\).

XI.11.1.3. Caution: In some older references, particularly from Eastern Europe, “compact” is used to mean “countably compact” (XI.11.7.1.). A space which is compact according to the modern definition XI.11.1.2. is called “bicom pact” in these references. Also, in some references, especially French ones and [Eng89], the term “compact” is reserved for Hausdorff spaces; a space which is compact in the sense of XI.11.1.2. but not necessarily Hausdorff is called “quasi-compact.” In some references like [Pea75], “bicom pact” means “compact and Hausdorff.” Check the definitions in any reference.

The first observation is that compactness of a subspace depends only on the relative topology of the subspace, not on the way it is embedded:

XI.11.1.4. Proposition. If \(Y\) is a subspace of a topological space \((X, T)\), then \(Y\) is a compact subspace of \(X\) if and only if \((Y, T_Y)\) is compact.

Proof: This is obvious from the fact that every relatively open subset of \(Y\) is of the form \(U \cap Y\), where \(U \in T\).

The next result, an immediate corollary of XI.11.2.2. and the Bolzano-Weierstrass theorem, gives the most important basic examples of compact spaces, and begins to give a picture of the meaning of compactness.

XI.11.1.5. Theorem. A subset of \(\mathbb{R}^n\) is compact if and only if it is closed and bounded.

Here is a far-reaching version (not quite a generalization) of XI.11.1.5.. Because of this, compact sets are often thought of as sets which are “absolutely closed” (although this is only really accurate in Hausdorff spaces). See XI.11.4.1. and XI.11.4.2. for generalizations of the second statement.
XI.11.1.6. Proposition. A closed subspace of a compact space is compact. A compact subspace of a Hausdorff space is closed.

Proof: Let \((X, \mathcal{T})\) be a compact space, and \(Y\) a closed subset of \(X\). Let \(\mathcal{U}\) be an open cover of \(Y\) in \(X\). Then \(\mathcal{V} = \mathcal{U} \cup \{X \setminus Y\}\) is an open cover of \(X\). Let \(\{U_1, \ldots, U_n, X \setminus Y\}\) be a finite subcover of \(\mathcal{V}\); then \(\{U_1, \ldots, U_n\}\) is a finite subcover of the cover \(\mathcal{U}\) of \(Y\).

If \((X, \mathcal{T})\) is a Hausdorff space and \(Y\) is a compact subspace of \(X\), and \(x \in X \setminus Y\), for each \(y \in Y\) let \(U_y\) and \(V_y\) be disjoint open neighborhoods (in \(X\)) of \(x\) and \(y\) respectively. Then \(\{V_y : y \in Y\}\) is an open cover of \(Y\) in \(X\). Let \(\{V_{y_1}, \ldots, V_{y_n}\}\) be a finite subcover. Then \(U = U_{y_1} \cap \cdots \cap U_{y_n}\) is an open neighborhood of \(x\) disjoint from \(Y\). Thus \(X \setminus Y\) is open.

Note that the Axiom of Choice is used in the second half of the proof. The result is true, however, without any Choice assumption (Exercise XI.11.12.2.).

A compact subspace of a general topological space, even a \(T_1\)-space, is not necessarily closed (Exercise XI.11.12.1.).

A continuous image of a closed set is not necessarily closed. But one of the important properties of compactness is that it is preserved under continuous images:

XI.11.1.7. Proposition. Let \((X, \mathcal{T})\) and \((Z, S)\) be topological spaces, and \(f : X \to Z\) a continuous function. If \(Y\) is a compact subset of \(X\), then \(f(Y)\) is a compact subset of \(Z\).

Proof: Let \(\mathcal{V} = \{V_i : i \in I\}\) be an open cover of \(f(Y)\) in \(Z\). For each \(i\), let \(U_i = f^{-1}(V_i)\). Then \(\mathcal{U} = \{U_i : i \in I\}\) is an open cover of \(Y\) in \(X\). If \(\{U_{i_1}, \ldots, U_{i_n}\}\) is a finite subcover of \(Y\), then \(\{V_{i_1}, \ldots, V_{i_n}\}\) is a finite subcover of \(f(Y)\).

An important corollary generalizes the Extreme Value Theorem of calculus:

XI.11.1.8. Corollary. Let \(X\) be a topological space, \(f : X \to \mathbb{R}\) a continuous function, and \(E\) a compact subset of \(X\). Then \(f\) is bounded on \(E\), and attains its maximum and minimum values on \(E\).

Proof: By XI.11.1.7., \(f(E)\) is compact in \(\mathbb{R}\), and therefore closed and bounded by XI.11.1.5..

There is a useful rephrasing of the definition of compactness, using the Finite Intersection Property. This characterization of compactness is strongly reminiscent of the Nested Intervals Property of \(\mathbb{R}\).

XI.11.1.9. Definition. Let \((X, \mathcal{T})\) be a topological space. A (nonempty) collection \(\mathcal{F} = \{F_i : i \in I\}\) of closed subsets of \(X\) has the Finite Intersection Property if, whenever \(F_{i_1}, \ldots, F_{i_n}\) is a finite collection of sets in \(\mathcal{F}\), we have \(F_{i_1} \cap \cdots \cap F_{i_n} \neq \emptyset\).
XI.11.1.10. **Proposition.** Let \((X, \mathcal{T})\) be a topological space. Then \((X, \mathcal{T})\) is compact if and only if,
whenever \(\mathcal{F} = \{F_i : i \in I\}\) is a nonempty collection of closed sets in \(X\) with the Finite Intersection Property,
we have \(\bigcap_{i \in I} F_i \neq \emptyset\).

**Proof:** Suppose \((X, \mathcal{T})\) is compact, and let \(\mathcal{F} = \{F_i : i \in I\}\) be a collection of closed sets in \(X\) with \(\bigcap_{i \in I} F_i = \emptyset\). Let \(U_i = X \setminus F_i\) for each \(i\). Then \(\mathcal{U} = \{U_i : i \in I\}\) is an open cover of \(X\). Let \(\{U_{i_1}, \ldots, U_{i_n}\}\) be a finite subcover. Then \(F_{i_1} \cap \cdots \cap F_{i_n} = \emptyset\), so \(\mathcal{F}\) does not have the Finite Intersection Property.

Conversely, suppose every collection of closed sets in \(X\) with the Finite Intersection Property has a nonempty intersection, and let \(\mathcal{U} = \{U_i : i \in I\}\) be an open cover of \(X\). Set \(F_i = X \setminus U_i\) for each \(i\). Then \(\mathcal{F} = \{F_i : i \in I\}\) is a collection of closed subsets of \(X\) with \(\bigcap_{i \in I} F_i = \emptyset\), so \(\mathcal{F}\) does not have the Finite Intersection Property, i.e. there is a finite set \(\{F_{i_1}, \ldots, F_{i_n}\}\) with \(F_{i_1} \cap \cdots \cap F_{i_n} = \emptyset\). But then \(\{U_{i_1}, \ldots, U_{i_n}\}\) is a finite subcover of \(\mathcal{U}\).

Here is a useful variation:

XI.11.1.11. **Proposition.** Let \(X\) be a topological space, \(\{E_i : i \in I\}\) a collection of closed subsets of \(X\), with at least one compact. If \(U\) is an open subset of \(X\) containing \(\bigcap_{i \in I} E_i\), then there is a finite subset \(F\) of \(I\) such that \(\bigcap_{i \in F} E_i \subseteq U\).

**Proof:** Fix an \(i_0\) with \(E_{i_0}\) compact. For each \(i\), let \(K_i = E_i \cap E_{i_0} \cap U^c\). Then the \(K_i\) are closed subsets of \(E_{i_0}\), and they have empty intersection, so they do not have the Finite Intersection Property, i.e. there are \(i_1, \ldots, i_n\) such that \(K_{i_1} \cap \cdots \cap K_{i_n} = \emptyset\). Then \(E_{i_0} \cap E_{i_1} \cap \cdots \cap E_{i_n} \subseteq U\).

XI.11.1.12. **Corollary.** Let \(X\) be a topological space. Let \((F_n)\) be a decreasing sequence of closed compact subsets of \(X\) ("closed" is redundant if \(X\) is Hausdorff) with \(F = \bigcap_n F_n\). If \(U\) is any open set in \(X\) with \(F \subseteq U\), then \(F_n \subseteq U\) for all sufficiently large \(n\).

Here is an interesting and important special case:

XI.11.1.13. **Corollary.** Let \(X\) be a topological space, \(p \in X\). Let \((V_n)\) be a decreasing sequence of closed compact neighborhoods of \(p\) ("closed" is redundant if \(X\) is Hausdorff) with \(\bigcap_n V_n = \{p\}\). Then the \(V_n\) form a local neighborhood base at \(p\) for the topology.

XI.11.2. Compactness and Convergence

The next theorem gives the main equivalent ways compactness is characterized:
XI.11.2.1. Theorem. Let \((X, \mathcal{T})\) be a topological space. The following are equivalent:

(i) \((X, \mathcal{T})\) is compact.

(ii) Every nonempty collection of closed subsets of \(X\) with the Finite Intersection Property has nonempty intersection.

(iii) Every net in \(X\) has a cluster point.

(iv) Every net in \(X\) has a convergent subnet.

(v) Every filter on \(X\) has a cluster point.

Proof: (i) \(\iff\) (ii) is XI.11.1.10., (iii) \(\iff\) (iv) is (i), and (iii) \(\iff\) (v) is (i).

(ii) \(\Rightarrow\) (iii): Let \((x_i)_{i \in I}\) be a net in \(X\). For each \(i\), let \(F_i\) be the closure of \(\{x_j : j \geq i\}\), and let \(\mathcal{F} = \{F_i : i \in I\}\). If \(i_1, \ldots, i_n \in I\), then since \(I\) is directed there is an \(i_0 \geq i_k\) for \(1 \leq k \leq n\). Thus \(x_{i_0} \in F_{i_1} \cap \cdots \cap F_{i_n}\), and hence \(F_{i_1} \cap \cdots \cap F_{i_n} \neq \emptyset\) and so \(\mathcal{F}\) has the Finite Intersection Property. By (ii), there is an \(x \in \cap_{i \in I} F_i\), and \(x\) is a cluster point of the net \((x_i)\).

(iii) \(\Rightarrow\) (ii): Let \(\mathcal{F}\) be a nonempty collection of closed sets with the Finite Intersection Property. We may assume that \(\mathcal{F}\) is closed under finite intersections. Set

\[
I = \{(x, F) \in X \times \mathcal{F} : x \in F\}.
\]

Put a preorder on \(I\) by setting \((x_1, F_1) \leq (x_2, F_2)\) if \(F_2 \subseteq F_1\). Then \(I\) is directed: for any \((x_1, F_1), (x_2, F_2)\) we have

\[
(x_1, F_1) \leq (x_3, F_1 \cap F_2)
\]

where \(x_3\) is any element of \(F_1 \cap F_2\). Now, for \(i = (x, F) \in I\), define \(x_i = x\). Then \((x_i)\) is a net in \(X\). By (iii) this net has a cluster point \(y\). If \(U\) is any neighborhood of \(y\), and \(F_0 \in \mathcal{F}\), and \(x_0 \in F_0\), then there is an \(i = (x, F)\) with \((x_0, F_0) \leq i\) (i.e. \(F \subseteq F_0\)) and \(x_i = x \in U\). Since \(x \in F \subseteq F_0\), we have that \(U \cap F_0 \neq \emptyset\). Fixing \(F_0\) and letting \(U\) vary, we conclude that \(y\) is a limit point of \(F_0\), hence \(y \in F_0\) since \(F_0\) is closed. This is true for all \(F_0 \in \mathcal{F}\), so \(y \in \cap_{F \in \mathcal{F}} F\) and \(\mathcal{F}\) has nonempty intersection. \(\Box\)

Note that no form of Choice is needed for this result.

XI.11.2.2. Corollary. Let \(X\) be a second countable topological space. Then \(X\) is compact if and only if every sequence in \(X\) has a convergent subsequence (a topological space with this property is called sequentially compact).

This result is false in general for spaces which are just first countable, even for normal spaces: the space \(\omega_1\) of ordinals less than the first uncountable ordinal, with the order topology \(\omega_1\), is a normal Hausdorff space which is first countable and sequentially compact, but not compact. A first countable topological space which is compact is sequentially compact, but \(\beta\mathbb{N}\) (XI.11.9.16.), which is not first countable, is compact but not sequentially compact. See XI.11.7.3.

There is a variation of XI.11.2.1.(v) which is useful. One direction of this result uses the Ultrafilter Property \(\omega_1\), which is equivalent to the Boolean Prime Ideal Theorem \(\omega_1\).
XI.11.2.3. Proposition. (BPI) Let \((X, T)\) be a topological space. Then \((X, T)\) is compact if and only if every ultrafilter on \(X\) converges.

Proof: If \(X\) is compact, then by XI.11.2.1. every ultrafilter on \(X\) has a cluster point, hence converges. Conversely, suppose every ultrafilter on \(X\) converges. Let \(F\) be a filter on \(X\). Then by the Ultrafilter Property there is an ultrafilter \(G\) on \(X\) containing \(F\), which converges by assumption. The limit of \(G\) is a cluster point for \(F\), so \(X\) is compact by XI.11.2.1.

XI.11.3. Compact Metrizable Spaces

There is a very clean characterization of compact metric spaces, using the idea of total boundedness:

XI.11.3.1. Definition. Let \(\rho\) be a metric on a set \(X\). Then \(\rho\) is totally bounded if for every \(\epsilon > 0\), a finite number of open \(\rho\)-balls of radius \(\epsilon\) cover \(X\).

In other words, \(\rho\) is totally bounded if for every \(\epsilon > 0\), there is a finite set of points \(\{x_1, \ldots, x_n\}\) such that every point of \(x\) is within \(\epsilon\) of at least one of the \(x_k\).

A totally bounded metric is bounded: taking \(\epsilon = 1\), if \(\{x_1, \ldots, x_n\}\) are the centers of balls of radius 1 covering \(X\), and \(M\) is the maximum of the distances between the \(x_k\)'s, then any two points of \(X\) are distance less than \(M + 2\) apart. But a bounded metric is not necessarily totally bounded: for example, the discrete metric on an infinite set is bounded but not totally bounded.

XI.11.3.2. Proposition. A totally bounded metric space is separable (and hence second countable by ()).

Proof: For each \(m \in \mathbb{N}\) let \(S_m = \{x_{m,1}, \ldots, x_{m,n_m}\}\) be a finite set of points of \(X\) such that the open balls of radius \(\frac{1}{m}\) centered at the \(x_{m,k}\) cover \(X\). If \(S = \bigcup_m S_m\), then \(S\) is a countable dense subset of \(X\).

XI.11.3.3. Proposition. Let \((X, \rho)\) be a totally bounded metric space. Then every sequence in \(X\) has a Cauchy subsequence.

Proof: For each \(m\), choose a finite set \(\{y_{k,m}\}\) in \(X\) such that every element of \(X\) is within \(\frac{1}{2m}\) of one of the \(y_{k,m}\).

Let \((x_n)\) be a sequence in \(X\). Since there are only finitely many \(y_{k,1}\), there are infinitely many \(x_k\) within \(\frac{1}{2}\) of some single \(y_{k,1}\). Thus there is a subsequence \((x_{n,1})\) of \((x_n)\) all of whose terms lie within \(\frac{1}{2}\) of this \(y_{k,1}\), hence within 1 of each other. Successively let \((x_{n,m+1})\) be a subsequence of \((x_{n,m})\), all of whose terms lie within \(\frac{1}{m+1}\) of some \(y_{k,m+1}\) and hence within \(\frac{1}{m}\) of each other. Then the diagonal sequence \((x_{n,n})\) is a subsequence of \((x_n)\) which is a Cauchy sequence.

The Countable AC is needed in this proof to choose the \(y_{k,m}\), and DC is needed to choose the subsequences.

The main characterization theorem is:
XI.11.3.4. **Theorem.** Let \((X, \rho)\) be a metric space. Then \(X\) is compact (in the metric topology) if and only if \(\rho\) is complete and totally bounded.

**Proof:** Suppose \(X\) is compact. Since \(X\) is first countable, every sequence in \(X\) has a convergent subsequence. In particular, if \((x_n)\) is a Cauchy sequence, it must have a convergent subsequence, hence must converge ( ). Thus \((X, \rho)\) is complete. If \(\rho\) is not totally bounded, there is an \(\epsilon > 0\) such that no finite set of open balls of radius \(\epsilon\) covers \(X\), so a sequence \((x_n)\) can be chosen so that \(\rho(x_n, x_m) \geq \epsilon\) for all \(n\) and \(m\). But such a sequence can have no convergent subsequence, a contradiction. Thus \(\rho\) is totally bounded.

Conversely, suppose \(\rho\) is complete and totally bounded. Suppose \(\mathcal{U} = \{U_i : i \in I\}\) is an open cover of \(X\). Since \(X\) is second countable (XI.11.3.2.), it is Lindelöf ( ), so \(\mathcal{U}\) has a countable subcover \(\{U_1, U_2, \ldots\}\). Suppose this cover does not have a finite subcover. For each \(n\), let \(x_n \in X \setminus \bigcup_{k=1}^{n} U_k\). By XI.11.3.3., \((x_n)\) has a Cauchy subsequence, which must converge to some \(x\) since \((X, \rho)\) is complete. We have \(x \in U_n\) for some \(n\), but \(U_n\) is open and \(x_k \notin U_n\) for all \(k > n\), so no subsequence of \((x_n)\) can converge to \(x\), a contradiction. Thus there is a finite subcover, which is a subcover of \(\mathcal{U}\). Thus \(X\) is compact.

Combining the previous results, we get:

XI.11.3.5. **Corollary.** Let \(X\) be a compact Hausdorff space. Then \(X\) is metrizable if and only if it is second countable.

**Proof:** If \(X\) is metrizable, it is second countable by XI.11.3.4. and XI.11.3.2. Conversely, since a compact Hausdorff space is regular, if it is second countable it is metrizable by the Urysohn Metrization Theorem ( ).

XI.11.3.6. There are compact Hausdorff spaces which are both separable and first countable, but not second countable and hence not metrizable (e.g. XI.11.12.4.).

**Lebesgue Numbers of an Open Cover**

The Lebesgue Property and Lebesgue numbers of an open cover are particularly relevant for compact metric spaces, but can be defined in general:

**XI.11.3.7. Definition.** Let \(\mathcal{U}\) be an open cover of a metric space \((X, \rho)\). \(\mathcal{U}\) has the **Lebesgue Property** if there is a \(\delta > 0\) such that, for every \(x \in X\), there is a \(U \in \mathcal{U}\) with \(B_\delta(x) \subseteq U\). Such a \(\delta\) is a **Lebesgue number** of the open cover \(\mathcal{U}\).

Any positive number smaller than a Lebesgue number for \(\mathcal{U}\) is a Lebesgue number for \(\mathcal{U}\). The supremum of all Lebesgue numbers for \(\mathcal{U}\) can be \(\infty\), and if finite may or may not be a Lebesgue number for \(\mathcal{U}\); thus \(\mathcal{U}\) need not have a largest Lebesgue number. If \(\mathcal{V}\) is a refinement of \(\mathcal{U}\) (in particular, if it is a subcover of \(\mathcal{U}\)), any Lebesgue number of \(\mathcal{V}\) is a Lebesgue number of \(\mathcal{U}\). The Lebesgue Property and Lebesgue numbers depend on the metric and are not topological properties.
XI.11.3.8. Examples. (i) In $\mathbb{R}$ with the usual metric, the open cover $\mathcal{U} = \{-n, n : n \in \mathbb{N}\}$ has the Lebesgue Property, and any positive number is a Lebesgue number for $\mathcal{U}$. 

(ii) In $\mathbb{R}$ with the usual metric, the open cover $\mathcal{U}$ consisting of all open intervals of length less than 2 has the Lebesgue Property, and any positive number less than 1 is a Lebesgue number for $\mathcal{U}$. The supremum of the Lebesgue numbers is 1, but 1 is not a Lebesgue number for $\mathcal{U}$.

(iii) In $(0, 1)$ with the usual metric, the open cover $\{(\frac{1}{n}, 1) : n \in \mathbb{N}\}$ does not have the Lebesgue Property.

(iv) Even a finite open cover need not have the Lebesgue Property. Let $X = (0, 1)$ with the usual metric. Fix two disjoint decreasing sequences $(x_n)$ and $(y_n)$ in $(0, 1)$ converging to 0, and set $U = (0, 1) \setminus \{x_n : n \in \mathbb{N}\}$ and $V = (0, 1) \setminus \{y_n : n \in \mathbb{N}\}$. Then the open cover $\{U, V\}$ does not have the Lebesgue Property.

XI.11.3.9. Proposition. Let $(X, \rho)$ be a metric space of bounded diameter $d$. If $\mathcal{U}$ is an open cover of $X$ by proper subsets, and $\mathcal{U}$ has the Lebesgue property, then any Lebesgue number for $\mathcal{U}$ is $\leq d$. If $\mathcal{U}$ is a finite open cover of $X$ by proper subsets, and $\mathcal{U}$ has the Lebesgue Property, then the supremum of all Lebesgue numbers for $\mathcal{U}$ is a Lebesgue number for $\mathcal{U}$, i.e. $\mathcal{U}$ has a largest Lebesgue number.

Proof: For any $x \in X$ and $U \in \mathcal{U}$, there is a $y \in X$ with $y \notin U$. Since $\rho(x, y) \leq d$, any Lebesgue number of $\mathcal{U}$ must be $\leq d$. If $\mathcal{U} = \{U_1, \ldots, U_n\}$ is a finite open cover by proper subsets, and $\delta$ is the supremum of the Lebesgue numbers of $\mathcal{U}$ ($\delta < \infty$ by the first part of the proof), fix $x \in X$. Then there must be a $k$ such that $B_{\delta - 1/m}(x) \subseteq U_k$ for infinitely many $m$; hence $B_{\delta}(x) \subseteq U_k$. So $\delta$ is a Lebesgue number for $\mathcal{U}$. 

The main result is:

XI.11.3.10. Proposition. Let $(X, \rho)$ be a compact metric space. Then any open cover of $X$ has the Lebesgue Property.

Proof: Let $\mathcal{U}$ be an open cover of $X$. Suppose $\mathcal{U}$ does not have the Lebesgue property. Then for each $n$ there are points $x_n, y_n \in X$ with $\rho(x_n, y_n) < \frac{1}{n}$, but for which there is no $U \in \mathcal{U}$ containing both $x_n$ and $y_n$. Passing to a subsequence if necessary, we may assume $(x_n)$ converges to a point $x \in X$. Then also $y_n \to x$. There is a $U \in \mathcal{U}$ with $x \in U$. Then $x_n$ and $y_n$ are both in $U$ if $n$ is sufficiently large, a contradiction.

See XI.11.12.3. for an alternate proof which gives an explicit Lebesgue number.

Here is a sample application:

XI.11.3.11. Corollary. Let $(X, \rho)$ and $(Y, \sigma)$ be metric spaces, with $X$ compact, and $F : X \to Y$ a continuous function. Then $f$ is uniformly continuous.

Proof: Let $\epsilon > 0$. For each $y \in Y$, let $U_y = f^{-1}(B_{\epsilon/2}(y))$. Then $\{U_y : y \in Y\}$ is an open cover of $X$. If $\delta > 0$ is the Lebesgue number of this open cover, and $x_1, x_2 \in X$ with $\rho(x_1, x_2) < \delta$, there is a $y$ with $B_\delta(x_1) \subseteq U_y$; thus $f(x_1)$ and $f(x_2)$ are both in $B_{\epsilon/2}(y)$ and $\sigma(f(x_1), f(x_2)) < \epsilon$. 

1113
XII.11.4. Separation Properties

The results of this subsection give important senses in which compact sets behave like finite sets (see XII.11.10.17. for another example). The first result is a strengthening of the second half of XII.11.1.6., with essentially the same proof:

XII.11.4.1. Proposition. Let \( X \) be a Hausdorff space, \( E \) a compact subset of \( X \), and \( y \) a point of \( X \setminus E \). Then \( E \) and \( y \) have disjoint open neighborhoods.

Proof: For each \( x \in E \), let \( U_x \) and \( V_x \) be disjoint open neighborhoods of \( x \) and \( y \) in \( X \). Then \( \{U_x : x \in E\} \) is an open cover of \( E \), so has a finite subcover \( \{U_{x_1}, \ldots, U_{x_n}\} \). Then \( U = U_{x_1} \cup \cdots \cup U_{x_n} \) and \( V = V_{x_1} \cap \cdots \cap V_{x_n} \) are disjoint open neighborhoods of \( E \) and \( y \).

There is a nice generalization:

XII.11.4.2. Proposition. Let \( X \) be a Hausdorff space, and \( E \) and \( F \) disjoint compact subsets of \( X \). Then \( E \) and \( F \) have disjoint open neighborhoods.

Proof: For each \( y \in F \), by XII.11.4.1. let \( U_y \) and \( V_y \) be disjoint open neighborhoods of \( E \) and \( y \). Then \( \{V_y : y \in F\} \) is an open cover of \( F \); let \( \{V_{y_1}, \ldots, V_{y_n}\} \) be a finite subcover. Then \( U = U_{y_1} \cap \cdots \cap U_{y_n} \) and \( V_{y_1} \cup \cdots \cup V_{y_n} \) are disjoint open neighborhoods of \( E \) and \( F \).

XII.11.4.3. Corollary. A compact Hausdorff space is normal.

In an almost identical manner (Exercise ()), we can show:

XII.11.4.4. Proposition. Let \( X \) be a regular space, and \( E \) and \( F \) disjoint subsets of \( X \), with \( E \) compact and \( F \) closed. Then \( E \) and \( F \) have disjoint open neighborhoods.

Note the following consequence of XII.11.1.12.:

XII.11.4.5. Proposition. Let \( X \) be a compact Hausdorff space, and \( p \) a point of \( X \). The following are equivalent:

(i) \( \{p\} \) is a \( G_δ \), and whenever \( (F_n) \) is a decreasing sequence of closed neighborhoods of \( p \) with \( \cap_n F_n = \{p\} \), then \( \{F_n : n \in \mathbb{N}\} \) is a local base at \( p \) for the topology of \( X \).

(ii) There is a countable local base at \( p \) for the topology of \( X \).

(iii) \( \{p\} \) is a \( G_δ \).

Proof: (i) \( \Rightarrow \) (ii): Let \( (U_n) \) be a sequence of open sets in \( X \) with \( \cap_n U_n = \{p\} \). Set \( V_0 = X \) and inductively let \( V_n \) be an open neighborhood of \( p \) with \( V_n \subseteq U_n \cap V_{n-1} \) (using regularity of \( X \)). Then \( (V_n) \) is a decreasing sequence of closed neighborhoods of \( p \) with intersection \( \{p\} \), so they form a local base at \( p \).

(ii) \( \Rightarrow \) (iii) is trivial (since \( X \) is Hausdorff, the intersection of any local base at \( p \) is \( \{p\} \)), and (iii) \( \Rightarrow \) (i) is a special case of XII.11.1.12.
XI.11.5. Automatic Continuity and Comparison of Topologies

XI.11.6. Products of Compact Spaces and Tikhonov’s Theorem

Perhaps the most important theorem of general topology is Tikhonov’s Theorem (see XI.11.9.21. for some historical comments):

XI.11.6.1. THEOREM. [Tikhonov’s Theorem] Let \( \{(X_i, T_i) : i \in I\} \) be a collection of topological spaces, \( X = \prod_{i \in I} X_i \), and \( T \) the product topology on \( X \). If each \( (X_i, T_i) \) is compact, then \( (X, T) \) is compact.

This theorem is one of the two theorems of topology, along with the Baire Category Theorem, which are used most extensively in analysis.

Tikhonov’s Theorem can, among other things, be interpreted as giving compelling evidence that the product topology is the “right” topology on the Cartesian product.

XI.11.6.2. Tikhonov’s Theorem depends on the Axiom of Choice; in fact, it is equivalent to the Axiom of Choice (cf. Exercise ()). Important and frequently-used special cases, however, need only weaker versions of AC or no choice at all. We will prove some important versions under weaker choice assumptions.

There are several known proofs of Tikhonov’s Theorem; they are for the most part variations of the arguments we use in the various special cases. For a more complete discussion of these proofs and their history, see [Kel75], [Mun75], . . .

Finite Products

The simplest case is that of finite products, where no version of AC is needed:

XI.11.6.3. THEOREM. Let \( (X_1, T_1), \ldots, (X_n, T_n) \) be a finite number of topological spaces, and \( T \) the product topology on \( X = X_1 \times \cdots \times X_n \). If each \( (X_k, T_k) \) is compact, then \( (X, T) \) is compact.

PROOF: The argument is a slight generalization of the one in (). We prove the theorem in the case \( n = 2 \); this case can be applied successively, or the arguments in the proof repeated finitely many times, to give the general result for finite products. We will also change notation slightly for clarity: we begin with two compact spaces \( (X, T) \) and \( (Y, S) \), and show that \( X \times Y \) is compact in the product topology.

Suppose \( (z_i)_{i \in I} \) is a net in \( X \times Y \), with \( z_i = (x_i, y_i) \). Then \( (x_i) \) is a net in \( X \), and since \( X \) is compact there is a convergent subnet \( (x_{\alpha(j)})_{j \in J} \), where \( \alpha : J \to I \), with limit \( x \in X \). The net \( (y_{\alpha(j)}) \) is a net in \( Y \), and since \( Y \) is compact, so has a convergent subnet \( (y_{\alpha(\beta(k))})_{k \in K} \), where \( \beta : K \to J \), with limit \( y \in Y \). The subnet \( (x_{\alpha(\beta(k))})_{k \in K} \) of \( (x_{\alpha(j)}) \) also converges to \( x \), and hence the subnet \( (z_{\alpha(\beta(k))}) \) of \( (z_i) \) converges to \( z = (x, y) \) by ().

XI.11.6.4. This proof can be modified to show that a countable product of compact spaces is compact, but there is a logical complication and one additional step needed. The additional step is to construct a “diagonal” subnet after a sequence of subnets has been chosen; see Exercise () for details. The logical complication is that an infinite sequence of subnets must be chosen, each depending on the previous one; for this, the Axiom of Dependent Choice is needed. Using another argument (), one can get away with the weaker Countable Axiom of Choice for this result (in fact it is equivalent to Countable AC).
The General Tikhonov Theorem

Next we prove the full Tikhonov Theorem (XI.11.6.1.). This proof is due to P. Chernoff [Che92]; cf. [Fol99, ]. At one point we use an argument similar to the one in the proof of XI.11.6.3.. This proof uses the full Axiom of Choice (in the form of Zorn’s Lemma), as it must.

XI.11.6.5. **Proof:** Let \( (x_\alpha)_{\alpha \in A} \) be a net in \( X = \prod_{i \in I} X_i \). We need to show that \( (x_\alpha) \) has a cluster point. If \( J_1 \subseteq J_2 \subseteq I \), write \( \pi_{J_i} \) for the projection from \( \prod_{i \in J_2} X_i \) onto \( \prod_{i \in J_1} X_i \) (the notation avoids mention of \( J_2 \) to avoid unnecessary complication). Consider the set of all pairs \( (J, y) \), where \( J \) is a nonempty subset of \( I \) and \( y \in \prod_{i \in J} X_i \) is a cluster point for the net \( (\pi_J(x_\alpha))_{\alpha \in A} \). The collection \( S \) of such pairs is nonempty since there is such a \( y \) whenever \( J \) is a singleton by the assumption that each \( X_i \) is compact. Put a partial ordering on \( S \) by setting \( (J_1, y_1) \leq (J_2, y_2) \) if \( J_1 \subseteq J_2 \) and \( y_1 = \pi_{J_1}(y_2) \).

Suppose \( C = \{(J_k, y_k)\} \) is a chain in \( S \), and set \( J_0 = \bigcup_k J_k \). For each \( i \in J_0 \), choose \( k \) with \( i \in J_k \) and let \( z_i = \pi_{\{i\}}(y_k) \). If \( i \in J_k \cap J_{k'} \), then either \( J_k \subseteq J_{k'} \) or vice versa, and if \( J_k \subseteq J_{k'} \) we have \( \pi_{\{i\}}(y_k) = \pi_{\{i\}}(\pi_{J_k}(y_{k'})) = \pi_{\{i\}}(y_{k'}) \), so \( z_i \) is well defined independent of the choice of \( k \). Set \( y = (z_i)_{i \in \prod_{i \in J_0} X_i} \). For each \( i \in J_0 \) we have that \( z_i \) is a cluster point of the net \( (\pi_{\{i\}}(x_\alpha))_{\alpha \in A} \). If \( U \) is a neighborhood of \( y_0 \in \prod_{i \in J_0} X_i \), then there are indices \( i_1, \ldots, i_n \in J_0 \) and neighborhoods \( U_r \) of \( z_{i_r} \) in \( X_{i_r} \) such that

\[
\prod_{r=1}^n U_r \times \prod_{i \in J_0 \setminus \{i_1, \ldots, i_n\}} X_i \subseteq U .
\]

Since \( C \) is totally ordered, there is a \( k \) such that \( i_1, \ldots, i_n \in J_k \); for any \( \alpha_0 \) there is an \( \alpha \geq \alpha_0 \) with

\[
\pi_{J_k}(x_\alpha) \in \prod_{r=1}^n U_r \times \prod_{i \in J_0 \setminus \{i_1, \ldots, i_n\}} X_i
\]

and hence \( \pi_{J_k}(x_\alpha) \in U \). So we have that \( y_0 \) is a cluster point of the net \( (\pi_{J_k}(x_\alpha))_{\alpha \in A} \) by (). Thus \( (J_0, y_0) \) is an upper bound for \( C \).

By Zorn’s Lemma, \( S \) has a maximal element \((J, y)\). We need to show that \( J = I \), for then \( y \) will be the desired cluster point of \((x_\alpha)\). Suppose \( J \neq I \), and let \( i \in I \setminus J \), \( J' = J \cup \{i\} \). There is a subnet \((\pi_{J'}(x_{\alpha})_{\beta \in B})_{\alpha \in A} \) of \((\pi_J(x_{\alpha}))_{\alpha \in A} \) which converges to \( y \) by (). The net \( \pi_{\{i\}}(x_{\alpha(\beta)})_{\beta \in B} \) has a subnet \((\pi_{\{i\}}(x_{\alpha(\beta)})_{\gamma \in C})_{\gamma \in C} \) which converges to some \( z \in X_i \) since \( X_i \) is compact. The subnet \( \pi_{J'}(x_{\alpha(\beta)})_{\gamma \in C} \) of \((\pi_J(x_{\alpha}))_{\beta \in B} \) converges to \( y \), so the subnet \((\pi_{J'}(x_{\alpha(\beta)})_{\gamma \in C})_{\alpha \in A} \) converges to \((y, z)\), and thus \((J', (y, z))\) is an element of \( S \) strictly larger than \((J, y)\), contradicting maximality. Thus \( J = I \) and the theorem is proved. \( \Box \)

Tikhonov’s Theorem for Hausdorff Spaces

Tikhonov’s Theorem for Hausdorff spaces does not require the full Axiom of Choice, only the Ultrafilter Property, which is equivalent to the Boolean Prime Ideal Theorem (II.6.3.11.).

The proof we give was developed by H. Cartan for Bourbaki. Cartan’s proof had an additional step (using the full Axiom of Choice) and gave a proof of the full Tikhonov Theorem, but it simplifies nicely to give an efficient proof in the Hausdorff case. The proof is deceptively quick to write, but it depends on earlier results about convergence and projection of ultrafilters.
XI.11.6.6.  **Theorem.** [Tikhonov’s Theorem for Hausdorff Spaces] Let \( \{ (X_i, \mathcal{T}_i) : i \in I \} \) be a collection of Hausdorff topological spaces, \( X = \prod_{i \in I} X_i \), and \( \mathcal{T} \) the product topology on \( X \). If each \( (X_i, \mathcal{T}_i) \) is compact, then \((X, \mathcal{T})\) is compact.

**Proof:** By XI.11.2.3. (which depends on BPI), it suffices to show that if \( \mathcal{F} \) is an ultrafilter on \( X \), then \( \mathcal{F} \) converges. For each \( i \in I \), the ultrafilter \( \mathcal{F}_i = \pi_i(\mathcal{F}) \) converges to a unique point \( x_i \in X_i \) since \( X_i \) is compact and Hausdorff. Then \( \mathcal{F} \) converges to \( x = (x_i) \in X \) by \( (\cdot) \).

XI.11.6.7.  If the \( X_i \) are not Hausdorff, the same proof works except that the limit point \( x_i \) is not necessarily unique. Thus an application of the Axiom of Choice is necessary to choose an \( x_i \) for each \( i \). (If \( I \) is countable, the Countable AC plus the BPI suffices; cf. XI.11.6.4.)

Tikhonov’s Theorem for the Hilbert Cube

It turns out that it can be proved that the Hilbert cube \([0,1]^N\) is compact without any form of choice. We give an argument here from [Wag93].

XI.11.6.8.  **Theorem.** The Hilbert cube \([0,1]^N\) is compact.

**Proof:** Suppose \( \mathcal{U} \) is an open cover of \([0,1]^N\) with no finite subcover. We will obtain a contradiction by repeatedly subdividing coordinatewise. By passing to a refinement, we may assume that the sets in \( \mathcal{U} \) are rectangular open sets of the form \( U_1 \times \cdots \times U_n \times [0,1] \times [0,1] \times \cdots \), where the \( U_k \) are open sets in \([0,1]\) (this can be done without using any form of choice by simply replacing each \( U \in \mathcal{U} \) with the collection of all rectangular open sets contained in \( U \)).

Divide the space into \([0,1/2] \times [0,1] \times \cdots \) and \([1/2,1] \times [0,1] \times \cdots \). At least one of these sets does not have a finite subcover of \( \mathcal{U} \); choose the first one which does not, and call it \( F_1 \). Further subdivide into eight pieces, ordered lexicographically:

\[
[0,1/4] \times [0,1/2] \times [0,1] \times \cdots, [0,1/4] \times [1/2,1] \times [0,1] \times \cdots, [1/4,1/2] \times [0,1] \times \cdots, etc.
\]

Let \( F_2 \) be the first of these sets in this order for which there is no finite subcover of \( \mathcal{U} \). Continue inductively to generate a decreasing sequence of closed sets \( \{ F_k \} \) which are products of subintervals. For each \( n \) the \( n \)’th coordinate intervals \( I_{k,n} \) of the \( F_k \) have an intersection consisting of a single point \( x_n \), and the point \( x = (x_n) \in [0,1]^N \) is in the intersection of all the \( F_k \) (in fact, this intersection is a singleton). There is a \( U \in \mathcal{U} \) with \( x \in U \). Since \( U \) is a rectangular open set determined by finitely many coordinates, we have that \( F_k \subseteq U \) for some sufficiently large \( k \), contradicting the choice of \( F_k \) as a set with no finite subcover from \( \mathcal{U} \).

XI.11.6.9.  It is shown more generally in [?] by a somewhat similar argument that compactness of a product \( \prod_{i \in I} X_i \) of compact spaces can be proved without any form of choice if the index set can be well ordered and there is a choice function for the family of all, or sufficiently many, closed sets in the \( X_i \). (Of course, if the AC is assumed, this proof then gives the full Tikhonov Theorem.)
XI.11.6.10. If, for each $n$, $X_n$ is a closed subset of the Hilbert cube, then without any form of choice it follows that $X = \prod_{n=1}^{\infty} X_n$ also embeds as a closed subset of the Hilbert cube, and thus from XI.11.6.8. it follows that $X$ and each $X_n$ is compact. But it does not seem to be possible to prove that a countable product of compact metrizable spaces is compact without some form of choice, even though such a space embeds in the Hilbert cube (by making some choices): a specific such embedding must be chosen for each $n$ before one can conclude by the above argument that the product embeds, requiring the Countable AC. If one tries to prove directly that the product space is totally bounded with respect to the product metric (proving completeness is no problem), choices have to be made also using the Countable AC. Thus this form of the theorem seems to require Countable AC; if so, it is logically no easier than the version for countable products of arbitrary compact spaces (XI.11.6.4.). It would also be in contrast with the corresponding results for arbitrary products: no more choice is needed to prove that arbitrary products of compact metrizable spaces (indeed, arbitrary products of compact Hausdorff spaces) are compact than to prove that arbitrary powers of $[0,1]$ are compact (each is equivalent to BPI; cf. ())).

XI.11.7. Variations on Compactness
Countable compactness, sequential compactness, quasicompactness, bicompressness, $\sigma$-compactness, local compactness paracompactness, pseudocompactness, metacompactness, Lindelof spaces, precompactness (relative compactness), …

XI.11.7.1. Definition. A topological space $X$ is countably compact if every countable open cover of $X$ has a finite subcover.

Some useful alternate characterizations of countably compact spaces are given by the next result:

XI.11.7.2. Theorem. Let $X$ be a topological space. The following are equivalent:

(i) $X$ is countably compact.

(ii) If $(F_n)$ is a sequence of closed sets in $X$ with the Finite Intersection Property, then $\cap_{n=1}^{\infty} F_n$ is nonempty.

(iii) Every sequence in $X$ has a cluster point.

Proof: (i) $\iff$ (ii) is proved by taking complements exactly as in the proof of XI.11.1.10. with the word “countable” added in appropriate places.

(iii) $\implies$ (i): Suppose $\{U_1, U_2, \ldots\}$ is a countable open cover of $X$ with no finite subcover. For each $n$, let $x_n \in X \setminus \bigcup_{k=1}^{n} U_k$. If $x \in X$, then $x \in U_m$ for some $m$; but $x_n \notin U_m$ for $n \geq m$, so $x$ is not a cluster point of $(x_n)$. Thus $(x_n)$ is a sequence in $X$ with no cluster point.

(i) $\implies$ (iii): Suppose $(x_n)$ is a sequence in $X$ with no cluster point. For each $n$, let $F_n$ be the closure of $\{x_k : k > n\}$, and let $U_n = F_n^{c}$. Then $U = \{U_n : n \in \mathbb{N}\}$ is an open cover of $X$ since any point of $X$ has a neighborhood containing only finitely many of the $x_n$. Since the $F_n$ are decreasing, the $U_n$ are increasing. If there is a finite subcover of $U$, then $U_n = X$ for some $n$. This is a contradiction since $F_n$ is nonempty. Thus $U$ has no finite subcover.

1118
XI.11.7.3. COROLLARY. A sequentially compact topological space (XI.11.2.2.) is countably compact. A first countable topological space is countably compact if and only if it is sequentially compact.

A countably compact space, even a compact Hausdorff space, which is not first countable need not be sequentially compact (XI.11.9.16.(v)).

XI.11.7.4. PROPOSITION. A countably compact Lindelöf space is compact. A countably compact metrizable space is compact.

PROOF: Let \( X \) be countably compact. If \( X \) is Lindelöf, then any open cover of \( X \) has a countable subcover, which has a finite subcover. If \( X \) is metrizable, fix a metric \( \rho \) on \( X \). Any Cauchy sequence in \( X \) has a cluster point, hence converges by (); thus \( (X, \rho) \) is complete. If \( X \) is not totally bounded, then for some \( \epsilon > 0 \) a sequence \((x_n)\) exists in \( X \) with \( \rho(x_n, x_m) \geq \epsilon \) for \( n \neq m \); this sequence cannot have a cluster point, a contradiction.

XI.11.7.5. EXAMPLE. Let \( \omega_1 \) be the first uncountable ordinal, with the order topology. Every sequence in \( \omega_1 \) has an upper bound, hence is contained in a compact initial segment. Thus \( \omega_1 \) is countably compact. But \( \omega_1 \) is not compact: the “identity net” in \( \omega_1 \) has no cluster point.

As a variation, the “long line” \( (\) is countably compact but not compact.

\(\sigma\)-Compact Spaces

XI.11.7.6. DEFINITION. A topological space \( X \) is \( \sigma\)-compact if \( X \) is a countable union of compact subsets of \( X \). More generally, a subset \( E \) of \( X \) is \( \sigma\)-compact if \( E \) is a union of a countable number of compact subsets of \( X \).

Some authors require a \( \sigma\)-compact space to be locally compact, but we will not.

XI.11.7.7. EXAMPLES. (i) Any compact space is \( \sigma\)-compact.
(ii) \( \mathbb{R}^n \) is \( \sigma\)-compact [the closed ball around 0 of radius \( k \) is compact for any \( k \)].
(iii) A manifold \( (\) is \( \sigma\)-compact if and only if it has only countably many connected components, i.e. satisfies the equivalent conditions (\).
(iv) Any countable topological space is \( \sigma\)-compact. A space with the discrete topology is \( \sigma\)-compact if and only if it is countable.

The next result is an immediate corollary of XI.11.1.7:

XI.11.7.8. PROPOSITION. Let \( X \) and \( Y \) be topological spaces, and \( f : X \rightarrow Y \) a continuous function. If \( E \) is a \( \sigma\)-compact subset of \( X \), then \( f(E) \) is a \( \sigma\)-compact subset of \( Y \).

Recall () that an \( F_{\sigma} \) in a topological space is a countable union of closed subsets.
XI.11.7.9. Proposition. Let $X$ and $Y$ be topological spaces, with $X$ $\sigma$-compact and $Y$ Hausdorff. Then

(i) Every $F_\sigma$ in $X$ is $\sigma$-compact.

(ii) Every $\sigma$-compact subset of $Y$ is an $F_\sigma$.

Proof: (i): Suppose $X = \bigcup_n K_n$, where $K_n$ is compact. If $F$ is a closed subset of $X$, then $F = \bigcup_n (F \cap K_n)$, and by XI.11.1.6. $F \cap K_n$ is compact. Thus every closed set in $X$ is $\sigma$-compact, and hence so is every $F_\sigma$.

(ii): If $E = \bigcup_n E_n \subset Y$ with $E_n$ compact, then $E_n$ is closed by XI.11.1.6., so $E$ is an $F_\sigma$.

XI.11.7.10. Corollary. Let $X$ be a $\sigma$-compact Hausdorff space. Then a subset of $X$ is $\sigma$-compact if and only if it is an $F_\sigma$.

It follows that the set of irrational numbers in $\mathbb{R}$ is not $\sigma$-compact since it is not an $F_\sigma$.

Combining these results, we get an interesting consequence. Although a continuous image of a closed set is not closed in general, we have:

XI.11.7.11. Proposition. Let $X$ and $Y$ be topological spaces, with $X$ $\sigma$-compact and $Y$ Hausdorff, and let $f : X \to Y$ be a continuous function. If $E$ is an $F_\sigma$ in $X$, then $f(E)$ is an $F_\sigma$ in $Y$.

Proof: $E$ is $\sigma$-compact by XI.11.7.9.(i), so $f(E)$ is also $\sigma$-compact by XI.11.7.8., and hence by XI.11.7.9.(ii) we conclude that $f(E)$ is an $F_\sigma$ in $Y$.

In particular, under the hypotheses, the image of any closed subset of $X$ is an $F_\sigma$ in $Y$. The hypotheses hold if $X$ and $Y$ are Euclidean spaces, or manifolds with $X$ separable.

XI.11.7.12. Proposition. A $\sigma$-compact topological space is Lindelöf. Thus a $\sigma$-compact regular space is normal.

Proof: Let $X = \cup_n K_n$, with $K_n$ compact. If $\mathcal{U}$ is an open cover of $X$, for each $n$ let $\mathcal{V}_n$ be a finite subset of $\mathcal{U}$ which covers $K_n$. Then $\mathcal{V} = \cup_n \mathcal{V}_n$ is a countable subset of $\mathcal{U}$ which covers $X$. (This argument uses the Countable AC.) The last statement follows from (i).

XI.11.8. Locally Compact Spaces

Many important spaces such as Euclidean spaces are not compact, but are “locally compact”:

XI.11.8.1. Definition. A Hausdorff space $X$ is locally compact if every point of $X$ has a neighborhood (not necessarily open) which is compact.

We will deal with the non-Hausdorff case in XI.11.8.20.
XI.11.8.2. Examples. (i) Any compact Hausdorff space is locally compact. (The whole space is a compact neighborhood of any point.)

(ii) \( \mathbb{R}^n \) is locally compact since every closed ball is compact. More generally, any open set in \( \mathbb{R}^n \) is locally compact in the relative topology for the same reason.

(iii) Any space with the discrete topology is locally compact.

(iv) Any closed subspace of a locally compact Hausdorff space is locally compact in the relative topology: if \( Y \) is a closed subset of a locally compact Hausdorff space \( X \), \( p \in Y \), and \( K \) is a compact neighborhood of \( p \) in \( X \), then \( K \cap Y \) is a compact neighborhood of \( p \) in \( Y \) in the relative topology. In particular, any closed subset of \( \mathbb{R}^n \) is locally compact in the relative topology.

(v) Any open subset of a compact Hausdorff space is locally compact (in the relative topology): if \( U \) is an open subset of a compact Hausdorff space \( X \), and \( p \in U \), then by XI.11.4.2, \( p \) and \( X \setminus U \) have disjoint neighborhoods \( V \) and \( W \) in \( X \). \( U \) is a compact neighborhood of \( p \) in \( X \) which is contained in \( U \), i.e. a compact neighborhood of \( p \) in \( U \).

Actually, any open subset of a locally compact Hausdorff space is locally compact (XI.11.8.8); in fact, any locally compact Hausdorff space is homeomorphic to an open set in a compact Hausdorff space (XI.11.8.4).

(vi) Spaces such as \( \mathbb{Q}, \mathbb{N} = \mathbb{N}^n \), and \( \mathbb{R}^n \) are not locally compact; in fact, no point in any of these spaces has a compact neighborhood.

The One-Point Compactification

XI.11.8.3. If \( X \) is a locally compact Hausdorff space, a single point can be added to \( X \) to make a compact Hausdorff space, called the one-point compactification of \( X \) and denoted \( X^\dagger \). Specifically, take a point not in \( X \) which we call \( \infty \), and let \( X^\dagger = X \cup \{ \infty \} \). Put a topology on \( X^\dagger \) by taking all open subsets of \( X \) to be open in \( X^\dagger \), along with all subsets consisting of \( \infty \) along with the complement of a compact subset of \( X \) (including the complement of \( \emptyset \), giving the whole space \( X^\dagger \)). It is simple and routine to verify that this is a topology (Exercise XI.11.12.12.), and that \( X \) is an open subset of \( X^\dagger \). See XI.11.12.12. for a generalization of the one-point compactification construction.

XI.11.8.4. Proposition. \( X^\dagger \) is a compact Hausdorff space with this topology.

Proof: It is easy to see that \( X^\dagger \) is compact. If \( \{U_i\} \) is an open cover, there is a set \( U_{i_0} \) containing \( \infty \). The complement of \( U_{i_0} \) is a compact subset of \( X \), so the open cover of \( X^\dagger \setminus U_{i_0} \) by the remaining \( U_i \) has a finite subcover \( \{U_{i_1}, \ldots, U_{i_n}\} \). Then \( \{U_{i_0}, U_{i_1}, \ldots, U_{i_n}\} \) is a finite subcover of \( X^\dagger \).

To see that \( X^\dagger \) is Hausdorff, it suffices to show that if \( p \in X \), then \( p \) and \( \infty \) have disjoint neighborhoods. Since \( X \) is locally compact, there is an open neighborhood \( U \) of \( p \) in \( X \) whose closure in \( X \) is compact (e.g. the interior of a compact neighborhood). Thus \( U \) and \( \{\infty\} \cup (X \setminus U) \) are disjoint neighborhoods of \( p \) and \( \infty \).

The one-point compactification of \( X \) is essentially unique. Thus it can often be realized or recognized in a different form:
XI.11.8.5. PROPOSITION. Let $X$ be a locally compact Hausdorff space, $Y$ a compact Hausdorff space, and $\phi: X \to Y$ a homeomorphism from $X$ onto a (necessarily open) subspace $\phi(X)$ of $Y$ with $Y \setminus \phi(X)$ a single point $q$. Then $\phi$ extends to a homeomorphism $\tilde{\phi}$ from $X^\dagger$ onto $Y$ with $\tilde{\phi}(\infty) = q$.

PROOF: The map $\tilde{\phi}$ is obviously completely determined; it is only necessary to show it is a homeomorphism. If $V$ is an open set in $Y$, and $V$ does not contain $q$, then since $\phi$ is continuous, $\tilde{\phi}^{-1}(V) = \phi^{-1}(V)$ is open in $X$, hence in $X^\dagger$. And if $q \in V$, then $V^c$ is a compact subset of $\phi(X)$, hence $\tilde{\phi}^{-1}(V^c)$ is compact since $\phi^{-1}$ is continuous, so $\tilde{\phi}^{-1}(V) = X^\dagger \setminus \phi^{-1}(V^c)$ is open in $X^\dagger$. Thus $\tilde{\phi}$ is continuous. A continuous bijection from a compact space to a Hausdorff space is a homeomorphism by (i), so $\tilde{\phi}$ is a homeomorphism.

XI.11.8.6. EXAMPLES. (i) Let $Y$ be any compact Hausdorff space, and $q \in Y$. Then $X = Y \setminus \{q\}$ is a locally compact Hausdorff space with $X^\dagger$ homeomorphic to $Y$. By the one-point compactification construction, every locally compact Hausdorff space arises this way.

(ii) An $n$-sphere with a point removed is homeomorphic to $\mathbb{R}^n$, e.g. by stereographic projection (i). Thus $(\mathbb{R}^n)^\dagger$ is homeomorphic to $S^n$. In particular, $\mathbb{R}^\dagger$ is homeomorphic to a circle.

XI.11.8.7. If $X$ is already compact, then $\emptyset$ is the complement of a compact subset of $X$, so $\{\infty\}$ is open in $X^\dagger$, i.e. $\infty$ is an isolated point in $X^\dagger$, and $X^\dagger$ is the separated union of $X$ and a one-point discrete space. Conversely, if $\infty$ is isolated in $X^\dagger$, then $X$ is a closed subset of $X^\dagger$, hence compact. Thus $X$ is dense in $X^\dagger$ if and only if $X$ is noncompact.

XI.11.8.8. It follows that any open subset of a locally compact Hausdorff space is locally compact: if $U$ is an open subset of a locally compact Hausdorff space $X$, then $U$ is an open subset of the compact Hausdorff space $X^\dagger$ and thus is locally compact in the relative topology by XI.11.8.2.(v).

We also get the following corollaries of the one-point compactification construction:

XI.11.8.9. PROPOSITION. A locally compact Hausdorff space is completely regular (i).

PROOF: $X^\dagger$ is normal by XI.11.4.3., hence completely regular, and complete regularity passes to subspaces.

However, a locally compact Hausdorff space need not be normal (XI.11.12.6., XI.19.5.8.).

XI.11.8.10. PROPOSITION. Let $X$ be a locally compact Hausdorff space. If $p \in X$ and $V$ is a neighborhood of $p$, then there is an open neighborhood $U$ of $p$ such that $U$ is compact and contained in $V$.

PROOF: There is a compact neighborhood $K$ of $p$ in $X$; the interior $W$ of $K$ is an open neighborhood of $p$ whose closure is compact. Replacing $V$ by $V \cap W$, we may assume $V^c$ is compact. Since $X$ is regular, $\{p\}$ and $V^c$ have disjoint neighborhoods $U$ and $Z$. Then $\bar{U} \subseteq V$, and $U$ is compact since it is a closed subset of $V$.  

1122
XI.11.8.11. Proposition. Let $X$ be a locally compact Hausdorff space. The following are equivalent:

(i) The point $\infty$ has a countable local base in $X^\dagger$.

(ii) $\{\infty\}$ is a $G_\delta$ in $X^\dagger$.

(iii) $X$ is $\sigma$-compact.

(iv) $X$ is Lindelöf.

Proof: It is obvious from the construction of $X^\dagger$ that (ii) $\iff$ (iii), and it follows from XI.11.4.5. that (i) $\iff$ (ii). (iii) $\implies$ (iv) by XI.11.7.12. For (iv) $\implies$ (iii), each $x \in X$ has an open neighborhood $V_x$ with $\bar{V}_x$ compact. $\{V_x : x \in X\}$ has a countable subcover $\{V_{x_n} : n \in \mathbb{N}\}$, and $X = \cup_n \bar{V}_{x_n}$.

XI.11.8.12. Proposition. Let $X$ be a locally compact, $\sigma$-compact Hausdorff space. Then there is a sequence $(U_n)$ of open sets in $X$ with $\bar{U}_n$ compact and contained in $U_{n+1}$ for each $n$, and $X = \cup_1^\infty U_n$.

Proof: Let $(K_n)$ be a sequence of compact subsets of $X$ with $X = \cup K_n$. Let $U_1$ and $V_1$ be disjoint neighborhoods of $K_1$ and $\{\infty\}$ in $X^\dagger$; then $U_1$ is open and the closure $\bar{U}_1$ of $U_1$ in $X^\dagger$ is compact and contained in $X$. Inductively take $U_{n+1}$ and $V_{n+1}$ to be disjoint open neighborhoods of $U_n \cup K_{n+1}$ and $\{\infty\}$ in $X^\dagger$.

XI.11.8.13. Theorem. Let $X$ be a locally compact Hausdorff space. The following are equivalent:

(i) $X$ is metrizable and $\sigma$-compact.

(ii) There is a countable base for the topology of $X$ consisting of compact sets.

(iii) $X$ is second countable.

(iv) $X$ is a Polish space.

(v) $X^\dagger$ is metrizable.

There are various other ways to phrase these conditions which are equivalent by general considerations, e.g. “$X$ is separable and metrizable” (4). There are metrizable locally compact spaces which do not satisfy the conditions, e.g. an uncountable discrete space.

Proof: (i) $\implies$ (v): Let $(U_n)$ be an increasing sequence of open sets in $X$ as in XI.11.8.12. Then $\bar{U}_n$ is compact and metrizable for each $n$, hence second countable (4). Thus $U_n$ is second countable. There is also a countable local base at $\infty$ in $X^\dagger$ by XI.11.8.11. Putting together a countable base for the topology of $U_n$ for each $n$ and a countable local base at $\infty$, we obtain a countable base for the topology of $X^\dagger$; hence $X^\dagger$ is a second countable compact Hausdorff space, so it is metrizable (4).

(v) $\implies$ (iv): A compact metrizable space is a Polish space; so $X^\dagger$ is Polish. Thus the open subset $X$ of $X^\dagger$ is also a Polish space.
(iv) ⇒ (iii): A separable metric space is second countable (\).

(iii) ⇒ (ii): It suffices to show that if \( \{ U_n \} \) is a countable base, then the collection
\[
\{ \hat{U}_n : n \in \mathbb{N}, \hat{U}_n \text{ compact} \}
\]
is also a base. Let \( p \in X \) and \( V \) a neighborhood of \( p \) in \( X \). There is an open set \( U \) containing \( p \) such that \( \hat{U} \) is compact and contained in \( V \) (XI.11.8.10.). Take \( U_n \) so that \( p \in U_n \subseteq U \). Then \( \hat{U}_n \subseteq V \), and \( \hat{U}_n \) is compact since it is a closed subset of \( \hat{U} \).

(ii) ⇒ (i): \( X \) is regular (XI.11.8.9.), hence metrizable by the Urysohn Metrization Theorem (\( ). (ii) trivially implies that \( X \) is \( \sigma \)-compact. ☑

XI.11.8.14. There is no universally accepted standard notation for the one-point compactification of a space \( X \). I have chosen a notation \( X^\dagger \) that is not widely used, and an explanation is in order. The most common notations are \( X^* \), \( X^\oplus \), \( X_1 \); other notations sometimes used are \( X^\ast \), \( X^\ast_\ast \), \( X^\ast_\ast \), and perhaps others.

There are two reasons I have chosen not to use \( X^\ast \). One is that topologists also often use this notation to mean something else, e.g. the corona space \( \beta X \setminus X \) (\( ). The other reason comes from my background in Operator Algebras, where \( \ast \) is normally used to mean something else (\( ); in fact, it is used to mean too many different things in Operator Algebras!\( ) In addition, there is a natural relationship between adding a point at infinity in topology and adding a unit in algebra: a commutative C*-algebra is an algebra of the form \( C_0(X) \), the continuous functions vanishing at infinity on a locally compact Hausdorff space \( X \) (\( ), and the unitization of this algebra is precisely the continuous functions on the one-point compactification of \( X \). Thus it makes sense to use the same notation for point-one compactification as for adding a unit to a C*-algebra. A common notation in algebra is to write \( A^\dagger \) for the unitization of the algebra \( A \), and thus \( X^\dagger \) would be logical notation for the one-point compactification, giving that \( C_0(X)^\dagger = C(X^\dagger) \). However, a C*-algebra \( A \) also has a positive cone which is usually denoted \( A_\ast \) or sometimes \( A^\dagger \), and the two notations are too easily confused. So in [Bla06] I settled on the notation \( A^\dagger \) for the unitization of a C*-algebra, and thus \( X^\dagger \) for the one-point compactification of a space (so that \( C_0(X)^\dagger = C(X^\dagger) \)), as a variation of \( A^\dagger \) which is easily distinguishable but similar enough to be suggestive, and I have kept that notation here. Some readers may not be happy with my choice, but it is my book . . .

Urysohn’s Lemma for Locally Compact Spaces

Although a locally compact space need not be normal (XI.19.5.8.), there is a version of Urysohn’s Lemma. We first make an observation and a definition:

XI.11.8.15. PROPOSITION. Let \( X \) be a locally compact Hausdorff space, and \( A \) a compact subset of \( X \), and \( V \) a neighborhood of \( A \) in \( X \). Then there is an open neighborhood \( U \) of \( A \) contained in \( V \) with \( \hat{U} \) compact.

PROOF: This is a routine compactness argument from XI.11.8.10. For each \( p \in U \), let \( U_p \) be an open neighborhood of \( p \) contained in \( V \) with \( \hat{U}_p \) compact. The open cover \( \{ U_p : p \in A \} \) of \( A \) has a finite subcover \( \{ U_{p_1}, \ldots, U_{p_n} \} \). Set \( U = U_{p_1} \cup \cdots \cup U_{p_n} \). ☑

1124
XI.11.8.16. **Definition.** Let $X$ be a topological space. A continuous function $f : X \to \mathbb{C}$ has **compact support** if the closure of the support $S_f = \{ x \in X : f(x) \neq 0 \}$ of $f$ is compact. Denote by $C_c(X)$ the set of all continuous functions of compact support from $X$ to $\mathbb{C}$.

XI.11.8.17. It is easily verified that $C_c(X)$ is a subalgebra of $C(X)$. But in general it need not contain any nonzero function. However, if $X$ is locally compact, $C_c(X)$ is large enough to separate points and closed sets:

XI.11.8.18. **Theorem.** [Urysohn’s Lemma, Locally Compact Case] Let $X$ be a locally compact Hausdorff space. If $A$ and $B$ are disjoint closed subsets of $X$ with $A$ compact, then there is a continuous function $f : X \to [0,1]$ of compact support with $f(x) = 1$ for all $x \in A$ and $f(x) = 0$ for all $x \in B$.

**Proof:** The set $V = B^c$ is a neighborhood of $A$. Let $U$ be an open neighborhood of $A$ in $X$ contained in $V$ with $\overline{U}$ compact. Regarding $X$, and hence $A, B, U$, as subsets of $X^\dagger$, let $C = X^\dagger \setminus U$. Then $A$ and $C$ are disjoint closed subsets of the compact, hence normal, space $X^\dagger$. If $g : X \to [0,1]$ with $g(x) = 1$ for all $x \in A$ and $g(x) = 0$ for all $x \in C$, then the restriction of $g$ to $X$ is the desired $f$.

XI.11.8.19. In particular, if $X$ is a locally compact Hausdorff space, $B$ a closed subset of $X$, and $p \in X$, $p \notin B$, then (applying the theorem with $A = \{p\}$) there is a continuous function $f : X \to [0,1]$ of compact support with $f(p) = 1$ and $f(x) = 0$ for all $x \in B$.

**The Non-Hausdorff Case**

XI.11.8.20. There is no natural definition of local compactness for non-Hausdorff spaces. Each of the following conditions, which are equivalent for Hausdorff spaces, is a reasonable potential definition for a topological space $X$:

(i) Every point of $X$ has a neighborhood (not necessarily open) which is compact.

(ii) For any $p \in X$ and any open neighborhood $V$ of $X$, there is a compact neighborhood $U$ (not necessarily open) of $p$ contained in $V$.

(iii) Every point of $X$ has an open neighborhood whose closure is compact.

(iii′) For any $p \in X$ and any open neighborhood $V$ of $X$, there is an open neighborhood $U$ of $X$ contained in $V$ whose closure is compact.

(iv) For any $p \in X$ and any open neighborhood $V$ of $X$, there is an open neighborhood $U$ of $X$ whose closure is compact and contained in $V$.

In general, (iv) $\Rightarrow$ (iii) $\iff$ (iii′) $\Rightarrow$ (i) and (iv) $\Rightarrow$ (ii) $\Rightarrow$ (i). In Hausdorff spaces, (i) $\Rightarrow$ (iv) (XI.11.8.10.), so all the conditions are equivalent. None of the other implications hold in general [SS95, Examples 9, 18, 35].
XI.11.9. Compactifications

It is often very convenient to embed a given topological space into a compact Hausdorff space. The first instance of this is to add \( \pm \infty \) to the real line to obtain the extended real line, which is topologically and order-theoretically the same as the compact space \([0, 1]\). There are some systematic ways to compactify a topological space, which we discuss in this section.

XI.11.9.1. Definition. Let \( X \) be a Hausdorff topological space. A compactification of \( X \) is a compact Hausdorff space \( Y \) and a homeomorphism \( \phi \) of \( X \) onto a dense subset of \( Y \).

Some authors consider compactifications where \( X \) and/or \( Y \) is not Hausdorff (cf. XI.11.9.20.), but we will only consider the Hausdorff case. By (), a (Hausdorff) space has a compactification if and only if it is completely regular.

XI.11.9.2. In some references, a pair \((Y, \phi)\) is called a compactification of \( X \) if \( Y \) is a compact Hausdorff space and \( \phi \) is simply an injective continuous function from \( X \) onto a dense subset of \( Y \). Instances of this are the standard maps of \( \mathbb{R} \) to a figure 8, a figure 6, a torus via an irrational angle wraparound (), or a solenoid (). Another instance would be a map from \( \mathbb{N} \) with the discrete topology onto a dense subset of \([0, 1]\). We will not consider these to be compactifications, but they are what we call compact representations (XI.11.9.9.).

XI.11.9.3. The density of \( X \) in a compactification is a natural condition, but is not restrictive: if \( \phi \) is a homeomorphism of \( X \) with a subspace of a compact Hausdorff space \( Z \), then the closure of \( \phi(X) \) in \( Z \) is a compactification of \( X \).

XI.11.9.4. There are several special instances of compactifications already considered:

(i) If \( (X, \rho) \) is a totally bounded metric space, then the completion of \( (X, \rho) \) is a compactification of \( X \).

(ii) If \( X \) is a totally ordered space with the order topology, then the order-completion of \( X \) with endpoints added if necessary, with the order topology, is a compactification of \( X \) (i).

(iii) If \( X \) is a locally compact, noncompact Hausdorff space, then the one-point compactification \( X^\dagger \) () is a compactification of \( X \). (If \( X \) is already compact, then \( X^\dagger \) is not a compactification of \( X \) since \( X \) is not dense in \( X^\dagger \); in fact, the only compactification of a compact space \( X \) is \( X \) itself. The fact that the one-point compactification is not a compactification in this case is an unfortunate inconsistency in standard terminology.)

(iv) There are more complicated compactifications of \( \mathbb{R} \) than the extended real line and the one-point compactification (circle). For example, there is a homeomorphism of \( \mathbb{R} \) onto the graph of \( y = \sin \left( \frac{1}{x} \right) \) for \( 0 < x < \frac{1}{\pi} \), so the topologist’s sine curve () is a compactification of \( \mathbb{R} \).

(v) If \( X \) is completely regular, and \( \phi \) is a homeomorphism of \( X \) onto a subspace of a cube (), then the closure of \( \phi(X) \) is a compactification of \( X \).

The compactification of (v) is actually universal: every compactification can be done (up to homeomorphism) in this way. For if \( Y \) is any compactification of \( X \), then \( Y \) can be embedded in a cube as in (). The construction of () using the restrictions to \( X \) of the coordinate functions of this embedding yields \( Y \).
XI.11.9.5. Since a compact metrizable space is second countable, a space with a metrizable compactification is second countable. Conversely, by the construction of (I) a second countable completely regular space can be embedded in the Hilbert cube, which is metrizable, and hence has a metrizable compactification.

XI.11.9.6. Although the homeomorphism $\phi$ is often understood, it is logically cleaner to regard it as a part of the compactification. Two compactifications $(Y, \phi)$ and $(Z, \psi)$ of a space $X$ are equivalent if there is a homeomorphism $\omega : Y \to Z$ with $\psi = \omega \circ \phi$. If there is just a continuous function $\omega : Y \to Z$ with $\psi = \omega \circ \phi$, we say $(Y, \phi)$ dominates $(Z, \psi)$. Such an $\omega$ is unique since it is completely determined on the dense subset $\phi(X)$ as $\psi \circ \phi^{-1}$, and it is necessarily surjective since $\omega(Y)$ is a compact subset of $Z$ containing the dense subset $\psi(X)$.

Dominance gives a partial ordering on the equivalence classes of compactifications of $X$, setting $(Y, \phi) \geq (Z, \psi)$ if $(Y, \phi)$ dominates $(Z, \psi)$. If $X$ is locally compact and noncompact, then the one-point compactification of $X$ is the smallest compactification of $X$ under this ordering; conversely, it is not hard to show (cf. (I)) that if $X$ has a minimal compactification, it must be a one-point compactification and $X$ must thus be locally compact. There is always a largest compactification of $X$ if $X$ is completely regular, the Stone-Čech compactification $\beta X$.

XI.11.9.7. More generally, if $X_1$ and $X_2$ are (completely regular) spaces with compactifications $(Y, \phi)$ and $(Z, \psi)$ respectively, and $f : X_1 \to X_2$ is a continuous function, an extension of $f$ to $(Y, Z)$ is a continuous function $\tilde{f} : Y \to Z$ with $\tilde{f} \circ \phi = \psi \circ f$. Such an extension, if it exists, is unique.

XI.11.9.8. A compactification $(Y, \phi)$ of $X$ naturally defines a uniform structure (I) on $X$ by restricting the unique uniform structure on $Y$ (I). (However, not every uniform structure on $X$ arises in this manner in general.) A continuous function $f : X_1 \to X_2$ extends to compactifications $(Y, \phi)$ and $(Z, \psi)$ in the sense of XI.11.9.7. if and only if $f$ is uniformly continuous for these uniform structures.

XI.11.9.9. More generally, we define a compact representation of a (completely regular) space $X$ to be a pair $(Y, \phi)$, where $Y$ is a compact Hausdorff space and $\phi$ is a continuous function from $X$ onto a dense subspace of $Y$. Thus a compactification is a special kind of compact representation, as are the “compactifications” of XI.11.9.2. Another important example of a compact representation is a bounded continuous function from $X$ to $\mathbb{R}$, e.g. a continuous function from $X$ to $[0,1]$. Equivalence, domination, and extension can be defined in this more general context. Any compact representation which dominates a compactification is itself a compactification.

The Stone-Čech Compactification

There is a largest (in the sense of XI.11.9.6.) compactification of any completely regular space $X$, called the Stone-Čech compactification of $X$ and denoted $\beta X$. This compactification is attributed to M. Stone and E. Čech (independently), but see XI.11.9.21.

The Stone-Čech compactification of a space $X$ can be constructed in a number of ways (Stone and Čech used rather different constructions). One construction is via Boolean algebras and/or ultrafilters (cf. XI.11.9.14.). A very slick construction is as the spectrum of the C*-algebra of bounded complex-valued continuous functions on $X$ (XV.14.2.21.), but this approach is probably not the best for beginning students or topologists. We will give two versions of a purely topological construction.

The first version is based on the next result, which is proved by a pullback construction:
XI.11.9.10. Proposition. Let $X$ be a completely regular space, and $\{ (Y_i, \phi_i) : i \in I \}$ a set of compact representations (XI.11.9.9.) of $X$. Then there is a compact representation $(Y, \phi)$, unique up to equivalence, which is the least upper bound of the $(Y_i, \phi_i)$.

Proof: It is obvious that the least upper bound, if it exists, is unique up to equivalence. We show existence. Let $Z = \prod_i Y_i$. Then $Z$ is compact by Tikhonov’s Theorem (the Hausdorff version XI.11.6.6. suffices). Define a map $\phi : X \to Z$ by $(\phi(x))_i = \phi_i(x)$ for $x \in X$. Then $\phi$ is continuous by the universal property of the product topology (). Let $Y'$ be the closure of $\phi(X)$ in $Z$. Then $(Y, \phi)$ obviously dominates $(Y_i, \phi_i)$ via coordinate projections. If $(Y', \psi)$ dominates each $(Y_i, \phi_i)$ via a map $\omega_i : Y' \to Y_i$, define $\omega : Y' \to Y$ by $(\omega(t))_i = \omega_i(t)$ for $t \in Y'$. Then $(Y', \psi)$ dominates $(Y, \phi)$ via $\omega$.

XI.11.9.11. One then gets an apparent proof of the existence of a maximal compactification by simply taking the least upper bound of the “set” of all compact representations of $X$. However, there is a set-theoretic problem: this “set” is not a set. The problem can be circumvented by noting that if $X$ has cardinality $\kappa$, then the cardinality of any compact representation is at most $2^{2^\kappa}$, so we could restrict to only compact representations whose underlying set is a subset of a fixed set of cardinality $2^{2^\kappa}$, and these compact representations form a set. One can also restrict to one compact representation in each equivalence class in the construction. (This appears to require the AC (), but the AC can be avoided by an argument working through XI.11.9.12.; anyway, use of the AC is not much of a problem here since some form of choice in the guise of Tikhonov’s Theorem is necessary to do almost anything with compactifications.)

Call the maximal compact representation $\beta X$; it is a compactification since $X$ has at least one compactification, which is dominated by $\beta X$. It is customary to identify $X$ with its image in $\beta X$.

XI.11.9.12. A more common and concrete construction of $\beta X$ is to let $C$ be the set of all continuous functions from $X$ to $[0, 1]$, and embed $X$ into $[0, 1]^C$ by taking $\phi(x)_f = f(x)$ for $f \in C$ and taking $Y$ to be the closure of $\phi(X)$. Since each such $f$ gives a compact representation of $X$, each of these is dominated by the $\beta X$ constructed previously, hence $(Y, \phi)$ is dominated by $\beta X$. On the other hand, since $\beta X$ is compact, it embeds into a cube (), and the coordinate functions of this embedding, restricted to $X$, are in $C$; it follows that $(Y, \phi)$ dominates $\beta X$, and therefore $(Y, \phi)$ is equivalent to $\beta X$.

We summarize in a theorem:

XI.11.9.13. Theorem. [Stone-Čech Compactification] Let $X$ be a completely regular space. There is a compact Hausdorff space $\beta X$ containing $X$ as a dense subspace, unique up to homeomorphism which is the identity on $X$, with the property that if $f$ is a continuous function from $X$ to any compact Hausdorff space $Y$, then $f$ extends uniquely to a continuous function $\bar{f} : \beta X \to Y$.

XI.11.9.14. We describe the ultrafilter version of the construction of $\beta X$ only for $X$ a set with the discrete topology. For the general version see [GJ76]. If $X$ is a discrete space, $\beta X$ can be identified with the set $\sigma X$ of all ultrafilters on $X$, with the hull-kernel topology (); the closure of a set $S$ of ultrafilters is the set of all ultrafilters containing the filter which is the intersection of the ultrafilters in $S$. It is easy to show that this space is a compact Hausdorff space (), and that the set of fixed ultrafilters, which can be naturally identified with $X$, is dense, so $\sigma X$ is a compactification of $X$. To show that $\sigma X$ dominates $\beta X$,
XI.11.9.15. If $X$ is locally compact, then the Stone-Čech compactification dominates the one-point compactification $X^\dagger$. Since $X$ is open in $X^\dagger$, its inverse image in $\beta X$, the image of $X$ in $\beta X$, is open. Conversely, if $X$ is open in $\beta X$, then $X$ is locally compact by XI.11.8.2.(v).

The set $\beta X \setminus X$ is called the corona or remainder of $X$, especially if $X$ is locally compact; in this case $\beta X \setminus X$ is compact.

XI.11.9.16. The Stone-Čech compactification of a space is rather huge, and often has pathological properties. We list without proof some key properties of some standard spaces:

(i) If $X$ is second countable and noncompact, then $\text{card}(\beta X) = 2^{2^{\omega_0}}$. In particular, $\text{card}(\beta \mathbb{N}) = \text{card}(\beta \mathbb{Q}) = \text{card}(\beta \mathbb{R}) = 2^{2^{\omega_0}}$. If $X$ is any space which is locally compact and $\sigma$-compact, but not compact, then $\text{card}(\beta X \setminus X) \geq 2^{2^{\omega_0}}$.

(ii) Every infinite closed subset of $\beta \mathbb{N} \setminus \mathbb{N}$ contains a copy of $\beta \mathbb{N}$, and in particular has cardinality $2^{2^{\omega_0}}$.

(iii) $\beta \mathbb{N}$ is extremally disconnected: the closure of every open set is open.

(iv) $\beta \mathbb{R}$ is connected (as is $\beta X$ for any connected $X$ (XI.13.1.10.)). $\beta \mathbb{R} \setminus \mathbb{R}$ has two connected components, one at $+\infty$ and the other at $-\infty$ (cf. XI.13.3.6.). But $\beta \mathbb{R} \setminus \mathbb{R}$ is totally path disconnected, and not locally connected at any point. In fact, if $X$ is locally compact and $\sigma$-compact, but not compact, then $\beta X \setminus X$ is an $F$-space: disjoint open $F_{\sigma}$’s have disjoint closures. Any $F$-space is totally path disconnected. In $\beta \mathbb{N} \setminus \mathbb{N}$, $\beta \mathbb{R} \setminus \mathbb{R}$, and many other corona spaces, every nonempty $G_\delta$ has nonempty interior.

(v) Although any sequence in $\beta \mathbb{N}$ has a cluster point (in fact, $2^{2^{\omega_0}}$ cluster points if it has infinite range), the only convergent sequences in $\beta \mathbb{N}$ are ones which are eventually constant. Thus any sequence of distinct points in $\beta \mathbb{N}$ has no convergent subsequence, and $\beta \mathbb{N}$ is compact but not sequentially compact. The same statements are true about $\beta \mathbb{R} \setminus \mathbb{R}$, so $\beta \mathbb{R} \setminus \mathbb{R}$ is also not sequentially compact.

For more detailed structure results about $\beta \mathbb{N}$ and related spaces, see [GJ76] and [vM84].

XI.11.9.17. There are, however, locally compact noncompact spaces for which the one-point compactification and the Stone-Čech compactification coincide. The simplest example is the space $\omega_1$ of ordinals less than the first uncountable ordinal, with the order topology, since every real-valued continuous function on $\omega_1$ is eventually constant; cf. also XI.19.5.6.. These spaces are pseudocompact: every real-valued continuous function is bounded.

XI.11.9.18. Note that either Tikhonov’s Theorem for Hausdorff spaces or the Ultrafilter Property is needed to prove Theorem XI.11.9.13.. In fact, this theorem is equivalent to the BPI (II.6.3.11.).

XI.11.9.19. Theorem. The following theorems are logically equivalent:

(i) Tikhonov’s Theorem for Hausdorff spaces.

(ii) Tikhonov’s Theorem for copies of $[0, 1]$.

**Proof:** (i) ⇒ (ii) and (iv) ⇒ (iii) are trivial. (ii) ⇒ (iv) is the standard construction of the Stone-Čech compactification (XI.11.9.12). So we need only prove (iii) ⇒ (i).

Let \( \{X_i : i \in I\} \) be an indexed collection of compact Hausdorff spaces, and let \( X = \prod X_i \) with the product topology. Let \( Y \) be the set \( X \) with the discrete topology, and \( \beta Y \) its Stone-Čech compactification. For each \( i \), the coordinate map \( \pi_i : X \to X_i \), regarded as a map from \( Y \) to \( X_i \), extends uniquely to a continuous function \( f_i \) from \( Y \) to \( X_i \), by the universal property of \( \beta Y \). The \( f_i \) define a continuous function from \( \beta Y \) to \( X \), which is surjective since its restriction to \( Y \) is the identity map from \( Y \) to \( X \). Thus \( X \) is a continuous image of the compact space \( \beta Y \), hence compact by (i).

Note that (ii) ⇒ (i) is a simple consequence of the fact that every compact Hausdorff space can be embedded in a product of intervals, but we did not need to use this argument.

XI.11.9.20. There is a compactification of any \( T_1 \) space \( X \) called the Wallman compactification, which is similar to the Stone-Čech compactification but not Hausdorff if \( X \) is not normal (it coincides with the Stone-Čech compactification if \( X \) is normal). The Wallman compactification shows that every \( T_1 \) space can be embedded as a dense subset of a compact \( T_1 \) space (for a simpler proof of this, see XI.11.12.12.).

XI.11.9.21. According to [Dud02], Tikhonov was the first to prove existence of the Stone-Čech compactification (in 1930), and Čech elaborated on Tikhonov’s work; Stone’s work appears to have been done independently, but later than Tikhonov (as Gel’fand once observed, Tikhonov obtained his results “previously but independently.”)

On the other hand, according to [Dud02], the general form (XI.11.6.1.) of Tikhonov’s Theorem was first proved by Čech in 1936; Tikhonov only proved that an arbitrary product of copies of \([0, 1]\) is compact.

XI.11.10. Paracompactness and Partitions of Unity

For some purposes, it is enough to be able to make an open cover of a space “locally finite” instead of actually (globally) finite, and it suffices to allow making a given open cover “finer” instead of just working with an actual subcover. It turns out that this is possible in the great majority of topological spaces encountered “naturally”; such spaces are called paracompact.

Paracompact spaces were only defined and named in 1944 by J. Dieudonné.

XI.11.10.1. **Definition.** Let \( \mathcal{U} \) be an open cover of a topological space \((X, T)\). \( \mathcal{U} \) is point finite if every \( x \in X \) is contained in only finitely many \( U \in \mathcal{U} \). \( \mathcal{U} \) is locally finite if each \( x \in X \) has an open neighborhood \( W \) such that \( W \cap U \neq \emptyset \) for only finitely many \( U \in \mathcal{U} \).

A locally finite cover is obviously point finite; the converse is false (Exercise (i).) A finite cover is obviously locally finite.

XI.11.10.2. **Definition.** Let \( \mathcal{U} \) and \( \mathcal{V} \) be open covers of a topological space \((X, T)\). \( \mathcal{V} \) is a refinement of \( \mathcal{U} \) if every \( V \in \mathcal{V} \) is contained in some \( U \in \mathcal{U} \).

Note that \( \mathcal{U} \) itself, or any subcover of \( \mathcal{U} \), is a refinement of \( \mathcal{U} \). If \( X \) is a metric space, \( \epsilon, \delta > 0 \), and \( \mathcal{U} \) and \( \mathcal{V} \) are the collections of all balls of radius \( \epsilon \) and \( \delta \) respectively, then \( \mathcal{V} \) is a refinement of \( \mathcal{U} \) if \( \delta \leq \epsilon \). If \( \mathcal{V} \) is a refinement of \( \mathcal{U} \) and \( \mathcal{W} \) is a refinement of \( \mathcal{V} \), then \( \mathcal{W} \) is a refinement of \( \mathcal{U} \).
It can happen that two distinct open covers are each refinements of the other. For example, if \( \mathcal{U} \) is the set of (bounded) open intervals in \( \mathcal{R} \) of rational length, and \( \mathcal{V} \) the set of open intervals of irrational length, then \( \mathcal{U} \) and \( \mathcal{V} \) are each refinements of the other.

**XI.11.10.3. Definition.** Let \((X, \mathcal{T})\) be a topological space. Then \((X, \mathcal{T})\) is **paracompact** if it is Hausdorff and every open cover of \((X, \mathcal{T})\) has a locally finite refinement.

Note that a paracompact space is by definition Hausdorff. It is clear that any compact Hausdorff space is paracompact. But many noncompact spaces are also paracompact, as the next theorem shows (see also XI.11.10.19.). This result was proved by A. H. Stone [Sto48] (cf. XI.11.12.13.); the slick proof we give is due to M. E. Rudin [Rud69].

**XI.11.10.4. Theorem.** Every metrizable space is paracompact.

**Proof:** Let \( X \) be a metrizable space, and fix a metric \( \rho \) on \( X \). Let \( \mathcal{U} = \{U_i : i \in I\} \) be an open cover of \( X \). We may well-order the index set \( I \) (using AC). Define, inductively on \( n \), a collection of open sets \( V_{im} \) for \( i \in I \) as follows. Suppose \( V_{im} \) has been defined for all \( i \) and for all \( m < n \). Let \( V_{in} \) be the union of all open balls \( B_{2^{-n}}(x) \) such that

1. \( i \) is the smallest index such that \( x \in U_i \).
2. \( x \notin V_{jm} \) for any \( j \) and any \( m < n \).
3. \( B_{3 \cdot 2^{-n}}(x) \subseteq U_i \).

If \( x \in X \), then there is a smallest \( i \) such that \( x \in U_i \) and an \( n \) large enough that (3) holds. Then, by (2), \( x \in V_{im} \) for some \( m \leq n \). Thus \( \mathcal{V} = \{V_{in} : i \in I, n \in \mathbb{N}\} \) is an open cover of \( X \). Obviously \( V_{in} \subseteq U_i \) for each \( i \) and \( n \), so \( \mathcal{V} \) refines \( \mathcal{U} \).

To show that \( \mathcal{V} \) is locally finite, fix \( x \in X \), and let \( i \) be the smallest index for which \( x \in V_{im} \) for some \( n \). Fix the smallest \( n \) for which \( x \in V_{im} \). Choose \( k \) so that \( B_{2^{-k}}(x) \subseteq V_{im} \).

We first claim that if \( m \geq n + k \), then \( B_{2^{-n-k}}(x) \) intersects no \( V_{jm} \) for any \( j \in I \). Fix \( j \). Since \( m > n \), every ball of radius \( 2^{-m} \) used to define \( V_{jm} \) has center \( y \) outside \( V_{in} \), hence \( \rho(x, y) \geq 2^{-k} \) by the choice of \( k \). But \( m \geq k + 1 \) and \( n + k \geq k + 1 \), so \( 2^{-n-k} + 2^{-m} \leq 2^{-k} \), so \( B_{2^{-n-k}}(x) \cap B_{2^{-m}}(y) = \emptyset \).

Finally, we claim that if \( m < n + k \), then \( B_{2^{-n-k}}(x) \) intersects \( V_{jm} \) for at most one \( j \); this will complete the proof that \( B_{2^{-n-k}}(x) \) intersects at most \( n + k \) \( V_{jm} \), and, since \( x \in X \) is arbitrary, that \( \mathcal{V} \) is locally finite. Suppose \( p \in V_{jm} \) and \( q \in V_{jm} \) for \( j_1 < j_2 \); we will show that \( \rho(p, q) > 2^{-n-k+1} \), so both cannot be in \( B_{2^{-n-k}}(x) \). There are points \( y \) and \( z \) such that \( p \in B_{2^{-m}}(y) \subseteq V_{jm} \) and \( q \in B_{2^{-m}}(z) \subseteq V_{jm} \). By (3), \( B_{3 \cdot 2^{-m}}(y) \subseteq U_{j_1} \). But \( z \notin U_{j_1} \) by (2), so \( \rho(y, z) \geq 3 \cdot 2^{-m} \) and \( \rho(p, q) > 2^{-m} \geq 2^{-n-k+1} \).

The AC is used in the proof. It is known that this theorem cannot be proved in ZF+(DC).

Paracompact spaces share nice separation properties with compact spaces:

**XI.11.10.5. Proposition.** Every paracompact space is normal.

Thus there are Hausdorff spaces, even completely regular spaces, which are not paracompact. There are even locally compact completely normal spaces which are not paracompact (Exercise XI.11.12.10.1.)
XI.11.10.6. A subset of a paracompact space is not paracompact in general (e.g. a subset of a compact Hausdorff space need not be normal). Even an open subset of a paracompact space need not be paracompact (Exercise XI.11.12.10.). But:

XI.11.10.7. Proposition. A closed subspace of a paracompact space is paracompact.

The proof is essentially identical to the proof of XI.11.1.6. with “finite subcover” replaced by “locally finite refinement.”

XI.11.10.8. Proposition. Let $X$ be a (Hausdorff) topological space, and $\{X_i : i \in I\}$ a partition of $X$ into clopen subsets. Then $X$ is paracompact if and only if each $X_i$ is paracompact.

Proof: If $X$ is paracompact, then each $X_i$ is paracompact by XI.11.10.7. Conversely, suppose each $X_i$ is paracompact. If $U$ is an open cover of $X$, then, for each $i$, $\mathcal{U}_i = \{U \cap X_i\}$ is an open cover of $X_i$, which has a locally finite refinement $\mathcal{V}_i$. Then $\bigcup_{i \in I} \mathcal{V}_i$ is a locally finite open cover of $X$ which refines $\mathcal{U}$. 

Paracompact spaces are the natural setting for some constructions of algebraic topology.

Partitions of Unity

For analysis purposes, the most important feature of paracompact spaces is the existence of “partitions of unity.” These provide a systematic and controlled way to write a general real- or complex-valued function as a sum of functions of “small” support, and allow “local” phenomena to be stitched together globally.

XI.11.10.9. Definition. Let $(X, T)$ be a topological space. A weak partition of unity on $X$ is a collection of continuous functions $\{f_i : i \in I\}$ from $X$ to $[0, 1]$ such that

(i) For each $x \in X$, $\sum_{i \in I} f_i(x) = 1$.

The collection is a partition of unity if in addition

(ii) Each $x \in X$ has a neighborhood $U$ such that $f_i \neq 0$ on $U$ for only finitely many $i$.

The collection is a strong partition of unity if in addition

(iii) For each $i$, there is an $x \in X$ with $f_i(x) = 1$.

If $\mathcal{U}$ is an open cover of $(X, T)$, and $\{f_i : i \in I\}$ is a partition of unity on $(X, T)$, then $\{f_i\}$ is subordinate to $\mathcal{U}$ if for each $i \in I$ there is a $U \in \mathcal{U}$ such that $Z_{f_i}^c \subseteq U$, where for $f : X \to \mathbb{C}$ continuous $Z_f^c$ is the cozero set of $f$, i.e.

$$Z_f^c = \{x : f(x) \neq 0\}$$

(note that $Z_f^c$ is open for any continuous $f$). The closure of $Z_f^c$ is called the support of $f$.

XI.11.10.10. If $\{f_i : i \in I\}$ is a partition of unity, set $U_i = Z_{f_i}^c = \{x \in X : f_i(x) > 0\}$. Then $\{U_i : i \in I\}$ is a locally finite open cover of $X$. If $\mathcal{U}$ is an open cover of $X$, then the partition of unity is subordinate to $\mathcal{U}$ if and only if this locally finite open cover is a refinement of $\mathcal{U}$. If a partition of unity is subordinate to a refinement of $\mathcal{U}$, it is subordinate to $\mathcal{U}$.
XI.11.10.11. There is some lack of uniformity in this terminology; what we call “weak partitions of unity” are often called “partitions of unity.” Our term “strong partition of unity” is nonstandard, but will be useful; it is a desirable nondegeneracy requirement. It is equivalent to saying that \{U_i\} is a minimal open cover of \(X\), i.e. no proper subcollection covers \(X\).

XI.11.10.12. Example. Let \(X = \mathbb{R}\). ****

XI.11.10.13. Theorem. Let \((X, \mathcal{T})\) be a paracompact space. If \(\mathcal{U}\) is any open cover of \((X, \mathcal{T})\), then there is a strong partition of unity on \(X\) subordinate to \(\mathcal{U}\).

Proof: Passing to a refinement if necessary, we may assume that \(\mathcal{U}\) is locally finite. We first construct a smaller open cover by transfinite induction. If \(\mathcal{U}\) is countable (or has a countable locally finite refinement, e.g. if \(X\) is second countable, or locally compact and \(\alpha\)-compact), the transfinite induction can be simplified to an ordinary induction.

Choose a well ordering \(\{U_\alpha\}\) of \(\mathcal{U}\). We will inductively define an open cover \(\{V_\alpha\}\) such that \(\overline{V_\alpha} \subseteq U_\alpha\) for each \(\alpha\). Suppose that \(V_\beta\) has been defined for all \(\beta < \alpha\) so that \(\{V_\beta : \beta \leq \alpha\} \cup \{U_\beta : \beta > \alpha\}\) is an open cover of \(X\) (this assumption is vacuous if \(\alpha = 0\)). Set

\[
F_\alpha = X \setminus \left[ \left( \bigcup_{\beta < \alpha} V_\beta \right) \cup \left( \bigcup_{\beta > \alpha} U_\beta \right) \right].
\]

Then \(F_\alpha\) is a closed subset of \(U_\alpha\) since \(U_\alpha \cap F_\alpha = X\). Since \(X\) is normal (XI.11.10.5.), there is an open set \(V_\alpha\) with \(F_\alpha \subseteq V_\alpha\) and \(\overline{V_\alpha} \subseteq U_\alpha\). If \(F_\alpha = \emptyset\), choose \(V_\alpha = \emptyset\). We have \(X = (\bigcup_{\beta < \alpha} V_\beta) \cup (\bigcup_{\beta > \alpha} U_\beta) \cup V_\alpha\), so the inductive step is finished.

We claim \(V = \{V_\alpha\}\) is an open cover of \(X\). Suppose not; let \(x \in X \setminus (\bigcup_\alpha V_\alpha)\). Then \(x\) is in only finitely many \(U_\alpha\), so there is an \(\alpha\) such that \(x \notin \bigcup_{\beta \geq \alpha} U_\beta\). For this \(\alpha\), \(x \notin (\bigcup_{\beta < \alpha} V_\beta) \cup (\bigcup_{\beta > \alpha} U_\beta)\). But \(\{V_\beta : \beta < \alpha\} \cup \{U_\beta : \beta \geq \alpha\}\) is an open cover of \(X\), a contradiction. Note that since \(V_\alpha \subseteq U_\alpha\) for each \(\alpha\), \(\{U_\alpha\}\), \(V\) is locally finite. Also note that if \(x \in F_\alpha\), then \(x \notin V_\beta\) for \(\beta < \alpha\) by construction, and \(x \notin V_\beta\) for \(\beta > \alpha\) since \(V_\beta \subseteq U_\beta\) and \(x \notin U_\beta\) by construction. Thus \(x \notin V_\beta\) for any \(\beta \neq \alpha\).

Now repeat the construction using the \(V_\alpha\) in place of the \(U_\alpha\) to inductively define open sets \(W_\alpha\) and

\[
E_\alpha = X \setminus \left[ \left( \bigcup_{\beta < \alpha} W_\beta \right) \cup \left( \bigcup_{\beta > \alpha} V_\beta \right) \right]
\]
such that \(E_\alpha \subseteq W_\alpha\) and \(\overline{W_\alpha} \subseteq V_\alpha\), and \(\{W_\alpha\}\) is an open cover of \(X\). Note that \(F_\alpha \subseteq E_\alpha\) for each \(\alpha\).

Discard any \(\alpha\) for which \(V_\alpha = \emptyset\), i.e. \(F_\alpha = \emptyset\) (since \(F_\alpha \subseteq W_\alpha\), these are also the \(\alpha\) for which \(W_\alpha = \emptyset\)). For each remaining \(\alpha\) let \(g_\alpha\) be a continuous function from \(X\) to \([0,1]\) such that \(g_\alpha \equiv 1\) on \(\overline{W_\alpha}\) and \(g_\alpha \equiv 0\) on \(X \setminus V_\alpha\) (XI.7.6.12.). For \(x \in X\), set \(g(x) = \sum_\alpha g_\alpha(x)\). Since \(V\) is locally finite, only finitely many \(g_\alpha\) are nonzero in a neighborhood of \(x\), so \(g(x)\) is finite, and \(g\) is continuous at \(x\). Since \(g_\alpha(x) = 1\) for at least one \(\alpha\), \(g(x) \geq 1\). For each \(x \in F_\alpha\), \(g_\alpha(x) = g_\alpha(x)/g(x)\); then \(f_\alpha\) is continuous, \(0 \leq f_\alpha(x) \leq 1\) for all \(\alpha\) and \(x\), \(f_\alpha \equiv 0\) on \(X \setminus V_\alpha\), and for each \(x\), only finitely many \(f_\alpha(x)\) are nonzero, and \(\sum_\alpha f_\alpha(x) = 1\). For any \(\alpha\), if \(x \in F_\alpha\), then \(x \notin V_\beta\) for any \(\beta \neq \alpha\), so \(f_\alpha(x) = 1\), and thus the \(f_\alpha\) satisfy (iii). Thus \(\{f_\alpha\}\) is a partition of unity subordinate to \(\mathcal{U}\).

Note that this proof is a little more complex than the standard proof of existence of partitions of unity, because of condition (iii). What the proof really shows is that if \(\mathcal{U}\) is a locally finite cover of a normal space \(X\), then there is a strong partition of unity subordinate to \(\mathcal{U}\). Note that this proof requires the Axiom of Choice.
XI.11.10.14. Conversely, a partition of unity subordinate to an open cover gives a locally finite refinement of the cover, so if every open cover of \( X \) supports a partition of unity subordinate to it, \( X \) must be paracompact. There is a better result:

XI.11.10.15. Theorem. Let \( X \) be a \( T_1 \) space. If for every open cover \( U \) of \( X \) there is a weak partition of unity subordinate to \( U \), then \( X \) is paracompact.

Proof: [Eng89] We first note that \( X \) must be completely regular. If \( E \) is a closed set in \( X \) and \( p \notin E \), choose a partition of unity \( (f_i) \) subordinate to the open cover \( \{ X \setminus E, X \setminus \{p\} \} \). There is an \( i \) such that \( f_i = 0 \) on \( E \) and \( f_i(p) > 0 \), and it gives an Urysohn function for \( (E, p) \).

Now let \( U \) be an open cover of \( X \), and \( \{ f_i : i \in I \} \) a partition of unity subordinate to \( U \). If \( \phi \) is a strictly positive real-valued continuous function on \( X \), then for each \( x_0 \in X \) there is an open neighborhood \( U \) of \( x_0 \) and a finite set \( I_0 \subseteq I \) such that \( f_i(x) < \phi(x) \) for all \( x \in U \) and \( i \notin I_0 \) [Choose \( I_0 \) so that \( 1 - \sum_{i \in I_0} f_i(x_0) < \phi(x_0) \), and \( U = \{ x \in X : 1 - \sum_{i \in I_0} f_i(x) < \phi(x) \} \}.

For \( x \in X \), set \( \phi(x) = \sup_{i \in I} f_i(x) \). Then \( \phi \) is strictly positive, and since the supremum is a finite supremum in a neighborhood of each point, \( \phi \) is continuous. For each \( i \) set \( V_i = \left\{ x \in X : f_i(x) > \frac{1}{2} \phi(x) \right\} \).

Then \( \{ V_i : i \in I \} \) is a locally finite open cover of \( X \) which refines \( U \).

XI.11.10.16. Corollary. Let \( (X, \rho) \) be a metric space. Then for any \( \epsilon > 0 \) there is a strong partition of unity \( \{ f_i : i \in I \} \) such that the diameter of \( Z_{f_i}^\epsilon \) is less than \( \epsilon \) for all \( i \).

Proof: \( X \) is paracompact (XI.11.10.4.), and the balls of radius \( < \epsilon/2 \) form an open cover of \( X \).

Paracompactness and Local Compactness

XI.11.10.17. Proposition. Let \( X \) be a topological space, \( K \) a compact subset of \( X \), and \( \{ U_i : i \in I \} \) a locally finite open cover of \( X \). Then \( K \cap U_i \neq \emptyset \) for only finitely many \( i \).

Proof: For each \( x \in K \), there is an open neighborhood \( V_x \) of \( x \) such that \( V_x \cap U_i \neq \emptyset \) only for \( i \) in a finite subset \( F_x \) of \( I \). Then \( \{ V_x : x \in K \} \) is an open cover of \( K \), so there is a finite subcover \( \{ V_{x_1}, \ldots, V_{x_n} \} \). The set \( U_i \) can have nonempty intersection with \( K \) only if \( i \) is in the finite subset \( F_{x_1} \cup \cdots \cup F_{x_n} \) of \( I \).
XI.11.10.18. **Proposition.** Let $X$ be a (necessarily Hausdorff) topological space which is locally compact, connected, and paracompact. Then $X$ is $\sigma$-compact.

**Proof:** For each $x \in X$, let $U_x$ be an open neighborhood of $x$ with $\overline{U}_x$ compact. Let $\{V_i : i \in I\}$ be a locally finite refinement of $\{U_x : x \in X\}$. Then $V_i$ is compact for each $i$.

Fix $i_1 \in I$ with $V_{i_1}$ nonempty, and set $W_1 = V_{i_1}$, $K_1 = \overline{V}_{i_1}$. There are only finitely many $i$ for which $V_i \cap K_1 \neq \emptyset$; let $W_2$ be their union, and $K_2 = \overline{W}_2$. Then $K_2$ is also compact, and $K_1 \subseteq W_2$. Repeat the process to get $W_n$ and $K_n$ for each $n$. Set $W = \cup_n W_n = \cup_n K_n$. Then $W$ is clearly open in $X$ and $\sigma$-compact. If $i \in I$ and $V_i \cap W \neq \emptyset$, then $V_i \cap K_n \neq \emptyset$ for some $n$, so $V_i \subseteq W_{n+1} \subseteq W$. Thus $X \setminus W$ is the union of the $V_i$ which are disjoint from $W$, hence open; thus $W$ is clopen. Since $X$ is connected and $W \neq \emptyset$, $W = X$. 

Conversely:

XI.11.10.19. **Theorem.** A locally compact, $\sigma$-compact Hausdorff space is paracompact. In fact, any open cover of a locally compact, $\sigma$-compact Hausdorff space has a countable locally finite refinement.

XI.11.11. **Compactly Generated Spaces**

The great majority of topological spaces encountered naturally, if not compact, at least have their topology completely determined by their compact subsets.

**XI.11.11.1. Definition.** Let $X$ be a topological space. $X$ is **compactly generated** if any subset $U$ of $X$ is open (in $X$) if (and only if) $U \cap K$ is relatively open in $K$ for every compact subset $K$ of $X$.

In other words, $X$ has the weak topology generated by the inclusion maps of its compact subsets. A set $U \subseteq X$ such that $U \cap K$ is relatively open in $K$ for every compact $K \subseteq X$ is called a $k$-open set in $X$ (cf. XI.11.12.14.), and a compactly generated space is called a $k$-space in some references like [Dug78].

Any compact space is obviously compactly generated. More generally:

**XI.11.11.2. Proposition.** Every locally compact (Hausdorff) space is compactly generated.

**Proof:** Let $X$ be locally compact, and $U \subseteq X$ $k$-open. Let $x \in U$. Then $x$ has an open neighborhood $V_x$ in $X$ such that $\overline{V}_x$ (closure in $X$) is compact. $U \cap V_x$ is relatively open in $\overline{V}_x$, i.e. there is an open set $W_x$ in $X$ such that $U \cap \overline{V}_x = W_x \cap \overline{V}_x$. Then $V_x \cap W_x$ is an open neighborhood of $x$ in $X$ which is contained in $U$. Since $x \in U$ is arbitrary, $U$ is open in $X$. 

Perhaps more significantly, every first countable space is compactly generated. We need a result of independent interest:
XI.11.11.3. PROPOSITION. Let $X$ be a topological space and $(x_n)$ a sequence in $X$. If $x_n \to x$, then $K = \{x\} \cup \{x_n : n \in \mathbb{N}\}$ is a compact subset of $X$.

Proof: Let $U$ be an open cover of $K$. Then $x \in U$ for some $U \in U$. Since $x_n \to x$, $x_n \in U$ for all but finitely many $n$. Finitely many other sets in $U$ cover the $x_n$ which are not in $U$. 

XI.11.11.4. Caution: This statement is false in general if “sequence” is replaced by “net.”

XI.11.11.5. PROPOSITION. Every first countable topological space is compactly generated.

Proof: Let $X$ be first countable, and $U \subseteq X$ $k$-open. We show that $U^c$ (complement in $X$) is closed. Since $X$ is first countable, it suffices to show that if $(x_n)$ is a sequence in $U^c$ and $x_n \to x$, then $x \in U^c$. Let $K = \{x\} \cup \{x_n : n \in \mathbb{N}\}$; then $K$ is compact, so $U \cap K$ is relatively open, i.e. $U^c \cap K$ is relatively closed. Since $x_n \in U^c \cap K$ for all $n$ and $x_n \to x \in K$, $x \in U^c \subseteq U^c$.

XI.11.11.6. Example. There are topological spaces which are not compactly generated. For example, if $X$ is the space of XI.11.12.8. (b), and $U = \{\alpha\}$, then $U \cap K$ is relatively open for every compact (i.e. finite) subset $K$ of $X$. But $U$ is not open in $X$.

This example is countable, hence $\sigma$-compact, and completely normal.

XI.11.11.7. DEFINITION. Let $X$ and $Y$ be topological spaces, and $f : X \to Y$ a function. Then $f$ is continuous on compact sets if, for every compact $K \subseteq X$, $f|_K$ is a continuous function from $K$ to $Y$.

XI.11.11.8. Any continuous function is continuous on compact sets. The converse is false in general: if $X$ is the space of XI.11.12.8. (b) and $Y$ is any topological space, any function from $X$ to $Y$ is continuous on compact (i.e. finite) sets. However:

XI.11.11.9. PROPOSITION. Let $X$ and $Y$ be topological spaces, with $X$ compactly generated, and $f : X \to Y$ a function. If $f$ is continuous on compact sets, it is continuous.

Proof: Let $V$ be an open set in $Y$, and $U = f^{-1}(V)$. If $K$ is any compact subset of $X$, then $U \cap K = (f|_K)^{-1}(V)$ is relatively open in $K$ since $f|_K$ is continuous. Thus $U$ is open in $X$ since $X$ is compactly generated.

XI.11.12. Exercises

XI.11.12.1. (a) Show that any set with the indiscrete topology () is compact.

(b) Show that any set with the finite complement topology () is compact and $T_1$.

(c) Show that every subset of the examples in (a) and (b) is compact. Thus a compact subset of a compact $T_1$-space need not be closed.

1136
XI.11.12.2. The aim of this exercise is to show without AC that a compact subset of a Hausdorff space is closed. Let $X$ be a Hausdorff space, and $Y \subseteq X$. Suppose $Y$ is not closed, and let $p \in Y \setminus Y$. Fix a net $(y_i)$ in $Y$ converging to $p$ (XI.3.2.21.). Then the net $(y_i)$ cannot have a cluster point in $Y$ (XI.7.4.1.), so $Y$ is not compact (XI.11.2.1.).

XI.11.12.3. Here is an alternate proof of XI.11.3.10. which gives an explicit Lebesgue number. Let $(X, \rho)$ be a compact metric space, and $U$ an open cover of $X$. Let $\{U_1, \ldots, U_n\}$ be a finite subcover of $U$. For $x \in X$, define

$$f(x) = \frac{1}{n} \sum_{k=1}^{n} \rho(x, U_k^c).$$

Then $f$ is a continuous function from $X$ to $(0, \infty)$.

(a) Let $\delta$ be the minimum of $f$ on $X$. Show that $\delta > 0$.

(b) Show that $\delta$ is a Lebesgue number for $U$.

XI.11.12.4. Let $X = F([0,1], [0,1]) \cong [0,1]^\ast$ be the space of all functions from $[0,1]$ to itself, with the product topology (topology of pointwise convergence). Recall (XI.7.4.1.) that $X$ is separable but not first countable. $X$ is compact by Tikhonov’s Theorem (XI.11.3.10.) suffices, and Hausdorff.

Let $Y$ be the subset of $X$ consisting of all nondecreasing functions from $[0,1]$ to $[0,1]$, with the relative topology (also the topology of pointwise convergence). $Y$ is called the Helly space.

(a) Show that $Y$ is a closed subspace of $X$, hence compact and Hausdorff.

(b) Show that the set of nondecreasing step functions (XI.11.12.3) with only rational discontinuities, taking only rational values, is dense in $Y$. Conclude that $Y$ is separable.

(c) Show that $Y$ is first countable. [Use the fact (XI.11.12.3) that a nondecreasing function has only jump discontinuities, and only finitely many jumps of more than $\epsilon$ for any fixed $\epsilon > 0$.]

(d) For each $t \in [0,1]$, let $f_t$ be the function with $f_t(x) = 0$ for $x < t$, $f_t(x) = 1$ for $x > t$, and $f_t(t) = 1/2$. Show that $\{f_t : t \in [0,1]\}$ is an uncountable subset of $Y$ which is discrete in the relative topology. Conclude that $Y$ is not second countable, and hence not metrizable.

(e) Although $F([0,1], [0,1])$ has cardinality $2^{\aleph_0}$, show that $Y$ has cardinality $2^{\aleph_0}$ (cf. XI.7.8.5.).

XI.11.12.5. (a) Let $X$ be the unit square $[0,1] \times [0,1]$. Give $X$ the order topology (XI.11.12.3) from the lexicographic ordering. Show that $X$ is compact, Hausdorff, first countable, but not separable, hence not metrizable.

(b) Do the same as in (a) with the second copy of $[0,1]$ replaced by a three-point set with a total ordering. What if a two-point set is used instead?

XI.11.12.6. The Tikhonov Plank. Let $X$ be the set of ordinals less than or equal to the first uncountable ordinal $\omega_1$, and $Y$ the set of ordinals less than or equal to $\omega$. Then $X$ and $Y$ are compact Hausdorff spaces in the order topology. So $X \times Y$ is a compact Hausdorff space, hence normal. Let $Z = (X \times Y) \setminus (\omega_1, \omega)$ (Z is the “plank” $X \times Y$ with the “upper right-hand corner” removed).

(a) $Z$ is an open set in $X \times Y$, hence locally compact; $Z^f \cong X \times Y$. Show that $X \times Y$ is also $\beta Z$ (cf. XI.11.9.17.). $Z$ is pseudocompact (XI.11.9.17.).

(b) Let $T = \{ (\alpha, \omega) : \alpha < \omega_1 \}$ and $R = \{ (\omega_1, \alpha) : \alpha < \omega \}$ be the “top and right edges” of $Z$. Show that $T$ and $R$ are disjoint closed subsets of $Z$ which do not have disjoint neighborhoods in $Z$. Thus $Z$ is not normal.

1137
XI.11.12.7. Rational Sequence Topology. [SS95, #65] Put a topology on \( \mathbb{R} \) as follows. For each irrational \( x \in \mathbb{R} \), fix a sequence \((q_{x,k})\) of rational numbers converging to \( x \). Let \( \mathcal{B} \) be the following collection of subsets of \( \mathbb{R} \):

(i) \( \{q\} \) for each \( q \in \mathbb{Q} \).
(ii) \( \{x\} \cup \{q_{x,k} : k \geq n\} \) for each \( x \in \mathbb{J} = \mathbb{R} \setminus \mathbb{Q} \), \( n \in \mathbb{N} \).

(a) Show that if \( x, y \in \mathbb{J}, x \neq y \), then \( \{q_{x,k} : k \in \mathbb{N}\} \cap \{q_{y,k} : k \in \mathbb{N}\} \) is finite.
(b) Show that \( \mathcal{B} \) is a base for a topology \( \mathbb{Q} \) on \( \mathbb{R} \).
(c) Show that \( \mathbb{Q} \) is stronger than the ordinary topology on \( \mathbb{R} \). Thus \( (\mathbb{R}, \mathbb{Q}) \) is Hausdorff. Each rational number is an isolated point of \( (\mathbb{R}, \mathbb{Q}) \).
(d) \( (\mathbb{R}, \mathbb{Q}) \) is first countable.
(e) \( \mathbb{Q} \) is a dense open subset of \( (\mathbb{R}, \mathbb{Q}) \); thus \( (\mathbb{R}, \mathbb{Q}) \) is separable.
(f) Each set in \( \mathcal{B} \) is compact in \( (\mathbb{R}, \mathbb{Q}) \) (XI.11.11.3). Thus there is a base for \( \mathbb{Q} \) consisting of compact open sets, so \( (\mathbb{R}, \mathbb{Q}) \) is locally compact and \( ind(\mathbb{R}, \mathbb{Q}) = 0 \) (XI.21.3.2). In particular, \( (\mathbb{R}, \mathbb{Q}) \) is completely regular (XI.11.8.9) and totally disconnected (XI.13.6.1).
(g) \( \mathbb{J} \) is a discrete closed subset of \( (\mathbb{R}, \mathbb{Q}) \) of cardinality \( 2^{\aleph_0} \). Thus by XI.7.8.9., \( (\mathbb{R}, \mathbb{Q}) \) is not normal.
(h) By XI.13.6.5., \( dim(\mathbb{R}, \mathbb{Q}) > 0 \), i.e. \( (\mathbb{R}, \mathbb{Q}) \) is not zero-dimensional (XI.13.6.3.). Also, \( Ind(\mathbb{R}, \mathbb{Q}) > 0 \).

XI.11.12.8. Let \( \alpha \) be a point of \( \beta \mathbb{N} \setminus \mathbb{N} \), and let \( \mathcal{F} \) be the corresponding free ultrafilter on \( \mathbb{N} \). Set \( X = \mathbb{N} \cup \{\alpha\} \), with the relative topology. Then \( X \) is a countable completely regular (hence normal) space.

(a) Show that the open sets in \( X \) consist precisely of all subsets of \( \mathbb{N} \) and all sets of the form \( F \cup \{\alpha\} \), where \( F \in \mathcal{F} \). (The space \( X \) could have been defined without reference to \( \beta \mathbb{N} \) by just taking \( \alpha \) to be a point not in \( \mathbb{N} \) and defining the open sets this way for the free ultrafilter \( \mathcal{F} \).)

(b) Show that \( \alpha \) does not have a countable neighborhood base in \( X \). If \( x_n = \alpha \), then \( \alpha \) is a cluster point of the sequence \( (x_n) \), but no subsequence of \( (x_n) \) converges to \( \alpha \). [Every infinite subset of \( \mathbb{N} \) contains an infinite subset which is not in \( \mathcal{F} \).]

(c) Although every singleton subset of \( X \) is a \( G_\delta \), \( X \) is not first countable.

(d) \( X \) is not compact; in fact, the only compact subsets of \( X \) are the finite subsets. The identity map from \( \mathbb{N} \) to \( X \) extends to a homeomorphism from \( \beta \mathbb{N} \) to \( \beta X \) [GJ76, ].

If \( \gamma \) is another point of \( \beta \mathbb{N} \setminus \mathbb{N} \), corresponding to another free ultrafilter \( \mathcal{G} \) on \( \mathbb{N} \), and \( Y = \mathbb{N} \cup \{\gamma\} \), then \( Y \) is not necessarily homeomorphic to \( X \); in fact, there are \( 2^{2^{\aleph_0}} \) homeomorphism classes of such spaces since there are \( 2^{2^{\aleph_0}} \) points in \( \beta \mathbb{N} \setminus \mathbb{N} \) and only \( 2^{\aleph_0} \) permutations of \( \mathbb{N} \) [GJ76, ].

(e) More generally, consider a topological space \( X \) which is countably infinite and in which every point but one is an isolated point. Identify the isolated points with \( \mathbb{N} \) and call the nonisolated point \( \alpha \). Show that \( X \) is necessarily perfectly normal, and that there is a free filter \( \mathcal{F} \) on \( \mathbb{N} \) such that the open sets in \( X \) consist of all subsets of \( \mathbb{N} \) and all sets of the form \( F \cup \{\alpha\} \) for \( F \in \mathcal{F} \). There is a weakest such topology on \( \mathbb{N} \cup \{\alpha\} \), which is the one-point compactification of \( \mathbb{N} \); the maximal such topologies are the ones described in (i) (i.e. where \( \mathcal{F} \) is an ultrafilter). Every such topology is obtained by taking a compactification \( Y \) of \( \mathbb{N} \) and letting \( \alpha \) be a point of \( Y \setminus \mathbb{N} \). [Consider \( \beta X \).]

See XI.6.1.3. for a more dramatic example of a countable normal space which is not first countable.
XI.11.12.9. Let $X$ be a Hausdorff space. Show that $X$ is countably compact if and only if $X$ does not contain a closed subspace homeomorphic to $\mathbb{N}$ (i.e. a countably infinite closed subset whose relative topology is the discrete topology).

XI.11.12.10. Let $X$ be the space $\omega_1$ of ordinals less than the first uncountable ordinal ($\omega_1$), with the order topology ($\omega_1$). Let $\mathcal{U}$ be the open cover of $X$ consisting of all sets of the form $[0, \alpha)$ for $\alpha \in X$. Show that $\mathcal{U}$ has no locally finite refinement. [If $\mathcal{V}$ is a refinement of $\mathcal{U}$, show that there is a sequence $(V_n)$ of distinct sets in $\mathcal{V}$ and a strictly increasing sequence $(\alpha_n)$ in $X$ with $\alpha_n \in V_n$, and thus that $\mathcal{V}$ cannot be locally finite at $\alpha = \sup \alpha_n$.] Thus $X$ is locally compact and normal, even completely normal (XI.16.1.1.), but not paracompact.

XI.11.12.11. Show that a locally finite open cover of a separable topological space is countable. Conclude that every separable paracompact space is Lindelöf.

XI.11.12.12. Let $X$ be a topological space. Define a one-point compactification of $X$ as follows. Let $X_\infty$ be $X \cup \{\infty\}$, where $\infty$ is something not in $X$. A subset $U$ of $X_\infty$ is open if $U \subseteq X$ and $U$ is open in $X$, or if $\infty \in U$ and $X \setminus U$ is closed and compact in $X$ (regarding $\emptyset$ as a closed compact subset of $X$).

(a) Show that such open sets form a topology on $X_\infty$.
(b) Show that the relative topology on $X$ from $X_\infty$ is the original topology on $X$.
(c) Show that $X_\infty$ is compact.
(d) Show that $X$ is dense in $X_\infty$ if and only if $X$ is not compact.
(e) Show that $\{\infty\}$ is closed in $X_\infty$; hence $X_\infty$ is $T_1$ if and only if $X$ is $T_1$.
(f) Show that $X_\infty$ is Hausdorff if and only if $X$ is Hausdorff and locally compact.

XI.11.12.13. If $X$ is a topological space, $\mathcal{U}$ an open cover of $X$, and $x \in X$, the star of $\mathcal{U}$ at $x$ is

$$\text{st}_x(\mathcal{U}) = \{U \in \mathcal{U} : x \in U\}.$$ 

The collection $\text{st}(\mathcal{U}) = \{\text{st}_x(\mathcal{U}) : x \in X\}$ is an open cover of $X$, and $\mathcal{U}$ is a refinement of this cover. An open cover $\mathcal{V}$ star-refines $\mathcal{U}$ if $\text{st}(\mathcal{V})$ refines $\mathcal{U}$. This implies that $\mathcal{V}$ refines $\mathcal{U}$, but is much stronger. A topological space $X$ is fully normal if $X$ is $T_1$ and every open cover of $X$ has a star-refinement.

(a) Let $(X, \rho)$ be a metric space, and for $\epsilon > 0$ let $\mathcal{U}_\epsilon$ be the open cover of $X$ consisting of all open balls of radius $\epsilon$. Show that $\mathcal{U}_{\epsilon/2}$ is a star-refinement of $\mathcal{U}_\epsilon$ for any $\epsilon > 0$.
(b) Show that a fully normal space is normal. [If $A$ and $B$ are disjoint closed subsets of $X$, consider the open cover $\{X \setminus A, X \setminus B\}$.]
(c) [Sto48] Show that every metrizable space is fully normal.
(d) [Sto48] Show that a topological space is fully normal if and only if it is paracompact.

XI.11.12.14. Let $(X, T)$ be a topological space, and let $T^k$ be the set of $k$-open sets in $X$. Show that $T^k$ is a topology on $X$ which is stronger than $T$; $(X, T)$ is compactly generated if and only if $T^k = T$. Is $(X, T^k)$ always compactly generated? [Show that $T$ and $T^k$ have the same compact sets.]
XI.11.12.15. (D. E. Cohen; cf. [Dug78, XI.9.4]) (a) Show that every compactly generated Hausdorff space is a quotient of a locally compact space. [Consider the separated union of the compact subsets of the space.]

(b) Show that any quotient space of a locally compact space is compactly generated. [If $f : X \to Y$ is a quotient map with $X$ locally compact and $U$ is a $k$-open set in $Y$, show that $f^{-1}(U) \cap V$ is open in $X$ for any open set $V$ in $X$ with compact closure.]

(c) ([Dug78, XI.9.5], but note that a Hausdorff hypothesis is omitted there) Conclude that any quotient space of a compactly generated Hausdorff space is compactly generated.
XI.11.13. Dini’s Theorem

Dini’s Theorem is an assertion that certain sequences of functions which converge pointwise actually converge uniformly. Since uniform convergence has all sorts of nice consequences not shared by pointwise convergence, such a result is very useful.

XI.11.13.1. Definition. Let $X$ be a set, and $(f_n)$ a sequence of real-valued functions on $X$. The sequence $(f_n)$ is nondecreasing if, for each $x \in X$, the sequence $(f_n(x))$ of real numbers is nondecreasing. Similarly, $(f_n)$ is nonincreasing if $(f_n(x))$ is nonincreasing for all $x \in X$. The sequence $(f_n)$ is monotone if it is either a nondecreasing sequence or a nonincreasing sequence.

Note that it is the sequence itself that is nondecreasing (etc.), not the individual functions $f_n$. (Indeed, if $X$ is a general set, it does not make sense to say an individual function from $X$ to $\mathbb{R}$ is nondecreasing.) This notion of nondecreasing (etc.) is sometimes called pointwise nondecreasing (etc.) One can similarly define strictly increasing, strictly decreasing, and strictly monotone sequences of functions.

Here is the general version of Dini’s Theorem:

XI.11.13.2. Theorem. [Dini’s Theorem, General Version] Let $X$ be a compact topological space, and $(f_n)$ a nondecreasing sequence of real-valued continuous functions on $X$ converging pointwise to a function $f$ (not assumed to be continuous). If $g$ is a real-valued continuous function on $X$ satisfying $g(x) < f(x)$ for all $x \in X$, then there is an $n$ such that $g(x) < f_n(x)$ for all $x \in X$. The same statement holds with inequalities reversed if $(f_n)$ is nonincreasing.

Proof: For each $n$, set $K_n = \{x \in X : g(x) \geq f_n(x)\}$. Then $K_n$ is closed since $g$ and $f_n$ are continuous; hence $K_n$ is compact ( ). Since $f_n(x) \leq f_{n+1}(x)$ for all $x \in X$, we have $K_{n+1} \subseteq K_n$ for all $n$. Also, $\bigcap_n K_n = \emptyset$, since if $x \in \bigcap_n K_n$, we have $g(x) \geq f_n(x)$ for all $n$, hence $g(x) \geq f(x)$, contrary to hypothesis. Thus $(K_n)$ is a decreasing sequence of compact subsets of $X$ with empty intersection, so $K_n = \emptyset$ for some $n$ by ( ). The proof of the last statement is analogous. $

As a corollary, we get the commonly stated version of Dini’s Theorem:

XI.11.13.3. Corollary. [Dini’s Theorem, Common Version] Let $X$ be a compact topological space, and $(f_n)$ a monotone sequence of real-valued continuous functions on $X$ converging pointwise to a continuous function $f$. Then $f_n \to f$ uniformly.

Proof: Let $\epsilon > 0$. If $(f_n)$ is nondecreasing, set $g(x) = f(x) - \epsilon$ for all $x$; if $(f_n)$ is nonincreasing, set $g(x) = f(x) + \epsilon$. $

Combining this result with ( ), we obtain:

XI.11.13.4. Corollary. Let $X$ be a compact topological space, and $(f_n)$ a monotone sequence of real-valued continuous functions on $X$ converging pointwise to a function $f$. Then $f_n \to f$ uniformly if and only if $f$ is continuous.
XI.12. Baire Spaces and the Baire Category Theorem

The Baire Category Theorem is one of the two theorems from topology (along with Tikhonov’s Theorem) which are most heavily used in advanced analysis. Some of the conclusions are remarkable, and can seem like “magic” or “too good to be true.”

It will be most convenient to phrase the theorem by defining the class of topological spaces, the Baire spaces, for which the conclusion holds and then showing that complete metric spaces and locally compact Hausdorff spaces are Baire spaces.

XI.12.1. Meager Sets and Baire Spaces

XI.12.1.1. Definition. Let $X$ be a topological space. A subset $A$ of $X$ is nowhere dense in $X$ if the complement of $A$ is dense in $X$.

A subset of $X$ is meager in $X$, or first category in $X$, if it is a countable union of nowhere dense subsets of $X$. A subset is second category in $X$ if it is not meager (first category) in $X$. A subset $A$ is residual in $X$, or comeager or generic in $X$, if $A^c$ is meager in $X$.

The (nonempty) topological space $X$ is a Baire space if no nonempty open subset of $X$ is meager in $X$, i.e. if every residual subset of $X$ is dense in $X$.

The terms “nowhere dense”, “meager”, “first category”, “second category”, “residual”, “generic”, and “comeager” are relative terms, and the ambient topological space $X$ must be mentioned or at least be understood. The term “Baire space”, however, is intrinsic.

The terminology “first category” and “second category” is Baire’s, and is still frequently used, but we prefer the more descriptive terminology “meager” and “residual.” Note that “second category” and “residual” are not the same; in a Baire space, every residual set is second category, but there are many subsets $A$ for which both $A$ and $A^c$ are second category. (In a non-Baire space, even $\emptyset$ can be residual.)

XI.12.1.2. Examples. (i) The complement of a nowhere dense set is dense, but a set with dense complement is not nowhere dense in general. For example, $\mathbb{Q}$ is not nowhere dense in $\mathbb{R}$ (in fact, it is dense). A set $A \subseteq X$ is nowhere dense in $X$ if and only if $A$ is nowhere dense in $X$.

(ii) The complement of a dense open set in a topological space $X$ is nowhere dense in $X$. In particular, the Cantor set is nowhere dense in $\mathbb{R}$.

(iii) $\mathbb{R}$ is not nowhere dense in $\mathbb{R}$ (in fact, no nonempty topological space is nowhere dense in itself). But $\mathbb{R}$ is nowhere dense in $\mathbb{C}$. Thus it is important to specify the ambient space.

(iv) If $X$ is $T_1$ and $x \in X$ is not an isolated point, then $\{x\}$ is nowhere dense in $X$. Thus a countable subset of $X$ containing no isolated points is meager. In particular, every countable subset of $\mathbb{R}$ (e.g. $\mathbb{Q}$) is meager.

(v) Any subset of a nowhere dense set is nowhere dense. Any subset of a meager set is meager. So any subset containing a dense $G_δ$ is residual. The converse is true in a Baire space (XI.12.1.4.).

(vi) Any discrete space is a Baire space, since a nonempty subset of a discrete space cannot be nowhere dense. On the other hand, by (iv), no countable $T_1$ space without isolated points is a Baire space.

(vii) A countable union of meager sets in $X$ is meager in $X$ (cf. II.5.4.8.).
XI.12.1.3.  PROPOSITION. Let $X$ be a topological space. The following are equivalent:

(i) $X$ is a Baire space.

(ii) The intersection of any sequence of dense open subsets of $X$ is dense.

(iii) The intersection of any finite or countable collection of dense $G_{δ}$’s is a dense $G_{δ}$.

PROOF: (i) ⇒ (ii): If $X$ is a Baire space and $(A_n)$ is a sequence of dense open subsets of $X$, then $A_n^c$ is closed and nowhere dense in $X$, so $\bigcup_{n=1}^{\infty}A_n^c$ is meager and $\bigcap_{n=1}^{\infty}A_n$ is residual, hence dense.

(ii) ⇒ (i): Suppose the intersection of any sequence of dense open subsets of $X$ is dense, and let $A$ be a residual subset of $X$. Then $A^c = \bigcup_{n=1}^{\infty}B_n$, where $B_n$ is nowhere dense in $X$. If $A_n$ is the complement of $B_n$, then $A_n$ is a dense open set in $X$, and $\bigcap_{n=1}^{\infty}A_n \subseteq A$. By assumption, $\bigcap_{n=1}^{\infty}A_n$ is dense in $X$, so $A$ is also dense in $X$.

For (iii), the only issue is whether the intersection is dense since in any topological space an intersection of countably many $G_{δ}$’s is a $G_{δ}$.

XI.12.1.4.  COROLLARY. Let $X$ be a Baire space. A subset $A$ of $X$ is residual in $X$ if and only if $A$ contains a dense $G_{δ}$.

PROOF: One direction was observed in XI.12.1.2 (v). Conversely, let $A$ be a residual subset of a Baire space $X$. Then $A^c = \bigcup_{n=1}^{\infty}B_n$, where $B_n$ is nowhere dense in $X$. If $A_n$ is the complement of $B_n$, then $A_n$ is a dense open set in $X$, and $\bigcap_{n=1}^{\infty}A_n$ is a dense $G_{δ}$ in $X$ which is contained in $A$.

XI.12.1.5.  If $X$ is a $T_1$ Baire space and $A$ is a countable dense subset of $X$ containing no isolated points, then $A$ is meager (XI.12.1.2), so cannot be a $G_{δ}$ since if it were $A^c$ would be an $F_{σ}$, hence also meager (Exercise XI.12.5.1). In particular, $\mathbb{Q}$ is not a $G_{δ}$ in $\mathbb{R}$.

XI.12.2.  The Baire Category Theorem

It turns out that many standard topological spaces are Baire spaces. The next theorem is the principal result of this section. It is named after R. Baire, who proved it in 1899 [3] (Baire actually only stated it for $\mathbb{R}^n$, but essentially the same proof gives the general result), and is called the “Baire Category Theorem” because of his category terminology (note that it has nothing to do with category theory []). The case of $\mathbb{R}$ was actually proved earlier (1897) by W. Osgood [Osg97], who used different terminology; Osgood also independently obtained the result for $\mathbb{R}^n$ [Osg00].
XI.12.2.1. **Theorem.** [Baire Category Theorem] (i) Every completely metrizable space (topological space whose topology is given by a complete metric) is a Baire space.

(ii) Every locally compact Hausdorff space is a Baire space.

The first sentence is often stated, “Every complete metric space is a Baire space.” But note that the property of being a Baire space is a purely topological property, not a metric property. Thus, for example, \((0, 1)\) is a Baire space since it is homeomorphic to \(\mathbb{R}\), even though the usual metric on \((0, 1)\) is not complete. See XI.10.3. for more detailed results about completely metrizable spaces.

**Proof:** The proofs of both parts are nearly identical. In both cases, we must show that if \((U_n)\) is a sequence of dense open subsets of \(X\), then \(\bigcap_{n=1}^{\infty} U_n\) is also dense in \(X\), i.e. if \(V\) is a nonempty open set in \(X\), then \(V \cap \bigcap_{n=1}^{\infty} U_n\) is nonempty.

First suppose the topology on \(X\) is given by a complete metric \(\rho\). Since \(U_1\) is dense in \(X\), \(V \cap U_1\) is nonempty. Choose \(x_1 \in V \cap U_1\), and let \(B_1\) be an open ball of radius \(\leq 1\) centered at \(x_1\) whose closure is contained in \(V \cap U_1\) (there exists such a ball since \(V \cap U_1\) is open in \(X\)). Since \(U_2\) is dense in \(X\), there is an \(x_2 \in B_1 \cap U_2\). Let \(B_2\) be an open ball centered at \(x_2\) of radius \(\leq 1/2\) whose closure is contained in \(B_1 \cap U_2\). Inductively define points \(x_n \in B_{n-1} \cap U_n\) and balls \(B_n\) centered at \(x_n\) of radius \(\leq 1/n\) whose closure is contained in \(B_{n-1} \cap U_n\). By construction, \(x_m\) is in the closure of \(B_n\) for all \(m > n\), and thus \(\rho(x_n, x_m) \leq 1/n\) for all \(m > n\). Thus \((x_n)\) is a Cauchy sequence in \((X, \rho)\). Since \(\rho\) is complete, \((x_n)\) converges to some \(x \in X\). We have that \(x\) is in the closure of \(B_n\) for each \(n\); thus \(x \in \bigcap_{n=1}^{\infty} U_n\). And \(x \in B_1 \subseteq V\). Thus \(V \cap \bigcap_{n=1}^{\infty} U_n\) is nonempty.

The proof of (ii) is similar, but easier. Choose \(x_1 \in V \cap U_1\) as before. There is an open neighborhood \(B_1\) of \(x_1\) with compact closure contained in \(V \cap U_1\). Inductively choose points \(x_n\) and open neighborhoods \(B_n\) such that the closure of \(B_n\) is compact and contained in \(B_{n-1} \cap U_n\). Then \((B_n)\) is a decreasing sequence of nonempty compact subsets of \(X\) and hence there is an \(x \in \bigcap_{n=1}^{\infty} B_n\). This \(x\) is in \(U_n\) for all \(n\), and also in \(V\).

XI.12.2.2. Note that the proof of this theorem uses the Axiom of Choice to choose the \(x_n\). In fact, only a sequence of choices must be made, each dependent on the previous ones, so the Axiom of Dependent Choice (DC) suffices. Actually, the Baire Category Theorem is logically equivalent to DC (Exercise II.6.4.7.). But if \(X\) is separable, no form of choice is necessary to prove the Baire Category Theorem (Exercise ())). (It can be proved without any form of choice that a separable metrizable space is second countable (); however, the Countable Axiom of Choice is needed to prove that a second countable topological space, even a second countable metrizable space, is separable, so Countable AC is needed to prove the Baire Category Theorem for second countable complete metrizable spaces.)

XI.12.2.3. There are many Baire spaces, even metrizable ones, which do not satisfy the hypotheses of XI.12.2.1. In particular, a metrizable Baire space need not be completely metrizable (XI.12.5.4.).

XI.12.2.4. One of the important ways the Baire Category Theorem is used in analysis is to prove the existence of objects with a certain (usually pathological) property by showing that the set of objects without the property is a meager subset of some complete metric space. Such proofs are often regarded as “nonconstructive” or “pure existence proofs” which prove existence without exhibiting a specific example. The claim is made in [Oxt71] that this point of view is incorrect (at least in the separable case), and that the proof of the Baire Category Theorem is an explicit construction which in applications gives a
concrete example. This claim is correct, at least in principle: the proof of the theorem does give a recipe for constructing an example. But the actual example is the limit of a Cauchy sequence which may be almost impossible to describe explicitly. Even the terms in the Cauchy sequence can be quite difficult to explicitly describe in many cases. (This point is acknowledged in \([Oxt71]\).)

Here is an interesting sample application of Baire Category. An explicit example of a continuous function which is not differentiable anywhere is given in \(\) . Here is a simpler argument which shows that such functions exist; in fact, in a category sense almost all continuous functions fail to be differentiable anywhere!

**XI.12.2.5.** Theorem. Let \([a, b]\) be a closed bounded interval in \(\mathbb{R}\), and \(C([a, b])\) the real-valued continuous functions on \([a, b]\), with supremum norm. If \(D\) is the set of functions in \(C([a, b])\) which have a (finite) derivative at at least one point of \([a, b]\), then \(D\) is a meager subset of \(C([a, b])\). Hence there is a residual set of functions on \([a, b]\) which are continuous everywhere but differentiable nowhere.

This argument in a sense shows more than the one in \(\) , and in a sense shows less: this argument shows not only that continuous nondifferentiable functions exist, but that such functions are “typical” (despite one’s impression from Calculus) and form a set which is uniformly very dense. However, it is hard to identify a specific example of such a function from the Baire Category argument.

There are some rather astounding variations on this result, such as the following theorem of J. MARCINKIEWICZ (1935).

**XI.12.2.6.** Theorem. Let \([a, b]\) be a closed bounded interval, and \((h_n)\) a sequence of nonzero real numbers converging to zero. Then there is a continuous function \(f : [a, b] \rightarrow \mathbb{R}\) with the following property: if \(\phi : [a, b] \rightarrow \mathbb{R}\) is any measurable function, then there is a subsequence \((h_{k_n})\) of \((h_n)\) such that

\[
\lim_{n \to \infty} \frac{f(x + h_{k_n}) - f(x)}{h_{k_n}} = \phi(x)
\]

for almost all \(x \in [a, b]\). (Thus \(f\) is differentiable at most on a set of measure zero.) In fact, there is a residual set of such \(f\).

See \([Str81, p. 316-317]\) for an outline of the proof.

**XI.12.3. Meager Sets vs. Null Sets**

Meager sets have a close formal resemblance to sets of Lebesgue measure zero. Both notions are reasonable interpretations of what it should mean to be “negligibly small.” The relationship is more than just an analogy; the theme of the book \([Oxt71]\) is the close connections between the concepts.

The two notions of smallness are not the same, however, as the next rather dramatic example shows:
XI.12.3.1. Example. There is a dense $G_δ$ in $\mathbb{R}$ of Lebesgue measure 0. Thus $\mathbb{R}$ can be partitioned into a disjoint union of a meager set and a set of measure 0. This follows immediately from () and the fact that $\mathbb{Q}$ is a dense subset of $\mathbb{R}$ of Lebesgue measure 0, but we give an explicit example.

Let $(r_n)$ be an enumeration of $\mathbb{Q}$. Let $I_{n,k}$ be the open interval of length $\frac{1}{2^n k}$ centered at $r_n$, and for each $k$ let $A_k = \bigcup_{n=1}^{\infty} I_{n,k}$. Then $A_k$ is open, and dense since $\mathbb{Q} \subset A_k$; and

$$\lambda(A_k) \leq \sum_{n=1}^{\infty} \frac{1}{2^n k} = \frac{1}{k}.$$ 

Thus $A = \cap_{k=1}^{\infty} A_k$ is a dense $G_δ$ in $\mathbb{R}$ of Lebesgue measure 0.

An even more dramatic example is possible: there is a dense $G_δ$ in $\mathbb{R}$ which not only has Lebesgue measure 0, but Hausdorff dimension 0, i.e. $s$-dimensional Hausdorff measure 0 for all $s > 0$. Such an example can be readily constructed by a refinement of the argument in XI.12.3.1., but there is a natural and significant example: the Liouville numbers. See ()

XI.12.4. The Baire Property

XI.12.4.1. Definition. Let $X$ be a topological space. If $A, B \subseteq X$, write $A =^* B$ if $A \triangle B$ is a meager subset of $X$ (i.e. “$A$ and $B$ differ by a meager set.”)

A subset $A$ of $X$ has the Baire property if $A =^* U$ for some open set $U$ in $X$, i.e. “$A$ differs from an open set by a meager set.”

XI.12.4.2. It is easy to check that $=^*$ is an equivalence relation on subsets of $X$. Note that the Baire property is a relative property of $A$ in $X$, not an intrinsic property of $A$. For example, every open set and every meager set in $X$ has the Baire property. In particular, there is no direct connection between having the Baire property and being a Baire space.

XI.12.4.3. Proposition. Let $X$ be a topological space. Then the collection of all subsets of $X$ with the Baire property is a $\sigma$-algebra, and is the $\sigma$-algebra generated by the open sets and the meager sets. In particular, every Borel set in $X$ has the Baire property.

Proof: If $U$ is open, then $U =^* \bar{U}$ since $\bar{U} \setminus U$ is nowhere dense, hence meager. Similarly, if $E$ is closed, $E =^* E^c$.

If $A =^* U$ with $U$ open, then $A^c \triangle U^c = A \triangle U$ is meager, so $A^c =^* U^c =^* (U^c)^0$, and $A^c$ has the Baire property. And if $A_n =^* U_n$ for all $n$ with each $U_n$ open, then

$$\left( \bigcup_n A_n \right) \triangle \left( \bigcup_n U_n \right) \subseteq \bigcup_n (A_n \triangle U_n)$$

and a countable union of meager sets is meager, hence $\cup_n A_n =^* \cup_n U_n$, so $\cup_n A_n$ has the Baire property. Thus the collection $\mathcal{D}$ of subsets with the Baire property is a $\sigma$-algebra.

If $\mathcal{A}$ is the $\sigma$-algebra generated by the open sets and the meager sets, then $\mathcal{A} \subseteq \mathcal{D}$. Conversely, if $A \in \mathcal{D}$, then $A \triangle U = \emptyset$ is meager for some open set $U$, and $A = M \triangle U$, so $A \in \mathcal{A}$. Thus $\mathcal{A} = \mathcal{D}$. 

1146
XI.12.4.4. COROLLARY. Let \( X \) be a topological space, and \( A \subseteq X \). The following are equivalent:

(i) \( A \) has the Baire property.

(ii) \( A = E \cup M \) with \( E \) a \( G_\delta \) and \( M \) meager.

(iii) \( A = F \setminus M \) with \( F \) an \( F_\sigma \) and \( M \) meager.

Proof: (ii) \( \Rightarrow \) (i) and (iii) \( \Rightarrow \) (i) by XI.12.4.3. For (i) \( \Rightarrow \) (ii), suppose \( A \triangle U = N \) for a meager set \( N \). Then there is a meager \( F_\sigma F \) with \( N \subseteq F \). Then \( E = U \setminus F \) is a \( G_\delta \), \( E \subseteq A \), and \( A \setminus E \subseteq N \) is meager. For (i) \( \Rightarrow \) (iii), apply (i) \( \Rightarrow \) (ii) for \( A^c \).

Baire Measurable Functions

XI.12.4.5. Definition. Let \( X \) and \( Y \) be topological spaces, and \( f : X \to Y \) a function. Then \( f \) is Baire measurable if \( f^{-1}(U) \) has the Baire property for every open set \( U \) in \( Y \).

XI.12.4.6. It follows from () that if \( f \) is Baire measurable, then \( f^{-1}(B) \) has the Baire property for any Borel set \( B \) in \( Y \). In particular, if \( f \) is Borel measurable, it is Baire measurable. (Of course, if \( f \) is continuous it is Borel measurable, hence Baire measurable.)

The next result is related to Luzin’s Theorem (), at least in spirit. It holds for any topological spaces, but is most interesting if \( X \) is a Baire space:

XI.12.4.7. Theorem. Let \( X \) and \( Y \) be topological spaces, and \( f : X \to Y \) a Baire measurable function. Then there is a residual \( G_\delta E \) in \( X \) such that \( f|_E \) is continuous.

XI.12.4.8. The set \( E \) is necessarily dense in \( X \) if \( X \) is a Baire space. Note that the conclusion is that the restriction of \( f \) to \( E \) is continuous, not that \( f \) is continuous on \( E \). In fact, \( f \) need not be continuous anywhere, even if \( X \) is a Baire space (e.g. \( \chi_Q : \mathbb{R} \to \mathbb{R} \); in this case we may take \( E = \emptyset \)).

In contrast, here is an important result in which actual continuity is obtained on a residual set.

XI.12.4.9. Theorem. Let \( X, Y, \) and \( Z \) be metrizable topological spaces, and \( f : X \times Y \to Z \) a function. Suppose \( f \) is separately continuous, i.e. for each \( x \in X \) the function \( f_x : Y \to Z \) given by \( f_x(y) = f(x, y) \) is continuous, and for each \( y \in Y \) the function \( f^y : X \to Z \) given by \( f^y(x) = f(x, y) \) is continuous. Then there is a residual \( G_\delta E \) in \( X \times Y \), with \( E^y = \{ x \in X : (x, y) \in E \} \) residual in \( X \) for each \( y \in Y \), such that \( f \) is continuous (i.e. jointly continuous) at all points of \( E \).

XI.12.4.10. In particular, if \( X \times Y \) is a metrizable Baire space, e.g. if \( X \) and \( Y \) are completely metrizable, then a separately continuous function from \( X \times Y \) to any metric space \( Z \) is jointly continuous on a dense \( G_\delta \).
XI.12.5. Exercises

XI.12.5.1. Let $X$ be a complete metric space, or a locally compact Hausdorff space, without isolated points. Show that no countable dense subset of $X$ is a $G_{δ}$. (Hence $\mathbb{Q}$ is not a $G_{δ}$ in $\mathbb{R}$.) In particular, $X$ is uncountable. [The complement of a dense $G_{δ}$ is meager.]

XI.12.5.2. (a) Show that a dense $G_{δ}$ in a Baire space is a Baire space in the relative topology.
(b) Use XI.11.9.13., XI.10.3.4., XI.12.2.1.(ii), and (a) to give an alternate proof of XI.12.2.1.(i).

The word “dense” cannot be eliminated in (a) (XI.12.5.4.).

XI.12.5.3. Prove the following strong converse to XI.12.5.2 (a): If a topological space $X$ contains a dense subspace which is a Baire space in the relative topology, then $X$ is a Baire space. [Use XI.2.3.9..]

XI.12.5.4. Let $X = (\mathbb{R} \times [\mathbb{R} \setminus \{0\}]) \cup (\mathbb{Q} \times \{0\})$, with the relative topology from $\mathbb{R}^2$.

(a) Apply XI.12.5.3. to show that $X$ is a Baire space.

(b) $X$ has a closed subspace, a $G_{δ}$, homeomorphic to $\mathbb{Q}$, which is not a Baire space (XI.12.1.2.(vi)). Thus a closed subspace of a Baire space, even a closed $G_{δ}$, is not necessarily a Baire space.

(c) $X$ is metrizable. But a closed subspace of a completely metrizable space is completely metrizable and hence a Baire space, so $X$ is not completely metrizable.

Simpler non-Hausdorff examples of non-Baire closed subspaces of Baire spaces can be given.

XI.12.5.5. [Boa96, p. 59–61] Use the Baire Category Theorem to show that on any closed bounded interval $[a,b]$, there is a continuous function which is not monotone on any subinterval, and in fact a residual set of such functions in $C([a,b])$. [Use subintervals with rational endpoints.] See XI.12.5.8. for a closely related result.

XI.12.5.6. [CSB54] Use the Baire Category Theorem to show that if $f$ is a $C^∞$-function on an interval $[a,b]$, and for every $x \in [a,b]$ there is an $n$ such that $f^{(n)}(x) = 0$, then $f$ is a polynomial, i.e. there is an $n$ such that $f^{(n)}(x) = 0$ for all $x \in [a,b]$.

XI.12.5.7. [Wei76] Let $[a,b]$ be a closed bounded interval, and $D_{0}'([a,b])$ the set of bounded functions on $[a,b]$ which are derivatives of differentiable functions (i.e. bounded functions on $[a,b]$ which have antiderivatives).

(a) Show that $D_{0}'([a,b])$ is a closed subspace of the Banach space of bounded real-valued functions on $[a,b]$ with the supremum norm, hence also a Banach space (cf. V.8.5.7.).

(b) Show that if $f \in D_{0}'([a,b])$, then $Z_f = \{ x \in [a,b] : f(x) = 0 \}$ is a $G_{δ}$ (cf. V.12.1.8., (i)).

(c) Let $D_{0}''([a,b])$ be the set of all $f \in D_{0}'([a,b])$ for which $Z_f$ is dense in $[a,b]$. Use (b) and the Baire Category Theorem to show that $D_{0}''([a,b])$ is a closed subspace of $D_{0}'([a,b])$, and thus also a Banach space.

(d) There is a $g \in D_{0}''([a,b])$ which is not identically zero (XI.22.7.3.). By translating and scaling $g$, show that for any $x \in [a,b]$ and $\epsilon > 0$ there is an $h \in D_{0}''([a,b])$ with $\|h\| < \epsilon$ and $h(x) \neq 0$.

(e) If $I$ is a closed (nondegenerate) subinterval of $[a,b]$, let

$$E^I = \{ f \in D_{0}'([a,b]) : f(x) \geq 0 \text{ for all } x \in I \} .$$
Show that $E_I^+$ is a closed subset of $D'_0([a,b])$. Use (d) to show that $E_I^+$ is nowhere dense in $D'_0([a,b])$. Do the same for $E_I^- = \{ f \in D'_0([a,b]) : f(x) \leq 0 \text{ for all } x \in I \}$. 

(f) Let $E$ be the set of all bounded derivatives of differentiable functions on $[a, b]$ which are monotone on some (nondegenerate) subinterval. Show that $E$ is a meager subset of $D'_0([a,b])$. [Let $(I_n)$ be an enumeration of the closed subintervals of $[a,b]$ with rational endpoints. Show that $E = \bigcup_n (E_{I_n}^+ \cup E_{I_n}^-)$.

XI.12.5.8. This problem is a continuation of XI.12.5.7., using the same notation.

(a) Let $\mathcal{D}_0([a,b])$ be the set of differentiable functions on $[a,b]$ whose derivative is in $D'_0([a,b])$. Show that $\mathcal{D}_0([a,b])$ is a subalgebra of $C_R([a,b])$. (The Baire Category Theorem is needed to prove it is closed under multiplication.)

(b) Show that $\mathcal{D}_0([a,b])$ separates points of $[a,b]$. Thus by the Stone-Weierstrass Theorem (XV.8.2.2.) $\mathcal{D}_0([a,b])$ is uniformly dense in $C_R([a,b])$.

(c) Give a direct proof of the result of (b) without using the Stone-Weierstrass Theorem, using:

**Lemma.** For every $\epsilon > 0$ there is an $f \in \mathcal{D}_0((0,1))$ with the following properties:

(i) $f(0) = 0$, $f(1) = 1$.

(ii) $f'(0) = f'(1) = 0$.

(iii) For every $x \in [0,1]$, $f'(x) < 1 + \epsilon$.

(iv) For every $x \in [0,1]$, $x - \epsilon < f(x) < x + \epsilon$.

(d) To prove the Lemma, let $g$ be an element of $\mathcal{D}_0([a,b])$ for some $[a,b]$ with $1 < \sup g' < 1 + \epsilon$, and let $c, d \in [a,b], c < d$, with $\frac{g(d) - g(c)}{d-c} > 1$. Replace $c$ and $d$ with nearby places where $g' = 0$. Rescale $[c,d]$ to $[0,1]$. Show that (iv) follows from (i), (iii), and the MVT.

(e) By translating and scaling the $f$ of the lemma, show that any piecewise-linear continuous function on any closed bounded interval can be uniformly approximated by functions in $\mathcal{D}_0([a,b])$. 

1149
XI.13. Connectedness

The notion of a connected topological space, or of a connected subset of a topological space, is fundamental in topology and especially in applications in analysis.

The idea is simple. If a topological space can be divided into two disconnected pieces, each piece must be a closed set since no point of one of the sets can be a limit point of the other. Since each set is the complement of the other, the sets must be open as well as closed. Conversely, if a space can be partitioned into two subsets which are each both open and closed, these sets disconnect the space.

A second, more restrictive, notion of connectedness which is perhaps more intuitively appealing is that of path-connectedness, that any two points of the space can be connected by a path. Path-connectedness implies connectedness (once we know that intervals are connected), but not conversely. Both types of connectedness are useful in topology and analysis.

XI.13.1. Connected Spaces

XI.13.1.1. A subset $U$ of a topological space $X$ is clopen if $U$ is both open and closed. ($X \setminus U$ is then also clopen.) In any topological space $X$, $\emptyset$ and $X$ are clopen; in many interesting topological spaces, these are the only clopen subsets.

Finite unions, finite intersections, and set-theoretic differences of clopen sets are clopen.

The term “clopen” is regarded as a language abomination in some circles and is somewhat unfashionable; but the term is useful and there is no good alternative, so we will use it.

XI.13.1.2. DEFINITION. Let $X$ be a topological space. A separation of $X$ is a decomposition $X = U \cup V$ of $X$ into two nonempty disjoint clopen subsets. $X$ is connected if it has no separation, i.e. if the only clopen subsets of $X$ are $\emptyset$ and $X$.

Connectedness is obviously a topological property of a space, preserved under homeomorphisms.

XI.13.1.3. EXAMPLES. (i) Any space with the indiscrete topology is connected.
(ii) A space with the discrete topology and more than one point is not connected.
(iii) The Sierpiński space ($\text{Sierpiński space}$) is connected.
(iv) An infinite set with the finite complement topology ($\text{finite complement topology}$) is connected.
(v) $\mathbb{Q}$ with the relative topology from $\mathbb{R}$ is not connected: for example, $U = \{x \in \mathbb{Q} : x < \sqrt{2}\}$ and $V = \{x \in \mathbb{Q} : x > \sqrt{2}\}$ form a separation of $\mathbb{Q}$.

Examples (i), (iii), and (iv) show that connectedness can behave strangely in non-Hausdorff spaces. The notion is most interesting for spaces with nice separation properties, although even there some of the behavior can be surprising.

By far the most important example of a connected topological space is:
XI.13.1.4. Theorem. $\mathbb{R}$ (with its usual topology) is connected.

Proof: Let $\mathbb{R} = U \cup V$ be a separation, and let $a \in U$, $b \in V$. We may assume $a < b$. Set

$$Y = \{x \in [a, b] : x \in U\}$$

and set $c = \sup(Y)$. We have $c < b$ since $(b - \epsilon, b] \subseteq V$ for some $\epsilon > 0$. Either $c \in U$ or $c \in V$. If $c \in U$, then $[c,c + \epsilon) \subseteq U$ for some $\epsilon > 0$, contradicting that $c = \sup(Y)$. If $c \in V$, then $(c - \epsilon, c] \subseteq V$ for some $\epsilon > 0$, so $c - \epsilon$ would be an upper bound for $Y$, another contradiction. So no separation exists.

Connected Subsets of a Space

XI.13.1.5. If $X$ is a topological space and $E \subseteq X$, we say $E$ is a connected subset of $X$ if $E$ is a connected space in the relative topology. This can be phrased in several equivalent ways:

XI.13.1.6. Proposition. Let $X$ be a topological space and $E \subseteq X$. The following are equivalent:

(i) $E$ is not connected.

(ii) There are open sets $U$ and $V$ in $X$ with $U \cap E$ and $V \cap E$ nonempty, such that $E \subseteq U \cup V$ and $U \cap V \cap E = \emptyset$.

(iii) There are nonempty subsets $A$ and $B$ of $E$ such that $E = A \cup B$ and $\overline{A} \cap B = A \cap \overline{B} = \emptyset$.

The proof is an easy exercise, and is left to the reader. A pair $\{U, V\}$ of open sets as in (ii) is called a separation of $E$ in $X$ (cf. XI.10.1.1.).

XI.13.1.7. Corollary. A subset of $\mathbb{R}$ is connected if and only if it is an interval or a singleton.

An interval is connected by (ii) and essentially the same argument as in the proof of XI.13.1.4. A subset of $\mathbb{R}$ which is not an interval or singleton can be separated as in XI.13.1.3.(v).

XI.13.1.8. An interesting question is whether, if $A$ and $B$ are subsets of a topological space $X$ which are separated as in (iii), then they have disjoint open neighborhoods (essentially, whether the $U$ and $V$ in (ii) can be chosen disjoint). The answer is: not always (Exercise XI.13.9.4.). It is not even always true if $X$ is a compact Hausdorff space [SS95, Example 86]. But it is true if $X$ is metrizable (XI.10.1.1.).

Closure of a Connected Set

XI.13.1.9. Proposition. Let $X$ be a topological space, and $E$ a connected subset of $X$. Then the closure $\bar{E}$ is also connected.

Proof: Suppose $\{U, V\}$ is a separation of $\bar{E}$ as in XI.13.1.6.(ii). Then $U \cap E$ or $V \cap E$ is empty, for otherwise $\{U, V\}$ would be a separation of $E$. If $V \cap E$ is empty, then $E \subseteq U$. Thus $\bar{E} \subseteq U$, since $\bar{E} \cap U = \bar{E} \cap V^c$ is closed. Thus $\bar{E} \cap V = \emptyset$, a contradiction. \(\square\)
XI.13.1.10. Corollary. Let $X$ be a topological space. If $X$ has a dense connected subset, then $X$ is connected. In particular, if $X$ is a topological space, $E$ a connected subset of $X$, and $Y$ a subset of $X$ with $E \subseteq Y \subseteq E$, then $Y$ is connected.

XI.13.2. Continuous Images of Connected Sets

One of the most important properties of connected sets is:

XI.13.2.1. Proposition. Let $X$ and $Y$ be topological spaces and $f : X \to Y$ a continuous function. If $E$ is a connected subset of $X$, then $f(E)$ is a connected subset of $Y$.

Informally, a continuous image of a connected space is connected.

Proof: Suppose $\{U, V\}$ is a separation of $f(E)$ as in XI.13.1.6.(ii). Then $\{f^{-1}(U), f^{-1}(V)\}$ is a separation of $E$.

XI.13.2.2. Corollary. Let $X$ be a topological space, and $f : X \to \mathbb{R}$ a continuous function. If $E$ is a connected subset of $X$, then $f(E)$ is an interval or singleton. In particular, if $f : \mathbb{R} \to \mathbb{R}$ is continuous and $I$ is an interval in $\mathbb{R}$, then $f(I)$ is an interval or singleton.

XI.13.2.3. Corollary. A connected completely regular space with more than one point has cardinality at least $2^{\mathfrak{c}}$.

Proof: Such a space has a nonconstant real-valued continuous function, whose range has cardinality $2^{\mathfrak{c}}$.

XI.13.2.4. More generally, a connected Urysohn space (XI.7.8.17.) has cardinality at least $2^{\aleph_0}$ (same proof). This corollary can fail for spaces which are not completely regular. There are countably infinite connected Hausdorff spaces [SS95, Examples 60, 75], even countable connected completely Hausdorff spaces [SS95, Example 127]. A connected regular space must be uncountable, since a countable topological space is Lindelöf, and a regular Lindelöf space is normal, hence completely regular. There is a connected regular space of cardinality $\aleph_1$ [SS95, Example 92].

The Intermediate Value Theorem

As a corollary, we get one of the most important properties of continuous functions on the real line:

XI.13.2.5. Corollary. [Intermediate Value Theorem] Let $I$ be an interval in $\mathbb{R}$, and $f : I \to \mathbb{R}$ a continuous function. If $a, b \in I$ and $d$ is any number between $f(a)$ and $f(b)$, then there is at least one $c \in I$ with $f(c) = d$. (See Figure 1.)
XI.13.3. Unions and Intersections

XI.13.3.1. A union of two or more connected subsets of a topological space $X$ frequently fails to be connected, e.g. the union of two disjoint open sets or of two sets with disjoint closures (e.g. two singletons in a $T_1$ space). However:

XI.13.3.2. **Proposition.** Let $X$ be a topological space, and $\{E_i : i \in I\}$ a collection of connected subsets of $X$. If $\cap_{i \in I} E_i \neq \emptyset$, then $\cup_{i \in I} E_i$ is connected.

**Proof:** Let $E = \cup_{i \in I} E_i$, and let $p \in \cap_{i \in I} E_i$. Suppose $A$ and $B$ are subsets of $E$ with $E = A \cup B$ and $A \cap B = \emptyset$, with $p \in A$. For each $i$ set $A_i = A \cap E_i$ and $B_i = B \cap E_i$. We have $E_i = A_i \cup B_i$ and $A_i \cap B_i = \emptyset$, so by XI.13.1.6.(iii) $A_i$ and $B_i$ cannot both be nonempty. But $p \in A_i$ for all $i$, so $B_i = \emptyset$ for all $i$, and hence $B = \cup_i B_i = \emptyset$. Thus $E$ is connected by XI.13.1.6.(iii).

XI.13.3.3. **Proposition XI.13.3.2.** can be used to “string together” connected subsets: the union of a sequence of connected subsets of a space is connected provided each successive pair has nonempty intersection.

XI.13.3.4. **Corollary.** Every topological vector space is connected. In particular, $\mathbb{R}^n$ is connected for any $n$.

**Proof:** Any topological vector space is the union of all lines through the origin, each of which is homeomorphic to $\mathbb{R}$ and hence connected.

See XI.13.8.3.(ii) for another proof.

Intersections

XI.13.3.5. The intersection of two connected subsets of a topological space is not connected in general. For example, if $X$ is a circle, the closed upper and lower semicircles are connected since they are homeomorphic to intervals (the whole circle is also connected by XI.13.3.2.), but the intersection consists of two points with the discrete topology.

Decreasing intersections are trickier. It turns out that a decreasing sequence of connected sets, even in $\mathbb{R}^2$, does not have connected intersection in general (Exercise XI.13.9.5.). However, we have:

XI.13.3.6. **Theorem.** Let $X$ be a Hausdorff space, and $\{E_i : i \in I\}$ be a collection of compact subsets of $X$. If $\cap_{i \in F} E_i$ is connected for each finite subset $F$ of $I$, then $\cap_{i \in I} E_i$ is connected. In particular, the intersection of a decreasing sequence of connected compact subsets of $X$ is connected.

“Hausdorff” cannot be weakened to $T_1$ (Exercise XI.13.9.6.).

**Proof:** Set $E = \cap_{i \in I} E_i$ and $E_F = \cap_{i \in F} E_i$ for $F \subseteq I$ finite. Then $E = \cap_F E_F$ is compact. Suppose $E$ is not connected. Then there are disjoint nonempty relatively clopen subsets $A, B$ of $E$ with $E = A \cup B$. Since $A$ and $B$ are relatively closed in $E$, they are compact. There are disjoint open neighborhoods $U$ and $V$ of $A$
and $B$ in $X$ (XI.11.4.2.). By XI.11.1.11. there is a finite subset $F$ of $I$ such that $E_F \subseteq U \cup V$. Since $E_F$ is connected, either $E_F \cap U$ or $E_F \cap V$ is empty. But $A \subseteq E_F \cap U$ and $B \subseteq E_F \cap V$, a contradiction. Thus $E$ is connected.

**XI.13.4. Components of a Space**

**XI.13.4.1. Definition.** Let $X$ be a topological space, and $p \in X$. The connected component (or just component) of $p$ in $X$ is the union of all connected subsets of $X$ containing $p$. (There is always at least one such set, $\{p\}$.)

**XI.13.4.2. Proposition.** Let $X$ be a topological space.

(i) The connected component of any point $p$ of $X$ is closed and connected, and is the largest connected subset of $X$ containing $p$.

(ii) If $p$ and $q$ are points of $X$, the connected components of $p$ and $q$ are either identical or disjoint.

**Proof:**

(i): The union $P$ of all connected subsets of $X$ containing $p$ is nonempty and connected by XI.13.3.2., and is obviously the largest connected subset of $X$ containing $p$. By XI.13.1.9., $P$ is a connected set containing $p$, hence $P \subseteq P$, i.e. $P$ is closed.

(ii): If $P$ and $Q$ are the components of $p$ and $q$ in $X$ respectively, and $P \cap Q \neq \emptyset$, then $P \cup Q$ is connected by XI.13.3.2. and contains $p$ and $q$, hence $P \cup Q = P = Q$.

**XI.13.4.3.** So the connected components of a space $X$ partition $X$ into disjoint closed subsets. Connected components can easily contain more than one point: if $X$ is connected, the connected component of any point of $X$ is all of $X$. At the other extreme, connected components can be singletons. This obviously happens for isolated points, but can happen for nonisolated points too: the components of the Cantor set $K$ are connected subsets of $\mathbb{R}$, hence points or intervals; since $K$ contains no intervals, the connected components of $K$ are single points. Intermediate possibilities also occur in many spaces.

The connected component of a point $p$ in a space $X$ depends on $X$; if $Y$ is a subspace of $X$ containing $p$, the connected component of $p$ in $Y$ can be smaller than the connected component in $X$ (it can even be smaller than the intersection of $Y$ with the connected component in $X$, as easy examples show).

**Quasi-Components**

**XI.13.4.4.** If $X$ is a topological space, $p \in X$, and $U$ is a clopen subset of $X$ containing $p$, then any connected subset of $X$ containing $p$ must be contained in $U$ (otherwise $\{U,U^c\}$ would give a separation), and in particular the component $P$ of $p$ in $X$ is contained in $U$. Thus

$$P \subseteq Q = \bigcap \{U \subseteq X \text{ clopen} : p \in U\}.$$

The set $Q$ is sometimes called the quasi-component of $p$ in $X$. It can be strictly larger than the component of $p$ in $X$ (Exercises XI.13.9.7. and XI.13.9.8.). However:
XI.13.4.5. Proposition. Let $X$ be a compact Hausdorff space. Then the quasi-component of any point is just its component.

“Hausdorff” cannot be weakened to $T_1$ in this result (Exercise XI.13.9.7.).

Proof: The argument is similar to the proof of XI.13.3.6. Let $p \in X$, and let $P$ and $Q$ be the component and quasi-component of $p$ in $X$. Since $P \subseteq Q$, it suffices to show that $Q$ is connected. Suppose $Q$ is not connected, and write $Q = A \cup B$ for disjoint nonempty relatively clopen subsets with $p \in A$. Then $A$ and $B$ are compact, so they have disjoint open neighborhoods $U$ and $V$ in $X$. Since $Q$ is the intersection of all clopen subsets of $X$ containing $p$ and each clopen set in $X$ is compact, by XI.11.1.11. there are finitely many clopen subsets $W_1, \ldots, W_n$ of $X$ containing $p$ such that $W = W_1 \cap \cdots \cap W_n$ is contained in $U \cup V$. $W$ is clopen, and $W$ is the disjoint union of $W \cap U$ and $W \cap V$. $W \cap U$ is open, and $W \cap U = W \cap V^c$ is also closed, i.e. $W \cap U$ is clopen and contains $p$, and thus $Q \subseteq W \cup U$, contradicting that $B$ is nonempty. Thus $Q$ is connected.

XI.13.4.6. Quasi-components, like components, are closed, and two quasi-components are either identical or disjoint. Thus the whole space partitions into quasi-components, each of which partitions into one or more components.

XI.13.5. Products of Connected Spaces

XI.13.5.1. Theorem. Let $\{X_i : i \in I\}$ be a collection of topological spaces. Then $\prod_i X_i$ is connected if and only if each $X_i$ is connected.

Proof: Let $X = \prod_i X_i$. If $X$ is connected, since each coordinate projection is continuous it follows from XI.13.2.1. that each $X_i$ is connected. Conversely, suppose each $X_i$ is connected. Let $p = (p_i)$ and $q = (q_i)$ be points of $X$. Let $F = \{i_1, \ldots, i_n\}$ be a finite subset of $I$. The subset $E_1 = \{(x_i) : x_i = p_i \text{ for } i \neq i_1\}$ is homeomorphic to $X_{i_1}$, hence connected, and contains the point $a_1$ with $x_{i_1} = q_{i_1}$ and $x_i = p_i$ for all $i \neq i_1$. Thus $a_1$ is in the connected component of $p$. Similarly, if $a_2$ is the point $(x_i)$ with $x_{i_1} = q_{i_1}$, $x_{i_2} = q_{i_2}$, and $x_i = p_i$ for $i \neq i_1, i_2$, then $a_2$ is in the connected component of $a_1$ and hence in the connected component of $p$. Repeating the argument finitely many times, if $q_F$ is the point $(x_i)$ with $x_i = q_i$ for $i \in F$ and $x_i = p_i$ for $i \notin F$, then $q_F$ is in the connected component of $p$. This is true for any finite $F$. Any open neighborhood of $q$ contains $q_F$ for some finite set $F$, so $q$ is in the closure of the component of $p$. But components are closed, so $q$ is in the component of $p$ in $X$. This is true for any $p$ and $q$, so $X$ consists of only one connected component, i.e. is connected.

XI.13.6. TotallyDisconnected and Zero-Dimensional Spaces

XI.13.6.1. Definition. Let $X$ be a topological space. $X$ is totally disconnected if for every pair $\{p, q\}$ of distinct points of $X$, there is a clopen set $U \subseteq X$ containing $p$ but not $q$. (In other words, the quasi-components of $X$ are single points.)

A totally disconnected topological space is Hausdorff: if $U$ is a clopen set containing $p$ but not $q$, then $U$ and $X \setminus U$ are disjoint open neighborhoods of $p$ and $q$. 

1155
XI.13.6.2. Some references define a space to be totally disconnected if its connected components are single points (what we have called “totally disconnected” is often then called “totally separated”). This definition is equivalent to the one we have given for compact Hausdorff spaces, but not in general; see Theorem XI.13.6.7. Definition XI.13.6.1. appears to be the usual definition used by topologists.

XI.13.6.3. Definition. Let $X$ be a topological space. $X$ is zero-dimensional if $X$ is $T_1$ and every finite open cover of $X$ has a refinement consisting of a partition of $X$ into clopen subsets.

More precisely, this is the specification that the covering dimension (XI.21.3.23.) of $X$ is zero. Some references give a different definition (that there is a base for the topology of $X$ consisting of clopen sets, i.e. that the small inductive dimension of $X$ is zero; cf. XI.21.3.2.). The two definitions are equivalent for $T_1$ Lindelöf spaces (in particular, for compact Hausdorff spaces and second countable metrizable spaces), but not in general; see Theorem XI.13.6.7. The $T_1$ condition cannot be reasonably weakened to $T_0$ (Exercise XI.13.9.1.).

XI.13.6.4. Actually, if $X$ is zero-dimensional, every finite open cover of $X$ has a refinement consisting of a finite partition of $X$ into clopen sets. Even more is true: a finite open cover $\{V_1, \ldots, V_n\}$ has a shrinking consisting of a partition, i.e. there is a partition $\{U_1, \ldots, U_n\}$ of $X$ into clopen sets with $U_j \subseteq V_j$ for each $j$ (XI.21.3.27.).

XI.13.6.5. Proposition. Let $E$ and $F$ be disjoint closed subsets of a zero-dimensional space $X$. Then there is a clopen set $U \subseteq X$ with $E \subseteq U$ and $F \subseteq X \setminus U$. In particular, a zero-dimensional topological space is normal.

Proof: Let $E$ and $F$ be disjoint closed subsets of a zero-dimensional space $X$. The open cover $\{X \setminus E, X \setminus F\}$ has a refinement consisting of a partition of the space into clopen subsets. Let $U$ be the union of all the sets in the partition which contain points of $E$; any such set is disjoint from $F$ since the partition refines $\{X \setminus E, X \setminus F\}$. Then $U$ is an open set containing $E$, and $F \subseteq X \setminus U$. $X \setminus U$ is the union of the remaining sets in the partition, hence is also open, i.e. $U$ is clopen.

There is a converse: if $X$ is $T_1$ and any two disjoint closed sets can be separated by a partition, i.e. there is a clopen set containing one but not the other ($\text{Ind}(X) = 0$ (XI.21.3.9.)), then $X$ is zero-dimensional (XI.21.3.28.).

XI.13.6.6. Proposition. Let $X$ be a $T_0$ space for which there is a base for the topology consisting of clopen sets. Then $X$ is completely regular.

Proof: Let $F$ be a closed set in $X$, and $p \in V = X \setminus F$. Then $V$ is an open neighborhood of $p$, so there is a clopen neighborhood $U$ of $p$ contained in $V$. Define $f : X \to [0, 1]$ by setting $f(x) = 1$ if $x \in U$ and $f(x) = 0$ if $x \in X \setminus U$. Then $f$ is continuous, $f(p) = 1$, and $f$ is identically 0 on $F$.
XI.13.6.7. **Theorem.** Let $X$ be a compact Hausdorff space. The following are equivalent:

(i) Each component of $X$ is a single point.

(ii) $X$ is totally disconnected.

(iii) There is a base for the topology of $X$ consisting of clopen sets ($\text{ind}(X) = 0$).

(iv) $X$ is zero-dimensional ($\text{dim}(X) = 0$).

(v) Any two disjoint closed sets in $X$ can be separated by a partition ($\text{Ind}(X) = 0$).

If $X$ is metrizable, these are also equivalent to

(vi) $X$ is homeomorphic to a subset of the Cantor set.

XI.13.6.8. For general topological spaces, we have (vi) $\Rightarrow$ (iv) $\Rightarrow$ (i), (iv) $\Rightarrow$ (vi) (XI.13.6.5.) and (iv) $\Rightarrow$ (iii); (v) $\Rightarrow$ (iv) for $T_1$ spaces (XI.21.3.28.), and (iii) $\Rightarrow$ (ii) for $T_0$ spaces (a space with the indiscrete topology and more than one point satisfies (iii) but not (ii)). (i) $\Rightarrow$ (ii) $\Rightarrow$ (iii) for compact Hausdorff spaces, but not in general: there are $G_\delta$ sets in $\mathbb{R}^2$ satisfying (i) but not (ii), and ones satisfying (ii) but not (iii) ([?, §46], [?], Exercise XI.13.9.3.); thus (i) $\Rightarrow$ (ii) and (ii) $\Rightarrow$ (iii) do not hold even in Polish spaces. See also Exercise XI.13.9.7.. (iii) $\Rightarrow$ (iv) for $T_0$ Lindelöf spaces, but not for general normal spaces [GJ76, 16M], so (iii), (iv), and (v) are equivalent for $T_1$ Lindelöf spaces (which are then automatically normal).

(iv) does not imply (vi) for compact Hausdorff spaces: an uncountable product of two-point spaces is a counterexample (the space from Exercise () is a more interesting counterexample). (iii) $\Rightarrow$ (vi) for arbitrary second countable $T_0$ spaces; thus (iii), (iv), (v), and (vi) are equivalent for second countable $T_1$ spaces (which are then automatically metrizable).

**Proof:** (i) $\Rightarrow$ (ii) is XI.13.4.5., and (ii) $\Rightarrow$ (i) is XI.13.4.4..

(iii) $\Rightarrow$ (ii): We use only that $X$ is $T_0$. Let $p$ and $q$ be points of $X$, and let $V$ be an open set containing $p$ but not $q$. Since the clopen sets form a base for the topology, there is a clopen set $U$ with $p \in U \subseteq V$. Then $U$ separates $p$ and $q$.

(ii) $\Rightarrow$ (iii): Let $p \in X$ and $V$ an open set containing $p$. For each $q \not\in V$, let $U_q$ be a clopen set containing $p$ but not $q$. Then $\{U_q^c : q \in V^c\}$ is an open cover for $V^c$. Since $V^c$ is closed and hence compact, there is a finite subcover $\{U_q^c : q \in V^c\}$. Then $U = U_{q_1} \cap \cdots \cap U_{q_n}$ is a clopen set containing $p$ and contained in $V$. Thus the clopen sets form a base for the topology.

(iv) $\Rightarrow$ (iii): We use only that $X$ is $T_1$. Let $p \in X$ and $V$ an open set containing $p$. Since $\{p\}$ is closed, $\{V, X \setminus p\}$ is an open cover of $X$, so it has a refinement consisting of a partition into clopen sets. The clopen set containing $p$ must be contained in $V$. Thus the clopen sets form a base for the topology.

(iii) $\Rightarrow$ (iv): We will use only that $X$ is $T_0$ and Lindelöf, and satisfies (iii). Then $X$ is completely regular by XI.13.6.6., and in particular $T_1$ (actually $X$ is automatically normal by XI.7.6.11., but we will not need this; after the fact $X$ will be normal by XI.13.6.5.). Let $\mathcal{V}$ be an open cover of $X$ (not necessarily finite). Since the clopen sets form a base for the topology, there is a refinement $\mathcal{W}$ of $\mathcal{V}$ consisting of clopen sets. $\mathcal{W}$ has a countable subcover $\{W_1, W_2, \ldots\}$. Set $U_1 = W_1, U_2 = W_2 \setminus W_1, U_3 = W_3 \setminus (W_1 \cup W_2)$, etc. (Any $U_n$ which are empty can be discarded.) Then $\{U_1, U_2, \ldots\}$ is a partition of $X$ into clopen sets, refining $\mathcal{W}$ and hence refining $\mathcal{V}$.

1157
Actually, any partition of a compact $X$ into clopen sets is necessarily finite since it forms an open cover of $X$ with no proper subcover.

(iii) $\Rightarrow$ (vi): We will use only that $X$ is $T_0$, second countable, and satisfies (iii).
We first show that there is a countable base for the topology of $X$ consisting of clopen sets. Let $\mathcal{V}$ be a countable base for the topology of $X$. For every pair $(V,W)$ in $\mathcal{V}$ with $V \subseteq W$, let $\mathcal{C}(V,W)$ be the set of all clopen sets $U$ with $V \subseteq U \subseteq W$. $\mathcal{C}(V,W)$ might potentially be empty for some $(V,W)$ (after the fact it turns out that it is always nonempty); but if it is nonempty, choose a clopen set $U_{V,W} \in \mathcal{C}(V,W)$. The collection $\mathcal{U}$ of all such $U_{V,W}$ is countable. $\mathcal{U}$ is a base for the topology of $X$ since if $p$ is any point of $X$ and $N$ any open neighborhood of $p$, there is a $W \in \mathcal{V}$ with $p \in W$ and $W \subseteq N$; since the clopen sets form a base, there is a clopen set $U$ with $p \in U$ and $U \subseteq W$; there is then a $V \in \mathcal{V}$ with $p \in V$ and $V \subseteq U$. Thus $\mathcal{C}(V,W) \neq \emptyset$ and $U_{V,W}$ is defined; then $p \in V \subseteq U_{V,W} \subseteq W \subseteq N$.
Now let $\{U_1,U_2,\ldots\}$ be a countable base for the topology of $X$ consisting of clopen sets. Define a function $f : X \rightarrow \mathbb{R}$ by letting $f(x)$ be the number with base 3 expansion
\[ d_1d_2d_3 \cdots \]
where $d_n = 2$ if $x \in U_n$ and $d_n = 0$ if $x \in U_n^c$. $f$ is one-to-one since $X$ is $T_0$. The range of $f$ is contained in the Cantor set $K$. The function $f$ is continuous since if $x_k \rightarrow x$, then for each $n$, if $x \in U_n$ we have $x_k \in U_n$ for all sufficiently large $k$, and similarly if $x \in U_n^c$, so the $n$th decimal term of $x_k$ agrees with the $n$th decimal term of $x$ for all sufficiently large $k$, and hence $f(x_k) \rightarrow f(x)$. Conversely, if $(x_k), x \in X$ and $f(x_k) \rightarrow f(x)$, then for each $n$ we have that the $n$th decimal term of $x_k$ agrees with the $n$th term of $x$ for all sufficiently large $k$, so if $x \in U_n$ we have $x_k \in U_n$ for sufficiently large $k$. Since the $U_n$ form a base for the topology of $X$, we have $x_k \rightarrow x$. Thus $f^{-1} : f(X) \rightarrow X$ is continuous and $f$ is a homeomorphism onto its image.

(vi) $\Rightarrow$ (iii) since the Cantor set satisfies (iii) and (iii) passes to subspaces.

The Countable AC is needed in several places in this proof.

XI.13.6.9. There is an extensive theory of dimension for topological spaces, discussed in (), for which the above theory is the dimension zero part; the theory is based on “higher-order connectedness.”

XI.13.7. Locally Connected Spaces

XI.13.7.1. Definition. Let $X$ be a topological space, $p \in X$. Then $X$ is locally connected at $p$ if every open neighborhood of $p$ contains a connected open neighborhood of $p$, i.e. if there is a local base for the topology at $p$ consisting of connected sets. $X$ is locally connected if it is locally connected at every point, i.e. if there is a base for the topology consisting of connected sets.

XI.13.7.2. Simple examples of locally connected spaces are $\mathbb{R}$ and any discrete space. The latter example shows that a locally connected space need not be connected. Any open set in a locally connected space is locally connected.

The Cantor set is not locally connected at any point. In fact, a nondiscrete totally disconnected space cannot be locally connected.

The topologist’s sine curve () is connected, but not locally connected at points on the $y$-axis. There are more extreme examples: there are compact subsets of Euclidean space, e.g. the pseudo-arc () or a solenoid (), which are connected but not locally connected at any point.
XI.13.7.3. If $X$ is locally connected, then the components of $X$ are open, hence clopen. The converse is not true since there are connected spaces which are not locally connected. Spaces whose components are open are precisely ones in which each point has at least one connected open neighborhood. If $X$ is locally connected, the connected components of any open subset $U$ of $X$ are also open, since $U$ is also locally connected. Conversely, if every component of every open subset of $X$ is open, then $X$ is locally connected.

XI.13.8. Path-Connected Spaces

An intuitively appealing variation of connectedness is path-connectedness. A space is path-connected if any two points can be connected by a continuous path; such a space is necessarily connected. Most familiar topological spaces such as (connected) manifolds and polyhedra are path-connected.

XI.13.8.1. Definition. Let $X$ be a topological space, $p, q \in X$. A path in $X$ from $p$ to $q$ is a continuous function $\gamma : [0, 1] \to X$ with $\gamma(0) = p$, $\gamma(1) = q$.

The space $X$ is path-connected if for any $p, q \in X$, there is a path from $p$ to $q$.

A path-connected space is also called arcwise connected. (Some references make a technical distinction between paths and arcs; cf. XI.13.8.11.)

Since an interval is connected (XI.13.1.7.), we obtain:

XI.13.8.2. Proposition. Let $X$ be a topological space, $p, q \in X$. If there is a path from $p$ to $q$, then $p$ and $q$ are in the same connected component of $X$. In particular, a path-connected space is connected.

Proof: If $\gamma$ is a path from $p$ to $q$, then by XI.13.2.1. the set $\gamma([0, 1])$ is a connected subset of $X$ containing both $p$ and $q$.

XI.13.8.3. Examples. (i) Any connected subset of $\mathbb{R}$ (interval or point) is path-connected.

(ii) Any convex set in $\mathbb{R}^n$ (or, more generally, in any topological vector space) is path-connected: the straight line segment between any two points is a path. In particular, any topological vector space, including $\mathbb{R}^n$, is path-connected.

(iii) The topologist’s sine curve ( ) is connected but not path-connected. There are more dramatic examples of such spaces (XI.13.8.6.).

Define a relation $\sim$ on $X$ by $p \sim q$ if there is a path from $p$ to $q$.

XI.13.8.4. Proposition. The relation $\sim$ is an equivalence relation.

Proof: If $\gamma$ is a path from $p$ to $q$, set $\tilde{\gamma}(t) = \gamma(1 - t)$ for $0 \leq t \leq 1$; then $\tilde{\gamma}$ is a path from $q$ to $p$, so $\sim$ is symmetric. The constant function from $[0, 1]$ to $X$ with value $p$ is a path from $p$ to $p$, so $\sim$ is reflexive. Now suppose $\gamma_1$ is a path from $p$ to $q$ and $\gamma_2$ a path from $q$ to $r$. Define $\gamma : [0, 1] \to X$ by

$$
\gamma(t) = \begin{cases} 
\gamma_1(2t) & \text{if } 0 \leq t \leq \frac{1}{2} \\
\gamma_2(2t - 1) & \text{if } \frac{1}{2} \leq t \leq 1 
\end{cases}
$$
Then $\gamma$ is a path from $p$ to $r$, so $\sim$ is transitive.

**XI.13.8.5.** **Definition.** The equivalence classes of $\sim$ are the **path components of $X$.**

As with components, the space $X$ partitions into a disjoint union of path components. By XI.13.8.2., each path component is contained in a connected component of $X$, i.e. each connected component partitions into one or more path components.

Unlike components, path components need not be closed. For example, the topologist’s sine curve () consists of two path components, one closed and the other dense and open. A solenoid () has uncountably many path components, each dense (and not open).

**XI.13.8.6.** A space $X$ is **totally path disconnected** if its path components are single points, i.e. if every continuous function from $[0,1]$ into $X$ is constant. There are connected compact metrizable spaces which are totally path disconnected, e.g. the pseudo-arc ().

**XI.13.8.7.** **Definition.** A topological space $X$ is **locally path-connected** at $p$ if there is a local base for the topology at $p$ consisting of path-connected sets, i.e. any open neighborhood of $p$ contains a path-connected open neighborhood of $p$. $X$ is **locally path-connected** if it is locally path-connected at each point, i.e. if there is a base for the topology consisting of path-connected sets.

A locally path-connected space is locally connected. There are connected and locally connected compact Hausdorff spaces which are not locally path-connected [?, Examples 46, 48]; however, a connected compact metrizable space which is locally connected is locally path-connected (Exercise XI.13.9.11.; in fact, the whole space is a continuous image of $[0,1]$ by the Hahn-Mazurkiewicz Theorem; cf. [HY88, 3.29–3.30], Exercise XI.13.9.12.). This result is false for noncompact sets (XI.13.9.14.).

**XI.13.8.8.** There are spaces which are path-connected but not locally path-connected: for example, the extended topologist’s sine curve () is not locally path-connected (not even locally connected) at points on the $y$-axis.

**XI.13.8.9.** If $X$ is locally path-connected at $p$, then the path component of $p$ in $X$ is open. If $X$ is locally path-connected, then all its path components are open, hence also closed since the complement of a path component is the union of the other path components. Thus in a locally path-connected space, the path components are the same as the components (and the quasi-components). In particular, if $X$ is connected and locally path-connected, it is path-connected.

**XI.13.8.10.** Since $\mathbb{R}^n$ is locally path-connected (open balls form a base for the topology of path-connected sets), any open set in $\mathbb{R}^n$ is locally path-connected. Hence the connected components of any open set in $\mathbb{R}^n$ are the same as the path components, and are open.

The same is true in any locally convex topological vector space (in particular, any normed vector space). In fact, any topological vector space, locally convex or not, is locally path-connected (there is a base for the topology consisting of balanced open sets, which are path-connected).
Path-Connected vs. Arcwise Connectedness

XI.13.8.11. Definition. A topological space $X$ is arcwise connected if, for every $p, q \in X$, $p \neq q$, there is a homeomorphism $\gamma : [0, 1] \to X$ with $\gamma(0) = p$ and $\gamma(1) = q$.

Arcwise connectedness is more restrictive than path-connectedness, which only requires that there be a continuous $\gamma$. A homeomorphic image of $[0, 1]$ in $X$ is called an arc in $X$. The Sierpiński space is path-connected but not arcwise connected, as it is a set of cardinality $\geq 2^{\aleph_0}$ with the finite complement topology.

The main technical result is that path-connectedness and arcwise connectedness are the same thing for Hausdorff spaces. We give a proof since this result is not discussed in most topology texts, and where it is the proofs given tend to use unnecessarily heavy machinery. Our proof, although somewhat complicated, is quite elementary.

XI.13.8.12. Theorem. Let $X$ be a Hausdorff space, $p, q \in X$, $p \neq q$. If there is a path in $X$ from $p$ to $q$, then there is an arc in $X$ from $p$ to $q$.

Proof: Set $p_0 = p$, $p_1 = q$. Let $\gamma : [0, 1] \to X$ be a path from $p_0$ to $p_1$ (i.e. $\gamma(0) = p_0$, $\gamma(1) = p_1$). We want to find an arc $\hat{\gamma} : [0, 1] \to X$ from $p_0$ to $p_1$. In fact, we will find an arc with $\hat{\gamma}([0, 1]) \subseteq \gamma([0, 1])$.

(i) Replacing $X$ by $\gamma([0, 1])$, we may assume $X$ is compact and metrizable. [The fact that $\gamma([0, 1])$ is metrizable is not essential to the rest of the proof, but makes part (vi) of the argument a little cleaner. The slickest proof I know of this fact is to apply XI.10.110.] Fix a metric $d$ on $X$. Then $\gamma$ is uniformly continuous, i.e. for every $\epsilon > 0$ there is a $\delta(\epsilon) > 0$ such that $d(\gamma(t), \gamma(s)) < \epsilon$ whenever $t, s \in [0, 1]$ and $|t - s| < \delta(\epsilon)$.

(ii) We may assume $\gamma(t) \neq p_0$ and $\gamma(t) \neq p_1$ for all $t \in (0, 1)$: since $X$ is Hausdorff, there is a largest $t \in [0, 1]$ for which $\gamma(t) = p_0$; call it $a_0$. We have $0 \leq a_0 < 1$. Then there is a smallest $t \in [a_0, 1]$ with $\gamma(t) = p_1$; call it $b_0$. We have $a_0 < b_0 \leq 1$. Replace $\gamma$ by $\gamma|_{[a_0, b_0]}$ (rescaled) if necessary.

(iii) Set $\gamma_1 = \gamma$. Let $a_1$ be the smallest $t$ such that $\gamma_1(t) = \gamma_1(s)$ for some $s \in [\frac{1}{2}, 1]$ [there is such a $t$ since $\gamma_1([\frac{1}{2}, 1])$ is compact and hence closed, so $\gamma_1^{-1}(\gamma_1([\frac{1}{2}, 1]))$ is closed]; then $0 < a_1 \leq \frac{1}{2}$. Let $b_1$ be the largest $t$ such that $\gamma_1(b_1) = \gamma_1(a_1)$; then $\frac{1}{2} \leq b_1 < 1$. Set $p_{1/2} = \gamma_1(a_1) = \gamma_1(b_1)$, and let $\gamma_2$ be $\gamma_1|_{[0, a_1]}$ rescaled to $[0, \frac{1}{2}]$ and $\gamma_1|_{[b_1, 1]}$ rescaled to $[\frac{1}{2}, 1]$. We have $\gamma_2([0, 1]) \subseteq \gamma_1([0, 1])$. The sets $A_{11} = \gamma_2([0, \frac{1}{2}])$ and $A_{12} = \gamma_2([\frac{1}{2}, 1])$ satisfy $A_{11} \cap A_{12} = \{p_{1/2}\}$.

(iv) Repeat the construction of (iii) for the restrictions of $\gamma_2$ to $[0, \frac{1}{2}]$ and $[\frac{1}{2}, 1]$. We obtain numbers $a_{21} \in (0, \frac{1}{4})$, $b_{21} \in [\frac{1}{4}, \frac{1}{2})$, $p_{1/4} = \gamma_2(a_{21}) = \gamma_2(b_{21})$ and $\gamma_3 : [0, \frac{1}{2}] \to X$ which is rescaled $\gamma_2$ on $[0, a_{21}]$ and $[b_{21}, 1/2]$, and similarly $a_{22} \in (\frac{1}{4}, \frac{1}{2})$, $b_{22} \in [\frac{1}{2}, \frac{3}{4})$, $p_{3/4} = \gamma_2(a_{22}) = \gamma_2(b_{22})$ and $\gamma_3 : [\frac{1}{2}, 1] \to X$ which is rescaled $\gamma_2$ on $[1/2, a_{21}]$ and $[b_{21}, 1]$. Put $\gamma_3$ and $\gamma_2$ together to form $\gamma_3 : [0, 1] \to X$, a path from $p_0$ to $p_1$ with $\gamma_3(1/2) = \gamma_2(1/2) = p_{1/2}$. We have $\gamma_3([0, \frac{1}{2}]) \subseteq \gamma_2([0, \frac{1}{2}])$ and $\gamma_3([\frac{1}{2}, 1]) \subseteq \gamma_2([\frac{1}{2}, 1])$, so $\gamma_3([0, 1]) \subseteq \gamma_2([0, 1])$.

(v) Continuing inductively in this way, a sequence $(\gamma_n)$ of paths from $p_0$ to $p_1$ is constructed, with $\gamma_n(k/2^m) = p_{k/2^m}$ for $m \leq n - 1$. We have $\gamma_n([0, 1]) \subseteq \gamma_n([0, 1])$, and more generally

$$\gamma_{n+1} \left( \left[ \frac{k}{2^m}, \frac{k+1}{2^m} \right] \right) \subseteq \gamma_n \left( \left[ \frac{k}{2^m}, \frac{k+1}{2^m} \right] \right)$$

for any $m \leq n - 1$ and any $k$. If $A_{n+1,k} = \gamma_{n+1} \left( \left[ \frac{k-1}{2^m}, \frac{k}{2^m} \right] \right)$, $A_{n+1,k} \cap A_{n+1,k+1} = \{p_{k/2^m}\}$ and $A_{n+1,k} \cap A_{n+1,k+j} = \emptyset$ for $j > 1$. 

1161
(vi) We claim that \((\gamma_n)\) converges uniformly on \([0, 1]\) to a path \(\tilde{\gamma}\), i.e. that \((\gamma_n)\) is a uniform Cauchy sequence. Let \(\epsilon > 0\), and fix \(N\) with \(2^{-N+1} < \delta(\epsilon)\). For any \(c \in [0, 1]\), there is a \(k\) such that \(\frac{k}{2^{N-1}} \leq c \leq \frac{k+1}{2^{N-1}}\). Then
\[
 Z = \gamma_N \left( \left[ \frac{k}{2^N}, \frac{k+1}{2^N} \right] \right)
\]
is \(\gamma([a, b])\) for some interval \([a, b]\) of length \(\leq 2^{-N+1} < \delta(\epsilon)\), so \(Z\) has diameter less than \(\epsilon\). If \(n, m \geq N\), we have \(\gamma_n(c), \gamma_m(c) \in Z\), so \(d(\gamma_n(c), \gamma_m(c)) < \epsilon\). Note that \(N\) depends only on \(\epsilon\) and not on \(c\).

We have
\[
\tilde{\gamma} \left( \left[ \frac{k}{2^n}, \frac{k+1}{2^n} \right] \right) \subseteq \gamma_n \left( \left[ \frac{k}{2^n}, \frac{k+1}{2^n} \right] \right)
\]
for any \(n, m \leq n - 1\), and \(k\).

(vii) The path \(\tilde{\gamma}\) is an arc. To show this, we need only show that \(\tilde{\gamma}\) is one-to-one (since \(X\) is Hausdorff). So suppose \(\tilde{\gamma}(c) = \tilde{\gamma}(d)\) for some \(c, d, c < d\). Choose \(n, k, j\) with \(j \geq 2\) and
\[
k \leq c < \frac{k+1}{2^n}, \quad \frac{k+j}{2^n} < d \leq \frac{k+j+1}{2^n}.
\]
But then
\[
\tilde{\gamma}(c) \in \gamma_{n+1} \left( \left[ \frac{k}{2^n}, \frac{k+1}{2^n} \right] \right)
\]
and these sets are disjoint, a contradiction.

**X.13.8.13.** COROLLARY. Let \(X\) be a Hausdorff space. If \(X\) is path-connected, then \(X\) is arcwise connected.

**X.13.9.** Exercises

**X.13.9.1.** Let \(X\) be the Sierpiński two-point space (\(\mathbb{S}^2\)). Every open cover of \(X\) has a refinement consisting of clopen sets, namely \(\{X\}\), but there is no base for the topology consisting of clopen sets. \(X\) is \(T_0\), but not \(T_1\) and hence not zero-dimensional by Definition X.13.6.3.; in fact, it is connected, and even path-connected: the function from \([0, 1]\) to \(X\) sending \([0, 1)\) to \(a\) and \(1\) to \(b\) is continuous.

**X.13.9.2.** (Erdős) Let \(X\) be the set of points in \(\ell^2\) (\(\mathbb{E}^2\)) with rational coordinates. Show that \(X\) is totally disconnected, but there is no base for the topology consisting of clopen sets (in fact, no clopen subset is bounded.)

**X.13.9.3.** [?, §27,VI] Let \(K\) be the Cantor set (\(\mathbb{C}\)). Define a function \(f : K \to \mathbb{R}\) as follows. If \(t \in K\), then \(t\) can be uniquely written as a finite or infinite sum
\[
t = \sum_k \frac{2}{3^n_t}
\]
(where \( t = 0 \) is the “empty sum”), i.e. \( n_k \) is the location of the \( k \)'th 2 in the base 3 decimal expansion of \( t \). Then set
\[
f(t) = \sum_{k} \frac{(-1)^{n_k}}{2^k}
\]
(with \( f(0) = 0 \)). Let \( X \) be the graph of \( f \), i.e. \( X = \{(t, f(t)) : t \in K\} \subseteq \mathbb{R}^2 \).
(a) Show that \( f \) is not continuous. Find the points of continuity of \( f \).
(b) Show that \( X \) is totally disconnected.
(c) Show that there is no base for the topology of \( X \) consisting of clopen sets.
(d) Show that there is a point \( p \in \mathbb{R}^2 \) such that \( X \cup \{p\} \) is not totally disconnected, although its connected components are single points.
(e) Show that \( X \) and \( X \cup \{p\} \) are \( G_\delta \) subsets of \( \mathbb{R}^2 \). \([f \) is a pointwise limit of a sequence of continuous functions.]

**XI.13.9.4.**  
Topologize \( X = \{a, b, c\} \) by taking the open sets to be \( \{\emptyset, \{a\}, \{a, b\}, \{a, c\}, X\} \). Then \( X \) is connected. The relative topology on \( E = \{b, c\} \) is the discrete topology and \( E \) is not connected. However, there is no separation \( \{U, V\} \) of \( E \) with \( U \) and \( V \) disjoint.

**XI.13.9.5.**  
Let \( X \) be the subset \( G \cup E \) of the plane, where \( G = \{(x, y) : 0 < x \leq \frac{1}{2}, y = \sin \left( \frac{1}{x} \right) \} \) and \( E = \{(0, 1), (0, -1)\} \). Since \( G \) is homeomorphic to \((0, 1)\), it is connected. \( G \) is dense in \( X \), so \( X \) is connected. Let \( E_n = E \cup \{(x, y) : 0 < x \leq \frac{1}{n^2}, y = \sin \left( \frac{1}{x} \right) \} \). Then \( E_n \) is connected for all \( n \), and \( E = \cap_n E_n \), but \( E \) is not connected. Note that \( E \) is compact, although the \( E_n \) are not compact.

**XI.13.9.6.**  
(a) Give \( \mathbb{N} \) the finite complement topology. Then \( \mathbb{N} \) is compact and \( T_1 \), and every infinite subset of \( \mathbb{N} \) is connected. Set \( E = \{1, 2\} \), and \( E_n = \{1, 2, n + 1, n + 2, \ldots\} \). Then \( E_n \) is compact and connected for all \( n \), but \( E = \cap_n E_n \) is not connected. \((E_n \) is not, however, closed in \( \mathbb{N}\).)
(b) Does the conclusion of **XI.13.3.6.** hold for arbitrary \( X \) if the \( E_i \) are assumed to be *closed* compact subsets?

**XI.13.9.7.**  
Let \( X \) be \( \mathbb{N} \) with two points \( a, b \) added. Topologize \( X \) by taking the open subsets to be all subsets with finite complement and all subsets of \( \mathbb{N} \).
(a) Show that \( X \) is a compact \( T_1 \) space.
(b) Show that the components of \( X \) are single points.
(c) Show that the quasi-component of \( a \) and \( b \) is \( \{a, b\} \), i.e. there is no clopen set containing \( a \) but not \( b \).

**XI.13.9.8.**  
Let \( X \) be the subset of \( \mathbb{R}^2 \) consisting of \( \{(\frac{1}{n}, t) : n \in \mathbb{N}, 0 \leq t \leq 1\} \) along with \((0, 0)\) and \((0, 1)\).
(a) Show that the components of \( X \) are \( \{(0, 0)\}, \{(0, 1)\}, \) and \( \{(\frac{1}{n}, t) : 0 \leq t \leq 1\} \) for fixed \( n \).
(b) Show that \((0, 0)\) and \((0, 1)\) are in the same quasi-component of \( X \).
XI.13.9.9. Let $X$ be the subset of $\mathbb{R}^2$ obtained by beginning with the line segment between $(0, 0)$ and $(1, 0)$ and adding the closed line segments between $\left(\frac{1}{n+1}, \frac{1}{n(n+m)}\right)$ for all $m, n \in \mathbb{N}$. $X$ is called the infinite broom. Is $X$ locally connected at $(0, 0)$? Note that if our usual convention that neighborhoods be open is relaxed, every neighborhood of $(0, 0)$ in $X$ contains a connected neighborhood. (This is false for points $(t, 0)$ with $0 < t < 1$). See [HY88, p. 113]. (Note that this $X$ is quite different from the ones in XI.18.4.1.)

XI.13.9.10. Theorem. Let $Y \subseteq \mathbb{R}^n (n > 1)$ be an absolute retract (e.g. $Y$ is homeomorphic to a closed ball of some dimension; cf. ()). Then $\mathbb{R}^n \setminus Y$ is connected.

Proof: Suppose $\mathbb{R}^n \setminus Y$ is not connected, i.e. it has a nonempty bounded component $U$. Let $p \in U$, and let $X = Y \cup U$. Then $X$ is compact since $\partial U \subseteq Y$. The identity map on $Y$ extends to a continuous function $f$ from $X$ onto $Y$ (i.e. $f$ is a retraction from $X$ onto $Y$).

Let $B$ be a closed ball centered at $p$ large enough that $X$ is contained in its interior. Let $g$ be radial retraction from $B \setminus \{p\}$ to $S = \partial B$. Define $r : B \to S$ by

$$r(x) = \begin{cases} g(f(x)) & \text{if } x \in X \\ g(x) & \text{if } x \in B \setminus X \end{cases}.$$ 

Then $r$ is a retraction from $B$ onto $S$, contradicting the No-Retraction Theorem ().

XI.13.9.11. (a) [HY88, Theorem 3.16] Show that any connected open set in a locally compact, locally connected Hausdorff space is path-connected.

(b) [HY88, Theorem 3.17] Show that every connected open set in a locally connected completely metrizable space is path-connected.

XI.13.9.12. Let $X$ be a compact space, $Y$ a (necessarily compact) Hausdorff space, and $f$ a continuous function from $X$ onto $Y$. If $X$ is locally connected, show that $Y$ is also locally connected. [If $U$ is an open set in $Y$, and $C$ is a component of $U$, show that $f^{-1}(C)$ is a union of components of $f^{-1}(U)$ and hence is open in $X$ (XI.13.7.3.). Use that $X \setminus f^{-1}(C)$ is compact to conclude that $C$ is open in $Y$.]

XI.13.9.13. Let $X$ be a connected locally compact Hausdorff space. Let $p$ be a point of $X$ and $U$ an open neighborhood of $p$ in $X$. Show that there is a nontrivial subcontinuum of $X$ (i.e. a connected compact subset containing more than one point) containing $p$ and contained in $U$. In fact, if $V$ is an open neighborhood of $p$ with compact closure, show that the connected component of $p$ in $V$ contains a point of $\partial V$. [Show that the quasi-component of $p$ in $V$ contains a point of $\partial V$, and apply XI.13.4.5..] This is a weak form of local connectedness.

The statements can fail if $X$ is not locally compact (XI.13.9.5..)

A point in a connected locally compact Hausdorff space need not have a connected compact neighborhood: consider the union of the graph of $y = \frac{1}{x} \sin \frac{1}{x}$ ($x > 0$) and the $y$-axis in $\mathbb{R}^2$. 

1164
XI.13.9.14. (F. Bernstein [Ber07]; cf. [HY88, p. 110]) (a) Show that there are exactly \(2^{\aleph_0}\) nontrivial closed connected subsets of \(\mathbb{R}^2\). Note that each has cardinality \(2^{\aleph_0}\).

(b) (AC) Well-order these nontrivial closed connected subsets \(\{X_\alpha : \alpha < \sigma\}\) according to the first ordinal \(\sigma\) of cardinality \(2^{\aleph_0}\). Inductively choose distinct points \(a_\alpha, b_\alpha\) in \(X_\alpha\), for each \(\alpha < \sigma\) (i.e. \(a_\alpha, b_\alpha, a_\beta, b_\beta\) are all distinct for \(\alpha \neq \beta\)).

(c) Let \(A = \{a_\alpha : \alpha < \sigma\}\) and \(B = \mathbb{R}^2 \setminus A\). Then \(b_\alpha \in B\) for all \(\alpha\).

(d) Show that \(A\) and \(B\) are connected and locally connected.

(e) Show that neither \(A\) nor \(B\) contains a subcontinuum of more than one point. In particular, they are totally path disconnected.

Thus \(\mathbb{R}^2\) is a disjoint union of two connected, locally connected subsets. Compare with XIII.3.9.13.

XI.13.9.15. Let \(X\) be a compact Hausdorff space. Define an equivalence relation \(\sim\) on \(X\) by \(x \sim y\) if \(x\) and \(y\) are in the same connected component of \(X\). Let \(X_c = X/\sim\) with the quotient topology; \(X_c\) is called the component space of \(X\).

(a) Show that the relation \(\sim\) is closed. [Use XI.13.4.5.]

(b) Show that the decomposition is usc (XI.8.2.1.). [If \(E\) is closed in \(X\) and \(x\) is not in the saturation of \(E\), show there is a clopen set in \(X\) containing \(x\) disjoint from \(E\).]

(c) Show that \(X_c\) is a compact Hausdorff space. [Use XI.8.3.9.]

(d) Show that \(X_c\) is totally disconnected.

(e) Is the decomposition necessarily lsc?

(f) Extend the results to the case where \(X\) is locally compact and normal. [Show that \(X_c\) embeds in \((\beta X)_c\).]

(g) To what extent does this construction work if \(X\) is not locally compact?

(h) Does a similar construction work for path components?
XI.14. Direct and Inverse Limits

Direct and, especially, inverse limits are important topological constructions. Actually, they have little to do with topology specifically; they can be defined for systems of sets, or more generally within a category. But they are especially useful in topology.

Caution: The use of the term “limit” in connection with direct and inverse limits has almost nothing to do (at least on the surface) with the usual use of the term “limit” in topology, e.g. “limit of a sequence.”

XI.14.1. Direct Systems and Direct Limits of Sets

XI.14.1.1. Definition. A direct system of sets over \( \mathbb{N} \) is a sequence \( (X_n) \) of sets and, for each \( n \), a function \( \phi_{n;n+1} : X_n \to X_{n+1} \).

Pictorially, we have

\[
X_1 \xrightarrow{\phi_{1;2}} X_2 \xrightarrow{\phi_{2;3}} X_3 \xrightarrow{\phi_{3;4}} \ldots
\]

Both the sets \( X_n \) and the maps \( \phi_{n,n+1} \) must be specified. Usually a direct system of sets over \( \mathbb{N} \) is denoted \( (X_n, \phi_{n,n+1}) \).

If \( n < m \), then there is an induced map \( \phi_{n,m} \) from \( X_n \) to \( X_m \) defined by composition:

\[
\phi_{n,m} = \phi_{m-1,m} \circ \phi_{m-2,m-1} \circ \cdots \circ \phi_{n+1,n+2} \circ \phi_{n,n+1}.
\]

If \( n < m < k \), then \( \phi_{n,k} = \phi_{m,k} \circ \phi_{n,m} \).

We can more generally define a direct system over any directed set \( I \):

XI.14.1.2. Definition. Let \( I \) be a (properly) directed set. A direct system of sets over \( I \) is an indexed collection \( \{X_i : i \in I\} \) of sets and, for each \( i, j \) with \( i < j \), a function \( \phi_{i,j} : X_i \to X_j \) satisfying \( \phi_{i,k} = \phi_{j,k} \circ \phi_{i,j} \) whenever \( i < j < k \).

We usually write \( (X_i, \phi_{i,j}) \) or \( (X_i, \phi_{i,j})_{i \in I} \) for a direct system of sets over \( I \).

If working in a category such as the category of topological spaces, the sets are objects in the category, e.g. topological spaces in the category of topological spaces, and the functions are required to be morphisms in the category, e.g. continuous functions in the category of topological spaces.

XI.14.1.3. We want to associate to a direct system a set \( X \) which “sits at \( +\infty \)”. To see how this works, first consider the case where \( I = \mathbb{N} \) and each \( \phi_{n,n+1} \) is injective. Then \( X_n \) can be identified with the subset \( \phi_{n,n+1}(X_n) \) of \( X_{n+1} \) for each \( n \), and the direct limit \( X \) is then the “union” of the \( X_n \). (It is not truly a union except in the rare case where each \( \phi_{n,n+1} \) is an inclusion map of a subset.)

If the \( \phi_{n,n+1} \) are not all injective, things are a little more complicated: \( X \) is not the “union” of the \( X_n \) since any elements which are identified (i.e. have the same image) in some \( X_m \) must be identified in \( X \). Thus in general the direct limit \( X \) informally consists of all objects which appear at any stage, with objects identified if they are eventually identified at some stage.

Here is the formal property that the direct limit must have:
XI.14.1.4. **Definition.** Let \((X_i, \phi_{i,j})\) be a direct system over a directed set \(I\). A direct limit for the direct system is a pair \((X; \phi_i)\), where \(X\) is a set and, for each \(i\), \(\phi_i : X_i \rightarrow X\) is a function such that \(\phi_i = \phi_j \circ \phi_{i,j}\) for any \(i, j\) with \(i < j\); pictorially, in the case \(I = \mathbb{N}\), we have a commutative diagram:

\[
\begin{array}{c}
X_1 \\
\downarrow_{\phi_{1,2}} \\
X_2 \\
\downarrow_{\phi_{2,3}} \\
X_3 \\
\downarrow_{\phi_{3,4}} \\
\vdots
\end{array}
\rightarrow
\begin{array}{c}
X
\end{array}
\]

with the following universal property:

If \(Y\) is a set and for each \(i\) there is a function \(\psi_i : X_i \rightarrow Y\) such that \(\psi_i = \psi_j \circ \phi_{i,j}\) for any \(i, j\) with \(i < j\), then there is a unique function \(\alpha : X \rightarrow Y\) such that \(\psi_i = \alpha \circ \phi_i\) for all \(i\).

We write \((X, \phi_i) = \lim \left(X_i, \phi_{i,j}\right)\) for a direct limit. A direct limit is often called an inductive limit.

Pictorially, the universal property in the case \(I = \mathbb{N}\) is the following commutative diagram:

\[
\begin{array}{c}
X_1 \\
\downarrow_{\phi_{1,2}} \\
X_2 \\
\downarrow_{\phi_{2,3}} \\
X_3 \\
\downarrow_{\phi_{3,4}} \\
\vdots
\end{array}
\rightarrow
\begin{array}{c}
X
\end{array}
\]

XI.14.1.5. **Theorem.** Let \((X_i, \phi_{i,j})\) be a direct system of sets over a directed set \(I\). Then

(i) There is a direct limit \((X, \phi_i)\).

(ii) If \((X, \phi_i)\) and \((Y, \psi_i)\) are direct limits, there is a unique bijection \(\alpha : X \rightarrow Y\) such that \(\psi_i = \alpha \circ \phi_i\) for all \(i\).

Thus up to natural identification there is a unique direct limit for any direct system.

**Proof:** We begin with (ii). This is a simple standard argument that shows that any object with a universal property is unique up to isomorphism.

Since \((X, \phi_i)\) satisfies the universal property, there is a unique function \(\alpha : X \rightarrow Y\) such that \(\psi_i = \alpha \circ \phi_i\) for all \(i\). Similarly, since \((Y, \psi_i)\) satisfies the universal property, there is a unique function \(\beta : Y \rightarrow X\) such that \(\phi_i = \beta \circ \psi_i\). There is also a unique function \(\gamma : X \rightarrow X\) such that \(\phi_i = \gamma \circ \phi_i\) for all \(i\). Since the identity map \(\iota\) on \(X\) has this property, \(\gamma = \iota\). But for each \(i\) we have

\[
\phi_i = \beta \circ \psi_i = \beta \circ \alpha \circ \phi_i
\]

so \(\beta \circ \alpha\) has the property of \(\gamma\) and thus equals \(\iota\). By a similar argument we have that \(\alpha \circ \beta\) is the identity on \(Y\). Thus \(\alpha\) and \(\beta\) are mutually inverse bijections.

1167
We now show existence. Let $Z$ be the subset of $\bigcup_{i \in I} X_i \times I$ defined by
\[ Z = \{ (x, i) : x \in X_i \} \subseteq \bigcup_{i \in I} X_i \times I \]
($Z$ is sometimes called the disjoint union of the $X_i$). Define a relation $\sim$ on $Z$ by setting $(x, i) \sim (x', j)$ if and only if there is a $k$, $i < k$ and $j < k$, such that $\phi_{i,k}(x) = \phi_{j,k}(x')$. It is easily checked that $\sim$ is an equivalence relation. Let $X$ be the set of equivalence classes. Write $[(x, i)]$ for the equivalence class of $(x, i)$ in $Z$.

Fix $i$. Define a function $\phi_i : X_i \to X$ by $\phi_i(x) = [(x, i)]$ for $x \in X_i$. It is easily checked that $\phi_i = \phi_j \circ \phi_{i,j}$ for $i < j$, since $[(x, i)] = [(\phi_{i,j}(x), j)]$ for $i < j$ and $x \in X_i$.

Now suppose $Y$ is a set and $\psi_i : X_i \to Y$ is a function for each $i$ with $\psi_i = \psi_j \circ \phi_{i,j}$ for $i < j$. Define $\alpha : X \to Y$ by $\alpha([(x, i)]) = \psi_i(x)$ for $x \in X_i$. We need only show that this function is well defined, since then obviously $\psi_i(x) = \alpha([(x, i)]) = \alpha(\phi_i(x))$ for $x \in X_i$. If $[(x, i)] = [(x', j)]$, fix $k$ such that $i < k$, $j < k$, and $\phi_{i,k}(x) = \phi_{j,k}(x')$. Then
\[ \psi_i(x) = \psi_k(\phi_{i,k}(x)) = \psi_k(\phi_{j,k}(x')) = \psi_j(x') \]
so $\alpha$ is well defined.

For uniqueness of $\alpha$, suppose $\beta$ is another map from $X$ to $Y$ with $\psi_i = \beta \circ \phi_i$ for all $i$. Let $[(x, i)] \in X$. We have
\[ \beta([(x, i)]) = \beta(\phi_i(x)) = \psi_i(x) = \alpha(\phi_i(x)) = \alpha([(x, i)]) \]
and so $\beta = \alpha$.

\[ \text{(XI.14.1.6)} \quad \text{Proposition. Let } (X, \phi_i) = \lim_{\to} (X_i, \phi_{i,j}). \text{ Then} \]
\begin{enumerate}
  \item For any $x \in X$, there is an $i$ and $x_i \in X_i$ with $x = \phi_i(x_i)$.
  \item If $x, x' \in X$, $x = \phi_i(x_i)$ and $x' = \phi_j(x'_j)$ for $x_i \in X_i$, $x'_j \in X_j$, then $x = x'$ if and only if there is a $k \in I$, $i < k$, $j < k$, such that $\phi_{i,k}(x_i) = \phi_{j,k}(x'_j)$.
\end{enumerate}

The simple proof is left to the reader.

**Passage to Subsystems**

\[ \text{XI.14.1.7} \quad \text{Suppose } (X_n, \phi_{n,n+1}) \text{ is a direct system over } \mathbb{N}. \text{ Let } (k_n) \text{ be a strictly increasing sequence in } \mathbb{N}, \text{ and let } Y_n = X_{k_n}, \psi_{n,n+1} = \phi_{k_n,k_{n+1}}. \text{ If } (X, \phi_n) = \lim_{\to} (X_n, \phi_{n,n+1}) \text{ and } (Y, \psi_n) = \lim_{\to} (Y_n, \psi_{n,n+1}), \text{ we will show there is a natural bijection between } X \text{ and } Y. \text{ For each } n, \text{ set } \alpha_n = \psi_n \circ \phi_{n,k_n} : X_n \to Y; \text{ there is then a unique } \alpha : X \to Y \text{ such that } \alpha_n = \alpha \circ \phi_n \text{ for all } n. \text{ If } \beta_n = \phi_{k_n} : Y_n = X_{k_n} \to X \text{ and } \beta : Y \to X \text{ is the unique function such that } \beta_n = \beta \circ \psi_n, \text{ we have} \]
\[ \beta \circ \alpha \circ \phi_n = \beta \circ \alpha_n = \beta \circ \psi_n \circ \phi_{n,k_n} = \beta_n \circ \phi_{n,k_n} = \phi_{k_n} \circ \phi_{n,k_n} = \phi_n \]
\[ \alpha \circ \beta \circ \psi_n = \alpha \circ \beta_n = \alpha \circ \phi_{k_n} = \psi_{k_n} \circ \phi_{k_n,k_{k_n}} = \phi_{k_n} \circ \phi_{k_n,k_{k_n}} = \phi_{k_n} = \psi_n \]
so we have $\beta \circ \alpha = \iota_X$ and $\alpha \circ \beta = \iota_Y$, i.e. $\alpha$ and $\beta$ are mutually inverse bijections.

Thus the direct limit over a subsystem is the “same” as the direct limit over the whole system. This is an analog (in a quite different setting) of the fact that the limit of a subsequence is the same as the limit of the whole sequence (if it exists).

More generally, the same result holds for direct limits over arbitrary directed sets (XI.14.1.10.).

1168
Induced Functions

**XI.14.1.8.** Let \((X_i, \phi_{i,j})\) and \((Y_i, \psi_{i,j})\) be direct systems over the same index set \(I\). Suppose there is for each \(i\) a function \(\alpha_i : X_i \to Y_i\) such that \(\alpha_j \circ \phi_{i,j} = \psi_{i,j} \circ \alpha_i\) for all \(i < j\). Let \((X, \phi_i) = \lim (X_i, \phi_{i,j})\), \((Y, \psi_i) = \lim (Y_i, \psi_{i,j})\). The maps \(\psi_i \circ \alpha_i\) are a coherent family of maps from the \(X_i\) to \(Y_i\), so by the universal property there is a unique function \(\alpha : X \to Y\) such that \(\alpha \circ \phi_i = \psi_i \circ \alpha_i\) for all \(i\). The function \(\alpha\) is called the *function induced by the \(\alpha_i\)*. For \(I = \mathbb{N}\) we have a commutative diagram:

![Diagram](image-url)

**XI.14.1.9.** Here is a general procedure including both **XI.14.1.7.** and **XI.14.1.8.**. Let \(I\) and \(J\) be directed sets, and \((X_i, \phi_{i,j})\) and \((Y_j, \psi_{j,j'})\) be inductive systems over \(I\) and \(J\) respectively. (Note that we have slightly changed our standard notation.) Let \(K\) be a cofinal subset of \(I\), and \(f\) a directed function \(\ell\) from \(K\) to \(J\), which for simplicity we will take to be order-preserving (this assumption can be eliminated at some technical cost, in the manner of Exercise II.4.5.3.). Suppose we have a compatible set \((\alpha_k)\) of functions \(\alpha_k : X_k \to Y_{f(k)}\) (i.e. if \(k < k'\), we have \(\alpha_{k'} \circ \phi_{k,k'} = \psi_{f(k),f(k')} \circ \alpha_k\)). For \(i \in I\), define \(\theta_i : X_i \to Y\) by \(\theta_i = \psi_{f(k)} \circ \alpha_k \circ \phi_{i,k}\) for any \(k \in K\), \(i < k\) (by compatibility this is well defined independent of the choice of \(k\)). The \(\theta_i\) are a compatible family of functions from the \(X_i\) to \(Y\), so there is a unique induced map \(\alpha : X \to Y\) such that \(\alpha \circ \phi_i = \theta_i\) for all \(i\). This is the function induced by \(f\) and the \(\alpha_k\).

**XI.14.1.10.** **Proposition.** Let \(I\) and \(J\) be directed sets, and \((X_i, \phi_{i,j})\) and \((Y_j, \psi_{j,j'})\) be direct systems over \(I\) and \(J\) respectively, with direct limits \((X, \phi_i)\) and \((Y, \psi_j)\). Let \(K\) and \(L\) be cofinal subsets of \(I\) and \(J\) respectively, and \(f : K \to J\) and \(g : L \to I\) order-preserving directed maps. Let \(\alpha_k : X_k \to Y_{f(k)}\) and \(\beta_k : Y_k \to X_{g(\ell)}\) be compatible families of maps, with \(\beta_k \circ \psi_{f(k),\ell} \circ \alpha_k = \phi_{k,g(\ell)}\) whenever \(k \in K\), \(\ell \in L\), \(f(k) < \ell\) and \(k < g(\ell)\), and \(\alpha_k \circ \phi_{g(\ell),k} \circ \beta_k = \psi_{\ell,f(k)}\) whenever \(g(\ell) < k\) and \(\ell < f(k)\). Then the induced functions \(\alpha : X \to Y\) and \(\beta : Y \to X\) are mutually inverse bijections.

The proof is very similar to the proof of **XI.14.1.7.**, and is left to the reader. Pictorially, if \(I = J = \mathbb{N}\), we have a commutative diagram:

![Diagram](image-url)
XI.14.1.11. Let \((X_i, \phi_{i,j})\) be a direct system of sets over \(I\), and for each \(i\) suppose \(Y_i \subseteq X_i\) and \(\phi_{i,j}(Y_i) \subseteq Y_j\) whenever \(i < j\). Set \(\psi_{i,j} = \phi_{i,j}^{-1} : Y_i \to Y_j\) for \(i < j\). Then \((Y_i, \psi_{i,j})\) is a direct system of sets over \(I\), and the inclusion maps \(\beta_i : Y_i \to X_i\) induce a function \(\beta : Y \to X\), where \((X, \phi_i) = \lim Y_i, \phi_{i,j}\) and \((Y, \psi_i) = \lim Y_i, \psi_{i,j}\).

XI.14.1.12. **Proposition.** The map \(\beta : Y \to X\) is injective; thus we may write \(\lim Y_i, \psi_{i,j}\) \(\subseteq \lim (X_i, \phi_{i,j})\). (Informally, direct limits of sets commute with taking subsets.)

**Proof:** Suppose \(\beta(y) = \beta(y')\). Let \(y = \psi_i(z)\), \(y' = \psi_j(z')\) for some \(z \in Y_i\), \(z' \in Y_j\). Then there is a \(k\) with \(i < k, j < k\), and \(\phi_{i,k}(z) = \phi_{j,k}(z')\). But then \(\psi_{i,k}(z) = \psi_{j,k}(z')\), so \(y = \psi_i(z) = \psi_j(z') = y'\). \(\square\)

XI.14.2. **Inverse Systems and Inverse Limits of Sets**

Inverse systems and limits work similarly to direct ones, but the arrows are reversed. The details turn out to be subtly different.

XI.14.2.1. **Definition.** An **inverse system of sets** over \(\mathbb{N}\) is a sequence \((X_n)\) of sets and, for each \(n\), a function \(\phi_{n+1,n} : X_{n+1} \to X_n\).

Pictorially, we have

\[
\cdots \xrightarrow{\phi_{4,3}} X_3 \xrightarrow{\phi_{3,2}} X_2 \xrightarrow{\phi_{2,1}} X_1
\]

If \(n < m\), then there is an induced map \(\phi_{m,n}\) from \(X_m\) to \(X_n\) defined by composition:

\[
\phi_{m,n} = \phi_{n+1,n} \circ \phi_{n+2,n+1} \circ \cdots \circ \phi_{m-2,m-1} \circ \phi_{m,m-1}.
\]

If \(n < m < k\), then \(\phi_{k,n} = \phi_{m,n} \circ \phi_{k,m}\).

We can again work over any directed set:

XI.14.2.2. **Definition.** Let \(I\) be a (properly) directed set. An **inverse system of sets over \(I\)** is an indexed collection \(\{X_i : i \in I\}\) of sets and, for each \(i, j\) with \(i < j\), a function \(\phi_{j,i} : X_j \to X_i\) satisfying \(\phi_{j,i} = \phi_{j,i} \circ \phi_{k,j}\) whenever \(i < j < k\).

We usually write \((X_i, \phi_{j,i})\) or \((X_i, \phi_{j,i})_{i \in I}\) for an inverse system of sets over \(I\).

XI.14.2.3. We want to associate to an inverse system a set \(X\) which “sits at \(-\infty\)”; \(X\) will map to each \(X_i\). To see how this works, first consider the case where \(I = \mathbb{N}\) and each \(\phi_{n+1,n}\) is injective (this is not actually a very interesting case for inverse limits). Then \(X_{n+1}\) can be identified with the subset \(\phi_{n+1,n}(X_{n+1})\) of \(X_n\) for each \(n\), and the inverse limit \(X\) is then the “intersection” of the \(X_n\). (It is not truly an intersection except in the rare case where each \(\phi_{n+1,n}\) is an inclusion map of a subset.)

If the connecting maps are surjective but not injective (the most interesting case), the inverse limit will be “larger” than the \(X_i\), since the preimage of any element of \(X_i\) will be at least as large as the preimage under \(\phi_{j,i}\), which increases in size as \(j\) increases.

Here is the universal property the inverse limit must have:
XI.14.2.4. Definition. Let \((X_i, \phi_{j,i})\) be an inverse system over a directed set \(I\). An inverse limit for the inverse system is a pair \((X, \phi_i)\), where \(X\) is a set and, for each \(i\), \(\phi_i : X \to X_i\) is a function such that \(\phi_i = \phi_{j,i} \circ \phi_j\) for any \(i, j\) with \(i < j\); pictorially, in the case \(I = \mathbb{N}\), we have a commutative diagram:

\[
\begin{array}{cccccc}
X & \rightarrow & X_3 & \rightarrow & X_2 & \rightarrow & X_1 \\
\phi_1 & & \phi_{2,3} & & \phi_{3,2} & & \phi_{4,3}
\end{array}
\]

with the following universal property:

If \(Y\) is a set and for each \(i\) there is a function \(\psi_i : Y \to X_i\) such that \(\psi_i = \phi_{j,i} \circ \psi_j\) for any \(i, j\) with \(i < j\), then there is a unique function \(\alpha : Y \to X\) such that \(\psi_i = \phi_i \circ \alpha\) for all \(i\).

We write \((X, \phi_i) = \lim_{\leftarrow} (X_i, \phi_{j,i})\) for an inverse limit. An inverse limit is often called a projective limit.

Pictorially, the universal property in the case \(I = \mathbb{N}\) is the following commutative diagram:

\[
\begin{array}{cccccc}
X & \rightarrow & X_3 & \rightarrow & X_2 & \rightarrow & X_1 \\
\phi_1 & & \phi_{2,3} & & \phi_{3,2} & & \phi_{4,3}
\end{array}
\]

XI.14.2.5. Theorem. Let \((X_i, \phi_{j,i})\) be an inverse system of sets over a directed set \(I\). Then

(i) There is an inverse limit \((X, \phi_i)\).

(ii) If \((X, \phi_i)\) and \((Y, \psi_i)\) are inverse limits, there is a unique bijection \(\alpha : Y \to X\) such that \(\psi_i = \phi_i \circ \alpha\) for all \(i\).

Thus up to natural identification there is a unique inverse limit for any inverse system.

Proof: The proof of (ii) is essentially identical to the proof of XI.14.5.(ii), and is left to the reader.

The argument for (i) is somewhat simpler than for direct limits once infinite Cartesian products have been defined (). Let \(Z\) be the Cartesian product of the \(X_i\), and define

\[X = \{(\cdots x_i \cdots) : x_i = \phi_{j,i}(x_j) \text{ for all } i, j \in I, i < j\} \subseteq \prod_{i \in I} X_i = Z\]

(the elements of \(X\) are called coherent threads in \(Z\)). For each \(i\), let \(\phi_i\) be the restriction to \(X\) of the \(i\)'th coordinate map, i.e.

\[\phi_i(\cdots x_i \cdots) = x_i\ .\]

It is obvious from the coherence that \(\phi_i = \phi_{j,i} \circ \phi_j\) if \(i < j\).
To show the universal property, let \((Y, \psi_i)\) satisfy the coherence condition. Simply define \(\alpha : Y \to X\) by
\[
\alpha(y) = (\cdots \psi_1(y) \cdots).
\]
Then clearly \(\psi_i = \phi_i \circ \alpha\) for all \(i\), and \(\alpha\) is the only possible function from \(Y\) to \(X\) with this property. 

**XI.14.2.6. Proposition.** Let \((X, \phi_i) = \lim_{\longleftarrow}(X_i, \phi_{j,i})\). If \(x, x' \in X\), then \(x = x'\) if and only if \(\phi_i(x) = \phi_i(x')\) for all \(i\).

**XI.14.2.7. Examples.** (i) Let \(X\) be a set and \(i\) the identity map on \(X\). Let \(I\) be a directed set. For \(i \in I\) set \(X_i = X\), and for \(i < j\) set \(\phi_{j,i} = i\). Then \((X_i, \phi_{j,i})\) is an inverse system over \(I\), and \((X, \iota)\) is an inverse limit for \((X_i, \phi_{j,i})\).

(ii) Let \(Y\) be a set, and \((X_n)\) a decreasing sequence of subsets of \(Y\). Let \(\phi_{n+1,n}\) be the inclusion map from \(X_{n+1}\) to \(X_n\). Let \(X = \bigcap_n X_n\) and \(\phi_n\) the inclusion map from \(X\) to \(X_n\). Then \((X_n, \phi_{n+1,n})\) is an inverse system over \(\mathbb{N}\), and \((X, \phi_n)\) is an inverse limit for \((X_n, \phi_{n+1,n})\). Here \(\mathbb{N}\) can be replaced by an arbitrary index set \(I\), if \(X_j \subseteq X_i\) whenever \(i < j\).

(iii) As a special case of (ii), let \(X_n = \{k \in \mathbb{N} : k \geq n\}\). Then \((X_n, \phi_{n+1,n})\) is an inverse system of nonempty sets with \(\lim(X_n, \phi_{n+1,n}) = \emptyset\).

It can even happen that the inverse limit of an inverse system of nonempty sets with surjective connecting maps is empty (Exercise XI.14.5.5.(b)), but not if the index set is \(\mathbb{N}\) (Exercise XI.14.5.5.(a)).

We will see much more interesting examples later.

**Induced Functions and Passage to Subsystems**

Induced functions and passage to subsystems in inverse limits works almost identically to the direct limit case.

**XI.14.2.8.** Suppose \((X_n, \phi_{n+1,n})\) is an inverse system over \(\mathbb{N}\). Let \((k_n)\) be a strictly increasing sequence in \(\mathbb{N}\), and let \(Y_n = X_{k_n}, \psi_{n+1,n} = \phi_{k_{n+1},k_n}\). If \((X, \phi_n) = \lim(X_n, \phi_{n+1,n})\) and \((Y, \psi_n) = \lim(Y_n, \psi_{n+1,n})\), we will show there is a natural bijection between \(X\) and \(Y\). For each \(n\), set \(\alpha_n = \phi_{k_n} : X \to Y_n = X_{k_n}\); there is then a unique \(\alpha : X \to Y\) such that \(\alpha_n = \psi_{n} \circ \alpha\) for all \(n\). If \(\beta_n = \phi_{k_n} \circ \psi_n : Y \to X_n\) and \(\beta : Y \to X\) is the unique function such that \(\beta_n = \phi_n \circ \beta\), we have
\[
\phi_n \circ \beta \circ \alpha = \beta_n \circ \alpha = \phi_{k_n, n} \circ \psi_n \circ \alpha = \phi_{k_n, n} \circ \alpha_n = \phi_{k_n} \circ \phi_{k_n} = \phi_n
\]
\[
\psi_n \circ \alpha \circ \beta = \alpha_n \circ \beta = \phi_k \circ \beta = \beta_k = \phi \circ \psi = \phi \circ \psi = \phi = \psi
\]
so we have \(\beta \circ \alpha = \iota_X\) and \(\alpha \circ \beta = \iota_Y\), i.e. \(\alpha\) and \(\beta\) are mutually inverse bijections.
XI.14.2.9. Let \((X_i, \phi_{j,i})\) and \((Y_i, \psi_{j,i})\) be inverse systems over the same index set \(I\). Suppose there is for each \(i\) a function \(\alpha_i : X_i \rightarrow Y_i\) such that \(\psi_{j,i} \circ \alpha_j = \alpha_i \circ \phi_{j,i}\) for all \(i < j\). Let \((X, \phi_i) = \lim(X_i, \phi_{j,i}),\) \((Y, \psi_i) = \lim(Y_i, \psi_{j,i})\). The maps \(\alpha_i \circ \psi_i\) are a coherent family of maps from \(X\) to \(Y_i\), so by the universal property there is a unique function \(\alpha : X \rightarrow Y\) such that \(\psi_i \circ \alpha = \alpha_i \circ \phi_i\) for all \(i\). The function \(\alpha\) is called the \textit{function induced by the} \(\alpha_i\). For \(I = \mathbb{N}\) we have a commutative diagram:

![Diagram](https://via.placeholder.com/150)

XI.14.2.10. Here is the general procedure including both XI.14.2.8. and XI.14.2.9.. Let \(I\) and \(J\) be directed sets, and \((X_i, \phi_{j,i}')\) and \((Y_j, \psi_{j,j})\) be inverse systems over \(I\) and \(J\) respectively. Let \(K\) be a cofinal subset of \(I\), and \(f\) a directed function \(f\) from \(K\) to \(J\), which for simplicity we will take to be order-preserving (this assumption can be eliminated at some technical cost, in the manner of Exercise II.4.5.3.). Suppose we have a compatible set \((\alpha_k)\) of functions \(\alpha_k : X_k \rightarrow Y_{f(k)}\) (i.e. if \(k < k'\) we have \(\alpha_k \circ \phi_{k',k} = \psi_{f(k'),f(k)} \circ \alpha_{k'}\)). For \(j \in J\), define \(\theta_j : X \rightarrow Y_j\) by \(\theta_j = \psi_{f(k),j} \circ \alpha_k \circ \phi_k\) for any \(k \in K, j < f(k)\) (by compatibility this is well defined independent of the choice of \(k\)). The \(\theta_j\) are a compatible family of functions from \(X\) to the \(Y_j\), so there is a unique induced map \(\alpha : X \rightarrow Y\) such that \(\psi_j \circ \alpha = \theta_j\) for all \(j\). This is the function induced by \(f\) and the \(\alpha_k\).

XI.14.2.11. \textbf{Proposition.} Let \(I\) and \(J\) be directed sets, and \((X_i, \phi_{j,i}')\) and \((Y_j, \psi_{j,j})\) be inverse systems over \(I\) and \(J\) respectively, with inverse limits \((X, \phi_i)\) and \((Y, \psi_j)\). Let \(K\) and \(L\) be cofinal subsets of \(I\) and \(J\) respectively, and \(f : K \rightarrow J\) and \(g : L \rightarrow I\) order-preserving directed maps. Let \(\alpha_k : X_k \rightarrow Y_{f(k)}\) and \(\beta_{\ell} : Y_{\ell} \rightarrow X_{g(\ell)}\) be compatible families of maps, with \(\beta_{\ell} \circ \psi_{f(k),\ell} \circ \alpha_k = \phi_{k,g(\ell)}\) whenever \(k \in K, \ell \in L, \ell < f(k)\) and \(k < g(\ell)\), and \(\alpha_k \circ \phi_{g(\ell),k} \circ \beta_{\ell'} = \psi_{f(k'),f(k)}\) whenever \(k < g(\ell)\) and \(\ell < f(k)\). Then the induced functions \(\alpha : X \rightarrow Y\) and \(\beta : Y \rightarrow X\) are mutually inverse bijections.

The proof is very similar to the proof of XI.14.1.7., and is left to the reader. Pictorially, if \(I = J = \mathbb{N}\), we have a commutative diagram:

![Diagram](https://via.placeholder.com/150)

XI.14.2.12. Like direct limits, inverse limits commute with taking subspaces. Let \((X_i, \phi_{j,i})\) be an inverse system of sets over \(I\), and for each \(i\) suppose \(Y_i \subseteq X_i\) and \(\phi_{j,i}(Y_j) \subseteq Y_i\) whenever \(i < j\). Set
$\psi_{j,i} = \phi_{j,i} y_j : Y_j \to Y_i$ for $i < j$. Then $(Y_i, \psi_{j,i})$ is an inverse system of sets over $I$, and the inclusion maps $\beta_i : Y_i \to X_i$ induce a function $\beta : Y \to X$, where $(X, \phi_i) = \varprojlim (X_i, \phi_{j,i})$ and $(Y, \psi_i) = \varprojlim (Y_i, \psi_{j,i})$. The next proposition is obvious:

**XI.14.2.13. Proposition.** The map $\beta : Y \to X$ is injective; thus we may write $\varprojlim (Y_i, \psi_{j,i}) \subseteq \varprojlim (X_i, \phi_{j,i})$. (Informally, inverse limits of sets commute with taking subsets.)

### XI.14.3. Direct Limits in Topology

If $(X_i, \phi_{i,j})$ is a direct system over a directed set $I$, and each $X_i$ is a topological space and all $\phi_{i,j}$ are continuous, then we want to put a topology on the direct limit so that all the maps in Definition XI.14.1.4. are continuous. So we need each $\phi_i$ continuous, and for the universal property to hold the topology must be the strongest one with this property, i.e. the topology on $X$ is induced by the functions $\phi_i$ in the sense of ()

**XI.14.3.1. Definition.** Let $(X_i, \phi_{i,j})$ be a direct system of topological spaces over a directed set $I$, i.e. each $X_i$ is a topological space and each $\phi_{i,j} : X_i \to X_j$ is continuous for $i < j$. The *inductive limit topology* on $X = \varinjlim (X_i, \phi_{i,j})$ is the topology on $X$ induced by the $\phi_i$, i.e. $U \subseteq X$ is open if and only if $\phi_i^{-1}(U)$ is open in $X_i$ for all $i$.

It is easily checked (cf. ()) that this is a topology on $X$ and that each $\phi_i$ is continuous.

**XI.14.3.2. Proposition.** Let $(X_i, \phi_{i,j})$ be a direct system of topological spaces, with $(X, \phi_i) = \varinjlim (X_i, \phi_{i,j})$. Give $X$ the inductive limit topology. If $Y$ is a topological space and for each $i$ there is a continuous function $\psi_i : X_i \to Y$ such that $\psi_i = \psi_j \circ \phi_{i,j}$ for any $i, j$ with $i < j$, then the unique function $\alpha : X \to Y$ such that $\psi_i = \alpha \circ \phi_i$ for all $i$ is continuous.

**Proof:** Let $V$ be an open set in $Y$, and $U = \alpha^{-1}(V)$. Then $\phi_i^{-1}(U) = \psi_i^{-1}(V)$ is open in $X_i$ for each $i$. Thus $U$ is open in $X$ by definition of the inductive limit topology.

**XI.14.3.3.** There is almost nothing one can say about properties of the inductive limit topology in general; it can be quite pathological (cf. Example XI.14.3.4.(i)). See [], [], ..., for other examples. But the inductive limit topology tends to be fairly strong, as Example XI.14.3.4.(ii) indicates.

**XI.14.3.4. Examples.** (i) Let $X$ be a set, and $\mathcal{T}_1, \mathcal{T}_2, \ldots$ a sequence of topologies on $X$ with $\mathcal{T}_{n+1}$ weaker than $\mathcal{T}_n$ for all $n$. Let $X_n$ be $X$ with the topology $\mathcal{T}_n$ for each $n$, and let $\phi_{n,n+1}$ be the identity map on $X$. Then $\phi_{n,n+1}$ is continuous. The direct limit is again $X$, and the inductive limit topology is $\mathcal{T} = \cap_n \mathcal{T}_n$. If each $\mathcal{T}_n$ is $\mathcal{T}_1$, then $\mathcal{T}$ is also $\mathcal{T}_1$; but if each $\mathcal{T}_n$ is Hausdorff (even metrizable), then $\mathcal{T}$ is not necessarily Hausdorff ()

(ii) Here is a common situation which can be generalized in several ways. Let $(X_n, \rho_n)$ be a metric space for each $n$, and $\phi_{n,n+1}$ an isometry of $X_n$ onto a closed subset of $X_{n+1}$. There is an induced metric $\rho$ on the direct limit $X$, since we can identify $X_n$ with a closed subset of $X$, $X_n \subseteq X_{n+1}$, $X = \cup_n X_n$. It might appear that the inductive limit topology is the topology induced by $\rho$. This is sometimes true, e.g. if $X_n = [0,1]$ with the usual metric, then $X \approx (0,1]$ with the usual topology. But it is false in general. In

\[1174\]
fact, the inductive limit topology is strictly stronger than the $\rho$-topology in general, and is often not even first countable, so sequences are inadequate to describe the topology. An example is obtained by taking $X_n = \mathbb{R}^n$ with the usual metric (or the $p$-metric for $1 \leq p \leq \infty$), identifying $\mathbb{R}^n$ with $\mathbb{R}^n \times \{0\} \subseteq \mathbb{R}^{n+1}$. The direct limit can be described in this case as $c_{\infty}$, the set of sequences of real numbers which are eventually 0. XI.14.3.5. implies that a sequence in $c_{\infty}$ (i.e. a sequence of sequences) converges in the inductive limit topology if and only if there is a fixed $n$ such that all the terms in each sequence vanish after the $n$'th place and the sequence of $k$'th coordinates converges for $1 \leq k \leq n$. The inductive limit topology on $c_{\infty}$ is not first countable: if $\sigma = (\epsilon_n)$ is any sequence of positive numbers, let $U_\sigma$ be the set of all sequences $(x_1, x_2, \ldots)$ in $c_{\infty}$ such that $|x_n| < \epsilon_n$ for all $n$. Then $U_\sigma \cap \mathbb{R}^n$ is open in $\mathbb{R}^n$ for all $n$, hence $U_\sigma$ is open in the inductive limit topology. In fact, the $U_\sigma$ form a local base at 0 for the inductive limit topology. But there is no countable local base at 0, since for any countable set $\{\sigma_k : k \in \mathbb{N}\}$ of such sequences, there is a $\sigma$ whose terms go to 0 faster than those of any $\sigma_k$.

In the situation of XI.14.3.4., we have the following result for sequences (which does not generalize to nets):

XI.14.3.5. Proposition. Let $(X_n, \rho_n)$ be a metric space for each $n$, and $\phi_{n,n+1}$ an isometry of $X_n$ onto a closed subset of $X_{n+1}$. Let $X = \lim(X_n, \phi_{n,n+1})$. Give $X$ the inductive limit topology $T$, and identify $X_n$ with a (closed) subset of $X$ for each $n$. If $(x_k)$ is a sequence in $X$, $x \in X$, then $x_k \to x$ in the $T$-topology if and only if there is an $n$ such that $x_k \in X_n$ for all $k$, $x \in X_n$, and $x_n \to x$ in $X_n$.

XI.14.3.6. Caution: Suppose $(X_i, \phi_{i,j})$ is a direct system of topological spaces, and for each $i$ we have $Y_i \subseteq X_i$, with $\phi_{i,j}(Y_i) \subseteq Y_j$ for $i < j$. Set $\psi_{i,j} = \phi_{i,j}|Y_i : Y_i \to Y_j$ for $i < j$. Give $Y_i$ the induced topology from $X_i$. Then $(Y_i, \psi_{i,j})$ is a direct system of topological spaces. If $\beta_i$ is the inclusion map of $Y_i$ into $X_i$ for each $i$, there is an induced map $\beta : Y \to X$, where $(X, \phi_{i,j}) = \lim(X_i, \phi_{i,j})$ and $(Y, \psi_i) = \lim(Y_i, \psi_{i,j})$. The map $\beta$ is injective by XI.14.1.12. and continuous by XI.14.3.2.

However, $\beta$ is not a homeomorphism onto its image in general. For example (from [Dug78]), let each $X_n$ be $[0, 1]$ with its usual topology, and let $\phi_{n,n+1}$ be the identity map. Let $Y_n = \{0\} \cup \left(\frac{1}{n}, 1\right]$. Then $X$ and $Y$ can both be identified with $[0, 1]$ with $\beta$ the identity map. $X$ has the usual topology on $[0, 1]$, but $Y$ has a strictly stronger topology, since $\{0\}$ is open in $Y$.

Thus direct limits of topological spaces do not commute with taking subspaces in general.

XI.14.4. Inverse Limits in Topology

XI.14.4.1. Inverse limits in topology are somewhat better behaved than direct limits. Suppose $(X_i, \phi_{i,i})$ is an inverse system over a directed set $I$, and each $X_i$ is a topological space and all $\phi_{j,i}$ are continuous. Since the inverse limit $(X, \phi_i)$ is constructed as a subset of the Cartesian product, the obvious topology to use on $X$ is the restriction of the product topology; this coincides with the topology defined by the maps $\phi_i$ (weakest topology for which all $\phi_i$ are continuous; cf. ())). This topology is called the inverse limit topology, but is rarely referred to by name since it is the only reasonable topology on the inverse limit. Another way to describe this topology is: if $(x_\sigma)$ is a net in $X$ and $x \in X$, then $x_\sigma \to x$ in $X$ if and only if $\phi_i(x_\sigma) \to \phi_i(x)$ in $X_i$ for all $i$ ()).
Thus $\varphi$: inverse system of topological spaces. If $i < j$

Suppose its image in the inverse limit case, as follows immediately from the fact that if $\lim_i x_i = x_i$. An inverse limit of a sequence of metrizable spaces is metrizable. These separation properties are preserved under products and taking subspaces. Normality is not, however, preserved in general. An inverse limit of a sequence of metrizable spaces do commute with taking subspaces.

If each $X_i$ is Hausdorff (resp. $T_0$, $T_1$, regular, completely regular), so is the inverse limit, since these separation properties are preserved under products and taking subspaces. Normality is not, however, preserved in general. An inverse limit of a sequence of metrizable spaces is metrizable.

**XI.14.4.3.** Inverse limits behave better than direct limits with respect to taking subspaces. Suppose $(X_i, \phi_{j,i})$ is an inverse system of topological spaces, and for each $i$ we have $Y_i \subseteq X_i$, with $\phi_{j,i}(Y_j) \subseteq Y_i$ for $i < j$. Set $\psi_{j,i} = \phi_{j,i}|_{Y_j} : Y_j \to Y_i$ for $i < j$. Give $Y_i$ the induced topology from $X_i$. Then $(Y_i, \psi_{j,i})$ is an inverse system of topological spaces. If $\beta_i$ is the inclusion map of $Y_i$ into $X_i$ for each $i$, there is an induced map $\beta : Y \to X$, where $(X, \phi_i) = \lim(X_i, \phi_{j,i})$ and $(Y, \psi_i) = \lim(Y_i, \psi_{j,i})$. The map $\beta$ is injective by XI.14.2.13. and continuous by XI.14.4.2. In contrast to the direct limit case (XI.14.3.6.), $\beta$ is a homeomorphism onto its image in the inverse limit case, as follows immediately from the fact that if $\prod_i X_i$ is regarded as a subset of $\prod_i Y_i$, the relative topology on $\prod_i Y_i$ from the product topology on $\prod_i X_i$ is exactly the product topology on $\prod_i Y_i$. Thus inverse limits of topological spaces do commute with taking subspaces.

**XI.14.4.4.** If each $X_i$ is Hausdorff (resp. $T_0$, $T_1$, regular, completely regular), so is the inverse limit, since these separation properties are preserved under products and taking subspaces. Normality is not, however, preserved in general. An inverse limit of a sequence of metrizable spaces is metrizable.

**XI.14.4.5.** Proposition. Let $(X_i, \phi_{j,i})$ be an inverse system of Hausdorff spaces. Then the inverse limit is a closed subset of $\prod_i X_i$.

**Proof:** Let $(x_\sigma)$ be a net in $X = \lim(X_i, \phi_{j,i})$ with $x_\sigma \to x \in \prod_i X_i$. Write $x_\sigma = (\cdots x_\sigma^n \cdots)$, $x = (\cdots x_i \cdots)$. Suppose $i,j \in I$, $i < j$. Then, since coordinate projections are continuous, we have $x_\sigma^j \to x_i$ and $x_\sigma^j \to x_j$. Since $\phi_{j,i}$ is continuous, $x_i^j = \phi_{j,i}(x_\sigma^j) \to \phi_{j,i}(x_j)$. By uniqueness of limits in Hausdorff spaces, $x_i = \phi_{j,i}(x_j)$. Thus $x \in X$.

Combining this result with Tikhonov’s theorem (), we obtain:

**XI.14.4.6.** Corollary. Let $(X_i, \phi_{j,i})$ be an inverse system of compact Hausdorff spaces. Then $\lim(X_i, \phi_{j,i})$ is also a compact Hausdorff space.

**XI.14.4.7.** The conclusion of XI.14.4.5. fails in general if the $X_i$ are not Hausdorff (e.g. if they have the indiscrete topology). But it is nonetheless true that an inverse limit of compact spaces is compact (XI.14.5.6.).

Inverse limits of compact Hausdorff spaces behave somewhat better than general inverse limits. For example:
XI.14.4.8. Proposition. Let \((X_i, \phi_{j,i})\) be an inverse system of compact Hausdorff spaces over a directed set \(I\), and \((X, \phi_i) = \varprojlim(X_i, \phi_{i,j})\). For each \(i\) set \(Y_i = \cap_{j > i} \phi_{j,i}(X_j) \subseteq X_i\). Then for each \(i\) we have that \(\phi_i(X) = Y_i\). In particular, if each \(X_i\) is nonempty, then \(X\) is nonempty.

Proof: (AC) Note that \(Y_i\) is compact, and nonempty if all \(X_i\) are nonempty. Assume all \(X_i\) are nonempty. Fix \(i_0 \in I\), and let \(\mathcal{F}\) be the collection of all finite subsets of \(I\) containing \(i_0\). Let \(x_{i_0} \in Y_{i_0}\). Set \(Z = \prod_{i \in I} X_i\), and for each \(F \in \mathcal{F}\) let \(Z_F\) be the set of all \(\cdots x_i \cdots \) \(\in Z\) such that, whenever \(i, j \in F\), \(i < j\), we have \(x_i = \phi_{j,i}(x_j)\), and \(x_{i_0}\) is the specified element. Then \(Z_F\) is a nonempty compact subset of \(Z\) [choose \(j \in I\) such that \(i < j\) for all \(i \in F\), and let \(x_j \in X_j\) with \(\phi_{j,i_0}(x_j) = x_{i_0}\); set \(x_i = \phi_{j,i}(x_j)\) for each \(i \in F\)]. The collection \(\{Z_F : F \in \mathcal{F}\}\) has the finite intersection property, so the intersection is nonempty, and any point \(x \in \cap F Z_F\) is in the inverse limit \(X\) and satisfies \(\phi_{i_0}(x) = x_{i_0}\). Thus \(\phi_i(X)\) contains \(Y_i\), and the reverse containment is trivial (this containment holds in general inverse limits).

XI.14.4.9. This result fails for general inverse limits (Exercise XI.14.5.6.).

As a companion, it is easy to recognize inverse limits in the compact Hausdorff case:

XI.14.4.10. Proposition. Let \((X_i, \phi_{j,i})\) be an inverse system of compact Hausdorff spaces over a directed set \(I\), and \((X, \phi_i) = \varprojlim(X_i, \phi_{i,j})\). For each \(i\) set \(Y_i = \cap_{j > i} \phi_{j,i}(X_j) \subseteq X_i\). Let \(Y\) be a compact Hausdorff space, and \(\psi\) a compatible family of continuous functions from \(Y\) onto \(Y_i\) (i.e. \(\psi = \phi_{j,i} \circ \psi_j\) for \(i < j\) and \(\psi(Y) = Y_i\) for all \(i\)), which separate points, i.e. if \(y \neq y'\) there is an \(i\) with \(\psi_i(y) \neq \psi_i(y')\). Then \((Y, \psi_i)\) is an inverse limit for \((X_i, \phi_{j,i})\).

Proof: Let \((X, \phi_i) = \varprojlim(X_i, \phi_{j,i})\), and \(\alpha : Y \to X\) the induced map. It suffices to show that \(\alpha\) is a bijection since it is continuous (). Since the \(\psi\) separate points, \(\alpha\) is injective. To show surjectivity, let \(x = (\cdots x_i \cdots) \in X\). Then \(x_i \in Y_i\) for all \(i\). For each \(i\) let \(y_i \in Y\) with \(\psi_i(y_i) = x_i\). Then \((y_i)\) is a net in \(Y\); let \(y\) be a cluster point. Since

\[
\psi_i(y_j) = \phi_{j,i}(\psi_j(y_j)) = \phi_{j,i}(x_j) = x_i
\]

for \(i < j\), we have \(\psi_i(y) = x_i\) for all \(i\) by continuity, so \(\alpha(y) = x\).

XI.14.4.11. Example. For each \(n\) let \(X_n\) be a finite set with \(2^n\) points, with the discrete topology. We may conveniently take \(X_n\) to be the set of all \(n\)-tuples of 0’s and 1’s. Let \(\phi_{n+1,n} : X_{n+1} \to X_n\) be a function for which the inverse image of each point of \(X_n\) consists of exactly two points. For example, we may take

\[
\phi_{n+1,n}((d_1, \ldots, d_n, d_{n+1})) = (d_1, \ldots, d_n)
\]

where \((d_1, \ldots, d_{n+1})\) is an \((n+1)\)’tuple of 0’s and 1’s. The inverse image \((X, \phi_n) = \varprojlim(X_n, \phi_{n+1,n})\) is a compact Hausdorff space which is naturally homeomorphic to the Cantor set: it can be thought of as the set of all sequences of 0’s and 1’s, with the topology of coordinatewise convergence, with

\[
\phi_n((d_1, d_2, \ldots)) = (d_1, \ldots, d_n)
\]

In fact it is easy to conclude from XI.14.4.10. that the Cantor set with these maps is an inverse limit.
XI.14.4.12. **Examples.** Some of the examples from () can be easily written as inverse limits of “nicer” spaces by projection.

(i) Let $X$ be one of the spaces $X_{k}$ of XI.18.4.1. Let $X_{n}$ be the subset of $X$ consisting of the horizontal line and the “whiskers” whose basepoint has $x$-coordinate $\geq \frac{1}{n}$. Define $\phi_{n+1,n} : X_{n+1} \rightarrow X_{n}$ by mapping all the points on the whiskers with basepoint $(\frac{1}{n+1},0)$ to the point $(\frac{1}{n+1},0)$. Then $\lim_{\rightarrow} (X_{n}, \phi_{n+1,n})$ is homeomorphic to $X$, and the map $\phi_{n} : X \rightarrow X_{n}$ just sends all the points of each whisker whose basepoint has $x$-coordinate $< \frac{1}{n}$ to the basepoint of the whisker.

(ii) Similarly, let $X$ be the Hawaiian earring (XI.18.4.6.). Let $X_{n}$ be the subset of $X$ consisting only of the first $n$ circles (with radius $\geq \frac{1}{n}$). Define $\phi_{n+1,n} : X_{n+1} \rightarrow X_{n}$ by mapping all the points on the $(n+1)$'st circle to $(0,0)$. Then $\lim_{\rightarrow} (X_{n}, \phi_{n+1,n})$ is homeomorphic to $X$, and the map $\phi_{n} : X \rightarrow X_{n}$ just sends all the points of each circle of radius $< \frac{1}{n}$ to $(0,0)$. However,

(iii) Let $X$ be the infinite broom (Exercise XI.13.9.9.). For each $n$ let $X_{n}$ be the subset of $X$ consisting only of the line segments from the origin to $((1, \frac{k}{n}))$ for $1 \leq k \leq n$. Define $\phi_{n+1,n} : X_{n+1} \rightarrow X_{n}$ by projecting the $(n+1)$'st line segment upwards onto the $n$'th and leaving the points of $X_{n}$ fixed. Then $X$ is naturally homeomorphic to $\lim_{\rightarrow} (X_{n}, \phi_{n+1,n})$, with $\phi_{n}$ the projection of all segments with right endpoint below $((1, \frac{1}{n}))$ upwards onto the $n$'th segment.

(iv) Let $X$ be the topologist’s sine curve (XI.18.4.3.). Let $X_{n}$ be the subset of $\mathbb{R}^{2}$ obtained by taking the part of $X$ to the right of the vertical line $x = \frac{2}{2n+1}$ and the vertical line segment between $\left(\frac{2}{2n+1},1\right)$ and $\left(\frac{2}{4n+1},1\right)$. Then $X_{n}$ is homeomorphic to $[0,1]$. Define $\phi_{n+1,n} : X_{n+1} \rightarrow X_{n}$ by projecting the points with $x$-coordinates $< \frac{2}{2n+1}$ horizontally to the right onto the line $x = \frac{2}{2n+1}$ and leaving the other points fixed. Then $X$ is naturally homeomorphic to $\lim_{\rightarrow} (X_{n}, \phi_{n+1,n})$, with $\phi_{n}$ the projection of all points with $x$-coordinates $< \frac{2}{4n+1}$ horizontally to the right onto the line $x = \frac{2}{4n+1}$. Thus $X$ is an inverse limit of copies of $[0,1]$. See XI.14.4.18. for more examples of spaces which can be written as inverse limits of copies of $[0,1]$.

XI.14.4.13. **Examples.** For $m \in \mathbb{N}$, write $\mathbb{Z}/m\mathbb{Z}$ for the cyclic group with $m$ elements (we usually denote this group by $\mathbb{Z}_{m}$, but this notation will be reserved for something else here). Let $a = (a_{1}, a_{2}, \ldots)$ be a sequence in $\mathbb{N} \setminus \{1\}$ with $a_{k} | a_{k+1}$ for all $k$. Consider the inverse system

$$
\cdots \xrightarrow{\pi_{4,3}} \mathbb{Z}/a_{3}\mathbb{Z} \xrightarrow{\pi_{3,2}} \mathbb{Z}/a_{2}\mathbb{Z} \xrightarrow{\pi_{2,1}} \mathbb{Z}/a_{1}\mathbb{Z}
$$

where $\pi_{n+1,n}$ is the quotient map from $\mathbb{Z}/a_{n+1}\mathbb{Z}$ to $\mathbb{Z}/a_{n}\mathbb{Z}$. Let $(\mathbb{Z}_{a}, \pi_{n})$ be the inverse limit. Then $\mathbb{Z}_{a}$ is a compact totally disconnected abelian topological group. If $a_{n} = p^{a}$ for a fixed prime $p$, we write $\mathbb{Z}_{p}$ for $\mathbb{Z}_{a}$; $\mathbb{Z}_{p}$ is called the $p$-adic numbers (cf. ()).

There is a natural quotient map $\rho_{n}$ from $\mathbb{Z}$ to $\mathbb{Z}/a_{n}\mathbb{Z}$ for each $n$. The $\rho_{n}$ define a homomorphism $\rho : \mathbb{Z} \rightarrow \mathbb{Z}_{a}$. If $m$ is in the kernel of $\rho$, then $a_{n} | m$ for all $n$, hence $m = 0$ and $\rho$ is injective. But $\rho$ is not surjective: in fact, $\mathbb{Z}_{a}$ has cardinality $2^{\aleph_{0}}$ (it is homeomorphic to the Cantor set by ()). However, $\rho(\mathbb{Z})$ is dense in $\mathbb{Z}_{a}$ (XI.14.4.19.).

The group $\mathbb{Z}_{a}$ is often, but not always, torsion-free (XI.14.5.9.). In particular, $\mathbb{Z}_{p}$ is torsion-free, $\mathbb{Z}_{p}$ and more generally $\mathbb{Z}_{a}$ has a natural structure as a topological ring, but this structure is not easily definable from the inverse limit construction.

There are several results about writing a general space as an inverse limit of “nicer” spaces. For example:
XI.14.4.14. Theorem. Let $X$ be a compact metrizable space. Then there is an inverse system $(X_n, \phi_{n+1,n})$ over $\mathbb{N}$, with each $X_n$ a smooth compact manifold with boundary and $\phi_{n+1,n}$ a smooth map for each $n$, with $X$ homeomorphic to $\lim_{\leftarrow} (X_n, \phi_{n+1,n})$.

Proof: We may identify $X$ with a (compact) subset of the Hilbert cube $(0,1)^n$. Fix a sequence $(\epsilon_n)$ with $0 < \epsilon_{n+1} < \frac{\epsilon_n}{2}$ for all $n$. Let $Y_n$ be the projection of $X$ onto the first $n$ coordinates, and regard $Y_n$ as a subset of $[0,1]^n \subseteq \mathbb{R}^n$. Let $U_n$ be a neighborhood of $Y_n$ in $\mathbb{R}^n$ as in XI.23.10.1. with $\epsilon = \epsilon_n$, and set $X_n = U_n$.

Since the projection from $\mathbb{R}^{n+1}$ to $\mathbb{R}^n$ is a contraction, it maps $X_{n+1}$ into $X_n$. Let $\phi_{n+1,n}$ be the restriction of the projection map to $X_{n+1}$. Then $(X_n, \phi_{n+1,n})$ is an inverse system of smooth compact manifolds with boundary, with smooth connecting maps.

We show that $X$ is homeomorphic to $\lim (X_n, \phi_{n+1,n})$. For each $n$ let $\psi_n$ be the restriction to $X$ of the projection from the Hilbert cube to $[0,1]^n$; then $\psi_n(X) = Y_n$ by definition of $Y_n$, and the conditions of XI.14.4.10. are satisfied.

If $X$ is a compact subset of $\mathbb{R}^m$, a simplified version of the argument shows that the $X_n$ can be taken to be $m$-dimensional.

XI.14.4.15. There are two drawbacks to this result, however:

(i) The connecting maps are not surjective.

(ii) If $X$ is finite-dimensional, the dimensions of the $X_n$ may be much larger than $\text{dim}(X)$. (If $\text{dim}(X) = d$, $X$ embeds in $\mathbb{R}^{2d+1}$ by the Whitney Embedding Theorem, so the $X_n$ can be chosen to have dimension $\leq 2d + 1$.)

These difficulties cannot be avoided if one wants to write $X$ as an inverse limit of smooth manifolds with boundary. But if we slightly more generally allow the $X_n$ to be polyhedra, we can do better:

XI.14.4.16. Theorem. Let $X$ be a compact metrizable space. Then there is an inverse system $(X_n, \phi_{n+1,n})$ over $\mathbb{N}$, with each $X_n$ a polyhedron and $\phi_{n+1,n}$ a surjective piecewise-linear map for each $n$, with $X$ homeomorphic to $\lim_{\leftarrow} (X_n, \phi_{n+1,n})$. If $\text{dim}(X) = d < \infty$, then the $X_n$ can be chosen so that $\text{dim}(X_n) = d$ for all $n$.

The proof is involved and uses some machinery, and will be given in (). This result was first proved by H. Freudenthal in 1937 [Fre37]. The examples in XI.14.4.11. and XI.14.4.12. are examples of writing compact metrizable spaces as inverse limits of polyhedra.

XI.14.4.17. Examples. (Solenoids.) Let $T$ be the unit circle in the plane, regarded as the compact topological group of complex numbers of absolute value 1. For each $n$, let $X_n = T$ and $\phi_{n+1,n} : X_{n+1} \to X_n$ defined by $\phi_{n+1,n}(z) = z^2$. Then $(X_n, \phi_{n+1,n})$ is an inverse system of compact Hausdorff spaces. Let $(X, \phi_n) = \lim_{\leftarrow} (X_n, \phi_{n+1,n})$. Then $X$ has a natural structure as a compact Hausdorff space which is an abelian topological group (XI.14.5.2.). In fact, it is easily seen using XI.14.4.10. that $X$ is homeomorphic to the solenoid () of type $2^\infty$. Thus a solenoid is homeomorphic to an inverse limit of circles.

The circle $T$ can be regarded as $\mathbb{R}/m\mathbb{Z}$ for any $m \in \mathbb{N}$. Thus we may regard the above $X$ as

$$\lim_{\leftarrow} (\mathbb{R}/2^{n-1}\mathbb{Z}, \pi_{n+1,n})$$
where \( \pi_{n+1,n} : \mathbb{R}/2^n \mathbb{Z} \to \mathbb{R}/2^{n-1} \mathbb{Z} \) is the natural quotient map. We have a commutative diagram

\[
\begin{array}{cccc}
\ldots & \xrightarrow{\pi} & \mathbb{R} & \xrightarrow{\pi} & \mathbb{R} & \xrightarrow{\pi} & \mathbb{R} & \xrightarrow{\pi} & \mathbb{R} \\
\ldots & \xrightarrow{\pi_{n+1,n}} & \mathbb{R}/2^n \mathbb{Z} & \xrightarrow{\pi_{n,n-1}} & \mathbb{R}/2^{n-1} \mathbb{Z} & \xrightarrow{\pi_{n-1,n-2}} & \mathbb{R}/2^{n-2} \mathbb{Z} & \xrightarrow{\pi_{n-2,n-3}} & \mathbb{R}/2^{n-3} \mathbb{Z}
\end{array}
\]

which induces a continuous group homomorphism \( \alpha : \mathbb{R} \to X \), which is injective. The range of \( \alpha \) is dense in \( X \) by XI.14.4.19, but is not all of \( X \): the range consists of all threads \( (x_n) \), where \( x_n \to 1 \) in \( T \) when \( \mathbb{R}/2^{n-1} \mathbb{Z} \) is identified with \( T \). Also, \( \alpha \) is not a homeomorphism onto its image: for example, we have \( \alpha(2^n) \to \alpha(0) \) in \( X \). In fact, the range of \( \alpha \), which is a subgroup of \( X \), is exactly the path component of the identity of \( X \). The other path components of \( X \) are exactly the cosets of \( \alpha(\mathbb{R}) \) in \( X \).

The other solenoids can be constructed by taking \( \phi_{n+1,n}(z) = z^{k_n} \) for a sequence \( (k_n) \) in \( \mathbb{N} \setminus \{1\} \).

**XI.14.4.18. Examples.**
1. **Knaster bucket-handle.** (cf. XI.18.4.28.) The Knaster bucket-handle can be written as an inverse limit of copies of \([0,1]\) by taking for each \( \phi_{n+1,n} \) the piecewise-linear map from \([0,1]\) to \([0,1]\) with \( \phi_{n+1,n}(0) = \phi_{n+1,n}(1) = 0 \) and \( \phi_{n+1,n} \left( \frac{1}{2} \right) = 1 \).

Other bucket-handles can be constructed similarly as inverse limits by taking a sequence \( (k_n) \) of natural numbers \( \geq 2 \) and letting \( \phi_{n+1,n} \) be the sawtooth function taking values 0 and 1 alternately at the numbers \( \frac{m}{2^{k_n+1}} \). The homeomorphism class of the bucket-handle is exactly determined by the equivalence class (XI.18.4.21) of the supernatural number \( \prod n k_n \). There is a qualitative difference between bucket-handles for which infinitely many \( k_n \) are even and ones with only finitely many even \( k_n \) (up to equivalence, ones with all \( k_n \) odd): the latter have two “endpoints” while the former have only one.

2. **Pseudo-Arc.** The pseudo-arc (XI.18.4.29) can also be written as an inverse limit of copies of \([0,1]\).

The maps \( \phi_{n+1,n} \) can also be taken to be piecewise-linear, but zigzag up and down similarly to the definition of a crooked embedding:

See [\( \square \) for details.

**XI.14.4.19. Proposition.** Let \( (X_i, \phi_{j,i}) \) be an inverse system of topological spaces, and \( (X, \phi_i) = \lim (X_i, \phi_{j,i}) \). If \( D \subseteq X \), then \( D \) is dense in \( X \) if and only if \( \phi_i(D) \) is dense in \( \phi_i(X) \subseteq X_i \) for all \( i \).

**Proof:** If \( D \) is dense in \( X \), then \( \phi_i(D) \) is dense in \( \phi_i(X) \) for all \( i \) by (\( \square \)). Conversely, suppose \( \phi_i(D) \) is dense in \( \phi_i(X) \) for each \( i \). Fix \( x \in X \). Let \( J \) be the set of all triples \((i, U, y)\), where \( i \in I \), \( U \) is an open neighborhood of \( \phi_i(x) \) in \( X_i \), and \( y \in D \), \( \phi_i(y) \in U \). Set \((i, U, y) < (i', V, y') \) if \( i < i' \) and \( \phi_{i',i}(V) \subseteq U \). Then \( J \) is a directed set. For \( j = (i, U, y) \in J \) set \( y_j = y \). Then \((y_j)\) is a net in \( D \), and \( y_j \to x \) since \( \phi_i(y_j) \to \phi_i(x) \) for all \( i \). Thus \( D \) is dense in \( X \).

In particular, if \( \phi_i(D) = X_i \) for all \( i \), then \( D \) is dense in \( X \) (this has a simplified direct proof using \( AC \)); but \( D \) can be a proper subset of \( X \) (XI.14.4.17).
XI.14.5. Exercises

XI.14.5.1. Modify the definition of direct and inverse systems and limits by also defining \( \phi_{i,i} \) to be the identity map on \( X_i \) for each \( i \), and replacing \( < \) by \( \leq \) throughout. Show that this modified definition also works over directed sets which are not properly directed. Describe the limit if the index set is not properly directed.

XI.14.5.2. (a) Let \( I \) be a directed set and \( G_i \) a group for each \( i \), with \( \phi_{i,j} : G_i \to G_j \) a homomorphism for \( i < j \). Let \( (G, \phi_i) = \lim \rightarrow (G_i, \phi_{i,j}) \). Show that \( G \) has a unique group structure making each \( \phi_i \) a homomorphism.

(b) If each \( G_i \) is abelian, show that \( G \) is abelian. What about the converse?

(c) Do the same if each \( G_i \) is a ring, vector space, or topological group.

(d) Do the analog of (a)–(c) for inverse systems and limits.

XI.14.5.3. [Dug78] Let \( T \) be the unit circle in the plane, regarded as the compact topological group of complex numbers of absolute value 1. For each \( n \), let \( X_n = T \) and \( \phi_{n,n+1} : X_n \to X_{n+1} \) defined by \( \phi_{n,n+1}(z) = z^n \). Then \( (X_n, \phi_{n,n+1}) \) is a direct system of compact Hausdorff spaces. Let \( (X, \phi_n) = \lim \rightarrow (X_n, \phi_{n,n+1}) \). Then \( X \) has a natural structure as a topological group (XI.14.5.2).

(a) Let \( H \) be the subgroup of \( T \) consisting of all roots of unity whose order is a power of 2. Show that \( X \) can be naturally identified with \( T/H \).

(b) Show that the inductive limit topology on \( X \) is the indiscrete topology.

(c) Repeat the exercise if \( \phi_{n,n+1}(z) = z^{k_n} \) for an arbitrary sequence \( (k_n) \) in \( \mathbb{N} \setminus \{1\} \).

XI.14.5.4. Construct an explicit countable subset \( A \) of \( c_0 \) such that 0 is in the closure of \( A \) in the inductive limit topology, but there is no sequence in \( A \) converging to 0. [For \( n, m \in \mathbb{N} \), consider the sequence with first term \( \frac{1}{n} \), \( n \)th term \( \frac{1}{m} \), and all other terms 0.]

XI.14.5.5. (a) Show (using DC) that if \( (X_n, \phi_{n+1,n}) \) is an inverse system of nonempty sets over \( \mathbb{N} \), and each \( \phi_{n+1,n} \) is surjective, and \( (X, \phi_n) = \lim \leftarrow (X_n, \phi_{n+1,n}) \), then \( X \) is nonempty and each \( \phi_n \) is surjective.

(b) (I. Farah) For each \( \alpha < \omega_1 \) let \( X_\alpha \) be the set of all injective functions from \( \alpha \) to \( \mathbb{N} \) for which the complement of the range is finite. If \( \alpha < \beta \), let \( \phi_{\beta,\alpha} : X_\beta \to X_\alpha \) be defined by \( \phi_{\beta,\alpha}(f) = f|_\alpha \). Then \( (X_\alpha, \phi_{\beta,\alpha}) \) is an inverse system of nonempty sets over the directed (well-ordered) set \( \omega_1 \). Show that each connecting map \( \phi_{\beta,\alpha} \) is surjective, but \( \lim \leftarrow (X_\alpha, \phi_{\beta,\alpha}) = \emptyset \).

XI.14.5.6. (a) If \( (X_i, \phi_{j,i}) \) is an inverse system of nonempty compact spaces, show that the inverse limit can be empty if the \( X_i \) are not Hausdorff. [Give the sets in XI.14.2.7.(iii) or XI.14.5.5.(b) the indiscrete topology or the finite complement topology.]

(b) Prove (using AC) that an inverse limit of compact spaces is compact (regarding \( \emptyset \) as a compact space) by adapting the proof of Tikhonov’s theorem.
XI.14.5.7. Let \((X_n, \phi_{n+1,n})\) be an inverse system over \(\mathbb{N}\) of nonempty finite sets with the discrete topology, and \((X, \phi_n) = \lim\limits_{\mathcal{I}} (X_n, \phi_{n+1,n})\).

(a) If \(\phi_{n+1,n}^{-1}(p)\) has at least two elements for each \(n\) and each \(p \in X_n\), show that \(X\) is homeomorphic to the Cantor set \([use()\]).

(b) Let \(X_n = \{k \in \mathbb{N} : k \leq n\}\), and define \(\phi_{n+1,n}(k) = k\) for \(k \leq n\), \(\phi_{n+1,n}(n + 1) = n\). Show that \(\lim\limits_{\mathcal{I}} (X_n, \phi_{n+1,n})\) is naturally homeomorphic to the one-point compactification of \(\mathbb{N}\) (equivalently, to \(\{0\} \cup \{\frac{1}{n} : n \in \mathbb{N}\} \subseteq \mathbb{R}\)).

XI.14.5.8. Let \(G\) be a group, \(I\) a directed set, and \(\{H_i : i \in I\}\) a collection of normal subgroups of \(G\) with \(H_j \subseteq H_i\) for \(i < j\). Set \(G_i = G/H_i\) for all \(i\). Then there is a natural quotient map \(\pi_j, i : G_j = G/H_j \to G/H_i = G_i\) for \(i < j\), and \((G_i, \pi_j, i)\) is an inverse system of groups. Set \((\hat{G}, \pi_i) = \lim\limits_{\mathcal{I}} (G_i, \pi_j, i)\). Then \(\hat{G}\) is a group, and there is a homomorphism \(\alpha : G \to \hat{G}\).

(a) Show that the kernel of \(\alpha\) is exactly \(\cap_i H_i\). In particular, \(\alpha\) is injective if (and only if) \(\cap_i H_i = \{e_G\}\).

(b) Show that \(\alpha\) is not surjective in general (cf. XI.14.4.13., XI.14.4.17.).

(c) If each \(G_i\) has a topology making it into a compact (Hausdorff) topological group, with the \(\pi_j, i\) continuous, then \(\hat{G}\) is a compact (Hausdorff) topological group in the inverse limit topology.

(d) If each \(G_i\) is finite, give \(G_i\) the discrete topology. Then \(\hat{G}\) is a compact totally disconnected (zero-dimensional) topological group. Every compact totally disconnected topological group arises in this manner as an inverse limit of finite groups ()

We may regard \(\hat{G}\) as a “completion” of \(G\) with respect to the subgroups \(H_i\). The examples of XI.14.4.13., XI.14.4.17., and ?? are special cases.

XI.14.5.9. Let \(\mathbb{Z}_a\) be the \(a\)-adic numbers as defined in XI.14.4.13. Show that \(\mathbb{Z}_a\) is torsion-free if and only if the supernatural number \(a_1 \prod_n a_n = \lim_{n \to \infty} a_n\) has all exponents either 0 or \(\infty\). [Use that \(\mathbb{Z}/mn\mathbb{Z} \cong \mathbb{Z}/m\mathbb{Z} \times \mathbb{Z}/n\mathbb{Z}\) if \(m\) and \(n\) are relatively prime () and XI.14.5.11.]

XI.14.5.10. Work out the details of writing the Cantor set, the Hawaiian earring, the infinite broom, the topologist’s sine curve, solenoids, Knaster bucket-handles, and the pseudo-arc as inverse limits as described in XI.14.4.11., XI.14.4.12., XI.14.4.17., and XI.14.4.18..

XI.14.5.11. Let \(I\) be an infinite index set (not ordered or directed). For each \(i \in I\), let \(X_i\) be a set. Let \(\mathcal{F}\) be the set of all finite subsets of \(I\), directed by inclusion. For each \(F \in \mathcal{F}\), define

\[Z_F = \prod_{i \in F} X_i\]

and if \(F \subseteq G \in \mathcal{F}\), let \(\pi_{G,F} : Z_G \to Z_F\) be the projection onto the coordinates in \(F\). Show that

\[\left(\prod_{i \in I} X_i, \pi_F\right)\]

is an inverse limit for \((Z_F, \pi_F)\), where \(\pi_F\) is the natural projection from \(\prod_{i \in I} X_i\) onto \(\prod_{i \in F} X_i\). If each \(X_i\) is a topological space, show that the inverse limit topology is the product topology.
Thus, once finite Cartesian products have been defined, infinite Cartesian products may be regarded as a special case of inverse limits. (However, this is not a logically sound way to define infinite Cartesian products, since infinite Cartesian products are used to construct inverse limits so there is a circularity problem.)

XI.14.5.12. Restricted Direct Products. Let $I$ be an infinite index set (not ordered or directed). For each $i \in I$, let $X_i$ be a locally compact Hausdorff space and $Y_i$ a compact open (hence clopen) subset of $X_i$. Let $\mathcal{F}$ be the set of all finite subsets of $I$, directed by inclusion. For each $F \in \mathcal{F}$, define

$$Z_F = \left\{ (\cdots, x_i, \cdots) \in \prod_{i \in I} X_i : x_i \in Y_i \text{ for all } i \notin F \right\} \subseteq \prod_{i \in I} X_i$$

and give $Z_F$ the restriction of the product topology. Then

$$Z_F \cong \prod_{i \in F} X_i \times \prod_{i \in I \setminus F} Y_i$$

and thus $Z_F$ is locally compact by (a). If $F \subseteq G \in \mathcal{F}$, the inclusion $\phi_{F,G}$ of $Z_F$ into $Z_G$ is a homeomorphism onto a clopen subset of $Z_G$. Let

$$(Z, \phi_F) = \lim\downarrow (Z_F, \phi_{F,G})$$

with the inductive limit topology. $Z$ is called the restricted direct product of the $X_i$ with respect to the $Y_i$, denoted

$$Z = \prod_{i \in I} (X_i, Y_i).$$

(a) As a set, $Z$ can be identified with the subset $\cup_F Z_F$ of $\prod_i X_i$, the set of tuples $(\cdots, x_i, \cdots)$ with $x_i \in Y_i$ for all but finitely many $i$.

(b) Show that $Z$ is locally compact and the image $\phi_F(Z_F)$ of $Z_F$ is a clopen subset (homeomorphic to $Z_F$) for each $F \in \mathcal{F}$.

(c) Show that the inductive limit topology on $Z$ is strictly stronger than the restriction to $Z$ of the product topology if $Y_i \neq X_i$ for infinitely many $i$. [The image $\phi_F(Z_F)$ is not open in $Z$ in the product topology.]

Restricted direct products are often used where the $X_i$ have additional structure such as a topological group (a). Here is one especially important application. The completions of the rational numbers $\mathbb{Q}$ to topological fields are precisely $\mathbb{R}$ and the $p$-adic numbers $\mathbb{Q}_p$ for primes $p$. Each of these is locally compact. The topological field $\mathbb{Q}_p$ contains the ring $\mathbb{Z}_p$ of $p$-adic integers as a compact open subring. Form

$$\mathbb{A}_\mathbb{Q} = \mathbb{R} \times \prod_p (\mathbb{Q}_p, \mathbb{Z}_p)$$

which is naturally a locally compact topological ring, called the ring of adeles of $\mathbb{Q}$. There is a natural embedding of $\mathbb{Q}$ into $\mathbb{A}_\mathbb{Q}$, whose image turns out to be dense. A similar construction can be done for any algebraic number field (finite extension of $\mathbb{Q}$). Rings of adeles are important in number theory; cf. \[.].
XI.14.5.13. (a) If $X$ and $Y$ are sets, use the notation $Y^X$ for the set of all functions from $X$ to $Y$. If $(X_i, \phi_{i,j})$ is a direct system of sets over $I$, and $Y$ is a set, for $i < j$ define $\phi_{i,j}^*: Y^{X_i} \to Y^{X_j}$ by

$$\phi_{i,j}^*(f) = f \circ \phi_{i,j}.$$ 

Then $(Y^{X_i}, \phi_{i,j}^*)$ is an inverse system of sets over $I$. If $(X, \phi)$ is a direct limit for $(X_i, \phi_{i,j})$, show that $(Y^X, \phi^*)$ is an inverse limit for $(Y^{X_i}, \phi_{i,j}^*)$, where $\phi^*(f) = f \circ \phi$. Thus we may write

$$\lim_{\text{inv}} (Y^{X_i}, \phi_{i,j}^*) \cong Y^{\lim_{\text{inv}} (X_i, \phi_{i,j})}.$$ 

(b) If $X$ and $Y$ are topological spaces, use the notation $Y^X$ for the set of all continuous functions from $X$ to $Y$. If $(X_i, \phi_{i,j})$ is a direct system of topological spaces over $I$, and $Y$ is a topological space, for $i < j$ define $\phi_{i,j}^*: Y^{X_j} \to Y^{X_i}$ by

$$\phi_{i,j}^*(f) = f \circ \phi_{i,j}.$$ 

Then $(Y^{X_i}, \phi_{i,j}^*)$ is an inverse system of topological spaces over $I$. If $(X, \phi)$ is a set-theoretic direct limit for $(X_i, \phi_{i,j})$, show that $(Y^X, \phi^*)$ is a set-theoretic inverse limit for $(Y^{X_i}, \phi_{i,j}^*)$, where $\phi^*(f) = f \circ \phi$. If all the spaces of functions are given the topology of pointwise convergence, show that the topology on $Y^X$ is the inverse limit topology.

(c) If $(X_i, \phi_{j,i})$ is an inverse system of sets over $I$, and $Y$ is a set, for $i < j$ define $\phi_{i,j}^*: Y^{X_i} \to Y^{X_j}$ by

$$\phi_{i,j}^*(f) = f \circ \phi_{j,i}.$$ 

Then $(Y^{X_i}, \phi_{i,j}^*)$ is a direct system of sets over $I$. If $(X, \phi)$ is an inverse limit for $(X_i, \phi_{j,i})$, is it true that $(Y^X, \phi^*)$ is a direct limit for $(Y^{X_i}, \phi_{i,j}^*)$, where $\phi^*(f) = f \circ \phi$? What is the relation between the two? What if the sets are topological spaces with modifications as in (b)?
XI.15. Uniform Structures

The theory of uniform structures fits somewhere between the theories of metric spaces and topological spaces. They are more general than metric spaces, but similarly give notions of uniform convergence and uniform continuity which are absent in general topological spaces. There is an underlying topology defined by a uniform structure, but the uniform structure is finer than the underlying topology since in general many different uniform structures can give the same topology, just as with metrics. Not every topology comes from a uniform structure; the ones that do turn out to be precisely the completely regular topologies.

There are two seemingly different standard approaches to the theory of uniform structures which turn out to be equivalent. One is based on metric spaces, the other on topological groups. The second approach seems more general, and it is remarkable that the two are actually the same.

The first approach uses a suitable family of pseudometrics. In the second approach, a uniform structure on a set \( X \) is a set of “neighborhoods” of the diagonal \( \Delta = \{(x, x) : x \in X\} \) in \( X \times X \), satisfying certain natural properties. Such a neighborhood \( W \) gives a uniform notion of closeness in \( X \): \( x \) and \( y \) are “\( W \)-close” if \( (x, y) \in W \). The two prototype examples of such systems are:

(i) If \( (X, \rho) \) is a metric space, then for every \( \epsilon > 0 \) there is a corresponding “neighborhood”

\[
W_{\rho, \epsilon} = \{(x, y) : \rho(x, y) < \epsilon\}
\]

of \( \Delta \) in \( X \times X \).

(ii) If \( X \) is a topological group, and \( U \) is a neighborhood of the identity element in \( X \), then there is a corresponding “neighborhood”

\[
W_U = \{(x, y) : xy^{-1} \in U\}
\]

of \( \Delta \) in \( X \times X \).

If \( X = \mathbb{R} \), these two types of neighborhoods are essentially the same if \( \mathbb{R} \) is regarded as a metric space with the standard metric, or as a topological group under addition; a typical “neighborhood” of \( \Delta \) is

\[
\{(x, y) \in \mathbb{R}^2 : |x - y| < \epsilon\}
\]

for some fixed \( \epsilon > 0 \), which is geometrically an open strip of uniform width around the line \( y = x \).

XI.15.1. Topologies and Uniform Structures Defined by Pseudometrics

A straightforward but powerful generalization of a metric space is a space with a family of pseudometrics. Recall () that a pseudometric on a set \( X \) is a function \( \rho : X \times X \to [0, \infty) \) with all the properties of a metric except that \( \rho(x, y) = 0 \) does not necessarily imply that \( x = y \).

XI.15.1.1. A family of pseudometrics on a set \( X \) is simply a set \( \mathcal{P} = \{\rho_i : i \in I\} \) of pseudometrics on \( X \). The family \( \mathcal{P} \) is called separating if \( \rho_i(x, y) = 0 \) for all \( i \) implies that \( x = y \), i.e. for any distinct \( x, y \in X \) there is an \( i \) such that \( \rho_i(x, y) > 0 \).

Note that a single metric on a set can be regarded as a separating family of pseudometrics with one element.
XI.15.1.2. To each pseudometric \( \rho \) on a set \( X \) we can associate open balls \( B^\rho_\epsilon(x) = \{ y \in X : \rho(x, y) < \epsilon \} \), just as in the metric case. If we have a family \( \mathcal{P} \) of pseudometrics, we may take the set of all open balls with respect to the pseudometrics in \( \mathcal{P} \) as a subbase for a topology, called the **topology induced by \( \mathcal{P} \)**, denoted \( T_\mathcal{P} \). These open balls do not form a base for \( T_\mathcal{P} \) in general if \( \mathcal{P} \) contains more than one pseudometric, but finite intersections do, i.e. sets of the form

\[
B^F_\epsilon(x) = \{ y \in X : \rho_i(x, y) < \epsilon \text{ for all } i \in F \}
\]

where \( F \) is a finite subset of \( I \) and \( \epsilon > 0 \), form a base for \( T_\mathcal{P} \), i.e. a subset \( U \) of \( X \) is open if and only if, for every \( x \in U \), there is a finite subset \( F \) of \( I \) and \( \epsilon > 0 \) such that \( B^F_\epsilon(x) \subseteq U \). (We will also use the analogous notation \( B^F_\epsilon(x) \), for a finite subset \( F \) of \( \mathcal{P} \).)

Exactly as in the metric case (), using the triangle inequality every open ball has this property, hence is an open set.

XI.15.1.3. Convergence in the topology \( T_\mathcal{P} \) is easily described. If \( (x_i) \) is a net in \( X \) and \( x_0 \in X \), then \( x_i \to x \) in \( (X, T_\mathcal{P}) \) if and only if \( \rho(x_i, x) \to 0 \) for every \( \rho \in \mathcal{P} \), i.e. if and only if for every \( \rho \in \mathcal{P} \) and \( \epsilon > 0 \) there is an \( i_0 \) such that \( \rho(x_i, x) < \epsilon \) for all \( i \geq i_0 \).

The next observation generalizes the fact that a metrizable topology is Hausdorff:

XI.15.1.4. **Proposition.** Let \( \mathcal{P} \) be a family of pseudometrics on a set \( X \). Then the following are equivalent:

(i) \( T_\mathcal{P} \) is \( T_0 \).

(ii) \( T_\mathcal{P} \) is Hausdorff.

(iii) \( \mathcal{P} \) is **separating**.

**Proof:** If \( \mathcal{P} \) is separating, for any \( x, y \in X \), \( x \neq y \), let \( \rho \in \mathcal{P} \) with \( \rho(x, y) > 0 \), and set \( \epsilon = \frac{\rho(x, y)}{2} \). Then \( B^\rho_\epsilon(x) \) and \( B^\rho_\epsilon(y) \) are disjoint open neighborhoods of \( x \) and \( y \), so \( T_\mathcal{P} \) is Hausdorff. If \( \mathcal{P} \) is not separating, let \( x, y \in X \), \( x \neq y \), with \( \rho(x, y) = 0 \) for all \( \rho \in \mathcal{P} \). Then any open set containing \( x \) also contains \( y \) and vice versa, so \( T_\mathcal{P} \) is not \( T_0 \).

Uniform Domination and Saturated Families

We need some tools to compare families of pseudometrics, generalizations of the notions of uniform domination and uniform equivalence of metrics ()

XI.15.1.5. **Definition.** Let \( \rho_1, \ldots, \rho_n, \sigma \) be pseudometrics on a set \( X \). Then \( \sigma \) is **uniformly dominated by \( \{\rho_1, \ldots, \rho_n\} \)** if for every \( \epsilon > 0 \) there is a \( \delta > 0 \) such that, whenever \( x, y \in X \) and \( \rho_k(x, y) < \delta \) for \( 1 \leq k \leq n \), then \( \sigma(x, y) < \epsilon \).

If \( \mathcal{P} \) is a family of pseudometrics on \( X \), then \( \sigma \) is **uniformly dominated by \( \mathcal{P} \)** if for every \( \epsilon > 0 \) there is a \( \delta > 0 \) and a finite subset \( \{\rho_1, \ldots, \rho_n\} \) of \( \mathcal{P} \) such that, whenever \( x, y \in X \) and \( \rho_k(x, y) < \delta \) for \( 1 \leq k \leq n \), then \( \sigma(x, y) < \epsilon \).
XI.15.1.6. Proposition. Let \( \mathcal{P} \) be a family of pseudometrics on a set \( X \). Then there is a smallest saturated family \( \mathcal{P} \) of pseudometrics on \( X \) containing \( \mathcal{P} \). \( \mathcal{P} \) consists precisely of all pseudometrics on \( X \) which are uniformly dominated by \( \mathcal{P} \).

If \( \mathcal{Q} \) is another family of pseudometrics on \( X \), then \( \mathcal{Q} \) is uniformly dominated by \( \mathcal{P} \) if and only if \( \mathcal{Q} \subseteq \mathcal{P} \), and \( \mathcal{P} \) and \( \mathcal{Q} \) are uniformly equivalent if and only if \( \mathcal{P} = \mathcal{Q} \). In particular, \( \mathcal{P} \) and \( \mathcal{P} \) are uniformly equivalent.

The proof is left as an exercise (Exercise ())).

XI.15.1.7. Proposition. Let \( \mathcal{P} \) and \( \mathcal{Q} \) be families of pseudometrics on a set \( X \). If \( \mathcal{Q} \) is uniformly dominated by \( \mathcal{P} \), then \( \mathcal{T}_\mathcal{P} \) is stronger than \( \mathcal{T}_\mathcal{Q} \). If \( \mathcal{P} \) and \( \mathcal{Q} \) are uniformly equivalent, then \( \mathcal{T}_\mathcal{P} = \mathcal{T}_\mathcal{Q} \). In particular, \( \mathcal{T}_\mathcal{P} = \mathcal{T}_\mathcal{P} \).

Proof: Let \( \sigma \in \mathcal{Q}, x \in X, \) and \( \epsilon > 0 \). Choose \( \delta > 0 \) and \( F = \{\rho_1, \ldots, \rho_n\} \) as in the definition. Then \( B_\delta(x) \subseteq B_\epsilon(x) \).

XI.15.1.8. The converse of XI.15.1.7. is false in general: families of pseudometrics generating the same topology need not be uniformly equivalent, even if they are singletons (metrics can be equivalent but not uniformly equivalent ())). Two families of pseudometrics generating the same topology are called equivalent.

Equivalently, but not uniformly equivalent families generate the same topology, but different uniform structures; thus uniform structures are more delicate than topologies.

XI.15.1.9. In light of XI.15.1.7., there is no loss of generality in considering only saturated families of pseudometrics. There is some technical advantage in working with saturated families: for example, the open balls form a base for the underlying topology instead of just a subbase. In fact, the open balls from a saturated family frequently give all, or almost all, of the open sets in the topology (they precisely give all the cozero sets, hence all open \( F_\sigma \)'s if the space is normal). And the \( \epsilon \) can be dispensed with in considering open balls from a saturated family \( \mathcal{P} \): since a saturated family of pseudometrics is closed under nonnegative scalar multiples, any ball of the form \( B_\sigma^\rho(x) \) for \( \rho \in \mathcal{P} \) is of the form \( B_1^\sigma(x) \) for some \( \sigma \in \mathcal{P} \) (specifically, \( \sigma = \epsilon \rho \)), so only balls of radius 1 need be considered.

Uniform Continuity and Uniform Convergence
Bounded Pseudometrics

XI.15.1.10. If \( \rho \) is a pseudometric on a set \( X \), then \( \hat{\rho} \), defined by

\[
\hat{\rho}(x, y) = \min\{\rho(x, y), 1\}
\]
is a bounded pseudometric on $X$ which is uniformly equivalent to $\rho$. So if $\mathcal{P}$ is a family of pseudometrics on $X$, define

$$\tilde{\mathcal{P}} = \{ \tilde{\rho} : \rho \in \mathcal{P} \}.$$ 

Then $\tilde{\mathcal{P}}$ is a family of bounded pseudometrics which is uniformly equivalent to $\mathcal{P}$. (Note, however, that $\tilde{\mathcal{P}}$ is never saturated unless $\mathcal{P} = \{0\}$, so if $\mathcal{P}$ is saturated and nonzero, then $\tilde{\mathcal{P}} \neq \mathcal{P}$; in fact, $\tilde{\mathcal{P}}$ is a proper subset of $\mathcal{P}$ in this case.) Thus we may always work with families of pseudometrics taking values in $[0, 1]$.

**Countably Generated Families of Pseudometrics**

**XI.15.1.11.** If $\mathcal{P} = \{ \rho_1, \rho_2, \ldots \}$ is a countable family of pseudometrics on a set $X$, define a pseudometric $\sigma$ by

$$\sigma(x, y) = \sum_{k=1}^{\infty} 2^{-k} \tilde{\rho}_k(x, y)$$

(it is routine and straightforward to verify that $\sigma$ is a pseudometric).

**XI.15.1.12.** Proposition. The pseudometric $\sigma$ is finitely uniformly dominated by $\mathcal{P}$.

**Proof:** Let $\epsilon > 0$. Choose $n$ so that $2^{-n+1} < \epsilon$. Set $\delta = \frac{\epsilon}{2n}$, and $\mathcal{F} = \{ \rho_1, \ldots, \rho_n \}$. Then, if $x, y \in X$ satisfy $\rho_k(x, y) < \delta$ for $1 \leq k \leq n$, we have

$$\sigma(x, y) = \sum_{k=1}^{n} 2^{-k} \tilde{\rho}_k(x, y) + \sum_{k=n+1}^{\infty} 2^{-k} \tilde{\rho}_k(x, y) < n\delta + 2^{-n} < \epsilon.$$ 

\(\Box\)

**XI.15.1.13.** Conversely, it is obvious that each $\rho_k$ is finitely uniformly dominated by $\mathcal{Q} = \{ \sigma \}$. So $\mathcal{Q}$ is a singleton family which is uniformly equivalent to $\mathcal{P}$, so in particular $T_{\mathcal{Q}} = T_{\tilde{\mathcal{P}}}$. Thus a uniform structure generated by a countable family of pseudometrics is equivalent to the uniform structure generated by a singleton.

The pseudometric $\sigma$ is a metric if and only if $\mathcal{P}$ is separating. Thus the uniform structure generated by a countable separating family of pseudometrics is also generated by a single metric. In particular, a topology defined by a countable separating family of pseudometrics is metrizable.

**XI.15.1.14.** Slightly more generally, a family $\mathcal{P}$ of pseudometrics is *countably generated* if there is a countable family $\mathcal{Q}$ of pseudometrics uniformly equivalent to $\mathcal{P}$. A uniform structure generated by a countably generated family of pseudometrics is also generated by one pseudometric (one metric if the family is separating).

**XI.15.1.15.** So the theory of uniform structures generated by families of pseudometrics is technically only a true generalization of the theory of metric spaces in that it allows families of pseudometrics which are not countably generated (as well as families which are not separating). However, as a practical matter the theory has merit even in the countably generated case: a metrizable space often has no natural metric, and a choice of a metric is arbitrary; but it may, and often does, have a natural family of pseudometrics generating the topology (cf. ())).
Pseudometrics and Real-Valued Continuous Functions

There is an intimate connection between pseudometrics and real-valued continuous functions on a set.

**XI.15.1.16.** Let $X$ be a set. If $f$ is a function from $X$ to $\mathbb{R}$, then there is a naturally associated pseudometric $\rho_f$ defined by

$$\rho_f(x, y) = |f(x) - f(y)|.$$  

Conversely, if $\rho$ is a pseudometric on $X$, and $x \in X$, there is an associated nonnegative real-valued function $f_{\rho, x}$ defined by

$$f_{\rho, x}(y) = \rho(x, y).$$

**XI.15.1.17.** If $f : X \to \mathbb{R}$ is a function, then $f$ is (essentially by definition) uniformly continuous with respect to any family of pseudometrics on $X$ containing $\rho_f$ (and the usual metric on $\mathbb{R}$). Conversely, if $\rho$ is a pseudometric on $X$, then it follows easily from the triangle inequality that, for any $x \in X$, $f_{\rho, x}$ is uniformly continuous with respect to any family of pseudometrics on $X$ containing $\rho$.

**XI.15.1.18.** Proposition. Let $\mathcal{P}$ be a family of pseudometrics on a set $X$. Then $\mathcal{T}_{\mathcal{P}}$ is the weakest topology on $X$ making each function $f_{\rho, x}$ continuous, for all $\rho \in \mathcal{P}$ and $x \in X$.

**XI.15.1.19.** Corollary. Let $\mathcal{P}$ be a separating family of pseudometrics on a set $X$. Then the topology $\mathcal{T}_{\mathcal{P}}$ is completely regular.

**Proof:** The proof is similar to the proof of (). Replacing $\mathcal{P}$ by $\hat{\mathcal{P}}$ if necessary, we may assume every $\rho \in \mathcal{P}$ takes values in $[0, 1]$, so $f_{\rho, x}$ takes values in $[0, 1]$ for all $\rho$ and $x$. Let $\mathcal{S}$ be the set of all $f_{\rho, x}$ for $\rho \in \mathcal{P}$, $x \in X$, and set $Z = [0, 1]^\mathcal{S}$. Then $Z$ is a compact Hausdorff space.

Define $\phi : X \to Z$ as follows. For each $y \in X$, let $\phi(y)$ be the point in $Z$ whose $f_{\rho, x}$th coordinate is $f_{\rho, x}(y) = \rho(x, y)$. Then $\phi$ is continuous for $\mathcal{T}_{\mathcal{P}}$ since its composition with each coordinate map is continuous, and $\phi$ is one-to-one since $\mathcal{P}$ is separating. The restriction of the topology on $Z$ to $\phi(X)$ gives a topology on $\phi(X) \cong X$ which is weaker than $\mathcal{T}_{\mathcal{P}}$ for which each $f_{\rho, x}$ is continuous; thus this topology is exactly $\mathcal{T}_{\mathcal{P}}$, i.e. $\phi$ is a homeomorphism onto its image. Thus $(X, \mathcal{T}_{\mathcal{P}})$ is homeomorphic to a subspace of a compact Hausdorff space.

**XI.15.1.20.** Now let $(X, \mathcal{T})$ be a topological space. Set

$$\mathcal{P}_\infty = \{\rho_f : f \text{ is a continuous function from } X \text{ to } [0, 1]\}$$

(one obtains an equivalent set of seminorms if all continuous functions from $X$ to $\mathbb{R}$ are used). Then the topology $\mathcal{T}_{\mathcal{P}_\infty}$ is weaker than $\mathcal{T}$. It may be strictly weaker: if $\mathcal{P}_\infty$ is separating, i.e. if continuous functions from $X$ to $[0, 1]$ separate points of $X$, then $\mathcal{T}_{\mathcal{P}_\infty}$ is completely regular, but $\mathcal{T}$ need not be completely regular even if it is regular [?, Example 91]. $\mathcal{T}_{\mathcal{P}_\infty}$ is the strongest completely regular topology weaker than $\mathcal{T}$ (if $\mathcal{P}_\infty$ is separating); in particular, $\mathcal{T} = \mathcal{T}_{\mathcal{P}_\infty}$ if $\mathcal{T}$ is completely regular. $\mathcal{P}_\infty$ (actually $\mathcal{P}_\infty$) is the “largest” family of seminorms giving the topology $\mathcal{T}_{\mathcal{P}_\infty}$, in the sense that if $\mathcal{Q}$ is a family of seminorms with $\mathcal{T}_{\mathcal{Q}} = \mathcal{T}_{\mathcal{P}_\infty}$, then $\mathcal{Q}$ is uniformly dominated by $\mathcal{P}_\infty$.  

1189
XI.15.1.21. Even if \((X, \mathcal{T})\) is metrizable, the family \(\mathcal{P}_\infty\) is not countably generated in general, and thus is not uniformly equivalent to a singleton family. Every real-valued continuous function on \((X, \mathcal{T}_{\mathcal{P}_\infty})\) is uniformly continuous with respect to \(\mathcal{P}_\infty\).

XI.15.2. General Uniform Structures
XI.16. Order Topology

XI.16.1. Definition and Properties

XI.16.1.1. Theorem. Any subspace of a space with the order topology is completely normal. In particular, any space with the order topology is normal.

Proof: [Cat06] Let $X$ be an ordered space with the order topology, and let $Y$ be a subspace. We will show that $Y$ has the following stronger property: if $\{A_i : i \in I\}$ is a collection of subsets of $Y$ which are separated, i.e. each $A_i$ is disjoint from the closure (in $Y$) of $\cup_{j \neq i} A_j$, then the $A_i$ have disjoint neighborhoods $V_i$ in $Y$ ($Y$ is said to be completely collectionwise normal).

Note that by (), if the $A_i$ are separated in $Y$, then the $A_i$ are separated in $X$, and if $\{U_i\}$ are disjoint neighborhoods in $X$, and $V_i = U_i \cap Y$, then $\{V_i\}$ are disjoint neighborhoods in $Y$. Thus for the proof we may assume $Y = X$.

Suppose $\{A_i\}$ are separated in $X$ (and in particular disjoint), and set $A = \cup_i A_i$. For each convex component $C$ of $X \setminus A$, choose a point $f(C) \in C$. For $p \in A$, $p$ not the largest point of $X$ (if there is one), choose $t_p \in X$ as follows. There is a $u_p > p$ such that $[p, u_p)$ contains no point of $A \setminus A_i$.

Choose $t_p$ to be a point of $A_i \cap (p, u_p)$ if $A_i \cap (p, u_p)$ is nonempty.

Choose $t_p = u_p$ if $(p, u_p) = \emptyset$.

If $(p, u_p) \neq \emptyset$ but $A_i \cap (p, u_p) = \emptyset$, then $(p, u_p)$ is contained in a unique convex component $C$ of $X \setminus A$; in this case $t_p = f(C)$.

Similarly, if $p$ is not the smallest point of $X$, choose $s_p < p$ in the same manner with inequalities reversed. Set $I_p = (s_p, t_p)$. (If $p$ is the largest point of $X$, set $I_p = (s_p, p]$, and if $p$ is the smallest point of $X$, set $I_p = [p, t_p)$.) Then $I_p$ is an open interval in $X$ containing $p$. This defines $I_p$ for each $p \in A$.

For each $i$, set $U_i = \cup_{p \in A_i} I_p$. Then $U_i$ is an open neighborhood of $A_i$. We claim the $U_i$ are disjoint. If $x \in U_i \cap U_j$ for $i \neq j$, there are $p \in A_i$ and $q \in A_j$ such that $x \in I_p \cap I_q$. We may suppose $p < q$. Then $s_q < x < t_p$. Since $q \notin I_p$ and $p \notin I_q$, $p < s_q < x < t_p < q$. Thus $t_p \in I_q$, and hence $t_p \notin A_i$, and $(p, t_p) \neq \emptyset$. Similarly, $s_q \notin A_j$ and $(s_q, q) \neq \emptyset$. By the way $t_p$ and $s_q$ were selected, we have $t_p = s_q = f(C)$ for the same convex component $C$ of $X \setminus A$, contradicting that $s_q < t_p$. Thus the $U_i$ are disjoint. $\emptyset$

Note that the AC is needed in several places in this proof. In fact, the AC (or something only slightly weaker) is necessary for this result [vD85].

XI.16.2. Completion of an Order Topology
XI.16.3. Function Space Notation and the Compact-Open Topology

There are several notations for function spaces used in the literature, and the usage is not always consistent. There is one predominant notation:

XI.16.3.1. Definition. Let $X$ and $Y$ be topological spaces. Denote by $Y^X$ the set of all maps (continuous functions) from $X$ to $Y$.

XI.16.3.2. The notation $C(X,Y)$ is also frequently used for $Y^X$. Some authors use $Y^X$ to denote the set of all functions from $X$ to $Y$, which we will write $F(X,Y)$. Although it is occasionally useful to consider this set, the set $C(X,Y)$ arises far more often. Our use of $Y^X$ to denote $C(X,Y)$, if done with care, includes all standard examples of this exponential notation:

XI.16.3.3. Examples. (i) If $X$ has the discrete topology, then for any $Y$ we have $Y^X = C(X,Y) = F(X,Y)$. If $X$ and $Y$ are just sets, with no topology, we can consider them to be topological spaces with the discrete topology so the notation $Y^X = F(X,Y)$ used in set theory is consistent with the topological notation. Note that the topology on $Y$ has no effect on the definition of $Y^X$ as a set in this case.

(ii) If $Y$ is a topological space (or just a set, regarded as a topological space with the discrete topology), and $n \in \mathbb{N}$, we can regard $n$ as the subset $\{1, \ldots, n\}$ of $\mathbb{N}$ (or, more commonly and properly in set theory, $\{0,1,\ldots,n-1\} \subseteq \mathbb{N}_0$), with the discrete topology. Then $Y^n$ (in the sense of XI.16.3.1.) is naturally the set of $n$-tuples of elements of $Y$, the usual meaning of $Y^n$. Similarly, $Y^\mathbb{N}$ denotes the set of sequences in $Y$ (where $\mathbb{N}$ has its usual discrete topology). This latter set is often, but somewhat less precisely, denoted $Y^\infty$. (iii) More generally, if $\kappa$ is a cardinal, we denote by $Y^\kappa$ the set of all functions from a set of cardinality $\kappa$ to $Y$. To be precise, we regard $\kappa$ as a set of ordinals as in (i), and give it the discrete topology. This set $Y^\kappa$ can be naturally identified with the Cartesian product of $\kappa$ copies of $Y$.

(iv) If $X$ is a set, the power set $\mathcal{P}(X)$ is often denoted $2^X$. If $X$ is a topological space, $2^X$ is often used to denote the set of closed subsets of $X$. Both notations are consistent with XI.16.3.1. if we give $2 = \{0,1\}$ the Sierpiński space topology with $\{0\}$ open and $\{1\}$ closed. We then identify a continuous function $f : X \to 2$ with the subset $f^{-1}(\{1\})$ of $X$.

XI.16.3.4. Both the notations $Y^X$ and $C(X,Y)$ are slight abuses, since the notation does not reflect the topologies of $X$ and $Y$ which are needed to determine $Y^X$ as a set. (The notation $F(X,Y)$ is not ambiguous.) The abuse is the same as in the common statement “Let $X$ be a topological space.”

XI.16.3.5. If $X$ is a topological space, the set $\mathbb{R}^X = C(X,\mathbb{R})$ is usually denoted $C_\mathbb{R}(X)$. Similarly, $\mathbb{C}^X = C(X,\mathbb{C})$ is usually denoted $C_\mathbb{C}(X)$ or just $C(X)$. Here $\mathbb{R}$ and $\mathbb{C}$ are always assumed to have their usual topologies.

The Compact-Open Topology

There are many important notions of convergence for functions, i.e. many topologies on spaces of functions. The most generally useful topology on $Y^X$ is the “topology of uniform convergence on compact sets” (“u.c. convergence”). If $Y$ is metrizable, or more generally if the topology on $Y$ comes from a uniform structure,
this topology can be defined in a straightforward way; the idea is that a net \((f_i)\) converges to \(f\) if and only if, for every compact subset \(K\) of \(X\), for sufficiently large \(i\) \(f_i(x)\) should be close to \(f(x)\) for all \(x \in K\). Even for a general topological space \(Y\), there is a clean way to define such a topology on \(Y^X\), called the compact-open topology.

**XI.16.3.6.** Definition. Let \(X\) and \(Y\) be topological spaces. The **compact-open topology** on \(Y^X\) is the topology generated by the subbase

\[
\{U_{K,O} : K \subseteq X \text{ compact, } O \subseteq Y \text{ open}\}
\]

\[U_{K,O} = \{f \in Y^X : f(K) \subseteq O\}.\]

**XI.16.3.7.** The set of \(U_{K,O}\) does not give a base for a topology in general; one needs to take finite intersections. So a basic open set for the compact-open topology is defined by taking a finite number of compact sets \(K_1, \ldots, K_n\) in \(X\), a corresponding finite number of open sets \(O_1, \ldots, O_n\) in \(Y\), and taking all maps from \(X\) to \(Y\) such that \(f(K_j) \subseteq O_j\) for \(1 \leq j \leq n\).

To obtain a base for the compact-open topology, it suffices to let the \(O\)'s range over a base for the topology of \(Y\).

The compact-open topology can be described in terms of convergence:

**XI.16.3.8.** Proposition. Let \(X\) and \(Y\) be topological spaces. Then a net \((f_i)\) in \(Y^X\) converges to \(f \in Y^X\) in the compact-open topology if and only if, for every compact subset \(K\) of \(X\), and every open set \(O\) in \(Y\) such that \(f(K) \subseteq O\), there is an \(i_0\) such that \(f_i(K) \subseteq O\) for all \(i \geq i_0\).

The proof is immediate from the definition, and is left to the reader.

Since singleton sets are compact, we obtain:

**XI.16.3.9.** Proposition. Let \(X\) and \(Y\) be topological spaces. If a net \((f_i)\) in \(Y^X\) converges to \(f \in Y^X\) in the compact-open topology, then \(f_i \to f\) pointwise on \(X\), i.e. \(f_i(x) \to f(x)\) for all \(x \in X\).

Proof: Let \(x \in X\). If \(O\) is any neighborhood of \(f(x)\) in \(Y\), then \(f(\{x\}) \subseteq O\), so there is an \(i_0\) such that \(f_i(\{x\}) \subseteq O\) for all \(i \geq i_0\), i.e. \(f_i(x) \in O\) for \(i \geq i_0\). \(\Box\)

**XI.16.3.10.** The compact-open topology is thus stronger than the topology of pointwise convergence; it is usually strictly stronger. But if every compact subset of \(X\) is finite, e.g. if \(X\) is discrete, the two topologies coincide. (There are nondiscrete spaces where every compact subset is finite, e.g. XI.11.12.8.; but such a space cannot have any nontrivial convergent sequences. See ()).

1193
XI.16.3.11.  

**Corollary.** If $Y$ is a topological space and $X$ a set with the discrete topology, then $Y^X$ can be identified with the Cartesian product of $\kappa$ copies of $Y$, where $\kappa = \text{card}(X)$, and the compact-open topology is the product topology.

XI.16.3.12.  

If $X$ and $Y$ are topological spaces, any constant function from $X$ to $Y$ is continuous. The subset $C$ of $Y^X$ of constant functions can be identified with $Y$. It is immediate from the definitions that this identification is a homeomorphism if $C$ is given the relative compact-open topology. If $Y$ is Hausdorff, then $C$ is closed in $Y^X$ in the compact-open topology. (The converse does not hold in general, e.g. if $X$ is a one-point space.)

We now examine separation properties.

XI.16.3.13.  

**Proposition.** Let $X$ and $Y$ be topological spaces. Give $Y^X$ the compact-open topology.

(i) $Y^X$ is Hausdorff if and only if $Y$ is Hausdorff.

(ii) $Y^X$ is regular if and only if $Y$ is regular.

**Proof:** $Y$ is homeomorphic to a subset of $Y^X$ (XI.16.3.12.), so if $Y^X$ is Hausdorff or regular, so is $Y$. Conversely, suppose $Y$ is Hausdorff, and $f$ and $g$ are distinct elements of $Y^X$. Then there is an $x \in X$ with $f(x) \neq g(x)$. Let $O_1$ and $O_2$ be disjoint open neighborhoods of $f(x)$ and $g(x)$ in $Y$. Then $U_{\{x\}, O_1}$ and $U_{\{x\}, O_2}$ are disjoint neighborhoods of $f$ and $g$ in $Y^X$.

Now suppose $Y$ is regular. Let $f \in Y^X$ and $V$ a compact-open neighborhood of $f$. Then there are compact sets $K_1, \ldots, K_n$ in $X$ and open sets $O_1, \ldots, O_n$ in $Y$ with $f(K_j) \subseteq O_j$ for $1 \leq j \leq n$ and

$$U_{K_1, O_1} \cap \cdots \cap U_{K_n, O_n} \subseteq V.$$  

Fix $j$. Since $f(K_j)$ is compact, by (i) there is an open set $O'_j$ in $Y$ with

$$f(K_j) \subseteq O'_j \subseteq \overline{O}'_j \subseteq O_j.$$  

Then $W = U_{K_1, O'_1} \cap \cdots \cap U_{K_n, O'_n}$ is a neighborhood of $f$ in $Y^X$. We claim $W \subseteq V$. Suppose $(g_i)$ is a net in $W$ and $g_i \to g \in Y^X$. If $x \in K_j$, then $g_i(x) \in O'_j$ for all $i$, so $g(x) \in O'_j \subseteq O_j$. Thus $g \in V$.  

XI.16.3.14.  

If $Y$ is normal, then $Y^X$ is not necessarily normal: if $S$ is the Sorgenfrey line (XI.7.8.10.), and $2 = \{0,1\}$ has the discrete topology, then $S$ is normal, but $S^2$ is not normal.

XI.16.3.15.  

**Example.** Let $X$ be a topological space. Consider $2^X$, where 2 has the Sierpiński topology. Then $2^X$ can be identified with the set of closed subsets of $X$ as in XI.16.3.3.(iv). What is the corresponding topology on the collection of closed subspaces? Since 2 is not Hausdorff, limits in $2^X$ will not be unique. If $(E_i)$ is a net of closed subspaces of $X$ and $E$ a closed subspace of $X$, then $E_i \to E$ in this topology if and only if, whenever $K$ is a compact subspace of $X$ disjoint from $E$, then there is an $i_0$ such that $K$ is disjoint
from $E_i$ for all $i \geq i_0$. In particular, if $E_i \to E$, and $x \notin E$, then there is an $i_0$ such that $x \notin E_i$ for any $i \geq i_0$. Thus we have

$$
\bigcap_i \left[ \bigcup_{j \geq i} E_j \right] \subseteq E.
$$

This condition is in general not sufficient to guarantee that $E_i \to E$, however. It is sufficient that

$$
E_0 := \bigcap_i \left[ \bigcup_{j \geq i} E_j \right] \subseteq E
$$

for if $E$ is a closed set containing $E_0$, and $K$ is a compact set disjoint from $E$, then $K$ is disjoint from $E_0$, so if $W_i$ is the complement of $\bigcup_{j \geq i} E_j$ the $W_i$ form an increasing open cover of $K$, which has a finite subcover, i.e. $K \subseteq W_{i_0}$ for some $i_0$. Then $K$ is disjoint from $E_i$ for all $i \geq i_0$. Thus $E_i \to E$.

If every point of $X$ has local base of compact neighborhoods, e.g. if $X$ is a locally compact Hausdorff space, $E_i \to E$, and $x \notin E$, then since $E$ is closed $x$ has a compact neighborhood $K$ disjoint from $E$. Then $K$ is disjoint from $E_i$ for all sufficiently large $i$, so $x \notin E_0$, i.e. $E_0 \subseteq E$. So in this case $E_i \to E$ if and only if $E$ is a closed set containing $E_0$.

We now examine the case where $Y$ is metrizable. In this case, the compact-open topology is precisely the topology of u.c. convergence:

**XI.16.3.16. Proposition.** Let $X$ be a topological space and $(Y, \rho)$ a metric space. If $(f_i)$ is a net in $Y^X$, then $f_i \to f \in Y^X$ if and only if, for every compact subset $K$ of $X$ and every $\epsilon > 0$, there is an $i_0$ such that $\rho(f_i(x), f(x)) < \epsilon$ for all $i \geq i_0$ and all $x \in K$.

**Proof:** Suppose the $\epsilon$-condition is satisfied. Let $K$ be a compact subset of $X$ and $O$ an open set in $Y$. Then, since $f(K)$ is compact, there is an $\epsilon > 0$ such that $\rho(f(x), Y \setminus O) \geq \epsilon$ for all $x \in K$. Fix $i_0$ such that $\rho(f_i(x), f(x)) < \epsilon$ for all $i \geq i_0$ and $x \in K$. Then $f_i(K) \subseteq O$ for all $i \geq i_0$. So $f_i \to f$ in the compact-open topology.

Conversely, if $f_i \to f$ in the compact-open topology, let $K$ be a compact subset of $X$ and $\epsilon > 0$. For each $x \in X$ let $V_x$ be the open ball of radius $\frac{\epsilon}{3}$ centered at $f(x)$. Then finitely many of these balls, say $\{V_{x_1}, \ldots, V_{x_n}\}$, cover $f(K)$ since $f(K)$ is compact. For each $j$, $1 \leq j \leq n$, let $K_j = f^{-1}(V_{x_j})$ and $O_j$ the open ball of radius $\frac{\epsilon}{3}$ around $f(x_j)$. For each $j$, $K_j$ is compact and $f(K_j) \subseteq O_j$. There is an $i_0$ such that $f_i(K_j) \subseteq O_j$ for all $j$ and for all $i \geq i_0$. Thus, if $x \in K$, then $x \in K_j$ for some $j$, so for any $i \geq i_0$ we have

$$
\rho(f_i(x), f(x)) \leq \rho(f_i(x), f_i(x_j)) + \rho(f_i(x), f(x_j)) + \rho(f(x), f(x)) < \frac{\epsilon}{3} + \frac{\epsilon}{3} + \frac{\epsilon}{3} = \epsilon.
$$

**XI.16.3.17.** If $X$ and $Y$ are topological spaces, the compact-open topology can be defined in the same way on $F(X, Y)$ as in XI.16.3.6. The relative topology on the subset $Y^X = C(X, Y)$ is exactly the compact-open topology defined in XI.16.3.6. However, the compact-open topology on $F(X, Y)$ does not reasonably coincide with the topology of uniform convergence on compact sets, and $Y^X$ is not closed in $F(X, Y)$ in general. See Exercise XI.16.4.1.
XI.16.4. Exercises

XI.16.4.1. (a) Let $X = \mathbb{N}^1$, the one-point compactification of $\mathbb{N}$, and let $Y = [0,1]$. Let $f_n : X \to Y$ be the function which is 1 on $\{1, \ldots, n\}$ and 0 otherwise, and let $f$ be the function which is 1 on $\mathbb{N}$ and 0 at $\infty$. Then $f_n \to f$ pointwise, each $f_n$ is continuous, but $f$ is discontinuous. Obviously $(f_n)$ does not converge to $f$ uniformly, hence does not converge uniformly on compact sets since $X$ is compact. Show that $f_n \to f$ in the compact-open topology on $F(X,Y)$.

(b) Let $X = \mathbb{N} \cup \{\alpha\}$ be the space of XI.11.12.8., and let $Y = [0,1]$. The only compact subsets of $X$ are the finite subsets; thus uniform convergence on compact sets is the same as pointwise convergence. If $f_n$ is defined as above, and $f$ is 1 on $\mathbb{N}$ and $f(\alpha) = 0$, then $f_n \to f$ uniformly on compact sets (pointwise), but each $f_n$ is continuous and $f$ is discontinuous. In this case, $f_n \to f$ also in the compact-open topology on $F(X,Y)$.

(c) Let $X = \mathbb{N}^1$ and $Y = \mathbb{R}$. Define $f : X \to Y$ by $f(k) = k$ for $k \in \mathbb{N}$, and $f(\infty) = 0$. Let $f_n(k) = k - \frac{1}{n}$, and $f_n(\infty) = 0$. Then $f_n \to f$ uniformly. Let

$$O = (-1,1) \cup \bigcup_{k \in \mathbb{N}} \left( k - \frac{1}{k}, k + \frac{1}{k} \right).$$

Then $O$ is open in $Y$. We have $f \in U_{X,O}$, but $f_n \notin U_{X,O}$ for any $n$. Thus $(f_n)$ does not converge to $f$ in the compact-open topology.

With some care, this example can be modified to make $Y = [0,1]$.

(d) Show that the proof of Proposition XI.16.3.16. shows the following:

**Proposition.** Let $(f_i)$ be a net of functions from a topological space $X$ to a metric space $(Y, \rho)$, and let $f$ be a function from $X$ to $Y$. If $f$ is continuous on each compact subset of $X$, then $f_i \to f$ in the compact-open topology if and only if $f_i \to f$ uniformly on each compact subset $K$ of $X$.

Note that there is no continuity assumption (or any other assumption) on the $f_i$. Even the limit function need not be continuous on all of $X$. (If $X$ is first countable, then continuity on compact subsets implies continuity on all of $X$ ; however, this can fail in general, as in (b).)

(e) If each $f_i$ is continuous (or just continuous on compact sets), and $f_i \to f$ uniformly on compact sets, then $f$ is continuous on compact sets (), and thus $f_i \to f$ in the compact-open topology.

Note that problem 8b in section 9.1 of [?] is wrong as stated.
XI.17. Cantor Sets

The Cantor set, and its variations, is a complicated but interesting closed subset of the unit interval in $\mathbb{R}$. It is well worth while to develop a good understanding of this set, since it is an important gateway to a number of varied aspects of analysis and topology.

XI.17.1. The Cantor Set

XI.17.2. Other Cantor Sets

The construction of the Cantor set can be obviously generalized: at each step we only need to remove an open interval from the interior of each of the remaining closed intervals at that step; it does not have to be exactly the middle third (the lengths of the remaining intervals must just approach zero). By varying the lengths of the removed intervals, we can obtain versions of the Cantor set with various measure-theoretic properties.

Symmetric Cantor Sets

We first consider the case where all removed intervals at each stage are centered and of the same length, so that all the remaining intervals at each step will have the same length. This restriction is not necessary, but without it notation becomes unwieldy, and the Cantor sets obtained with the restriction, while quite general, retain a pleasant amount of symmetry and homogeneity.

XI.17.2.1. Let $\alpha = (\alpha_0, \alpha_1, \alpha_2, \ldots)$ be a sequence of real numbers such that $\alpha_0 = 1$ and $0 < \alpha_n < \frac{\alpha_{n-1}}{2}$ for $n \geq 1$. Begin with $K_0 = [0, 1]$. Remove an open interval from the middle of $K_0$ to obtain the set $K_1$ consisting of two closed intervals of length $\alpha_1$; the removed interval has length $1 - 2\alpha_1 = \alpha_0 - 2\alpha_1$. Continue inductively: at the $n$'th stage remove open intervals from the middle of each of the closed intervals in $K_{n-1}$ to obtain $2^n$ closed intervals of length $\alpha_n$; the $2^n-1$ removed intervals each have length $\alpha_{n-1} - 2\alpha_n$. Let $K_n$ be the union of the resulting intervals. We have that $K_n$ is a closed subset of $[0, 1]$, hence compact $(\cdot)$, and $K_n+1 \subseteq K_n$ for all $n$.

XI.17.2.2. Definition. The set $K_\alpha = \cap_n K_n$ is the Cantor set of type $\alpha$.

XI.17.2.3. We thus obtain a large variety of Cantor sets. The Cantor set of $(\cdot)$ is the Cantor set of type $\alpha$, where $\alpha_n = 3^{-n}$ for all $n$. This set will simply be denoted $K$ and called “the Cantor set,” i.e. the phrase “the Cantor set” without additional qualification always means the standard one.

All Cantor sets constructed in this way are topologically the same as the Cantor set, and embedded in $[0, 1]$ in the same way:

XI.17.2.4. Proposition. Let $K_\alpha$ be any Cantor set. Then there is a strictly increasing continuous function $\phi : [0, 1] \to [0, 1]$ with $\phi(K) = K_\alpha$. In particular, $K_\alpha$ is homeomorphic to $K$.

We always have $\alpha_n < 2^{-n}$, so $\alpha_n \to 0$ rather rapidly. The faster the $\alpha_n$ converge to 0, the “smaller” the set $K_\alpha$ is. By choosing this rate carefully, one can obtain arbitrary Hausdorff and packing dimensions for $K_\alpha$:
XI.17.2.5. **Theorem.** Let $K_\alpha$ be a Cantor set of type $\alpha = (\alpha_0, \alpha_1, \alpha_2, \ldots)$. Then

(i) The Hausdorff dimension ($\dim$) of $K_\alpha$ is

$$
\dim_H(K_\alpha) = \liminf_{n \to \infty} \frac{n \log 2}{-\log \alpha_n}.
$$

(ii) The packing dimension ($\dim$) of $K_\alpha$ is

$$
\dim_P(K_\alpha) = \limsup_{n \to \infty} \frac{n \log 2}{-\log \alpha_n}.
$$

In particular, if $0 \leq s_H \leq s_P \leq 1$, there is a $K_\alpha$ with $\dim_H(K_\alpha) = s_H$ and $\dim_P(K_\alpha) = s_P$.

XI.17.2.6. **Examples.**

(i) If $0 < s < 1$, set $\alpha_n = 2^{-n/s}$ for all $n$. Then $\dim_H(K_\alpha) = \dim_P(K_\alpha) = s$.

(ii) If $\alpha_n = 2^{-n^2}$ for all $n$, then $\dim_H(K_\alpha) = \dim_P(K_\alpha) = 0$.

XI.17.2.7. If $\dim_H(K_\alpha) = s$, this result does not give information about $\mathcal{H}^s(K_\alpha)$. By a more delicate analysis, we can make this measure arbitrary as long as $0 < s < 1$ (Since $\mathcal{H}^0$ is counting measure, we have $\mathcal{H}^0(K_\alpha) = \infty$ for all $\alpha$, and $\mathcal{H}^1$ is Lebesgue measure on $\mathbb{R}$, so $\mathcal{H}^1(K_\alpha) \leq \mathcal{H}^1([0,1]) = 1$ for all $\alpha$). We can do the same for packing measure. We have:

If $\dim_H(K_\alpha) = 1$, we can make $K_\alpha$ have positive Lebesgue measure:

XI.17.2.8. **Example.** Let $0 < d < 1$. We will construct a $K_\alpha$ such that $\lambda(K_\alpha) = d$. Set

$$
c = \frac{3 - 2d}{1 - d} \in (3, \infty)
$$

and note that $d = \frac{c - 3}{c - 2}$. Choose the $\alpha_n$ so that the removed open intervals at the $n$'th stage have length $c^{-n}$. This can be done inductively by setting $\alpha_0 = 1$ and solving $c^{-n} = \alpha_n - 2\alpha_{n-1}$ for $\alpha_n$. If $b = c^{-1}$, we have successively

$$
\alpha_1 = \frac{1 - b}{2}, \quad \alpha_2 = 1 - b + b^2, \quad \alpha_3 = 2 - 2b + 2b^2 + b^3, \cdots
$$

At the $n$'th step, $2^{n-1}$ intervals of length $c^{-n}$ are removed; hence the complement of $K_\alpha$ in $[0,1]$ has Lebesgue measure

$$
\sum_{n=1}^{\infty} \frac{2^{n-1}}{c^n} = \frac{1}{2} \sum_{n=1}^{\infty} \left[ \frac{2}{c} \right]^n = \frac{1}{2} \cdot \frac{\frac{2}{c}}{1 - \frac{2}{c}} = \frac{1}{c - 2}
$$

since the removed intervals are disjoint, and thus we have

$$
\lambda(K_\alpha) = 1 - \frac{1}{c - 2} = \frac{c - 3}{c - 2} = d.
$$

Denote this Cantor set by $K_d$. We could also take $d = 0$ in this construction ($c = 3$) to get the ordinary Cantor set, although this set does not have Hausdorff dimension 1.

Note that there is no $K_\alpha$ with $\lambda(K_\alpha) = 1$, since for any $\alpha$ we have that $[0,1] \setminus K_\alpha$ is a nonempty open set and thus has strictly positive Lebesgue measure.

More general Hausdorff and packing dimensions

1198
Asymmetric Cantor Sets
For Cantor sets with Lebesgue measure zero, there is a feasible alternate notation which works also in the asymmetric case.

XI.17.2.9. Let \( \lambda = (\lambda_k) \) be a sequence of strictly positive numbers with \( \sum_{k=1}^{\infty} \lambda_k = 1 \). At the first stage, remove a suitable open interval of length \( \lambda_1 \) from the interior of \( I_1 = [0, 1] \). It will turn out that there is a uniquely located such subinterval for which the subsequent process works, not necessarily centered in \([0,1]\). This leaves two closed subintervals \( I_2 \) and \( I_3 \) (numbered from left to right). Remove a suitable open subinterval of length \( \lambda_2 \) from \( I_2 \), and one of length \( \lambda_3 \) from \( I_3 \), leaving four closed intervals \( I_4 \) to \( I_7 \). Continue the process, and let \( C_\lambda \) be the remaining set at the end. Then \( C_\lambda \) is a Cantor set of Lebesgue measure zero (Exercise ()).

XI.17.2.10. To make the process work, the lengths of the remaining intervals at each stage must be sums of suitable subseries of the original series. The length of \( I_2 \) must be \( \sum \lambda_k \), where the \( \lambda_k \) are all numbers of the form \( 2^m + j \), \( 0 \leq j \leq 2^{m-1} - 1 \) for \( m \geq 1 \), and the length of \( I_3 \) must be \( \sum \lambda_k \), where the \( \lambda_k \) are of the form \( 2^m + j \), \( 2^{m-1} \leq j \leq 2^m - 1 \), \( m \geq 1 \), i.e.

\[
\ell(I_2) = \lambda_2 + \lambda_4 + \lambda_5 + \lambda_8 + \lambda_9 + \lambda_{10} + \lambda_{11} + \lambda_{16} + \cdots
\]

\[
\ell(I_3) = \lambda_3 + \lambda_6 + \lambda_7 + \lambda_{12} + \lambda_{13} + \lambda_{14} + \lambda_{15} + \lambda_{24} + \cdots
\]

and these uniquely determine \( I_2 \) and \( I_3 \) (note that \( 1 = \ell(I_1) = \ell(I_2) + \ell(I_3) \)) and hence uniquely determine the interval which must be removed from \( I_1 \). Lengths of subsequent intervals are uniquely determined in the same manner.

XI.17.2.11. The Cantor set \( C_\lambda \) depends on the ordered sequence \( \lambda \). In rare cases, a reordering of the sequence can yield the same Cantor set; two sequences yielding the same Cantor set must be reorderings of each other.

XI.17.2.12. The sets \( K_\alpha \) which have Lebesgue measure 0 are among the \( C_\lambda \). In fact, if \( (\alpha_n) \) is given, take \( \lambda_k = \alpha_{n-1} - 2\alpha_n \) for \( 2^{n-1} \leq k < 2^n \).

More generally, any Cantor set of Lebesgue measure 0 in \([0,1]\) containing 0 and 1 is a \( C_\lambda \). If \( C \) is such a Cantor set, then \( U_1 = [0, 1] \setminus C \) is a countable union of disjoint open intervals. Let \( \lambda_1 \) be the maximum length of the disjoint subintervals. Remove an interval of length \( \lambda_1 \) from \( U \), leaving open sets \( U_2 \) and \( U_3 \) on either side. Let \( \lambda_2 \) be the maximum length of an open subinterval in \( U_2 \), etc. This generates a sequence \( (\lambda_k) \), and it is easily seen that \( C = C_\lambda \) (Exercise ()).

The same construction can be done in any interval \([a,b]\) of \( \mathbb{R} \), starting with a series \( \sum_{k=1}^{\infty} \lambda_k \) whose sum is \( b - a \). Every Cantor subset of \( \mathbb{R} \) of Lebesgue measure 0 is such a set, i.e. a translated and scaled version of a \( C_\lambda \).

The Hausdorff measure and Hausdorff dimension of the \( C_\lambda \) have been studied by a number of authors: [Bor49], [BT54], [CMMS04], [CMPS05], [CHM10].
XI.17.3. Exercises

XI.17.3.1. (i) Show that for every $a \in [0, 1]$, there is a $b \in [0, 1]$ such that $a + b$ and $a - b$ are in $K$. [Write $a$ in its ternary expansion. Let the $n$'th digit of the ternary expansion of $b$ be 1 if the $n$'th digit of the expansion of $a$ is 1, and 0 otherwise.]

(ii) Show that every number in $[0, 2]$ can be written as the sum of two elements of $K$. [If $x \in [0, 2]$, set $a = x/2$ and choose $b$ as in (i).] How many ways are there of doing it?

(iii) Conclude from (ii), (i), and () that the Hausdorff dimension of $K$ is at least $1/2$. (In fact, by XI.17.2.5., the Hausdorff dimension of $K$ is $\frac{\log 2}{\log 3} \approx 0.63$.)
XI.18. The Topology of $\mathbb{R}^n$

XI.18.1. Invariance of Domain and the Jordan Curve Theorem

In this subsection, we describe two remarkable results about Euclidean space. Both of these fall into the category of facts which at first glance are “intuitively obvious,” but which become highly nonobvious when thought about more carefully.

We begin with the original Jordan Curve Theorem in $\mathbb{R}^2$.

XI.18.1.2. Definition. A Jordan curve in $\mathbb{R}^2$ is the image of a one-to-one continuous function from the circle $S^1$ to $\mathbb{R}^2$. A Jordan curve is also called a simple closed curve.

A Jordan curve can also be defined as the image of a continuous function $\gamma$ from a closed bounded interval $[a, b]$ into $\mathbb{R}^2$ which is one-to-one except that $\gamma(a) = \gamma(b)$. There is no assumption of smoothness or differentiability. Such a “parametrization” of the curve is highly nonunique and is not part of the structure of the curve.

A Jordan curve is intuitively a closed loop in the plane which does not cross itself. In fact, since $S^1$ is compact and Hausdorff, a Jordan curve is homeomorphic to $S^1$ by $\gamma$. (Conversely, any subset of $\mathbb{R}^2$ which is homeomorphic to $S^1$ is trivially a Jordan curve.) Geometric circles, ellipses, and polygons are elementary examples of Jordan curves. A “figure 8” is not a Jordan curve. For a more complicated example, see Figure XI.17. For more extreme examples, see Figures XI.18, XIV.25, and XIV.12.1.17.

Figure XI.17: A complicated Jordan curve (in white). Artwork by Robert Bosch
One would intuitively expect that a Jordan curve would divide the plane into two disjoint regions, the “inside” and the “outside” of the curve, just as a geometric circle does. But when more complicated examples are considered, this conclusion is less obvious; for example, is it obvious what is the “inside” and “outside” of the curve in Figure XI.17? (In particular, is the point marked with the yellow x inside or outside? Try to find a path out from this point.) Nonetheless, it does turn out to be true:

\textbf{XI.18.1.3. Theorem.} [Jordan Curve Theorem] Let $C$ be a Jordan curve in $\mathbb{R}^2$. Then $\mathbb{R}^2 \setminus C$ has exactly two connected components, one bounded and one unbounded, whose common boundary is $C$.

This result is due to C. Jordan in 1887. It is questionable whether Jordan’s proof can be regarded as complete; certainly his exposition leaves much to be desired. Conventional wisdom says that Jordan’s proof was flawed and that the first complete, correct proof was given by O. Veblen in 1905; however, this assertion may not stand up under examination [Hal07]. There have been many other proofs given over the years; see [Mae84] for a particularly nice one. We will not give a proof here. If the curve is polygonal or piecewise-smooth, the proof is relatively simple since such a curve locally divides the plane in two parts; however, the general case is difficult since a Jordan curve can be locally pathological such as the example in Figure XI.18 (although it turns out to still locally divide the plane).

Figure XI.18: A locally pathological Jordan curve
This curve, made of two intertwined spirals, is only locally pathological at one point, but small copies of the spirals can be successively added densely, replacing small arcs of the curve, to make a curve locally pathological at every point. (Much more complicated local pathology is possible too!)

There is a more refined version of the Jordan Curve Theorem, first proved by A. Schönflies in 1908(?)[]. This result is commonly called the Jordan-Schönflies theorem.

XI.18.1.4. Theorem. [Jordan-Schönflies Theorem] Let $S^1$ be the unit circle in $\mathbb{R}^2$, and $\gamma : S^1 \to \mathbb{R}^2$ a one-to-one continuous function. Then $\gamma$ extends to a homeomorphism from $\mathbb{R}^2$ onto $\mathbb{R}^2$.

It is easy to see that the Jordan-Schönflies Theorem implies XI.18.1.3. (Exercise ()). The conclusion is stronger: the “inside” (bounded component of the complement) is not only connected, but even homeomorphic to the open unit disk (and hence to $\mathbb{R}^2$ itself), and the “outside” (the unbounded component of the complement) is homeomorphic to $\mathbb{R}^2$ with a point removed. It really says that every subset of $\mathbb{R}^2$ homeomorphic to $S^1$ is topologically embedded in $\mathbb{R}^2$ in the same way.

We omit the proof, which is not easy and would take us too far afield. See [CV98], for example.

The Jordan Curve Theorem in $\mathbb{R}^n$

One natural approach to generalizing the Jordan curve theorem is to consider subsets of $\mathbb{R}^n$ homeomorphic to $S^{n-1}$. Such a subset could be called a Jordan sphere in $\mathbb{R}^n$ (this is nonstandard terminology, and it is questionable whether the name is really appropriate, so we will avoid using it).

XI.18.1.5. One might hope in analogy with the Jordan-Schönflies Theorem that a homeomorphism from the unit sphere $S^{n-1}$ in $\mathbb{R}^n$ to a subset $C$ of $\mathbb{R}^n$ would extend to a homeomorphism from $\mathbb{R}^n$ onto $\mathbb{R}^n$, i.e. that all Jordan spheres in $\mathbb{R}^n$ are topologically embedded in the same way, but the example of the “Alexander horned sphere” in $\mathbb{R}^3$ (XI.18.4.37.) shows that this statement is false in general, and thus the Jordan-Schönflies Theorem is special to $\mathbb{R}^2$. But remarkably, the Jordan Curve Theorem remains true:

XI.18.1.6. Theorem. [Jordan Curve Theorem in $\mathbb{R}^n$] Let $C$ be a subset of $\mathbb{R}^n$ ($n \geq 2$) homeomorphic to $S^{n-1}$. Then $\mathbb{R}^n \setminus C$ has exactly two connected components, one bounded and one unbounded, whose common boundary is $C$.

This theorem is due to Lebesgue and Brouwer. We again omit the proof; see, for example, [].

XI.18.1.7. The statement is not quite true for $n = 1$. The “unit sphere” $S^0$ in $\mathbb{R}^1$ consists of two points $\{\pm 1\}$ whose complement has three connected components. But topologists usually state the theorem by replacing $\mathbb{R}^n$ by its one-point compactification $S^n$ (the statement is easily seen to be equivalent; cf. Exercise ()), and this version also applies when $n = 1$.

There is a related result (which is used in the proof of XI.18.1.6.). Let $B^n$ be the closed unit ball in $\mathbb{R}^n$. Note that $B^n$ is homeomorphic to $[0, 1]^n$.
XI.18.1.8. **Theorem.** Let $B$ be a subset of $\mathbb{R}^n$ ($n \geq 2$) homeomorphic to $B^n$ (i.e. to $[0,1]^n$). Then $\mathbb{R}^n \setminus B$ is connected.

The statement also holds with $\mathbb{R}^n$ replaced by $S^n$, even for $n = 1$.

XI.18.1.9. It has been an active project in topology, not yet completed, to generalize the Jordan-Schönflies Theorem to higher dimensions. Restrictions on the embedding maps must, of course, be made. Perhaps the best result so far is that the statement is true for “locally flat” embeddings (embeddings which extend to a thin spherical shell) ([?], [?]). The result for smooth embeddings is known for $n \neq 4$, but is still open for $n = 4$.

XI.18.1.10. One might also wonder about subsets of $\mathbb{R}^n$ (or $S^n$) homeomorphic to $S^m$ for $m < n - 1$. Such subsets always have connected complements, but the ways they can be embedded (even leaving out “wild” embeddings such as the Alexander Horned sphere, e.g. restricting to smooth or piecewise-linear embeddings) are very complicated. The study of smooth embeddings of $S^1$ into $\mathbb{R}^3$ is a fascinating and active branch of modern topology called knot theory (XI.18.4.32.).

**Brouwer’s Invariance of Domain**

A very important consequence of the Jordan Curve Theorem in $\mathbb{R}^n$ is the theorem that open sets in Euclidean space are invariant under homeomorphisms. This result, called invariance of domain, was proved by L. Brouwer in 1912 [I].

XI.18.1.11. **Theorem.** [Invariance of Domain] Let $U$ be a nonempty open subset of $\mathbb{R}^n$, and $f$ a one-to-one continuous function from $U$ to $\mathbb{R}^m$. Then

(i) $m \geq n$.

(ii) If $m = n$, then $f(V)$ is open in $\mathbb{R}^n$ for every open subset $V$ of $U$ (in particular, $f(U)$ is open in $\mathbb{R}^n$), i.e. $f$ is an open mapping and a homeomorphism onto its range.

Before outlining the proof, we list some of the most important consequences.

XI.18.1.12. **Corollary.** Let $U$ be an open subset of $\mathbb{R}^n$. Then any subset of $\mathbb{R}^n$ which is homeomorphic to $U$ is also open.

The next corollary is especially noteworthy:

XI.18.1.13. **Corollary.** Let $U$ be a nonempty open subset of $\mathbb{R}^n$. Then $U$ is not homeomorphic to any subset of $\mathbb{R}^m$ for any $m < n$. In particular, $\mathbb{R}^n$ is not homeomorphic to $\mathbb{R}^m$ for $n \neq m$.

This result also follows from the fact that any nonempty open set in $\mathbb{R}^n$ is topologically $n$-dimensional ().
XI.18.1.14. **Corollary.** Let $U$ be an open subset of $\mathbb{R}^n$, and $f : U \to \mathbb{R}^n$ a continuous function which is locally one-to-one. Then $f$ is an open mapping.

XI.18.1.15. We now outline the proof of XI.18.1.11.; actually we give a complete proof assuming XI.18.1.6. and XI.18.1.8.. We first prove (ii), so assume $m = n$. Let $x \in U$, and fix $\epsilon > 0$ with $A = B_\epsilon(x) \subseteq U$. Since $A$ is compact and $f$ is one-to-one on $A$, $B = f(A)$ is homeomorphic to $B^n$, and hence the open set $\mathbb{R}^n \setminus B$ is connected by XI.18.1.8.. If $C = f(\partial A)$, then $C$ is homeomorphic to $\partial A \cong S^{n-1}$, and hence the open set $\mathbb{R}^n \setminus C$ has two components. But $D = f(B_\epsilon(x)) = f(A \setminus \partial A)$ is connected since $B_\epsilon(x)$ is connected (), and $D$ and $\mathbb{R}^n \setminus B$ are disjoint connected sets whose union is $\mathbb{R}^n \setminus C$, so they must be the two components. But the components of an open set are open, so $D$ is open in $\mathbb{R}^n$ and contains $f(x)$. This argument can be repeated for any $x \in U$, so $f(U)$ is open. The same argument works for any open subset $V$ of $U$. Thus the inverse map from $f(U)$ to $U$ is continuous.

To prove (i), Suppose $m < n$. Define $\tilde{f} : U \to \mathbb{R}^n \cong \mathbb{R}^m \times \mathbb{R}^{n-m}$ by $\tilde{f}(x) = (f(x), 0)$. Then $\tilde{f}$ is one-to-one and continuous, but $\tilde{f}(U)$ is not open, a contradiction.

XI.18.1.16. If $U$ is an open set in $\mathbb{R}^n$ and $f$ is a one-to-one continuous function from $U$ to $\mathbb{R}^m$ ($m \geq n$), then the restriction of $f$ to any compact subset $K$ of $U$ is a homeomorphism from $K$ to $f(K)$ by (). But if $m > n$, $f$ does not give a homeomorphism from $U$ to $f(U)$ in general. For example, there is an evident one-to-one continuous map from $\mathbb{R}$ onto a figure 8 in $\mathbb{R}^2$. There are more dramatic examples: there is a one-to-one continuous function from $\mathbb{R}$ onto a dense subset of the 2-torus (or $n$-torus for any $n > 1$) obtained by “wrapping around” at an irrational angle (). See also XI.18.4.16..

XI.18.2. **$\mathbb{R}^n$ is $n$-Dimensional**

Everyone “knows” that $\mathbb{R}^n$ is $n$-dimensional. But what does this mean? Specifically, what does “dimension” mean? And how can $\mathbb{R}^n$ be distinguished from $\mathbb{R}^m$ for $m \neq n$ by its properties?

$\mathbb{R}^n$ is a set with several types of structure: algebraic, geometric, topological, and analytic. Efforts have been made to define and/or describe the “dimension” of $\mathbb{R}^n$ in terms of each of these types of structure, and various theories of dimension have been studied in different contexts; the only thing these various theories have in common is that they all assign the same number $n$ to $\mathbb{R}^n$, justifying the use of the name “dimension” for all of them.

XI.18.2.1. Specifically, we have:

(i) The vector space dimension () of $\mathbb{R}^n$ as a real vector space is $n$.

(ii) The topological dimension () of $\mathbb{R}^n$ as a topological space is $n$.

(iii) The Hausdorff dimension () of $\mathbb{R}^n$ is $n$.

XI.18.2.2. There is one respect in which all Euclidean spaces are the same, however: cardinality. Contrary to CANTOR’s expectations (he first thought the cardinality of $\mathbb{R}^n$ should be $\aleph_n$), the cardinality of $\mathbb{R}^n$ is $2^{\aleph_0}$ for all $n$ (). Thus some additional structure beyond set theory is needed to distinguish $\mathbb{R}^n$ from $\mathbb{R}^m$ for $n \neq m$.

XI.18.3. When is $\mathbb{R}^n$ “Similar” to $\mathbb{R}^m$?

In this section, we ask a rather vague and subjective question: for which $n$ and $m$ are $\mathbb{R}^n$ and $\mathbb{R}^m$ “essentially similar”? The answer depends partly on what type of mathematician is answering it.

XI.18.3.1. Of course, in a certain technical sense, $\mathbb{R}^n$ and $\mathbb{R}^m$ are different for any $n \neq m$ since they are not homeomorphic (or linearly isomorphic); thus they by definition differ in some describable topological (or algebraic) way. But qualitatively all Euclidean spaces, especially ones of large dimension, seem to be “similar.” The question is really: how large does $n$ have to be for Euclidean spaces of dimension $\geq n$ all to behave essentially the same way? Is there really such a dividing line at all?

XI.18.3.2. In calculus or real analysis, the appropriate answer seems to be that all Euclidean spaces of dimension $\geq 2$ are essentially similar, but essentially different from $\mathbb{R}^1$. Calculus on $\mathbb{R}^2$ is quite different in character from calculus on $\mathbb{R}^1$, but calculus on $\mathbb{R}^5$, or $\mathbb{R}^{100}$, is not essentially different from calculus on $\mathbb{R}^2$ except for the trivial difference that notation becomes more complicated in larger dimensions. This statement is not unrestrictedly true: there are some features and results of vector analysis which are special to $\mathbb{R}^2$ and $\mathbb{R}^3$, e.g. ones related to cross product, divergence, and curl (); but even these results are mostly just special cases or interpretations of the general Stokes’ Theorem (), which holds in any dimension.

There are analytic properties unique to three- and four-dimensional space which arise in mathematical physics, e.g. stability of configurations under a gravitational force satisfying an inverse-square law. However, it is unclear whether we should regard these results as deep mathematical reasons why physical space must be three-dimensional, or space-time four-dimensional, or whether the three-dimensionality of the universe (as we currently perceive and understand it) and the compatibility of physical laws with three-dimensionality are just physical facts not entailed by mathematical considerations.

XI.18.3.3. A functional analyst might well give an even less discriminating answer: that all finite-dimensional Hilbert spaces (in particular, all Euclidean spaces) are essentially similar and essentially trivial, and the first important distinction is between finite-dimensional and infinite-dimensional Hilbert spaces.

XI.18.3.4. On the other hand, a topologist would likely say that the Euclidean spaces of dimension $\leq 5$ are all essentially different, while those of dimension $\geq 5$ are essentially similar. They would probably go on to add that $\mathbb{R}^4$ is “more different” than any of the others, for various reasons (). One can identify simple and important topological differences between $\mathbb{R}^2$ and $\mathbb{R}^3$, e.g. XI.18.5.3., Classification of closed manifolds, Banach-Tarski, Poincaré Conjecture, and between $\mathbb{R}^3$ and $\mathbb{R}^n$ for $n \geq 5$ (). Topologists even consider “low-dimensional topology” (of dimension $\leq 4$) to be a separate subdiscipline.

XI.18.3.5. There is a qualitative difference between even- and odd-dimensional spaces, however: for example, even and odd spheres are qualitatively different. Only odd spheres have globally nonvanishing vector fields (), only even spheres have orientation-reversing homeomorphisms without fixed points, etc. The differences can be interpreted as reflecting the difference between the complex $K$-theories of even and odd spheres ()

There are many other differences in the structure of $n$-manifolds for different $n$: for example, every $n$-dimensional PL manifold has a smooth structure (in fact a unique one) if $n \leq 6$, but if $n \geq 7$ there are closed $n$-dimensional PL-manifolds which do not have a smooth structure. And smooth structures, if they exist, need not be unique. The $n$-sphere has a unique smooth structure for $n = 1, 2, 3, 5, 6, 12$ and 61, and
more than one for all other \( n \leq 126 \) except possibly \( n = 4 \) (open), and all other odd \( n \) [\( \text{[]} \)]. The cases of even \( n > 126 \) are partially but not completely known.

It may be a stretch to regard the question as including the structure of manifolds of different dimensions, since the definition of a general manifold is rather subtle; but it is less of a stretch to include the structure of spheres, since the \( n \)-sphere is just the one-point compactification of \( \mathbb{R}^n \), or the unit sphere in \( \mathbb{R}^{n+1} \). One might also legitimately consider the topology of open subsets of \( \mathbb{R}^n \) (cf. XI.18.5.6–XI.18.5.8).

**XI.18.3.6.** There are more esoteric dimensional restrictions arising from topology. Two 1-spheres (circles) can be linked nontrivially in \( \mathbb{R}^n \) if and only if \( n = 3 \). But if \( m > 1 \), the question of whether two disjoint (topological) \( m \)-spheres can be nontrivially linked in \( \mathbb{R}^n \) (\( n > m \)) is much more subtle: for example, two 50-spheres can be nontrivially linked in \( \mathbb{R}^n \) if and only if \( 52 \leq n \leq 95 \) or \( 98 \leq n \leq 101 \) [Rol76].

**XI.18.3.7.** An algebraist might say \( \mathbb{R}^1, \mathbb{R}^2, \mathbb{R}^4, \) and \( \mathbb{R}^8 \) are similar to each other and different from all other \( \mathbb{R}^n \) because of III.6.3.2. In fact, for arbitrarily large \( n \), the algebraic structure of \( \mathbb{R}^n \) is significantly impacted by the number-theoretic properties of \( n \) (https://mathoverflow.net/questions/34186/does-the-truth-of-any-statement-of-real-matrix-algebra-stabilize-in-sufficiently), and much of the algebraic structure can be interpreted geometrically.

**XI.18.3.8.** In geometric measure theory, there is a significant difference between \( \mathbb{R}^n \) for \( n \leq 7 \) and for \( n \geq 8 \): if \( n \leq 7 \), an area-minimizing rectifiable \((n-1)\)-current in \( \mathbb{R}^n \) is a smooth submanifold (\( \text{[]} \)), but this is not necessarily true if \( n \geq 8 \). See [Mor09, 10.7].

**XI.18.3.9.** There is a potentially much higher dividing line from the Borsuk conjecture (or problem): BORSUK asked whether any bounded subset of \( \mathbb{R}^n \) is the union of \( n + 1 \) subsets of strictly smaller diameter. The statement is known to be true for \( n \leq 3 \) and false for \( n \geq 64 \). The smallest \( n \) for which the statement fails is in at least one combinatorial sense an important transition point.

**XI.18.3.10.** There are also interesting and important questions concerning sphere packings. One tries to fill \( \mathbb{R}^n \) with solid equal-size \( n \)-balls as densely as possible. The problem is even tricky to state precisely: we first seek the supremum of the density of all possible packings, and then to find a packing (or “all” packings) realizing the supremum (optimal packings; one should impose additional conditions on optimal packings such as some type of incompressibility, part of the difficulty in phrasing the problem carefully). In \( \mathbb{R}^2 \) a hexagonal lattice is easily shown to give the unique optimal packing. In \( \mathbb{R}^3 \) the cubic face centered lattice (\( \text{[]} \)) is optimal (Kepler’s Conjecture), although the proof is very difficult and was only recently completed [HF11]; it is not the unique optimal packing, although the other optimal packings are easily described variations. Optimal packings are known in dimensions \( \leq 8 \) and 24, and are lattice packings in these dimensions. In dimensions 10, 11, and 13 there are irregular packings which are denser than any known lattice packing, and it may be that in these dimensions, and possibly in all sufficiently large dimensions, optimal packings are necessarily irregular. It is unclear whether there even are any optimal packings (i.e. ones realizing the supremum) in every dimension. See [CS99] for details. Sphere packing problems in large numbers of dimensions have applications in number theory, coding, algebra, and mathematical physics as well as in geometry.

**XI.18.3.11.** As to the general question of whether there exists a “dividing line,” many (but certainly not all) questions or phenomena stabilize for high dimensions and are difficult only due to “accidents of small dimension.” From the right point of view, this philosophy applies even to such problems as the notorious one
of computing higher homotopy groups $\pi_n(S^q)$ of spheres, which is not completely solved and is perhaps not even completely solvable in principle. Viewed in the usual way, by fixing $q$ and letting $n$ vary, the question can seem intractable. But if we instead fix $n$ and let $q$ vary, the problem stabilizes nicely for $q \geq n$ and the complications can be said to be only due to “accidents of small dimension.”

Of course, as seen above, if dividing lines exist at all, they may vary from problem to problem.

XI.18.3.12. Perhaps the best answer to the original question may be that it simply reflects the limitations of our current knowledge. Even topologists as recently as the 1960s might not have said that $\mathbb{R}^4$ is essentially different from $\mathbb{R}^3$; the most profound differences have all been discovered since then. Mathematicians 100 years from now may regard $\mathbb{R}^{18}$ and $\mathbb{R}^{19}$ (or maybe $\mathbb{R}^{17}$ and $\mathbb{R}^{19}$, to pick prime numbers) as being as different as $\mathbb{R}^3$ and $\mathbb{R}^4$ due to some phenomenon not yet imagined.

XI.18.3.13. If you want to start some lively discussions, ask your colleagues or instructors this question! I decided to pose the question on MathOverflow (https://mathoverflow.net/questions/267909/when-are-mathbb-rn-and-mathbb-rm-essentially-similar) and the ensuing discussion has informed and improved my own discussion above.
XI.18.4. Compact Subsets of $\mathbb{R}^n$

In this section, we describe a number of examples of compact subsets of Euclidean space with unusual, even bizarre, properties. We will state some of the properties of the examples without proof; readers with some topological background are encouraged to verify the asserted properties.

Mathematicians tend to have two types of reactions to examples of this sort. Some find them fascinating; others have more a sense of revulsion and want to sweep them into an obscure corner. I myself have the first reaction. But even if you fall into the second camp, it is still very important to be aware of the existence of such examples, since they graphically illustrate two vital mathematical principles:

(i) The number and variety of mathematical objects, even ones of relatively restricted type such as closed bounded subsets of the plane, is often vast, far beyond the limits of one’s initial imagination.

(ii) When proving results about general mathematical objects of a specified type, it is necessary to stick strictly to arguments drawing logical conclusions from explicit axiomatic assumptions, without appeal to intuition or heuristic arguments, especially ones based on pictures or diagrams which may not accurately reflect the full range of possibilities for the objects studied.

Of course, various other examples, such as the examples of continuous and/or differentiable functions with pathological properties which are scattered through this book, also illustrate these principles.

It turns out that subsets similar to some of these occur naturally in mathematics, both pure and applied, such as strange attractors for nonlinear dynamical systems.

Some of the examples of this section are fractals, and their fractal properties will be examined in ( ).

Uncountably Many Mutually Nonhomeomorphic Compact Subsets of $\mathbb{R}^2$

XI.18.4.1. If $k = (k_1, k_2, \ldots)$ is a sequence of natural numbers with $k_1 \geq 2$, construct a compact subset $X_k$ of $\mathbb{R}^2$ as follows. Begin with the closed segment from $(0,0)$ to $(1,0)$. For each $n$, add the closed line segments between $(1/n, 0)$ and $(1/(n+1), 1/(n(n+1)))$ for $1 \leq m \leq k_n$.

For example, Figure XI.31 shows $X_k$ for $k = (2, 3, 1, 1, \ldots )$.

It is clear that $X_k$ is a closed bounded subset of $\mathbb{R}^2$. It can be shown with some straightforward elementary topological arguments (Exercise XI.18.5.1.) that the $X_k$ for distinct sequences $k$ are mutually nonhomeomorphic. Since there are uncountably many $(2^{k_0})$ such $k$, there are uncountably many $(2^{k_0})$ mutually nonhomeomorphic compact subsets of the plane. Since there are only $2^{k_0}$ closed subsets of $\mathbb{R}^2$, there are exactly $2^{k_0}$ homeomorphism classes of closed bounded subsets of the plane.

Each of the $X_k$ is path-connected and topologically one-dimensional. They are even contractible; in fact, they are absolute retracts (dendrites) ( ). Note that these spaces are quite different from the infinite broom of XI.13.9.9.

There is an enormous variety of variations possible on this construction.
Figure XI.31: $X_k$ for $k = (2, 3, 1, 1, \ldots)$.
Uncountably Many Mutually Nonhomeomorphic Compact Subsets of $\mathbb{R}$

XI.18.4.2. Any countable ordinal $\alpha$ can be order-embedded in $\mathbb{R}$ ($\alpha$). Any countable ordinal which is not a limit ordinal can be embedded as a compact subset of $\mathbb{R}$ (with the order topology). There are $\aleph_1$ such ordinals.

However, these are not all distinct topologically. But the ordinals $\omega^\sigma + 1$ are all distinct topologically: the derived series ($\omega$) as a topological space has length $\sigma$. This space is countable if $\sigma$ is countable. Thus there are at least $\aleph_1$ topologically distinct compact countable subsets of $\mathbb{R}$.

It is trickier to explicitly construct $2^{\aleph_0}$ topologically distinct compact subsets of $\mathbb{R}$. Here is a way (cf. [Rei62]). Let $K$ be the Cantor set, and $c_n = 1 - \frac{1}{3^n}$. Then $c_n \in K$, and is the right endpoint of the rightmost open interval $I_n$ removed at the $n$th step of the construction of $K$. Let $m = (m_1, m_2, \ldots)$ be a strictly increasing sequence in $\mathbb{N}$, and for each $n$ attach to $K$ a copy of $\omega^{m_n}$ in $I_n$ which is relatively closed and converges to $c_n$ (see Figure ()). Let $X_m$ be the resulting subset of $\mathbb{R}$. Then $X_m$ is a compact totally disconnected subset of $\mathbb{R}$ for each $m$, and the $X_m$ are topologically distinct for distinct $m$. There are $2^{\aleph_0}$ such $m$, since they are in one-one correspondence with the infinite subsets of $\mathbb{N}$. See Exercise XI.18.5.2.. Since there are only $2^{\aleph_0}$ compact subsets of $\mathbb{R}$, there are exactly $2^{\aleph_0}$ homeomorphism classes.

The Topologist’s Sine Curve

XI.18.4.3. Let $X$ be the graph of $y = \sin \left( \frac{x}{\pi} \right)$ for $0 < x \leq 1$ (the right endpoint is not important), along with the closed segment on the $y$-axis between $(0, -1)$ and $(0, 1)$. Then $X$ is the closure of the graph part, and is a compact subset of $\mathbb{R}^2$. See Figure XI.32.

![The Topologist’s Sine Curve](image)

Figure XI.32: The Topologist’s Sine Curve
Since the graph is connected (even path-connected), $X$ is the closure of a connected set and hence is connected. However, $X$ is not path-connected; it has two path components, the graph and the segment on the $y$-axis.

**XI.18.4.4.** A variation is to “close up” $X$ by adding an arc connecting $(1,0)$ with $(0,-1)$. This is often called the “extended topologist’s sine curve” or “Warsaw circle.” See Figure XI.33. This space is path-connected but not locally path-connected. In some references, the added arc goes from $(1,0)$ around to $(0,0)$ from the left; this space is topologically different but essentially similar.

![Image of the extended topologist’s sine curve or Warsaw circle](image)

**Figure XI.33:** The Extended Topologist’s Sine Curve or Warsaw Circle

**XI.18.4.5.** The topologist’s sine curve can be used to construct a “counterexample” to the Four-Color Theorem (Figure XI.34). Each of the five regions pictured has a boundary with each of the others which at least contains an entire arc, and thus they must all be colored differently. This shows that the Four-Color Theorem must be stated carefully to rule out examples of this sort (cf. [?]).
Figure XI.34: A counterexample to the Four-Color Theorem?
The Hawaiian Earring

XI.18.4.6. Let $X$ be the union of all circles in $\mathbb{R}^2$ with center $(\frac{1}{n}, 0)$ and radius $\frac{1}{n}$, for $n \in \mathbb{N}$ (Figure XI.35).

Figure XI.35: The Hawaiian Earring

The fundamental group of the Hawaiian earring is uncountable: for each subset $S$ of $\mathbb{N}$, there is a loop $\gamma_S$ which goes around the circle of radius $1/n$ if and only if $n \in S$, and no two of these loops are homotopic.

XI.18.4.7. Let $Y$ be the union of all circles in $\mathbb{R}^2$ with center $(n, 0)$ and radius $n$, for $n \in \mathbb{N}$. Then $Y$ is not homeomorphic to $X$, since it is not compact. The fundamental group of $Y$ is a free group on a countable number of generators. In fact, $Y$ is homotopy equivalent (but not homeomorphic) to an infinite wedge of circles (XI.9.1.13., XI.9.5.8.) [collapse a suitable closed neighborhood of $0$ to a point]. See also XI.9.5.5.
Subsets Constructed as Intersections

A number of pathological examples can be made by constructing a decreasing sequence of increasingly complicated compact subsets of Euclidean space and taking the intersection. This construction is already familiar in the definition of the Cantor set ( ).

The Sierpiński Gasket

This subset of $\mathbb{R}^2$ is constructed as an intersection, and is the first of several straightforward higher-dimensional versions of the Cantor set.

Begin with a (solid) triangle in $\mathbb{R}^2$, say an equilateral triangle. Bisecting each side and connecting the midpoints forms four subtriangles. Remove the (open) middle one. Then repeat the process in each of the three remaining triangles and iterate. The intersection is called the Sierpiński gasket (the name is due to B. Mandelbrot; the set is also known as the Sierpiński triangle or the Sierpiński sieve). It is path-connected, compact, and topologically one-dimensional. See Figure XI.36 (from http://en.wikipedia.org/wiki/File:Sierpinski_Triangle.svg).

![Figure XI.36: Six steps in the construction of the Sierpiński Gasket](http://en.wikipedia.org/wiki/File:Sierpinski_Triangle.svg)

The Sierpiński Carpet

XI.18.4.8. As a variation, begin with a (solid) square. Divide it into 9 equal-sized squares, and remove the open middle square. Repeat the process in each of the eight remaining squares, and iterate. See

1227
Figure XI.37 (from http://commons.wikimedia.org/wiki/File:Sierpinski6.png?uselang=fr). This set is called the Sierpiński carpet, or Sierpiński curve.

Like the Sierpiński gasket, the Sierpiński carpet is topologically one-dimensional.

![Sierpiński Carpet](http://commons.wikimedia.org/wiki/File:Sierpinski6.png)

**Figure XI.37**: Six steps in the construction of the Sierpiński Carpet

**XI.18.4.9.** It is not obvious whether the Sierpiński carpet is homeomorphic to the Sierpiński gasket. In fact, they are not homeomorphic. For each point of the Sierpiński gasket has arbitrarily small open neighborhoods whose boundary consists of finitely many points (no more than 4), while small open neighborhoods of points in the Sierpiński carpet always have uncountably many boundary points. See [Kur68, §51] for a discussion.

**XI.18.4.10.** The Sierpiński carpet is universal for one-dimensional compact subsets of the plane: every compact subset of the plane which is topologically one-dimensional is homeomorphic to a subset of the
Sierpiński carpet[]. In particular, the Sierpiński gasket is homeomorphic to a subset of the Sierpiński carpet (try to find one!) A pseudo-arc can also be embedded topologically in the Sierpiński carpet.

**Swiss Cheese**

**XI.18.4.11.** The Sierpiński carpet is (topologically) a special case of a general construction: begin with a closed disk in $\mathbb{R}^2$, and remove a sequence of disjoint open disks to obtain a set with empty interior. Such a subset of $\mathbb{R}^2$ is called a *Swiss cheese*. There is a great topological variety among Swiss cheeses; some are similar topologically to the Sierpiński gasket, and some are homeomorphic to the Sierpiński carpet. The one pictured in [XI.38](http://hans.math.upenn.edu/~pstorm/images/round_Sierpinski_carpet.png) is made in a regular manner and is a fractal; some are much more irregular. As with Cantor sets, Swiss cheeses of positive planar Lebesgue measure can be constructed, as well as ones of zero planar measure; in fact, Swiss cheeses of Hausdorff dimension between 1 and 2 can be constructed, although the exact Hausdorff dimensions are subtle to compute ([Mel66], [Lar66]).

If topological disks are used instead of geometric ones, an even greater variety can be obtained; both the Sierpiński carpet and the Sierpiński gasket are special cases of this construction, as are the Lakes of Wada.

Swiss cheeses are used extensively in the theory of function algebras(); see [FH10] for a good survey, including their topological structure.
Figure XI.38: A “Swiss cheese.” (Small white disks continue throughout the black spots.)
The Menger Sponge

XI.18.4.12. There is a three-dimensional analog of the Sierpiński carpet, due to K. Menger [Men26]. Begin with the unit cube in \( \mathbb{R}^3 \). Dividing each edge in three equal segments leads to a decomposition of the cube into 27 equal-sized subcubes. Remove the central subcube and the central subcubes on each face (i.e. keeping all closed subcubes intersecting an edge of the cube). Seven subcubes are removed in all. Do the same in each of the 20 remaining subcubes and iterate. The intersection is called the Menger sponge. Each outside face of the Menger sponge is a copy of the Sierpiński carpet. See Figure XI.39 (from \( \text{http://en.wikipedia.org/wiki/File:Menger-Schwamm-farbig.png} \)).

![Four steps in the construction of the Menger Sponge](http://en.wikipedia.org/wiki/File:Menger-Schwamm-farbig.png)

Figure XI.39: Four steps in the construction of the Menger Sponge

The Menger sponge is compact, connected, locally connected, and topologically one-dimensional. It is universal for one-dimensional separable metrizable spaces: every separable metrizable space of dimension \( \leq 1 \) is homeomorphic to a subset of the Menger sponge [Men26]. Thus the Menger sponge is sometimes called the Menger Universal Curve (although it is not a “curve” in any normal sense). It is homogeneous and has a topological characterization [And58].

For any \( k, n \in \mathbb{N}, k < n \leq 2k + 1 \), there is a similar subset \( M^n_k \) of \( \mathbb{R}^n \) which is universal for compact subsets of \( \mathbb{R}^n \) of dimension \( \leq k \) [Sta71]; \( M^{n+1}_k \) is universal for all separable metrizable spaces of dimension
$M_3^1$ is the Menger sponge, $M_2^2$ the Sierpiński carpet, and $M_0^1$ the Cantor set. To make $M_2^2$, begin with the unit cube in $\mathbb{R}^3$, subdivide into 27 subcubes, and just remove the center cube; then iterate.

**Sierpiński Pyramids**

At least two versions of the Sierpiński Gasket can be made in $\mathbb{R}^3$. Begin with a pyramid with either a triangular or square base. In the triangular case (say, a regular tetrahedron), bisect each edge and keep the four subpyramids whose vertices are one original vertex and the three midpoints of the adjacent edges; then iterate. The intersection is a compact set called the tetrahedral Sierpiński Pyramid which is topologically one-dimensional. It has the unusual property that its Hausdorff dimension is an integer (2) which is greater than its topological dimension.

A variation is to begin with a pyramid with square base, bisect the edges, and keep the five subpyramids consisting of the top pyramid with four vertices at the midpoints of the slant edges and the four pyramids with top vertex at one of these midpoints and bottom vertices at a corresponding original vertex, two midpoints of base edges, and the midpoint of the base. See Figure XI.40, from [http://en.wikipedia.org/wiki/File:Sierpinski_pyramid.png](http://en.wikipedia.org/wiki/File:Sierpinski_pyramid.png).

![Sierpiński Pyramid](http://en.wikipedia.org/wiki/File:Sierpinski_pyramid.png)

**Figure XI.40:** Seven steps in the construction of the Sierpiński Pyramid with square base and its “inverse”
Solenoids

XI.18.4.13. Let $s = (n_1, n_2, \ldots)$ be a sequence of natural numbers with $n_k \geq 2$ for all $k$. Construct a compact subset of $\mathbb{R}^3$ as follows (in understanding the construction, try taking all $n_k$ to be 2 at first). Let $X_0$ be a solid torus. Inside $X_0$ take a thinner solid torus $X_1$ which “winds around” $n_1$ times. (Think of wrapping a wire around the “hole” in $X_0$ $n_1$ times and connecting the ends of the wire to make a thin solid torus.) See XI.41 for the case $n_1 = 2$ (from http://en.wikipedia.org/wiki/File:Smale-Williams_Solenoid.png).

Now within $X_1$ take an even thinner solid torus $X_2$ which wraps around $X_1$ $n_2$ times, i.e. every cross-

Figure XI.41: First step in the construction of the solenoid of type $(2, 2, \ldots)$

section disk of $X_1$ will cut $X_2$ in $n_2$ cross-sectional disks. Repeat the process countably many times and let $X = \cap_k X_k$. $X$ is called the solenoid of type $s$.

A nice animated construction of the solenoid of type $(2, 2, \ldots)$ can be found at http://en.wikipedia.org/wiki/File:Solenoid.gif.

XI.18.4.14. Solenoids can also be naturally constructed in several other ways. One good way is as inverse limits of circles (XI.14.4.17).

XI.18.4.15. A solenoid is connected but not locally connected: locally, a solenoid looks like $\mathbb{R} \times K$, where $K$ is the Cantor set. In fact, each solenoid can be constructed (up to homeomorphism) from $[0, 1] \times K$ by identifying $\{0\} \times K$ with $\{1\} \times K$ in an appropriate way, e.g. by identifying $K$ with the $p$-adic integers () and identifying $(1, x)$ with $(0, x + 1)$ (this gives the solenoid of type $(p, p, p, \ldots)$).

XI.18.4.16. A solenoid is not path-connected. There are uncountably many path components, each of which is dense and a one-to-one continuous image of $\mathbb{R}$. This is seen most easily by viewing the solenoid as an inverse limit as in (), but can also be deduced from the description in XI.18.4.15. (in this picture, the path components correspond to the cosets of $\mathbb{Z}$ in the $p$-adic integers).
XI.18.4.17. Up to homeomorphism, a solenoid depends only on the sequence $s$. Solenoids corresponding to different sequences are “usually” nonhomeomorphic, but ones corresponding to sequences differing only “slightly” can be homeomorphic.

To give a precise description of the homeomorphism classes, we use the supernatural numbers:

XI.18.4.18. **Definition.** A *supernatural number* is an expression of the form

$$n = 2^{e_2}3^{e_3}5^{e_5} \ldots$$

where each prime appears and each exponent $e_p$ is in $\{0\} \cup \mathbb{N} \cup \{\infty\}$.

An ordinary natural number is a supernatural number in which all $e_p$ are finite and all but finitely many are 0. Sometimes we want to exclude the ordinary natural numbers from the supernatural numbers; we call supernatural numbers which are not ordinary natural numbers *infinite*. When writing a supernatural number, we usually leave out all primes with exponent 0; thus if $n$ is the supernatural number with $e_2 = \infty$ and $e_p = 0$ for $p \neq 2$, we write $n$ as $2^\infty$.

Two supernatural numbers can be multiplied by adding the corresponding exponents. This multiplication extends the ordinary multiplication on $\mathbb{N}$.

We say one supernatural number $n$ *divides* another supernatural number $m$ if $e_p(n) \leq e_p(m)$ for all $p$, i.e. if there is a supernatural number $r$ such that $m = nr$. (Note, however, that $r$ is not necessarily unique, i.e. that there is not a well-defined quotient in general, if the exponents for some $p$ are both infinite.) There is a “largest” supernatural number, the one for which $e_p = \infty$ for all $p$, and all supernatural numbers divide this one.

Note that the supernatural numbers are not the same thing as the nonstandard natural numbers $^*\mathbb{N}$ of ()).

XI.18.4.19. The supernatural numbers are in natural one-one correspondence with the additive subgroups () of $\mathbb{Q}$ containing $\mathbb{Z}$: the group $\mathbb{Z}(n)$ is the set of all rational numbers whose denominator divides $n$. For example, $\mathbb{Z}(2\infty)$ is the set of dyadic rationals ()). The group corresponding to the largest supernatural number is $\mathbb{Q}$ itself; $\mathbb{Z}$ corresponds to the supernatural number 1 (i.e. $e_p = 0$ for all $p$), the smallest supernatural number.

The group $\mathbb{Z}(n)$ is cyclic (has a smallest positive element) if and only if $n$ is an ordinary natural number.

XI.18.4.20. To each sequence $(n_k)$ of natural numbers, there is a naturally associated supernatural number $\prod n_k$, for which, for every $p$, $e_p$ is the sum of the powers of $p$ occurring in the $n_k$’s. This will be an ordinary integer if and only if all but finitely many $n_k$ are 1. Many different sequences can give the same associated supernatural number (for example, reordering the sequence does not change the associated supernatural number, and there are much more drastic changes that work too).

It can be shown without too much difficulty (knowing the first statement of XI.18.4.17.) that if two sequences give the same supernatural number, the corresponding solenoids are homeomorphic. But it is not quite true that solenoids corresponding to different supernatural numbers are nonhomeomorphic. For a correct statement, we need an equivalence relation on supernatural numbers:

XI.18.4.21. **Definition.** Let $n$ and $m$ be supernatural numbers. Then $n$ and $m$ are *equivalent* if there are ordinary natural numbers $n$ and $m$ such that $nn = mm$. 

1234
Supernatural numbers \( n \) and \( m \) are equivalent if and only if only finitely many of their exponents differ, and each by only a finite amount. The supernatural numbers equivalent to any ordinary natural number are precisely all ordinary numbers.

This equivalence is natural because of the following results, the first of which is quite easy:

**XI.18.4.22. Proposition.** Two additive subgroups of \( \mathbb{Q} \) containing \( \mathbb{Z} \) are isomorphic as groups if and only if their associated supernatural numbers are equivalent.

**XI.18.4.23. Theorem.** Two solenoids are homeomorphic if and only if their associated supernatural numbers are equivalent.

**XI.18.4.24.** Thus the equivalence classes of infinite supernatural numbers exactly parametrize the homeomorphism classes of solenoids. The equivalence class of supernatural numbers can be recovered directly from the intrinsic topology of the solenoid \( X \): the first cohomotopy group \( \pi^1(X) \) is isomorphic to the additive subgroup of \( \mathbb{Q} \) associated to the equivalence class of supernatural numbers of \( X \).

**XI.18.4.25.** There is another important connection. Any solenoid \( X \) can be made into a compact abelian topological group. Its Pontrjagin dual group \( \hat{\pi} \) is isomorphic to \( \pi^1(X) \). The solenoids are the only compact connected one-dimensional Hausdorff spaces besides the circle which can be made into abelian topological groups. See XVI.5.2.1.(b).

**XI.18.4.26.** Solenoids are homogeneous. It was shown in [Hag77] that every homogeneous continuum in which every nondegenerate subcontinuum is an arc is a solenoid (or circle). A solenoid is also indecomposable.

**XI.18.4.27.** Solenoids arise naturally as attractors of important nonlinear dynamical systems ().

**Knaster’s Bucket-Handle**

This is a “poor man’s solenoid,” somewhat easier to visualize and with similar topological properties, at least locally. It is perhaps the simplest example of an indecomposable continuum. It can be constructed as an intersection (see Figure XI.43), but has a simpler direct definition:

**XI.18.4.28. Definition.** The *Knaster bucket-handle* is the union of the following closed half-circles in \( \mathbb{R}^2 \):

- All half-circles in the upper half-plane with center \( \left( \frac{1}{2}, 0 \right) \) with endpoints in the Cantor set \( K \).
- All half-circles in the lower half-plane with center \( \left( \frac{5}{3^{2n}}, 0 \right) \) \((n \geq 1)\) passing through a point of \( K \cap \left[ \frac{2}{3^n}, \frac{1}{3^{n-1}} \right] \).
Figure XI.42: The Knaster bucket-handle

See Figure XI.42 (from http://upload.wikimedia.org/wikipedia/commons/thumb/3/30/The_Knaster_%22bucket-handle%22_continuum.svg/2000px-The_Knaster_%22bucket-handle%22_continuum.svg.png).

It can be shown that the Knaster bucket-handle is indecomposable (cf. [? 48, V]): although it is connected, it has uncountably many path components (composants), one an injective continuous image of $[0, +\infty)$ and the rest injective continuous images of $\mathbb{R}$. A proper subcontinuum cannot contain any entire path component, so its intersection with any path component is an arc; it follows that it must be contained in a path component, i.e. the complement of any proper subcontinuum is dense.

It turns out there is no Borel subset containing exactly one point from each path component (cf. [?]).

There are numerous variations of the construction, with slightly different properties. All these can be described as inverse limits of intervals; see XI.14.4.18.

Attractors called “horseshoes” () are types of Knaster bucket-handles.

Figure XI.43: Four steps in the intersection construction of the Knaster bucket-handle
The Pseudo-Arc

XI.18.4.29. The construction of a pseudo-arc is somewhat involved.

We first need the notion of a *crooked* path. Let \( R \) be a (solid) rectangle, subdivided into a strip \( R_1, \ldots, R_m \) of subrectangles, \( a \) a point in the interior of \( R_1 \), and \( b \) a point in the interior of \( R_m \):

\[
\begin{array}{cccc}
& a & & \\
R_1 & R_2 & R_3 & \ldots \\
& b & & \\
& & & R_m
\end{array}
\]

Figure XI.44: Strip Subdivision of a Rectangle

A path \( \gamma \) from \( a \) to \( b \) within \( R \) is *crooked* with respect to \( R_1, \ldots, R_m \) if it has the following property: whenever \( t_1, t_2 \in [0,1], t_1 < t_2, \gamma(t_1) \in R_i, \) and \( \gamma(t_2) \in R_j \) with \( |i-j| > 2 \), there are \( s_1, s_2 \) with \( t_1 < s_1 < s_2 < t_2 \) and

- if \( i < j \), then \( \gamma(s_1) \in R_{j-1} \) and \( \gamma(s_2) \in R_{i+1} \)
- if \( j < i \), then \( \gamma(s_1) \in R_{j+1} \) and \( \gamma(s_2) \in R_{i-1} \).

Instead of a rectangle divided into subrectangles, a chain () of closed balls can be used. A crooked path is defined in the same way.

Thus, for example, if \( m = 4 \), a crooked path from \( a \) to \( b \) must first go to \( R_3 \), then back to \( R_2 \), and then to \( R_4 \). So the simplest crooked path looks like this:

\[
\begin{array}{cccc}
& a & & \\
R_1 & R_2 & R_3 & R_4 \\
& b & & \\
& & & \\
& & & \\
& & & \\
& & & \\
& & & \\
& & & \\
\end{array}
\]

Figure XI.45: Crooked Path of Length 4

Crooked paths rapidly become more complex as \( m \) increases (if \( \ell(m) \) is the number of horizontal segments in a minimal crooked path of length \( m \), for \( m \geq 4 \) we have the recursive formula

\[
\ell(m) = 2\ell(m-1) + \ell(m-2)
\]

with \( \ell(2) = \ell(3) = 1 \). For example, if \( m = 5 \), a crooked path from \( a \) to \( b \) must first go to \( R_3 \), then back to \( R_2 \), then \( R_4 \), then \( R_2 \), then \( R_4 \), then \( R_3 \), and finally \( R_5 \):

A crooked path from \( a \) to \( b \) in general consists of a crooked path from \( a \) to a point in \( R_{m-1} \), followed by a crooked path from that point to a point in \( R_{m-2} \), followed by a crooked path from that point to \( b \). Thus
Figure XI.46: Crooked Path of Length 5

the picture on [HY88, p. 142] is not correct: an actual crooked path is far more complicated (there would be $14,398,739,476,117,879 \approx 1.4 \times 10^{16}$ horizontal segments for a minimal crooked path of length 45).

To construct a pseudo-arc, fix two points $a$ and $b$ in $\mathbb{R}^2$, and then:

1. Let $X_1$ be a narrow (solid) rectangle of width $< 1$, containing $a$ and $b$ in its interior, and subdivide $X_1$ into a strip of subrectangles $R_{1,1}, \ldots, R_{1,k_1}$, each of diameter $\leq 1$, with $a$ in the interior of $R_{1,1}$ and $b$ in the interior of $R_{1,k_1}$. Alternatively, let $X_1$ be the union of a chain of closed balls from $a$ to $b$.

2. Take a path from $a$ to $b$ in $X_1$ which is simple (does not cross itself) and crooked for the $R_{1,j}$.

3. Fatten up the path within $X_1$ into a thin strip $X_2$ homeomorphic to a (solid) rectangle, and subdivide $X_2$ into a strip of subsets $R_{2,1}, \ldots, R_{2,k_2}$ homeomorphic to subrectangles, of diameter $\leq \frac{1}{2}$, with $a$ in the interior of $R_{2,1}$ and $b$ in the interior of $R_{2,k_2}$. Alternatively, cover the path with a chain of closed balls, and let $X_2$ be the union.

4. Take a simple path from $a$ to $b$ in $X_2$ which is crooked for the $R_{2,j}$, and iterate the process.

Let $X = \cap_{n=1}^{\infty} X_n$. Then $X$ is a compact subset of $\mathbb{R}^2$ containing $a$ and $b$. Since each $X_n$ is homeomorphic to a (solid) rectangle, it is connected; thus $X$ is connected by XI.13.3.6. $X$ is called a pseudo-arc.

A pseudo-arc is compact and connected (a continuum), and topologically one-dimensional. It is an indecomposable continuum: it cannot be written as a union of two proper subcontinua. In this respect it is enormously different from an ordinary arc. In fact, a pseudo-arc is a hereditarily indecomposable continuum: every subcontinuum is also indecomposable. Actually, every subcontinuum of the pseudo-arc with more than one point is homeomorphic to the whole pseudo-arc (an ordinary arc has this property too). And unlike an ordinary arc which has endpoints topologically different from the other points of the arc, a pseudo-arc is homogeneous: for any points $p$ and $q$, there is a homeomorphism of the pseudo-arc to itself sending $p$ to $q$. These properties are proved in [Bin48], where it is also shown that the pseudo-arc is the unique homogeneous hereditarily indecomposable continuum, and also [Bin51a] the unique chainable (hereditarily indecomposable) continuum. In particular, up to homeomorphism the pseudo-arc does not depend on the details of the choice of the $X_n$, so it makes sense topologically to refer to the pseudo-arc. The pseudo-arc can be constructed as an inverse limit of intervals (XI.14.4.18.(ii)).

There is no nonconstant continuous function from an ordinary arc into a pseudo-arc; thus the path components of a pseudo-arc are singletons, i.e. the pseudo-arc is connected but totally path-disconnected.
XI.18.4.30. Pseudo-arcs may seem pathological, but “almost every” continuum in $\mathbb{R}^2$ is a pseudo-arc [Bin51a], in the sense that if the set $C$ of continua in $\mathbb{R}^2$ is given the Hausdorff metric (,) making it into a compact metrizable space, the set of continua which are not pseudo-arcs is meager (). See http://topology.auburn.edu/pm/pseudodraw.pdf for an interesting discussion of the pseudo-arc, including the difficulties inherent in trying to draw a picture of it.

XI.18.4.31. There is also a similar pseudo-circle, described in [Bin51a], whose complement is homeomorphic to the complement of a circle (a bounded component homeomorphic to a disk and an unbounded one). The pseudo-circle is also a hereditarily indecomposable continuum (every proper subcontinuum is a point or a pseudo-arc), and there is also a uniqueness statement up to homeomorphism for pseudo-circles. However, the pseudo-circle is not homogeneous ([?], [?]). This is a little counterintuitive, since an ordinary circle is homogeneous and an ordinary arc is not; the situation is reversed in the pseudo case. The homogeneity/nonhomogeneity of these spaces is a very subtle matter. There is another similar continuum in the plane, called a circle of pseudo-arcs [BJ59], which separates the plane like a circle and is homogeneous (but not indecomposable). There are in fact $2^{\aleph_0}$ topologically distinct hereditarily indecomposable continua in the plane [Bin51a] (there are also hereditarily indecomposable continua of every dimension; cf. [Bin51b], [Kel42]).

There are bizarre plane continua which look nothing like a pseudo-arc: an example is given in [AC59], also constructed as an intersection (or inverse limit), with the property that no two proper subcontinua (containing more than one point) are homeomorphic. Such a continuum can contain neither an arc nor a pseudo-arc (and hence cannot contain any of the other examples of this section), has empty interior and is topologically one-dimensional, and is highly (“totally”) nonhomogeneous. This space is not indecomposable; in fact, it contains no indecomposable subcontinuum of more than one point.

The Lakes of Wada

XI.18.4.32. This subset of $\mathbb{R}^2$, first described by K. Yoneyama [] and credited by him to T. Wada, is constructed as an intersection. The pun name “lakes of Wada” may have been first used in [HY88]. A somewhat similar example was previously described by Brouwer [].

A tropical island $X_0$ named Wada is surrounded by blue ocean. There are two lakes on the island, one with green water and one with brown, with no islands (i.e. the lakes are homeomorphic to open disks). At the first step, canals are dug from the ocean so that every spot of land is within 1 km of blue water. Call the remaining land $X_1$. In the second step, canals are dug from the green lake to within 1/2 km of every spot of land, so that the green lake plus canals is still homeomorphic to an (open) disk. Call the remaining land $X_2$. In the third step, canals are dug from the brown lake to within 1/4 km of every spot of land. In the fourth step, the ocean is used again, and then the green lake, then the brown, repeated cyclically. Call the remaining land $X$ after infinitely many steps, i.e. $X = \cap_{n=1}^{\infty} X_n$.

The construction can (in principle) clearly be continued indefinitely, since each $X_n$ is homeomorphic to a large closed disk with two small open disks removed from its interior (with the boundaries of the three disks pairwise disjoint). At the end, each lake is still homeomorphic to an open disk, and the ocean to the complement in $\mathbb{R}^2$ of a closed disk (if the construction is done on a 2-sphere such as the surface of the earth instead of $\mathbb{R}^2$, the ocean is also an open disk). However, the boundary of each of these three disjoint connected open subsets of $\mathbb{R}^2$ is the set $X$: every point of $X$ is arbitrarily close to blue, green, and brown water. The set $X$ is compact and connected, and has empty interior (it is topologically one-dimensional, and topologically similar to a pseudo-arc). It is unclear to what extent the homeomorphism type of $X$ depends on the details of the construction of the canals.
Instead of two lakes, we can start with $n$ lakes and end up with $n + 1$ disjoint connected open sets in $\mathbb{R}^2$ whose common boundary is the same connected compact set $X$. With care, the construction can even be done with countably many initial lakes. Thus, if $n$ is any natural number or $\aleph_0$, there are $n$ disjoint open subsets of the 2-sphere, each homeomorphic to an open disk, with dense union, which share a common boundary.

Basins of attraction for nonlinear systems frequently resemble lakes of Wada. These basins of attraction are called Wada basins.

The lakes of Wada show again (cf. XI.18.4.5.) that care must be exercised in formulating the Four-Color Theorem.

**Nontrivial Embeddings**

There are classes of examples of subsets of $\mathbb{R}^3$ (or $\mathbb{R}^n$) in which the subset itself is a familiar or nicely behaved one, but is embedded in Euclidean space in an unusual or strange way. There are two general subtypes: “tame” embeddings which are locally nice (e.g. smooth embeddings of manifolds), and “wild” embeddings which are not locally nice.

**Knots**

This is the simplest instance of interesting tame embeddings, consisting of topological circles embedded in $\mathbb{R}^3$ in a nontrivial way.
XI.18.4.33. Definition. A knot is a smooth embedding of $S^1$ into $\mathbb{R}^3$.

Knot theory is a fascinating and active branch of modern topology; see Figure XI.48, from http://www.math.unl.edu/~mbrittenham2/ldt/table9.gif, for some examples of knots (some of the pictures are of links, made up of more than one circle), and Figure XI.49 for a nice depiction of the simplest nontrivial knot, the trefoil knot (in a mathematical knot, the blue tube has no thickness). There are many other knot images and animations on the internet. See e.g. [] for more information on knot theory.

Figure XI.48: Some Knots and Links
Figure XI.49: A Trefoil Knot. Artwork by Jim Belk
Higher-Dimensional Knots

XI.18.4.34. One might also wonder about subsets of $\mathbb{R}^n$ (or $S^n$) homeomorphic to $S^m$ for $1 < m < n - 1$. Such subsets always have connected complements, but the ways they can be embedded (even leaving out “wild” embeddings, e.g. restricting to smooth or piecewise-linear embeddings) are very complicated.

Wild Arcs

XI.18.4.35. An arc in a topological space $X$ is a copy of $[0,1]$ in $X$ (a subspace of $X$ homeomorphic to $[0,1]$). Even an arc in $\mathbb{R}^3$ can be wildly embedded. The simplest and best-known example is due to Fox and Artin [FA48] (Figure XI.50, from http://www.sciencedirect.com/science/article/pii/S0960077901002429, originally from [HY88]):

![Image of the Fox-Artin Wild Arc](http://www.sciencedirect.com/science/article/pii/S0960077901002429)

Figure XI.50: The Fox-Artin Wild Arc

This embedding is wild at the two endpoints. The complement of the arc is not simply connected.

XI.18.4.36. By successively replacing small subarcs of this arc with a small copy of the whole wild arc, a sequence of embeddings of $[0,1]$ into $\mathbb{R}^3$ can be obtained which are wild at many points. If done carefully, this sequence of embeddings can be made to converge uniformly on $[0,1]$ to an embedding (arc) which is wild at every point.

See [Bor47] for a different kind of pathological arc in $\mathbb{R}^3$.

Alexander’s Horned Sphere

XI.18.4.37. The Alexander horned sphere is a subset of $\mathbb{R}^3$ homeomorphic to $S^2$ whose exterior is not homeomorphic to the exterior of the unit sphere in $\mathbb{R}^3$ (it is not simply connected []). The union of the horned sphere and its interior is homeomorphic to $B^3$, and the interior is homeomorphic to the open unit ball. By extending the horns into the ball instead of outside, a homeomorph of $S^2$ in $\mathbb{R}^3$ can be made whose interior is not topologically a ball, and by making horns both inside and outside both the interior and exterior can be made pathological.

There are many pictures and animations of the horned sphere on the internet (Figure XI.52 is from http://conan777.files.wordpress.com/2010/04/hornedsphere3.jpg), although I still think the best picture is the classic one in [HY88] (Figure XI.51, from http://www.sciencedirect.com/science/article/pii/S0960077901002429). For a beautiful animation of the Alexander Horned Sphere, see https://www.youtube.com/watch?v=Pe2mnrLUYFU.
XI.18.4.38. The Alexander Horned Sphere is wild at a Cantor set of points. By successively adding small pairs of horns densely, a sequence of embeddings of $S^2$ into $\mathbb{R}^3$ can be obtained which converges uniformly to an embedding which is wild at every point (cf. XI.18.4.36.). The horns can be added outside, inside, or both inside and outside.

XI.18.4.39. There are other rather different wild embeddings of $S^2$ into $\mathbb{R}^3$. A simple one is to fatten up the Fox-Artin wild arc (Figure XI.50) into a tube tapering to a point at the ends. A variation, also discussed in [FA48], is shown in Figure XI.53, from [GH78] (the knots repeat and approach $p,q,r,s$). See also [Rus73]. Actually, the first wild sphere was obtained by L. ANTOINE (who was blind!) [?], who also constructed Antoine’s necklace (XI.18.4.40.).
Figure XI.52: Construction of an Alexander horned sphere
Figure XI.53: A Few Steps in the Construction of a Wild Sphere

1247
Antoine’s Necklace

XI.18.4.40. This is another subset of $\mathbb{R}^3$ defined by an intersection, a Cantor set wildly embedded in $\mathbb{R}^3$. Begin with a solid torus $X_1$ in $\mathbb{R}^3$. Inside take a chain $X_2$ of smaller interlocked solid tori as in Figure XI.54 (the number of interlocked tori is unimportant as long as it is at least three, although the final embedding of the Cantor set depends on the number of tori at each stage [She68]):

![Figure XI.54: First step in the construction of Antoine's Necklace](image)

Inside each of these smaller solid tori put a similar chain of even smaller interlocked solid tori, and iterate in such a way as to make the diameters of the solid tori at the $n$’th stage $X_n$ go to zero as $n \to \infty$. The intersection $X$ is *Antoine’s Necklace*.

![Figure XI.55: Two steps in the construction of Antoine’s Necklace](image)

Figure XI.56 shows three stages of the construction.

The connected components of $X$ are contained in the connected components of $X_n$ for each $n$; since the diameters of these connected components approach zero as $n \to \infty$, the connected components of $X$ have diameter zero, i.e. are single points. Thus $X$ is totally disconnected. However, it is clear that $X$ can have no isolated points, since every point of $X$ is arbitrarily close to points from different components of $X_n$ for large enough $n$. Thus $X$ is homeomorphic to the Cantor set $K$.

However, the complement of $X$ in $\mathbb{R}^3$ is not simply connected. If $\gamma$ is a loop around the “hole” in $X_1$, then $\gamma$ cannot be shrunk to a point in the complement of $X_n$ for any $n$ (this seems “obvious”, but some
Figure XI.56:  Three steps in the construction of Antoine’s Necklace

nontrivial topology is needed to prove it). If it could be shrunk to a point in the complement of \(X\), the homotopy would trace out a continuous image of a disk, a compact set \(Y\) in \(\mathbb{R}^3\). This set would be disjoint from \(X_n\) for sufficiently large \(n\) by a simple compactness argument (the complements of the \(X_n\) give an open cover of \(Y\)). Thus \(\gamma\) could be shrunk to a point in the complement of some \(X_n\), a contradiction.

So \(X\) is embedded in \(\mathbb{R}^3\) in a very different way than the ordinary Cantor set, regarded as a subset of the \(x\)-axis in \(\mathbb{R}^3\). The construction and its variations are described in [BM88], where the set is described as a necklace that “cannot fall apart” despite having no string.

It also follows from results in [BM88] that any uncountable compact space which can be embedded in a surface in \(\mathbb{R}^3\) (e.g. any uncountable compact subset of \(\mathbb{R}^2\)) can be embedded in \(\mathbb{R}^3\) in uncountably many essentially different ways.

It is known that any subset \(Z\) of \(\mathbb{R}^2\) homeomorphic to the ordinary Cantor set \(K\) (sitting in the \(x\)-axis) is embedded in the same way as \(K\): there is a homeomorphism of \(\mathbb{R}^2\) onto itself carrying \(Z\) onto \(K\) [CV98].

See [Rus92] for some generalizations of Antoine’s necklace and wild embeddings of spheres in \(\mathbb{R}^n\). See also Exercise XI.18.5.4..
**Other Examples**

**XI.18.4.41.** These examples only scratch the surface of the possibilities. Many other examples can be found in books like [SS95], [Bor67], [Edg08], and [Fal14].

When noncompact subsets of Euclidean space are considered, the possibilities become far greater and more bizarre. For example:

**XI.18.4.42.** Proposition. [Kur66, p. 263] Up to homeomorphism, there are $2^{2^\aleph_0}$ distinct subsets of $\mathbb{R}$, or of any separable metric space of cardinality $2^{\aleph_0}$.

**Proof:** If $A$ is a subset of $\mathbb{R}$, then $A$ is separable. There are only $2^{\aleph_0}$ continuous functions from any separable space to $\mathbb{R}$, since such a function is completely determined by its values on a countable dense set. Thus there can only be $2^{\aleph_0}$ subsets of $\mathbb{R}$ homeomorphic to $A$. Since there are $2^{2^\aleph_0}$ subsets of $\mathbb{R}$, there must be $2^{2^\aleph_0}$ homeomorphism classes.

Since there are only $2^{\aleph_0}$ Borel sets in $\mathbb{R}$, “most” of these sets are not even homeomorphic to Borel sets. (Actually, any subset of $\mathbb{R}$ homeomorphic to a Borel set is a Borel set.)

**XI.18.5. Exercises**

**XI.18.5.1.** Let $k$ and $X_k$ be as in XI.18.4.1. Suppose $k'$ is another sequence of natural numbers and $\phi : X_k \to X_{k'}$ is a homeomorphism.

(a) For various points $p$ in $X_k$, consider the number and homeomorphism type of connected components of $X_k \setminus \{p\}$. Observe that this data must be the same for $X_{k'} \setminus \{\phi(p)\}$.

(b) Use (a) to show that necessarily $\phi \left( \left( \frac{1}{2^n}, 0 \right) \right) = \left( \frac{1}{2^n}, 0 \right)$ for all $n$.

(c) Conclude that $k = k'$.

(d) If the sequences $k$ and $k'$ are strictly increasing and distinct, there is a simpler proof that $X_k$ and $X_{k'}$ are not homeomorphic, since for each $n \geq 2$ there is a unique point $p \in X_k$ such that $X_k \setminus \{p\}$ has exactly $k_n + 2$ components. Show that there are $2^{\aleph_0}$ such sequences (they are in one-one correspondence with the infinite subsets of $\mathbb{N}$).

**XI.18.5.2.** This problem is an elaboration of XI.18.4.2. Recall the notation of (). For a compact space $X$, let $X_\infty$ be the stable perfect subset ($K$ in the case $X = X_m$ for some $m$), $S^{(k)}(X)$ the set of isolated points of the $k$’th derived set $X^{(k)}$, and

$$B^{(k)}(X) = \left[ \overline{S^{(k)}(X)} \setminus S^{(k)}(X) \right] \cap X_\infty .$$

A homeomorphism from $X$ to a space $Y$ must send $X_\infty$ to $Y_\infty$ and $B^{(k)}(X)$ to $B^{(k)}(Y)$ for each $k$. Show that $B^{(k)}(X_m) \neq B^{(k+1)}(X_m)$ if and only if $k = m_n$ for some $n$. Conclude that the $X_m$ are mutually nonhomeomorphic for distinct $m$.  

1250
XI.18.5.3. (a) Let $X$ be a compact connected subset of $\mathbb{R}^2$. Show that if $\mathbb{R}^2 \setminus X$ is connected, it is homeomorphic to $\mathbb{R}^2 \setminus \{0\}$. [Use XI.23.10.1., and show the boundary there can be taken to be a single curve.] Contrast with XI.19.5.13..

(b) Show more generally that if $X$ and $Y$ are compact subsets of $\mathbb{R}^2$ such that $U = \mathbb{R}^2 \setminus X$ and $V = \mathbb{R}^2 \setminus Y$ are connected, then $U$ and $V$ are homeomorphic if and only if the component spaces $X_c$ and $Y_c$ (XI.13.9.15.) are homeomorphic. This generalizes both (a) and XI.19.5.13..

(c) Let $X$ be a compact connected subset of $\mathbb{R}^2$. Show that the unbounded component of $\mathbb{R}^2 \setminus X$ is homeomorphic to $\mathbb{R}^2 \setminus \{0\}$, and that each bounded component is homeomorphic to an open disk. [For the unbounded component, apply (a) to the union of $X$ and the bounded components of $\mathbb{R}^2 \setminus X$. For bounded components, invert in a small circle within the component.] Make an analogous statement about complements of compact connected subsets of $S^2$.

These results are special to $\mathbb{R}^2$ (analogous results hold more simply in $\mathbb{R}^1$): several examples from this section show that nothing like this holds in $\mathbb{R}^3$.

XI.18.5.4. Modify the construction of Antoine’s Necklace as follows.

(a) Consider the following linked set of solid tori (picture from [Gar01]; the surfaces should not touch):

![Figure XI.57: Variation of Borromean Rings](figure.png)

The number $n$ of solid tori is not important as long as it is at least 3 (although, as with Antoine’s Necklace, the number probably affects the final embedding); the case $n = 3$ is the usual Borromean Rings (Figure XI.48 $6_2^2$). Show that the entire set of tori is linked nontrivially, that any two of the solid tori are not linked, and that if any one of the tori is removed the remaining ones are unlinked.

(b) Replace each of these solid tori by a set of smaller solid tori contained in it, linked in the same way. Iterate the construction so that the diameters of the solid tori go to zero, and take the intersection $X$.

(c) Show that $X$ is homeomorphic to the Cantor set.
(d) Show that the complement of $X$ is not simply connected; thus $X$ is nontrivially (wildly) embedded in $\mathbb{R}^3$.

(e) If $T$ is one of the solid tori in the construction, then $X \cap T$ is a clopen set in $X$. Show that every clopen set in $X$ is a finite disjoint union of such sets.

(f) Two disjoint compact subsets $A$ and $B$ of $\mathbb{R}^n$ are unlinked (or separated by spheres) if there is a homeomorphism of $\mathbb{R}^n$ sending $A$ and $B$ into disjoint open balls. Show that if $A$ and $B$ are disjoint clopen sets in $X$, then there is a partition of $A$ into clopen sets $C$ and $D$ such that $\{B, C, D\}$ are pairwise unlinked in $\mathbb{R}^3$. Conclude that $X$ is not embedded in $\mathbb{R}^3$ in the same way as Antoine’s Necklace (any version).

(g) What happens if we use other linkings of the embedded solid tori at each stage, and perhaps vary the linkings from stage to stage? We could, for example, at infinitely many stages knot the solid tori, or replace each solid torus with a thinner solid torus wrapping twice around inside it as in the construction of the solenoid (Figure XI.41). See [She68], [Sko86], and [SS13], and the references therein.

**XI.18.5.5. Knotted Solenoids.** Let $S$ be a solenoid (XI.18.4.13).

(a) By construction, $S$ is a subset of a solid torus $T$. If $K$ is a knot, fatten up $K$ into a solid torus $T_K$ and let $\phi$ be a homeomorphism of $T$ onto $T_K$. Let $S_K = \phi(S)$. $S_K$ can be regarded as a knotted version of $S$. Show that if $K_1$ and $K_2$ are knots, show that $S_{K_1}$ and $S_{K_2}$ are embedded in $\mathbb{R}^3$ in the same way if and only if $K_1 \cong K_2$.

(b) If $K$ is a knot, then $K$ can be embedded nontrivially in a solid torus with winding number greater than 1 (write the knot as the closure of a braid; cf. (6)). By fattening up $K$ inside the solid torus, we obtain a knotted solid torus. Another knot can be embedded in this in the same way. Iterating this construction and taking an intersection, an “infinitely knotted” solenoid is obtained. Classify the solenoid obtained via the winding numbers and show that any solenoid can be embedded in $\mathbb{R}^3$ in 280 essentially different ways.

**XI.18.5.6.**

(a) Let $S$ be a solenoid embedded in $\mathbb{R}^3$ in the standard (unknotted) way, with $G = \pi^1(S)$ the corresponding subgroup of $\mathbb{Q}$. Show that the fundamental group of $\mathbb{R}^3 \setminus S$ is $G$. Note that $\mathbb{R}^3 \setminus S$ is a connected open subset of $\mathbb{R}^3$, hence a connected 3-manifold.

(b) Compute the fundamental groups of the complements of the knotted solenoids of XI.18.5.5., which are also connected 3-manifolds.

**XI.18.5.7.** Let $G$ be any countable group. Show that there is a connected open subset of $\mathbb{R}^5$ (hence a connected 5-manifold) with fundamental group $G$. [See http://mathoverflow.net/questions/192230/is-there-a-manifold-with-fundamental-group-mathbbq for an outline of the construction.] Conversely, the fundamental group of any manifold is countable (6).

**XI.18.5.8. The Whitehead Continuum and the Whitehead Manifold.** [6] Here is an interesting construction reminiscent of the construction of solenoids. Let $T_0$ be a solid (unknotted) torus in $\mathbb{R}^3$, and $T_1$ a thinner solid torus embedded in $T_0$ as in Figure XI.58.

For each $k$ let $T_{k+1}$ be a thin solid torus embedded in $T_k$ in the same way. Note that each $T_k$ is unknotted in $\mathbb{R}^3$.

Let $W = \cap_{k=1}^\infty T_k$. Since each $T_k$ is compact and connected, $W$ is also compact and connected. $W$ is called the Whitehead continuum (the exact space depends on the details of the construction).

(a) If $S$ is a meridian circle for $T_0$, show that
(i) $S$ and the longitude axis circle of $T_1$ form a nontrivial link in $\mathbb{R}^3$, called the Whitehead link (XI.59).

(ii) $S$ is not null-homotopic in $T_0 \setminus T_1$.

(iii) $S$ is null-homotopic in $\mathbb{R}^3 \setminus T_1$. [This can be seen directly, but the easiest approach is to note that there is a homeomorphism of $\mathbb{R}^3$ interchanging the circles.]

(b) Discuss other properties of $W$. Is it path-connected? Simply connected?

(c) The complement of $W$ is more interesting. Regard the construction as being done in the one-point compactification $S^3$ of $\mathbb{R}^3$, and let $E = S^3 \setminus W$. The complement of a solid torus in $S^3$ is another solid torus; thus $E$ is an increasing union of solid tori. Show that each is embedded in the next as $T_1$ is embedded in $T_0$. Show that $E$ is a connected, noncompact 3-manifold, and that $E$ is simply connected [use (a)(iii).] Conclude from () that $E$ is contractible (or give a direct argument). $E$ is called the Whitehead manifold. (Unlike for $W$, up to homeomorphism $E$ does not depend on the details of the construction.)

1253
(d) Show that no neighborhood of \( \infty \) in the one-point compactification \( E^\dagger \) of \( E \) is simply connected [\( E^\dagger \) is homeomorphic to the quotient \( S^3/W \) of \( S^3 \) obtained by collapsing \( W \) to a point. Use (a)(ii).] Thus \( E^\dagger \) is not a manifold. Conclude that \( E \) is not homeomorphic to \( \mathbb{R}^3 \).

(e) Show that \( E \times \mathbb{R} \) is homeomorphic to \( \mathbb{R}^4 \), as is \( (\mathbb{R}^3/W) \times \mathbb{R} \). (However, contrary to statements in some references like [CWY10], \( (S^3/W) \times \mathbb{R} = E^\dagger \times \mathbb{R} \) is not homeomorphic to \( \mathbb{R}^4 \) since it has two ends and is not contractible.)

(f) If \( p \) is a point of \( W \), then \( E \subseteq S^3 \setminus \{p\} \cong \mathbb{R}^3 \), and thus \( E \) is homeomorphic to an open subset of \( \mathbb{R}^3 \).

(g) Some more properties of \( E \): \( E \) is the union of two open subsets, each homeomorphic to \( \mathbb{R}^3 \), whose intersection is also homeomorphic to \( \mathbb{R}^3 \) [Gab11]; \( E \) does not have any orientation-reversing diffeomorphism [AW07]; \( E \) does not admit a complete metric with strictly positive scalar curvature [CWY10], unlike \( \mathbb{R}^3 \), which does have such a metric, e.g. by identifying it with

\[ \{(x, y, z, w) : w = x^2 + y^2 + z^2 \} \subseteq \mathbb{R}^4. \]

(h) Let \( n = (n_1, n_2, \ldots) \) be a sequence in \( \mathbb{N} \). Vary the construction of \( W \) and \( E \) by wrapping \( T_k \) around \( T_{k-1} \) \( n_k \) times before linking as in Figure XI.58. Let \( W_n \) be the intersection and \( E_n = S^3 \setminus W_n \). (Thus the Whitehead continuum is \( W_n \) where \( n_k = 1 \) for all \( k \).) Show that \( W_n \) and \( E_n \) have the same properties as before. Show that \( 2^{n_0} \) distinct homeomorphism classes of \( E_n \) are obtained. Thus there are \( 2^{n_0} \) topologically distinct contractible open subsets of \( \mathbb{R}^3 \). See [McM62] for details.

In contrast, every simply connected open subset (in particular, every contractible open subset) of \( \mathbb{R}^2 \) is homeomorphic to \( \mathbb{R}^2 \). In fact, the only simply connected 2-manifolds are \( \mathbb{R}^2 \) and \( S^2 \).

Not every contractible 3-manifold is of the form of (h); cf. [McM62], [TW97]. There does not appear to be any reasonable classification of contractible 3-manifolds. The already known existence of exotic contractible 3-manifolds seems to have been overlooked in [BT82, p. 147].

XI.18.5.9. The House with Two Rooms. Let \( X \) be the subset of \( \mathbb{R}^3 \) pictured in Figure XI.60 (from [Hat02]).

\[ \text{Figure XI.60: The House With Two Rooms} \]

(a) \( X \) is a finite union of planar rectangles, and thus is a two-dimensional (compact) polyhedron in \( \mathbb{R}^3 \).

(b) Let \( Y \) be the rectangular solid in \( \mathbb{R}^3 \) generated by \( X \) (convex hull of \( X \)). Show that there is a deformation retraction of \( Y \) onto \( X \). [Push down the upper hole and expand the indentation to fill the bottom room, and similarly push up the lower hole.] Conclude \( X \) is an absolute retract, and in particular is contractible.
XI.18.5.10. **The Rational Ruler.** Construct a subset $X$ of the closed unit square $[0,1]^2 \subseteq \mathbb{R}^2$ as follows. Begin with the horizontal segment $[0,1]$ on the $x$-axis, and for each $r \in \mathbb{Q} \cap [0,1]$, $r = \frac{p}{q}$ in lowest terms, add the closed vertical segment between $(r,0)$ and $(r,\frac{1}{n})$.

(a) Show that $X$ is a compact subset of $\mathbb{R}^2$.

(b) Construct a retraction of $[0,1]^2$ onto $X$ as follows. Set $X_n = X \cup \left\{ (x,y) : 0 \leq x \leq 1, 0 \leq y \leq \frac{1}{n} \right\}$.

(note that $X = \cap_n X_n$) and construct a uniformly convergent sequence of retractions from $[0,1]^2$ onto $X_n$. Conclude () that $X$ is an absolute retract.

XI.18.5.11. ([Lub53]; cf. [Bor67, p. 150-151]) Let $n \in \mathbb{N}$. Adapt the Lakes of Wada construction to construct in $\mathbb{R}^3$ a connected two-dimensional absolute neighborhood retract $X_n$ such that the complement of $X$ in $\mathbb{R}^3$ has exactly $n$ components, the boundary of each of which is $X$. ($X$ thus has a locally nice structure, a least in a homotopy sense, unlike the examples in $\mathbb{R}^2$ like the Lakes of Wada which necessarily are locally quite pathological [?].)

XI.18.5.12. Show that there is no reasonable analog of the four-color theorem in $\mathbb{R}^3$, even for polyhedra. [Lay $n$ boards with rectangular cross-section side-by-side on the $xy$-plane in $\mathbb{R}^3$ with long dimension parallel to the $x$-axis, and on top of them lay $n$ boards with long dimension parallel to the $y$-axis. Glue the $k$'th horizontal board to the $k$'th vertical board to make a single cross-shaped polyhedron for each $k$. See http://demonstrations.wolfram.com/AnInfinitelyColorableSetOf3DRegions/.] Another more informal argument I heard somewhere: “Imagine a bowl of spaghetti where every noodle touches all the others.”] There are meaningful higher-dimensional analogs of the graph-theoretic versions of the four-color theorem, however.

XI.18.5.13. The Hahn-Mazurkiewicz Theorem says that a Hausdorff topological space is a continuous image of $[0,1]$ if and only if it is compact, metrizable, connected, and locally connected (and thus automatically path-connected and locally path-connected). Thus the Sierpiński gasket, Sierpiński carpet, and Menger sponge are all continuous images of $[0,1]$. Find explicit continuous surjections. [The construction of a space-filling curve () may provide some insight.]

XI.18.5.14. **The Infinite Comb.** Consider the compact subset of $\mathbb{R}^2$ consisting of the line segments from 0 to 1 on the $x$ and $y$ axes and the vertical segments from 0 to 1 with $x$-coordinate $\frac{1}{n}$ for each $n$ (the exact location of the $x$-coordinates of the vertical segments are unimportant as long as they form a sequence of numbers in $(0,1]$ converging to 0). See Figure XI.61.
(a) Show that the infinite comb is contractible.

(b) Show that the infinite comb is not locally connected at points on the positive $y$-axis. Thus it is not strongly contractible to any of these points. It is strongly contractible to any other point.

(c) Figures XI.62 and XI.63 show a number of variations of the infinite comb. Which of these are contractible? Which are strongly contractible, to which points? Which pairs of these are homeomorphic? (The first space in XI.62 is called Zeno’s maze in [Pug15], but I have not found this name in other references.) Show that all have trivial fundamental group, i.e. are simply connected.

Figure XI.61: The Infinite Comb
Figure XI.62: Infinite Comb Variations I
Figure XI.63: Infinite Comb Variations II
XI.18.5.15. **The Infinite Ladder.** A variation of the infinite comb is to add the horizontal segment from 0 to 1 with $y$-coordinate 1 (Figure XI.64). This space is somewhat similar to the Hawaiian Earring, but with a crucial difference: show that the fundamental group is countable.

![The Infinite Ladder](image)
XI.19. Manifolds

There are two types of mathematical objects commonly called manifolds: topological manifolds and differentiable, or smooth, manifolds (there are also PL manifolds, which are something in between). There is also a notion of “manifold with boundary,” both topological and smooth. The term “manifold” is also used in a few other related and even entirely unrelated senses in parts of mathematics. One must be aware of context whenever the term “manifold” is used. Smooth manifolds are special types of topological manifolds with specified extra structure (smooth manifolds come in a number of flavors). Both types of manifolds occur in analysis. In this section, we describe the basics of both theories; each theory is very extensive and goes far beyond what we do here.

XI.19.1. Topological Manifolds

Topological manifolds are generalizations of curves and surfaces. The property of a curve or surface we use is that near each point, a small piece of the curve or surface looks like an open ball in Euclidean space (of dimension 1 or 2 respectively). Our generalization will allow for higher-dimensional objects also, and will be intrinsic, not requiring our space to be embedded in a Euclidean space.

XI.19.1.1. Definition. A topological space $X$ is locally Euclidean if every point $p \in X$ has an open neighborhood which is homeomorphic to an open ball in $\mathbb{R}^n$ for some $n \geq 0$ (which may vary from point to point), where $\mathbb{R}^0$ is a single point. Such a neighborhood is called a coordinate patch and a homeomorphism with an open ball in $\mathbb{R}^n$ is a coordinate chart, and the $n$ is called the local dimension of $X$ at $p$. $X$ is $n$-dimensional if it is has the same local dimension $n$ at every point.

Roughly speaking, a topological manifold will just be a topological space which is locally Euclidean. But it turns out we should make a few additional technical restrictions to rule out pathologies that can occur in bizarre examples.

XI.19.1.2. Some initial remarks about the definition:

(i) The local dimension is well defined by the Invariance of Domain Theorem ().

(ii) All points within a coordinate patch have the same local dimension; thus the local dimension is locally constant (justifying the terminology “local dimension.”) Hence the local dimension is constant on components of $X$ (). In particular, a connected locally Euclidean space has the same local dimension at every point.

(iii) An $n$-dimensional metrizable locally Euclidean topological space has topological dimension $n$ (), so the terminology “$n$-dimensional” is consistent. The topological dimension of a general metrizable locally Euclidean space is the maximum or supremum of the local dimensions at all points. (This can fail in the nonmetrizable case, cf. [Fed95].)

(iv) Since an open ball in $\mathbb{R}^n$ is first countable, even second countable, a locally Euclidean space is first countable. But it need not be second countable (XI.19.1.9., XI.19.5.5.). A locally Euclidean space is locally second countable (XI.1.3.7.).

(v) Since open balls in $\mathbb{R}^n$ are locally compact, a (Hausdorff) locally Euclidean space is locally compact () and hence completely regular ().

(vi) Since an open ball in $\mathbb{R}^n$ is path-connected, a locally Euclidean space is locally path-connected; hence the components and path components coincide and are clopen sets ().
(vii) An open ball in $\mathbb{R}^n$ is homeomorphic to $\mathbb{R}^n$. Thus the definition can be equivalently rephrased: $X$ is locally Euclidean if every point $p \in X$ has an open neighborhood which is homeomorphic to $\mathbb{R}^n$ for some $n$. This is the form given in many references. However, it seems preferable to write the definition as we have, since in most examples there are more natural homeomorphisms of point neighborhoods with open balls in $\mathbb{R}^n$ than with $\mathbb{R}^n$ itself. For example, it is immediate from our definition that any open set in $\mathbb{R}^n$ is locally Euclidean (in the relative topology).

(viii) Since an open ball in $\mathbb{R}^n$ is $T_1$, a locally Euclidean topological space is locally $T_1$, hence $T_1$ (XI.7.3.5.). But it need not be Hausdorff (XI.19.1.3.(v)). This is one of the pathologies we want to exclude in the definition of a topological manifold.

**XI.19.1.3. Examples.** (i) Any open set in $\mathbb{R}^n$ is an $n$-dimensional locally Euclidean space with the relative topology.

(ii) A curve in $\mathbb{R}^n$ is a 1-dimensional locally Euclidean space (with the relative topology), provided it has no endpoints and does not cross or loop back onto itself (more precisely, if it is homeomorphic to an open interval or a circle, or a separated disjoint union of such curves). A simple curve (arc) with endpoints is an example of a manifold with boundary (I). “Curves” such as a figure 8, a figure 6, or a “Warsaw circle” (XI.18.4.4.) are not locally Euclidean and are not manifolds with boundary.

(iii) A surface in $\mathbb{R}^3$ is a 2-dimensional locally Euclidean space with the same restrictions as in (ii), which are more complicated to state precisely. Examples include a sphere, torus, a cylinder without its end circles, or a Möbius strip without its edge. A cylinder with end circles included, or a Möbius strip with its edge included, is a manifold with boundary.

(iv) The unit sphere in $\mathbb{R}^{n+1}$ is an $n$-dimensional locally Euclidean space for any $n$. The closed unit ball is not locally Euclidean, but is a manifold with boundary.

(v) A locally Euclidean space need not be Hausdorff. Here is the standard example. Let $X$ be $\mathbb{R} \cup \{0\}$, with the topology consisting of all open subsets of $\mathbb{R}$ and all sets consisting of $0'$ along with an open neighborhood or deleted open neighborhood of 0. Since $\mathbb{R}$ is an open subset of $X$, every point of $\mathbb{R}$ has a locally Euclidean neighborhood; and $0'$ does also, e.g. $\{0\} \cup (\mathbb{R} \setminus \{0\})$. Thus $X$ is locally Euclidean (and 1-dimensional). But 0 and $0'$ do not have disjoint neighborhoods. See Exercise XI.19.5.14. for a more interesting example.

There are far more complicated examples; see Exercises XI.19.5.5. and XI.19.5.8.

**XI.19.1.4. Theorem.** Let $M$ be a topological space which is Hausdorff, locally compact, and locally second countable, in which every component is open (e.g. Hausdorff and locally Euclidean). The following are equivalent:

(i) $M$ is paracompact.

(ii) $M$ is metrizable.

(iii) Every component of $M$ is Lindelöf.

(iv) Every component of $M$ is $\sigma$-compact.

(v) Every component of $M$ is second countable.

(vi) Every component of $M$ is a Polish space.
The following are equivalent, and imply (i)–(vi):

(vii) $M$ is Lindelöf.

(viii) $M$ is $\sigma$-compact.

(ix) $M$ is second countable.

(x) $M$ is a Polish space.

If $M$ satisfies (i)–(vi), then $M$ satisfies (vii)–(x) if and only if $M$ has only countably many components. In particular, if $M$ is connected, then (i)–(x) are equivalent.

**Proof:** Since the components of $M$ are clopen (), obviously (vii)–(x) each imply that $M$ has only countably components; and if $M$ has only countably components, then (vii) $\iff$ (iii), (viii) $\iff$ (iv), (ix) $\iff$ (v), and (x) $\iff$ (vi). So we need only prove that (i)–(vi) are equivalent.

Since $M$ is locally compact, (iii) $\iff$ (iv) by XI.11.8.11., and by XI.11.8.13., (v) and (vi) are equivalent and imply (iv) and that every component of $M$ is metrizable. Since the components of $M$ are clopen, $M$ is metrizable if and only if each component is metrizable (), so (v) $\Rightarrow$ (ii). (ii) $\Rightarrow$ (i) by XI.11.10.4.. $M$ is paracompact if and only if each component of $M$ is paracompact (XI.11.10.8.), and if a component is paracompact it is $\sigma$-compact by XI.11.10.18.. Thus (i) $\Rightarrow$ (iv). And since $M$ is locally second countable, (iii) $\Rightarrow$ (v) by XI.1.3.8..

**XI.19.1.5.** There are connected Hausdorff locally Euclidean topological spaces not satisfying the conditions of Theorem XI.19.1.4.. Such a space can be normal (Exercise XI.19.5.5.) or nonnormal (Exercises XI.19.5.8.–XI.19.5.9.). Separability is also not equivalent to the conditions of the theorem; such examples can be separable (Exercise XI.19.5.9.) or nonseparable (Exercises XI.19.5.5. and XI.19.5.8.). Conditions (vii)–(x) imply separability, and are equivalent to separability in the presence of (i)-(vi).

**XI.19.1.6.** There is no universal consensus on the proper definition of a topological manifold. All of the following are reasonable candidates which have in fact all appeared in various references. They are arranged roughly, but not exactly, in increasingly restrictive order. Throughout, $X$ denotes a topological space.

(i) $X$ is locally Euclidean.

(ii) $X$ is Hausdorff and locally Euclidean.

(iii) $X$ is Hausdorff, locally Euclidean, and satisfies conditions (i)–(vi) of XI.19.1.4..

(iv) $X$ is Hausdorff, locally Euclidean, and satisfies conditions (i)–(x) of XI.19.1.4..

(i)$'$ $X$ is locally Euclidean and has constant local dimension.

(ii)$'$ $X$ is Hausdorff, locally Euclidean, and has constant local dimension.

(iii)$'$ $X$ is Hausdorff, locally Euclidean, satisfies conditions (i)–(vi) of XI.19.1.4., and has constant local dimension.

1262
(iv)' $X$ is Hausdorff, locally Euclidean, satisfies conditions (i)–(x) of XI.19.1.4., and has constant local dimension.

(i)" $X$ is connected and locally Euclidean.

(ii)" $X$ is Hausdorff, connected, and locally Euclidean.

(iii)" $X$ is Hausdorff, connected, locally Euclidean, and satisfies conditions (i)–(vi) of XI.19.1.4..

(iv)" $X$ is Hausdorff, connected, locally Euclidean, and satisfies conditions (i)–(x) of XI.19.1.4..

(Note that (iii)" and (iv)" are identical.)

We will take (iii) as our definition, which is probably the most common choice. Reasonable arguments can be made for all of the versions (although the arguments for (i)–(i)" are weak; manifolds should at least be Hausdorff). Almost all spaces arising in practice which one would want to call manifolds satisfy (iv)" or at least (iv)'. However, almost all properties of such spaces hold equally well for ones satisfying (iii), with identical proofs; practically all interesting things about manifolds happen separately in each component, so it doesn’t really matter how many components there are as long as each individual component is well behaved. Definition (iii) can also be given very cleanly:

XI.19.1.7. Definition. A topological space $X$ is a (topological) manifold if it is metrizable and locally Euclidean.

A space satisfying (iv)" is then just a connected manifold, one satisfying (iv) is a separable manifold, and one satisfying (iii)' is an $n$-dimensional manifold (usually just called an $n$-manifold) for some $n$. It seems rather artificial to allow manifolds with nonconstant local dimension, and they rarely arise in practice; we can restrict to the constant local dimension case by just using the term “$n$-manifold”.

XI.19.1.8. A compact Hausdorff locally Euclidean space automatically satisfies (viii), hence (i)–(x), and in particular is a manifold.

XI.19.1.9. The case $n = 0$ is allowed in the definition of a manifold. A 0-manifold is just a set with the discrete topology.

XI.19.2. Topological Manifolds With Boundary

We would like to extend the notion of manifold to include such examples as curves with endpoints, surfaces with boundary curves, and closed balls in $\mathbb{R}^n$. These will be examples of “manifolds with boundary.”

The basic tool is the notion of a half-space:

XI.19.2.1. Definition. The $n$-dimensional half-space ($n \geq 1$) is the subset

$$\mathbb{H}^n = \{(x_1, \ldots, x_n) \in \mathbb{R}^n : x_n \geq 0\}$$

with the relative topology from $\mathbb{R}^n$. Its boundary $\partial \mathbb{H}^n$ is the set of $n$-tuples with last coordinate zero. We also define $\mathbb{H}^0$ to be a single point, with $\partial \mathbb{H}^0 = \emptyset$.
XI.19.2.2. Definition. A *topological* manifold with boundary is a metrizable space $X$ in which every point has an open neighborhood homeomorphic to an open set in $\mathbb{H}^n$ for some $n \geq 0$ (which may vary from point to point.) Such an open set is called a *coordinate patch*, and the homeomorphism is called a *coordinate chart*. If the $n$ is constant, $X$ is called an $n$-manifold with boundary. A point of $X$ with a neighborhood homeomorphic to $\mathbb{R}^n$ (or to an open set in $\mathbb{R}^n$) is called an *interior point* of $X$, and a point which maps to a point in $\partial \mathbb{H}^n$ under a coordinate chart is called a *boundary point* of $X$. Denote by $\partial X$ the set of boundary points of $X$, called the *boundary* of $X$.

Note that the use of “interior point” and “boundary point” here is not the same as the general use in topology: such points may not be interior or boundary points respectively in the topological sense. Indeed, since a manifold with boundary is not naturally embedded as a subset of a larger topological space, topological interior and boundary do not really even make sense.

XI.19.2.3. Just as with manifolds, manifolds with boundary are locally compact and locally path-connected, and the components and path components coincide and are clopen subsets. Each component is second countable and $\sigma$-compact, and a Polish space.

XI.19.2.4. Examples. (i) $\mathbb{H}^n$ is an $n$-manifold with boundary. The boundary points are the points of $\partial \mathbb{H}^n$.

(ii) Any (topological) manifold $X$ is a manifold with boundary, with $\partial X = \emptyset$. (So the term “manifold with boundary” does not imply that the boundary is nonempty.)

(iii) Since $\mathbb{H}^1$ is a ray, a closed or half-open interval $I$ in $\mathbb{R}$ is a 1-manifold with boundary $\partial I$ consisting of the endpoint(s). In fact, a complete list (up to homeomorphism) of connected 1-manifolds with boundary is: an open interval, a half-open interval, a closed interval, and a circle.

(iv) A closed disk $D$ in $\mathbb{R}^2$ is a 2-manifold with boundary, with $\partial D$ the boundary circle. More generally, a closed ball in $\mathbb{R}^n$ is an $n$-manifold with boundary.

(v) A Möbius strip $M$ is a 2-manifold with boundary, with $\partial M$ a circle.

(vi) A figure 8 or figure 6 is not a manifold with boundary, since in each case there is one point which does not have any neighborhood homeomorphic to an open set in $\mathbb{H}^1$ (or $\mathbb{H}^n$ for any $n$).

(vii) An open disk with a relatively open subset of the bounding circle added (i.e. a relatively open subset of a closed disk) is a manifold with boundary; more generally, an open subset of any manifold with boundary is a manifold with boundary. But an open disk with a subset of the bounding circle added which is not relatively open is not a manifold with boundary, although this is not entirely obvious.

The next result may seem obvious, but a rigorous proof is rather involved on one point.

XI.19.2.5. Theorem. Let $X$ be an $n$-manifold with boundary. Then

(i) The interior and the boundary of $X$ are disjoint. $\partial X$ is closed in $X$, and the set of interior points is dense and open.

(ii) The interior of $X$ is an $n$-manifold, and $\partial X$ (if nonempty) is an $(n-1)$-manifold.

It is obvious that the set of interior points is dense and open, and that the interior is an $n$-manifold. (Under any coordinate chart, points going to a point of $\mathbb{H}^n \setminus \partial \mathbb{H}^n$ are interior points.) The issue in proving
that the interior and boundary are disjoint is to show that a point of \( \partial \mathbb{H}^n \) does not have an open neighborhood in \( \mathbb{H}^n \) homeomorphic to an open set in \( \mathbb{R}^n \) (or in \( \mathbb{R}^m \) for any \( m \)). This is nontrivial to prove directly, but is an immediate consequence of the Invariance of Domain Theorem. The simplest direct proof, which uses some algebraic topology, is that a point of \( \partial \mathbb{H}^n \) has a deleted neighborhood in \( \mathbb{H}^n \) which is contractible, while no point of \( \mathbb{R}^n \) has a contractible deleted neighborhood. It follows from the disjointness that \( \partial X \) is closed. Showing that \( \partial X \) is an \((n-1)\)-manifold is straightforward, since the points of \( \partial X \) in a coordinate patch around a point of \( \partial X \) form a set homeomorphic to a relatively open set in \( \partial \mathbb{H}^n \), which is homeomorphic to \( \mathbb{R}^{n-1} \).

**XI.19.2.6. Convention:** In geometry/topology, the term “manifold” is often used to mean “manifold with boundary” (with, of course, the possibility that the boundary is empty). In particular, the term “compact manifold” normally means “manifold with boundary which is compact” (i.e. the whole space is compact, not just the boundary). To refer to a manifold in the sense of **XI.19.1.7.** which is compact, the term closed manifold (which has no real logical meaning) is normally used. The term open manifold is also sometimes used to mean a manifold which is noncompact and has empty boundary. The same conventions are used for smooth manifolds.

In some references, a manifold with empty boundary is called unbounded. However, this term seems much too fraught with potential misinterpretation to be appropriate, especially in an analysis book. I also have a very hard time calling a circle or sphere “unbounded.”

In this book, we will strive for minimum ambiguity at the possible cost of excessive pedantry on these terms: we will always use the phrase “manifold with boundary” when a boundary is allowed, and we will avoid using “compact manifold”, writing “manifold with boundary” if a boundary is allowed and “closed manifold” otherwise. (There is still some ambiguity: is a “closed submanifold” of a manifold a submanifold which is a closed subset of the manifold, or a submanifold which is compact? We will be explicit about which is meant when this occurs.) And we will not use the term “unbounded” in the context of manifolds, except when they are explicit subsets of Euclidean space, where the term “unbounded” has its usual meaning for subsets (i.e. not contained in a ball of finite radius). We will avoid the term “open manifold.”

**XI.19.3. New Manifolds From Old**

**XI.19.4. Classification of Topological Manifolds**

**Number of Manifolds**

**XI.19.4.1.** How many topologically distinct topological manifolds (with or without boundary) are there? Since according to our definition any discrete space is a manifold, the question is meaningless; we should restrict to connected manifolds, or at least to manifolds with only countably many components, i.e. separable manifolds.

Any separable manifold with boundary is a Polish space, and there are \( 2^{\aleph_0} \) topologically distinct Polish spaces (\ref{exercise:xi.19.5.10}), so there are at most \( 2^{\aleph_0} \) topologically distinct separable manifolds with boundary. On the other hand, if \( n > 1 \) there are \( 2^{\aleph_0} \) topologically distinct connected open subsets of \( \mathbb{R}^n \) (**XI.19.5.13.**), each of which is a separable connected \( n \)-manifold, so up to homeomorphism there are exactly \( 2^{\aleph_0} \) separable manifolds, and exactly \( 2^{\aleph_0} \) separable manifolds with boundary. The same is true if “separable” is replaced by “connected.”

There are \( 2^{2^{\aleph_0}} \) topologically distinct 2-dimensional connected Hausdorff locally Euclidean spaces, both with and without boundary (Exercise **XI.19.5.10.**).
The question is more interesting and difficult in the compact case (a compact manifold with boundary is automatically separable). In fact:

**XI.19.4.2.** Theorem. There are only countably many homeomorphism classes of compact manifolds with boundary.

For each \( n > 1 \), there are infinitely many topologically distinct connected closed \( n \)-manifolds \([\ldots]\). See [CK70] for a proof of XI.19.4.2.

**XI.19.5. Exercises**

**XI.19.5.1.** (a) Show that an open set in a locally Euclidean space is locally Euclidean in the relative topology. Show that an open set in a topological manifold is a topological manifold in the relative topology.

(b) Show that a finite cartesian product of locally Euclidean spaces is locally Euclidean. Show that a finite cartesian product of topological manifolds is a topological manifold. What about products of topological manifolds with boundary? [Consider \( \mathbb{H}^n \times \mathbb{H}^m \).]

**XI.19.5.2.** Let \( X \) be a locally Euclidean space, and \( U \) and \( V \) open subsets of \( X \). Suppose \( \phi \) is a homeomorphism from \( U \) to \( V \). Let \( X/\phi \) be the topological space obtained from \( X \) by identifying \( U \) and \( V \) via \( \phi \), with the quotient topology.

(a) Show that \( X/\phi \) is locally Euclidean.

(b) Show that the example of XI.19.3.(v) is obtained this way by letting \( X \) be two disjoint copies of \( \mathbb{R} \) and \( U \) and \( V \) the two copies of \( \mathbb{R} \setminus \{0\} \).

(c) Under what conditions will \( X/\phi \) be Hausdorff?

(d) Construct a circle from \( \mathbb{R} \) by this method, and a Möbius strip from \( \mathbb{R}^2 \).

(e) Generalize to a family of open subsets \( \{U_i : i \in I\} \), with specified homeomorphisms \( \phi_i \) of \( U_i \) with a fixed space \( U_0 \).

**XI.19.5.3.** Let \( X \) and \( Y \) be topological manifolds with boundary. Let \( \phi \) be a homeomorphism from \( \partial X \) to \( \partial Y \) (existence of such a \( \phi \) entails that \( X \) and \( Y \) have the same dimension, at least locally), and \( X \cup_\phi Y \) the topological space obtained from the disjoint union of \( X \) and \( Y \) by identifying \( \partial X \) and \( \partial Y \) by \( \phi \). (We say \( X \) and \( Y \) are *glued* along the boundary via \( \phi \)).

(a) Show that \( X \cup_\phi Y \) is a topological manifold.

(b) What manifold results from gluing two disks along the boundary, which is a circle? What if one or both disks are replaced by a Möbius strip, whose boundary is also a circle?

(c) The boundary of a cylinder is two disjoint circles. What if two cylinders are glued together along the boundary circles? Does the resulting manifold depend on the homeomorphisms chosen?

(d) Show that if \( X \) and \( Y \) are smooth manifolds with boundary, and \( \phi \) is a diffeomorphism, then \( X \cup_\phi Y \) is a smooth manifold.

**XI.19.5.4.** Show that \([0,1) \times (0,1), [0,1) \times [0,1), [0,1) \times [0,1)\], and a closed disk with a single boundary point removed are all homeomorphic to \( \mathbb{H}^2 \) and hence are topological 2-manifolds with boundary.
XI.19.5.5. **The Long Line.** Denote by \( \omega_1 \) the ordered set of ordinals less than the first uncountable ordinal \( \omega \). Give \( L_0 := \omega_1 \times [0,1) \) the lexicographic ordering, and the order topology \( \). \( L_0 \) is called the *long ray*.

(a) If \( a, b \in L_0, a < b \), then the interval \( [a, b] \) is homeomorphic to a closed bounded interval in \( \mathbb{R} \). [Use the fact that any countable successor ordinal is order-isomorphic to a closed subset of \([0, 1)\).] Hence the open interval \( (a, b) \) is homeomorphic to \( \mathbb{R} \). Show that \( L_0 \) is order-complete and that it has no countable cofinal subset. Show that \( L_0 \) is countably compact and sequentially compact, and that every real-valued continuous function on \( L_0 \) is eventually constant.

(b) \( L_0 \) is not locally Euclidean since it has an endpoint (smallest point). If this is removed, a 1-dimensional locally Euclidean space \( L_+ \) is obtained which is called the *open long ray* or *half-long line*. \( L_+ \) is normal, even completely normal (and in particular Hausdorff), as is any space with the order topology (XI.16.1.1.), and is connected since it is order-complete. \( L_+ \) has a countable coinitial set but no countable cofinal set.

(c) Show that the open cover \( \{(a, b) : a, b \in L_+, a < b\} \) of \( L_0 \) has no locally finite refinement. Thus \( L_+ \) is not paracompact. Show directly that \( L_+ \) does not satisfy any of the other conditions of XI.19.1.4.. \( L_+ \) is also not separable. \( L_+ \) is not countably compact or sequentially compact.

(d) Let \( -L_0 \) be a copy of \( L_0 \) with ordering reversed, and \( L \) be the union of \( -L_0 \) and \( L_0 \) with the endpoint of \( -L_0 \) identified with the initial point of \( L_0 \), with the order topology (the points of \( -L_0 \) smaller than the points of \( L_0 \)). Then \( L \) is a 1-dimensional locally Euclidean space which is connected and normal, with neither a countable coinitial set nor a countable cofinal set, does not satisfy any of the conditions of XI.19.1.4., and is not separable. \( L \) is called the *long line*. If \( a, b \in L, a < b \), then the subset \( [a, b] \) of \( L \) is homeomorphic to \([0, 1]\), and \((a, b)\) is homeomorphic to \( \mathbb{R} \). Show that \( L \) is countably compact and sequentially compact, and that every real-valued continuous function on \( L \) is eventually constant in each direction.

(e) Show that \( L, L_+, \) and \( L_0 \) are not contractible.

(f) Show that if \( M \) is a connected 1-dimensional Hausdorff locally Euclidean space, then \( M \) is homeomorphic to exactly one of the following: \( \mathbb{R}, L, L_+ \), or a circle \( S^1 \).

XI.19.5.6. Let \( L \) and \( L_0 \) be as in XI.19.5.5.. Show that the Stone-Čech compactification \( \) of \( L_0 \) coincides with the one-point compactification \( \). Show that the Stone-Čech compactification of \( L \) consists of adding two points to \( L \), one at each “end.”

XI.19.5.7. [?, Appendix A] Consider the following Cartesian products of the spaces from XI.19.5.5.(f):

- \( L \times L \), the *big plane*.
- \( L \times L_+ \), the *big half-plane*.
- \( L_+ \times L_+ \), the *big quadrant*.
- \( L \times \mathbb{R} \), the *wide plane* or *long strip*.
- \( L_+ \times \mathbb{R} \), the *half-long strip*.
- \( L \times S^1 \), the *long cylinder*.
- \( L_+ \times S^1 \), the *half-long cylinder*.
(a) Show that each is a connected 2-dimensional Hausdorff locally Euclidean space not satisfying the conditions of XI.19.1.4.

(b) There are four obvious copies of \( L \) in \( L \times L \), the “\( x \)-axis”, the “\( y \)-axis”, and the “diagonals.” Show that the diagonals are embedded differently than the axes. [Show that any copy of \( \omega_1 \) in \( L \times L \) which hits the \( x \)-axis in uncountably many points has only countably many points off the \( x \)-axis, but this is false for the diagonals.] The same is true in \( L_0 \times L_0 \), where \( L_0 \) is the long ray (there is only one diagonal here). Use this to show that that no two of the above spaces are homeomorphic (it is hardest to distinguish between the big half-plane, the big quadrant, and the half-long strip; cf. XI.19.5.4.). [For another approach, use (c).]

(c) Identify the initial circle of \( L_0 \times S^1 \) to a point. Show that a sequentially compact connected 2-dimensional Hausdorff locally Euclidean space is obtained not satisfying the conditions of XI.19.1.4., sometimes called the big disk. Show that the big disk is not homeomorphic to any of the spaces of (a) (it is hardest to distinguish it from the big plane).

(d) Let \( E \) be the “octant” \( \{ (x, y) \in L_0 \times L_0 : y \leq x \} \). \( E \) has two edges, the \( x \)-axis \( A \) and the diagonal \( D \). Let \( \sigma \) be a finite or infinite sequence of \( A \)'s and \( D \)'s. Let \( M_\sigma \) be the space obtained from the finite disjoint union of \( E \)'s, the same number as the number of terms in \( \sigma \), by taking the \( n \)'th term of \( \sigma \) as the first edge of the \( n \)'th copy of \( E \) and the other edge as the second edge, and identifying the first edge of the \( (n+1) \)'st copy of \( E \) with the second edge of the \( n \)'th copy. Then delete the first edge of the first copy of \( E \) and, if \( \sigma \) is finite, the second edge of the last copy. As a variation if \( \sigma \) is finite, identify the second edge of the last copy of \( E \) with the initial edge of the first copy to obtain a space \( M'_{\sigma} \). All these spaces are connected 2-dimensional locally Euclidean Hausdorff spaces, and the \( M'_{\sigma} \) are sequentially compact. Show that all \( M_\sigma \) and \( M'_{\sigma} \) are mutually nonhomeomorphic, except that if \( \sigma \) is finite, \( \sigma \) can be replaced by its complementary sequence obtained by interchanging \( A \)'s and \( D \)'s and reversing order, and in the case of \( M'_{\sigma} \), \( \sigma \) can be cyclically permuted. We have:

The big plane is \( M'_{\sigma} \), where \( \sigma = (A, D, A, D, A, D, A) \) or \( (D, A, D, A, D, A, D, A) \).

The big half-plane is \( M_\sigma \), where \( \sigma = (A, D, A, D) \).

The big quadrant is \( M_\sigma \), where \( \sigma = (A, D) \).

The big disk can be regarded as \( M'_{\sigma} \), where \( \sigma \) is the empty sequence. The “open octant” is the space \( M_{\sigma} \), where \( \sigma = (A) \) or \( (D) \). The \( M'_{\sigma} \) construction works even for infinite sequences, even (countably) transfinitely [Nyi84].

(e) Describe the Stone-Čech compactification of each of the above spaces.

XI.19.5.8. The Prüfer Manifold. This is an example of a 2-dimensional connected locally Euclidean space not satisfying the conditions of XI.19.1.4.

This space was first described by T. Radó in 1925 [?], and credited to his teacher, H. Prüfer. We describe a version of the construction from [?]; see also [?, Appendix A]. There are actually two rather different spaces constructed this way; only the first, described in this problem, is called the “Prüfer manifold,” and the second, described in Exercise XI.19.5.9., is a variation of a space (called the Moore manifold) constructed by R. L. Moore [?]. See [Roy88, p. 208-209] for a description of Moore’s construction. To add to the terminological confusion, all these spaces are examples of a class of spaces called Moore spaces. A variation of the Prüfer manifold is described in [CV98, p. 268-272].

Although these examples are customarily called “manifolds”, they are not manifolds according to the definition in this book since they are not metrizable (in fact, not even normal).
Begin with an uncountable collection \( \{ \mathbb{R}^2_a : a \in \mathbb{R} \} \) of copies of the plane, and an additional copy \( \mathbb{R}^2_+ \) of the open upper half plane. Take the separated union \( U \) of the \( \mathbb{R}^2_a \) and \( \mathbb{R}^2_+ \); then \( U \) is a 2-manifold. Identify the open upper half plane of each \( \mathbb{R}^2_a \) with \( \mathbb{R}^2_+ \) by

\[
(x, y) \in \mathbb{R}^2_a \ (y > 0) \quad \longleftrightarrow \quad (xy + a, y) \in \mathbb{R}^2_+
\]

and let \( P \) be the quotient space. \( P \) is called the Pr"{u}fer manifold.

(a) Show that \( P \) is a connected 2-dimensional locally Euclidean space (cf. Exercise XI.19.5.2.(a)).

(b) Show that \( P \) is Hausdorff (cf. Exercise XI.19.5.2.(c)).

(c) Let \( \mathcal{Z} \) be the union of the copies of the \( x \)-axis in \( \mathbb{R}^2_a \) for all \( a \). Show that in the relative topology \( \mathcal{Z} \) is a separated union of uncountably many copies of \( \mathbb{R} \): the \( x \)-axis of each \( \mathbb{R}^2_a \) is clopen in \( \mathcal{Z} \). Thus \( \mathcal{Z} \) and hence \( P \) is not second countable, so \( P \) does not satisfy the conditions of XI.19.1.4.

(d) Let \( A \) be the subset of \( \mathcal{Z} \) consisting of the points on the \( x \)-axis of \( \mathbb{R}^2_a \) for \( a \) rational, and \( B = \mathcal{Z} \setminus A \) the set of points on the \( x \)-axis of \( \mathbb{R}^2_a \) for \( a \) irrational. Then \( A \) and \( B \) are disjoint closed subsets of \( P \). Use the Baire Category Theorem () to prove that \( A \) and \( B \) do not have disjoint neighborhoods in \( P \). Thus \( P \) is not normal.

(e) Show that \( P \) is not separable. [Consider points in the open lower half-spaces of the \( \mathbb{R}^2_a \).]

(f) Show that \( P \) is contractible (cf. [?, Appendix A]).

**XI.19.5.9.** This problem is a continuation of XI.19.5.8.

(a) Let \( P_0 \) be the union of \( \mathcal{Z} \) and the upper half plane of \( P \) (i.e. the image of \( \mathbb{R}^2_+ \) in \( P \)). Then \( P_0 \) is a “2-dimensional locally Euclidean space with boundary.” \( P_0 \) is connected and separable since \( \mathbb{R}^2_+ \) is dense in \( P_0 \), but \( \partial P_0 = \mathcal{Z} \) consists of a separated union of uncountably many copies of \( \mathbb{R} \).

(b) Let \( Q \) be obtained by gluing two copies of \( P_0 \) along the boundary. Then \( Q \) is a 2-dimensional connected Hausdorff locally Euclidean space which is separable but does not satisfy the conditions of XI.19.1.4.

(c) \( Q \) can alternately be constructed from \( P \) by identifying for each \( a \) the open lower half plane of \( \mathbb{R}^2_a \) with a new copy \( \mathbb{R}^2_0 \) of the open lower half plane by

\[
(x, y) \in \mathbb{R}^2_a \ (y < 0) \quad \longleftrightarrow \quad (xy + a, y) \in \mathbb{R}^2_0
\]

and taking the quotient topology.

(d) The closed subsets \( A \) and \( B \) of \( \mathcal{Z} \) in XI.19.5.8.(d) also do not have disjoint neighborhoods in \( Q \), so \( Q \) is not normal.

(e) \( Q \) is not simply connected: the fundamental group of \( Q \) is quite complicated (uncountable).

(f) Another example can be constructed from \( P_0 \) by identifying, for each \( a \), the positive and negative \( x \)-axes of \( \mathbb{R}^2_a \) by folding over at 0. A separable locally Euclidean space \( M \) is obtained. This is the Moore manifold. The Moore manifold is contractible (), hence simply connected.

**XI.19.5.10.** If \( A \subseteq \mathbb{R} \), modify the construction of \( P \), \( P_0 \), \( Q \), and \( M \) by attaching \( \mathbb{R}^2_a \) if and only if \( a \in A \). Call the resulting spaces \( P_A \), \( P_0^A \), \( Q_A \), \( M_A \).

(a) Show that if \( A \) is countable, \( P_A \) and \( M_A \) are homeomorphic to \( \mathbb{R}^2 \). If \( \text{card}(A) = n \), \( 1 \leq n \leq \aleph_0 \), \( Q_A \) is homeomorphic to a plane with a discrete set of points of cardinality \( n - 1 \) removed (where \( \aleph_0 - 1 = \aleph_0 \)).
(b) [Bla] Show that if $A$ is a subset of $\mathbb{R}$, there at most $2^{\aleph_0}$ subsets $B$ of $\mathbb{R}$ such that the spaces $P_A^0$ and $P_B^0$ are homeomorphic. [Regard all the $P_A^n$ as subsets of $P_0$. A homeomorphism from $P_A^n$ to $P_B^n$ can be regarded as a continuous function from $P_A^n$ to $P_0$. But since $P_A^n$ is separable, and $P_0$ has cardinality $2^{\aleph_0}$, there are only $2^{\aleph_0}$ continuous functions from $P_A^n$ to $P_0$. cf. XI.18.4.42.] So there are $2^{\aleph_0}$ topologically distinct $P_A^0$. Show similarly that there are $2^{\aleph_0}$ topologically distinct $M_A$. The $P_A^0$ and $M_A$ are all separable and contractible. There are also $2^{\aleph_0}$ topologically distinct $P_A$ and $Q_A$. The $M_A$ and $P_A$ constructions can be combined into a unified family.

A family of $2^{\aleph_0}$ mutually nonhomeomorphic simply connected 2-dimensional Hausdorff locally Euclidean spaces, as well as a family of $2^{\aleph_0}$ mutually nonhomeomorphic sequentially compact simply connected 2-dimensional Hausdorff locally Euclidean spaces (the maximum number possible), is constructed in [Nyi84], which is a thorough study of nonmetrizable “manifolds.” However, these examples are not separable or contractible.

XI.19.5.11. ([Kne60]; cf. [Spi79, p. 643]) Construct a three-dimensional version of $Q$ by taking a copy $\mathbb{R}_a^3$ for each $a \in \mathbb{R}$, and identifying $(x, y, z) \in \mathbb{R}_a^3$, $y \neq 0$, with the point in a fixed copy of $\mathbb{R}^4$ with coordinates $(a + yx, y, z + a)$ if $y > 0$ and $(a + yx, y, z - a)$ if $y < 0$.

(a) Show that the quotient $Q^3$ is a connected separable Hausdorff locally Euclidean space with local dimension 3.

(b) Show that the surfaces $z = c$ give a foliation () of $Q^3$ with only one leaf, which is two-dimensional. Thus there is a stronger topology on $Q^3$ under which it is a connected Hausdorff locally Euclidean space of local dimension 2 (not separable).

(c) For an arbitrary subset $A$ of $\mathbb{R}$, similarly construct $Q_A^3$. Show there are $2^{\aleph_0}$ distinct homeomorphism classes. Describe $Q_A^3$ if $A$ is finite or countable. There is still a similar foliation of $Q_A^3$, but it has multiple leaves in general.

XI.19.5.12. [Spi79, Problem A-8] Show that a connected Hausdorff locally Euclidean space which is not a single point has cardinality $2^{\aleph_0}$.

XI.19.5.13. [Spi79, Problem 1-24] (a) Let $X$ and $Y$ be totally disconnected closed subsets of $\mathbb{R}^2$. Show that if $\mathbb{R}^2 \setminus X$ and $\mathbb{R}^2 \setminus Y$ are homeomorphic, then $X$ and $Y$ are homeomorphic. [See XI.18.5.3.]

(b) Conclude from () and () that there are $2^{\aleph_0}$ topologically distinct connected open subsets of $\mathbb{R}^2$.

(c) There are also $2^{\aleph_0}$ topologically distinct connected relatively open subsets of the closed unit disk in $\mathbb{R}^2$, each containing the entire boundary circle.

(d) Show that these spaces remain topologically distinct even if the Cartesian product with $\mathbb{R}^m$ for any $m$ is taken. Thus there are $2^{\aleph_0}$ topologically distinct connected open sets in $\mathbb{R}^n$ for any $n > 1$; in fact, see XI.18.5.6.–XI.18.5.8.(h). (There is only one nonempty connected open set in $\mathbb{R}$ up to homeomorphism, and only countably many open sets in $\mathbb{R}$ in all up to homeomorphism, since every open set is a countable disjoint union of open intervals (.)

XI.19.5.14. [Hat02, 1.3.25] An Interesting Non-Hausdorff Locally Euclidean Space. Let $T$ be the invertible linear transformation on $\mathbb{R}^2$ given by $T(x, y) = (2x, y/2)$. Define an equivalence relation on $E = \mathbb{R}^2 \setminus \{0\}$ by $v \sim w$ if $T^n v = w$ for some $n \in \mathbb{Z}$. Let $M$ be the quotient of $E$ by this equivalence relation, and $\pi: E \to M$ the quotient map.
(a) Show that each equivalence class is closed and discrete in $E$, and that $M$ is $T_1$ and second countable.

(b) Show that $M$ is the disjoint union of four cylinders $C_1, C_2, C_3, C_4$, each homeomorphic to $S^1 \times \mathbb{R}$, where $C_j$ is the image of the open $j$'th quadrant in $E$, and four circles $X_+, X_-, Y_+, Y_-$, where $X_+$ is the image of the positive $x$-axis, $X_-$ the image of the negative $x$-axis, and $Y_\pm$ the images of the positive and negative $y$-axis. $C_1 - C_4$ are open in $M$ and $X_\pm, Y_\pm$ are closed in $M$. The “horizontal” circle in $C_j$ at height $|r|$ is the image of the part of the hyperbola $xy = r$ in the $j$'th quadrant.

(c) The set $\{(x, y) : 1 \leq x < 2\}$ maps one-one onto $C_1 \cup X_+ \cup C_4$ under $\pi$, and the image in $M$ is open and homeomorphic to $S^1 \times \mathbb{R}$. Similarly, $\{(x, y) : -2 \leq x < -1\}$ maps one-one onto $C_2 \cup X_- \cup C_3$, $\{(x, y) : 1 \leq y < 2\}$ maps one-one onto $C_1 \cup Y_+ \cup C_2$ and $\{(x, y) : -2 \leq y < -1\}$ maps one-one onto $C_3 \cup Y_- \cup C_4$. These cylinders are open in $M$. Conclude that $M$ is locally Euclidean.

(d) The closure of $C_1$ is $C_1 \cup X_+ \cup Y_+$. Show that if $p \in X_+$ and $q \in Y_+$, then $p$ and $q$ do not have disjoint neighborhoods. Thus $M$ is not Hausdorff. Similarly, points in $X_\pm$ and $Y_\pm$ do not have disjoint neighborhoods. (However, $X_+$ and $X_-$ have disjoint neighborhoods, as do $Y_+$ and $Y_-$.) Describe the closure of $C_2 - C_4$.

(e) Let $S$ be the image of a vertical line segment $\{(x, y) : x = x_0, 0 < y \leq y_0\}$. Show that the closure of $S$ consists of $S$, one point of $X_+$, and all of $Y_+$. Find a sequence in $S$ which converges to a point in $X_+$ and has every point of $Y_+$ as a cluster point, and a subsequence which converges to any arbitrarily given point of $Y_+$. Do the same for other vertical and horizontal line segments.

(f) Show that $\pi$ is a covering map $()$ from $E$ to $M$.

Let $N$ be the space obtained from $M$ by additionally identifying diametrically opposed points of $E$ ($N$ is the quotient of $E$ by the action of the subgroup $G$ of $SL_2(\mathbb{R})$ generated by $T$ and $-I$, which is isomorphic to $\mathbb{Z} \times \mathbb{Z}_2$). Then $N$ consists of two open cylinders $C_+$ (the image of $C_1$ and $C_3$) and $C_-$ (the image of $C_2$ and $C_4$), and two closed circles $X$ (the image of $X_+$ and $X_-$) and $Y$ (the image of $Y_+$ and $Y_-$. $C_+ \cup X \cup C_-$ and $C_+ \cup Y \cup C_-$ are open subsets of $N$ homeomorphic to $S^1 \times \mathbb{R}$; thus $N$ is a cylinder $S^1 \times \mathbb{R}$ with the circle $S^1 \times \{0\}$ “doubled.” If $C_+$ is identified with $S^1 \times \mathbb{R}_+$ by taking the images of the hyperbolas $xy = r$ as horizontal circles and images of rays from the origin as vertical lines (one only needs rays of slope between $1/2$ and $2$), then points of $X$ are obtained by approaching $0$ along the image of a vertical ray in the right half-plane, i.e. a line spiraling around the cylinder at a certain rate, and points of $Y$ are obtained by approaching along the image of a horizontal ray, i.e. a line spiraling around the cylinder at the same rate but in the opposite direction. The quotient map from $E$ to $N$ is also a covering map, i.e. $G$ acts properly discontinuously on $E$ $()$.

XI.19.5.15. Show that a metrizable topological space $X$ is a manifold with boundary if and only if every point of $X$ has a closed neighborhood homeomorphic to a closed ball in a Euclidean space.
XI.20. The Brouwer Fixed-Point Theorem

The Brouwer Fixed-Point Theorem, in its various equivalent formulations, is arguably the most important fact about the topology of Euclidean space (although the Heine-Borel Theorem () is arguably more fundamental), and indeed one of the most important results in all of topology. It essentially makes possible notions of “higher-order connectedness.” Among other things, the entire subject of algebraic topology is at least implicitly based on this result. A coherent theory of dimension for topological spaces, and many applications in analysis, also depend on this theorem.

XI.20.1. Statements of the Results

XI.20.1.1. We use the following notation. Let $B^n$ be the closed unit ball and $S^{n-1}$ the closed unit sphere in $\mathbb{R}^n$, i.e.

$$B^n = \{x \in \mathbb{R}^n : \|x\| \leq 1\}$$
$$S^{n-1} = \{x \in \mathbb{R}^n : \|x\| = 1\}.$$ 

In writing these, we implicitly assume $n \in \mathbb{N}$ (although they also make sense if $n = 0$: $B^0$ is a single point and $S^{-1} = \emptyset$). The term “map” will mean “continuous function.”

XI.20.1.2. Theorem. [Brouwer Fixed-Point Theorem] Every continuous function $f : B^n \to B^n$ has a fixed point, i.e. there is a point $x \in B^n$ with $f(x) = x$.

XI.20.1.3. Theorem. [No-Retraction Theorem] There is no retraction () from $B^n$ to $S^{n-1}$.

XI.20.1.4. Theorem. [No-Contraction Theorem] The sphere $S^{n-1}$ is not contractible, i.e. the identity map on $S^{n-1}$ is not homotopic to a constant map.

XI.20.1.5. We will show by elementary arguments that these three statements are equivalent. Thus to prove all the theorems it suffices to prove any one of them. We will also obtain some additional equivalent formulations of the theorem.

XI.20.1.6. If $n = 1$, the statements are quite simple. $B^1 = [-1, 1]$ and $S^0 = \{-1, 1\}$. Thus the Brouwer Fixed-Point Theorem for $n = 1$ is (), essentially the Intermediate Value Theorem of calculus. The No-Retraction Theorem is also the Intermediate Value Theorem, or the fact that a connected space cannot be mapped continuously onto a disconnected space. The No-Contraction Theorem is obvious, since $S^0$ is not even connected (cf. ()).

If $n = 2$, the statements are also fairly elementary to prove; see XI.20.2.. But if $n \geq 3$, all (known) proofs are fairly involved and/or use considerable machinery of some sort. There are many quite varied proofs known, and which one is the “best” is a quite subjective matter.

To prove that XI.20.1.2.–XI.20.1.4. are equivalent, it is convenient to show the negations of the statements are equivalent (although this seems a little perverse, since the ultimate result is that these statements are all false):
XI.20.1.7. **Theorem.** Let $n \in \mathbb{N}$. The following statements are equivalent:

(i) There is a continuous function $f : B^n \to B^n$ with no fixed point.

(ii) There is a retraction $r : B^n \to S^{n-1}$.

(iii) $S^{n-1}$ is contractible.

XI.20.1.8. To prove (ii) $\Rightarrow$ (iii), note that there is a contraction of $B^n$. The simplest one is given by the function $g(t, x) = t x$ for $0 \leq t \leq 1$, $x \in B^n$. If there were a retraction $r : B^n \to S^{n-1}$, the function $h(t, x) = r(tx)$ ($0 \leq t \leq 1$, $x \in S^{n-1}$) would give a contraction of $S^{n-1}$ (to the point $x_0 = r(0)$). [Note that essentially the same argument shows that if $X$ is a contractible space and $r$ is a retraction of $X$ onto a subspace $Y$, then $Y$ is also contractible.]

XI.20.1.9. For the converse (iii) $\Rightarrow$ (ii), suppose $h : [0, 1] \times S^{n-1} \to S^{n-1}$ is a contraction of $S^{n-1}$ with $h(1, x) = x$ for all $x \in S^{n-1}$ and $h(0, x) = x_0$ for all $x \in S^{n-1}$, where $x_0$ is a fixed element of $S^{n-1}$. Define $r : B^n \to S^{n-1}$ by $r(x) = h \left( \|x\|, \frac{x}{\|x\|} \right)$ for $x \neq 0$ and $r(0) = x_0$. It is easily checked that $r$ is continuous (only continuity at 0 is an issue), and is therefore a retraction from $B^n$ to $S^{n-1}$.

Thus XI.20.1.7. (ii) and (iii) are equivalent.

XI.20.1.10. To prove (ii) $\Rightarrow$ (i), let $r$ be a retraction of $B^n$ to $S^{n-1}$. Then the map $f : B^n \to B^n$ defined by $f(x) = -r(x)$ has no fixed point.

XI.20.1.11. The proof of (i) $\Rightarrow$ (ii) is the hardest to write carefully, but the argument is geometrically simple and appealing. Suppose $f : B^n \to B^n$ has no fixed point. For each $x \in B^n$, the line segment from $f(x)$ to $x$ is nontrivial, and can be extended until it hits $S^{n-1}$ in a point we call $r(x)$:

![Figure XI.65: Definition of the retraction](image)

The function thus defined will be a retraction from $B^n$ to $S^{n-1}$.

1273
The only issue is whether \( r \) is continuous. This is geometrically plausible, and can be established carefully as follows. The vector \( r(x) \) is of the form \( f(x) + t(x - f(x)) \) for some \( t \geq 1 \). We can determine \( t \) explicitly using inner products and the quadratic formula:

\[
\begin{align*}
\langle f(x) + t(x - f(x)), f(x) + t(x - f(x)) \rangle &= 1 \\
\langle f(x), f(x) \rangle + 2t\langle x - f(x), f(x) \rangle + t^2\langle x - f(x), x - f(x) \rangle - 1 &= 0 \\
\|x - f(x)\|^2t^2 - 2\langle f(x) - x, f(x) \rangle t + (\|f(x)\|^2 - 1) &= 0 \\
t &= \frac{\langle f(x) - x, f(x) \rangle + \sqrt{(\langle f(x) - x, f(x) \rangle)^2 + \|x - f(x)\|^2(1 - \|f(x)\|^2)}}{\|x - f(x)\|^2}
\end{align*}
\]

which is a continuous function of \( x \) since the denominator is never zero.

This completes the proof of XI.20.1.7.

\[\square\]

**Essential Maps**

**XI.20.1.12.** If \( X \) is a topological space of “dimension” less than \( n \) (we have not yet carefully defined what this means), and \( f \) is a map from \( X \) into \( \mathbb{R}^n \) (or \( B^n \)), the range of \( f \) should be a set of dimension \(< n \) and should thus have dense complement; so it should be possible to perturb \( f \) to a uniformly close function \( g \) such that the range of \( g \) does not include some specified point, e.g. the origin. Actually, the existence of such pathological functions as space-filling curves () casts doubt on the intuition behind this argument, but it turns out rather remarkably that the conclusion is correct.

Another argument leading to the conclusion is that a system of \( n \) equations in fewer than \( n \) variables “usually” does not have a solution. In special cases there might happen to be a solution, but it should be possible to perturb such a system to a “nearby” system with no solution. On the other hand, it is essentially the content of the Inverse Function Theorem () that if we have a “smooth” system of \( n \) equations in \( n \) variables which has a locally unique solution, then any “nearby” smooth system also has a (locally unique) solution.

**XI.20.1.13.** Definition. Let \( X \) be a topological space. A map (continuous function) \( f : X \to B^n \) is **inessential** if for every \( \epsilon > 0 \) there is a map \( g : X \to B^n \) with \( \|f - g\|_{\infty} = \sup\{\|f(x) - g(x)\| : x \in X\} < \epsilon \) and with \( 0 \notin g(X) \). A map \( f \) from \( X \) to \( B^n \) is **essential** if it is not inessential, i.e. every map sufficiently uniformly close to \( f \) has \( 0 \) in the range.

**XI.20.1.14.** This use of the term **essential** is somewhat nonstandard. In topology, it is usually said that a map \( f : X \to Y \) is essential if it is not homotopic to a constant map. Thus any map from a topological space to a contractible space such as \( B^n \) would be inessential. We will use the term in our sense only in relation to maps into \( B^n \).

**XI.20.1.15.** The definition of an essential map makes use of the standard metric on \( B^n \). But the definition would be unchanged if any other metric giving the standard topology were used instead, since any two metrics giving the same compact topology are uniformly equivalent (). Thus the property of being essential or inessential is a purely topological property.

We then obtain another statement equivalent to the Brouwer Fixed-Point Theorem:
XI.20.1.16. \textbf{Theorem.} The identity map from $B^n$ to $B^n$ is essential.

XI.20.1.17. To prove that this statement is equivalent to the No-Retraction Theorem, and thus to the Brouwer Fixed-Point Theorem, suppose that the identity map $f$ on $B^n$ is inessential, and fix $g : B^n \to B^n$ with $\|f-g\| < \frac{1}{2}$ and $g(x) \neq 0$ for all $x \in B^n$. We will gradually modify $g$ on the annulus $\{ x \in B^n : \frac{1}{2} \leq \|x\| \leq 1 \}$ to a function $h : B^n \to B^n$ with $h(x) \neq 0$ for all $x \in B^n$ and $h(x) = x$ for $x \in S^{n-1}$. We will take $h(x)$ to be a point on the line segment between $x$ and $g(x)$, closer to $x$ as $\|x\|$ approaches 1. The precise formula is

$$h(x) = \begin{cases} g(x) & \text{if } \|x\| \leq \frac{1}{2} \\ (2\|x\| - 1)x + (2 - 2\|x\|)g(x) & \text{if } \frac{1}{2} \leq \|x\| \leq 1 \end{cases} .$$

It is clear that $h$ is a continuous function from $B^n$ to $B^n$ and that $h(x) = x$ if $\|x\| = 1$. To show that $h(x) \neq 0$ for all $x$, it suffices to note that if $\|x\| \geq \frac{1}{2}$, then $0$ is not on the line segment between $x$ and $g(x)$ since $\|x - g(x)\| < \frac{1}{2}$.

There is a retraction $r$ from $B^n \setminus \{0\}$ to $S^{n-1}$, e.g. radial projection; the map $r \circ h$ would then be a retraction from $B^n$ to $S^{n-1}$. Thus by the No-Retraction Theorem, $f$ cannot be inessential.

Conversely, suppose there is a retraction $r$ from $B^n$ to $S^{n-1}$. By scaling, for any $\epsilon > 0$ there is a retraction $r_\epsilon$ from $B^n = \{ x \in \mathbb{R}^n : \|x\| \leq \epsilon \}$ onto $S^{n-1} = \{ x \in \mathbb{R}^n : \|x\| = 1 \}$. Define $g_\epsilon : B^n \to B^n$ by

$$g_\epsilon(x) = \begin{cases} r_\epsilon(x) & \text{if } \|x\| \leq \epsilon \\ x & \text{if } \epsilon \leq \|x\| \leq 1 \end{cases} .$$

Then $\|f - g_\epsilon\| \leq 2\epsilon$ and $g_\epsilon(x) \neq 0$ for all $x \in B^n$, so $f$ is inessential. Thus XI.20.1.16. implies the No-Retraction Theorem.

\textbf{Partitions and the Lebesgue Covering Theorem}

XI.20.1.18. We now discuss two more equivalent versions of the Brouwer Fixed-Point Theorem. The statements are slightly more technical, and are phrased in terms of the $n$-cube

$$I^n = [-1,1]^n = \{(x_1, \ldots, x_n): -1 \leq x_k \leq 1\}$$

which is obviously homeomorphic to $B^n$. We will let $A_k$ and $B_k$ $(1 \leq k \leq n)$ be the opposite $k$-faces of $I^n$:

$$A_k = \{(x_1, \ldots, x_n) \in I^n : x_k = -1\}$$

$$B_k = \{(x_1, \ldots, x_n) \in I^n : x_k = 1\}$$

which are obviously disjoint closed subsets of $I^n$. The union of all the $A_k$ and $B_k$ is the boundary $\partial I^n$ of $I^n$, which is homeomorphic to $S^{n-1}$.

Recall the definition of a partition (XI.7.6.4.).

XI.20.1.19. \textbf{Theorem.} [Face Partition Theorem] For $1 \leq k \leq n$, let $P_k$ be a partition between $A_k$ and $B_k$ in $I^n$. Then

$$P_1 \cap \cdots \cap P_n \neq \emptyset .$$
XI.20.1.20. We show that the Face Partition Theorem for \( n \in \mathbb{N} \) is equivalent to the No-Retraction Theorem for the same \( n \), and hence to the Brouwer Fixed-Point Theorem. It is again convenient to prove that the negations of the statements are equivalent.

Suppose there is a retraction \( r \) from \( I^n \) to \( \partial I^n \). Let \((r_1, \ldots, r_n)\) be the coordinate functions of \( r \), and set

\[
P_k = r_k^{-1}(\{0\})
\]

\[
U_k = r_k^{-1}([-1, 0])
\]

\[
V_k = r_k^{-1}((0, 1])
\]

Then \( P_k \) is a partition between \( A_k \) and \( B_k \) for each \( k \), and clearly \( P_1 \cup \cdots \cup P_n = \emptyset \), so the statement of the Face Partition Theorem is false.

Conversely, let \( P_k \) be a partition between \( A_k \) and \( B_k \) for each \( k \), with associated open sets \( U_k \) containing \( A_k \) and \( V_k \) containing \( B_k \), such that \( P_1 \cap \cdots \cap P_n = \emptyset \). For each \( k \), define \( f_k : I^n \to [-1, 1] \) by

\[
f_k(x) = \begin{cases} 
\rho(x, P_k) & \text{if } x \in U_k \\
\frac{\rho(x, P_k) + \rho(x, A_k)}{\rho(x, P_k) + \rho(x, B_k)} & \text{if } x \in P_k \\
\frac{-\rho(x, P_k)}{\rho(x, P_k) + \rho(x, B_k)} & \text{if } x \in V_k 
\end{cases}
\]

where \( \rho \) is the standard metric on \( I^n \). Then \( f_k \) is continuous. If \( f : I^n \to I^n \) is the function with coordinate functions \((f_1, \ldots, f_n)\), then \( f(x) \neq 0 \) for all \( x \in I^n \). Let \( r \) be a retraction of \( I^n \setminus \{0\} \) onto \( \partial I^n \), and let \( g = r \circ f \). It is easy to check that \( g(A_k) \subseteq B_k \) and \( g(B_k) \subseteq A_k \). It follows that \( g \) cannot have a fixed point, so the statement of the Brouwer Fixed-Point Theorem is false.

XI.20.1.21. Theorem. [Lebesgue Covering Theorem] Let \( \mathcal{F} \) be a finite collection of closed sets covering \( I^n \), with the property that no \( F \in \mathcal{F} \) meets both \( A_k \) and \( B_k \) for any \( k \). Then there are distinct \( F_1, \ldots, F_{n+1} \) in \( \mathcal{F} \) with

\[
F_1 \cap \cdots \cap F_{n+1} \neq \emptyset
\]

(i.e. \( \mathcal{F} \) has order \( \geq n \)).

XI.20.1.22. It is easy to show that the Lebesgue Covering Theorem implies the Brouwer Fixed-Point Theorem. Again we show the contrapositive. Suppose \( r \) is a retraction of \( I^n \) onto \( \partial I^n \). Let

\[
\mathcal{F} = \{r^{-1}(A_k), r^{-1}(B_k) : 1 \leq k \leq n\}
\]

which is a finite cover of \( I^n \) by \( 2n \) sets satisfying the hypotheses of the Lebesgue Covering Theorem, but no \( n+1 \) of the sets can have nonempty intersection.

To show the Face Partition Theorem, and hence the Brouwer Fixed-Point Theorem, implies the Lebesgue Covering Theorem is more complicated, and requires a lemma (cf. [Eng95, Lemma 1.2.9]):

1276
**XI.20.1.23. Lemma.** Let $X$ be a metrizable space, or more generally a completely normal space ($\sim$), and $E$ a closed subset of $X$. Let $Y$ and $Z$ be disjoint closed subsets of $X$. Let $\tilde{P}$ be a partition between $Y \cap E$ and $Z \cap E$ in $E$. Then there is a partition $P$ between $Y$ and $Z$ in $X$ with $P \cap E \subseteq \tilde{P}$.

**Proof:** There are relatively open subsets $\tilde{U}$, $\tilde{V}$ of $E$ such that $Y \cap E \subset \tilde{U}$, $Z \cap E \subset \tilde{V}$, $\tilde{U} \cap \tilde{V} = \emptyset$, and $E \setminus (\tilde{U} \cup \tilde{V}) = \tilde{P}$. The closure of $Z \cup \tilde{V}$ (in $X$) is $Z \cup [\tilde{V}]^-$, and $Y \cap [\tilde{V}]^- = (Y \cap E) \cap [\tilde{V}]^- = \emptyset$ since $[\tilde{V}]^- \subset E$ because $E$ is closed, and $Y \cap E \subseteq U$, which is relatively open in $E$. Thus $Y$ is disjoint from the closure of $Z \cup \tilde{V}$. We also have that $\tilde{U}$ is disjoint from both $Z$ and $[\tilde{V}]^-$. So $Y \cup \tilde{U}$ is disjoint from the closure of $Z \cup \tilde{V}$. By a symmetric argument $Z \cup \tilde{V}$ is disjoint from the closure of $Y \cup \tilde{U}$. Thus by (1) there are disjoint open sets $U$ and $V$ in $X$ with $Y \cup U \subseteq U$ and $Z \cup \tilde{V} \subseteq V$. Set $P = X \setminus (U \cup \tilde{V})$. Then $P$ is a partition between $Y$ and $Z$ in $X$, and $P \cap E$ is disjoint from both $\tilde{U}$ and $\tilde{V}$, i.e. $P \cap E \subseteq \tilde{P}$. \hfill $\Diamond$

**XI.20.1.24.** We now show that the Face Partition Theorem for an $n \in \mathbb{N}$ implies the Lebesgue Covering Theorem for the same $n$ (cf. [Eng95, Theorem 1.8.15]). Let $\mathcal{F}$ be a finite collection of closed subsets of $I^n$ satisfying the hypotheses of the Lebesgue Covering Theorem. For $1 \leq k \leq n$ set

$$\mathcal{F}_k = \{ F \in \mathcal{F} : A_k \cap F \neq \emptyset \}$$

$$\mathcal{E}_1 = \mathcal{F}_1, \quad \mathcal{E}_{k+1} = \mathcal{F}_{k+1} \setminus (\mathcal{E}_1 \cup \cdots \cup \mathcal{E}_k) \text{ for } 1 \leq k \leq n$$

$$E_k = \cup \{ F : F \in \mathcal{E}_k \} \text{ for } 1 \leq k \leq n + 1.$$ Then the $E_k$ are closed, and we have

$$A_k \subseteq I^n \setminus (E_{k+1} \cup \cdots \cup E_{n+1})$$

$$B_k \subseteq I^n \setminus E_k.$$ Set $\tilde{P}_0 = I^n$, and for $1 \leq k \leq n$ set

$$\tilde{P}_k = E_1 \cap \cdots \cap E_k \cap (E_{k+1} \cup \cdots \cup E_{n+1})$$

$$\tilde{U}_k = \tilde{P}_{k-1} \setminus (E_{k+1} \cup \cdots \cup E_{n+1})$$

$$\tilde{V}_k = \tilde{P}_{k-1} \setminus (E_1 \cap \cdots \cap E_k).$$ Then, for $1 \leq k \leq n$, $\tilde{P}_k$ is closed, $\tilde{P}_k \subseteq \tilde{P}_{k-1}$, $A_k \cap \tilde{P}_{k-1} \subseteq \tilde{U}_k$, $B_k \cap \tilde{P}_{k-1} \subseteq \tilde{V}_k$, $\tilde{U}_k \cap \tilde{V}_k = \emptyset$, and

$$\tilde{P}_{k-1} \setminus (\tilde{U}_k \cup \tilde{V}_k) = \tilde{P}_{k-1} \cap \tilde{P}_k = \tilde{P}_k$$

so $\tilde{P}_k$ is a partition between $A_k \cap \tilde{P}_{k-1}$ and $B_k \cap \tilde{P}_{k-1}$ in $\tilde{P}_{k-1}$. Apply Lemma XI.20.1.23. successively to obtain for each $k$ a partition $P_k$ between $A$ and $B$ in $I^n$ with $P_k \cap \tilde{P}_{k-1} \subseteq \tilde{P}_k$. Thus by the Face Partition Theorem

$$\emptyset \neq P_1 \cap \cdots \cap P_n \subseteq \tilde{P}_n = E_1 \cap \cdots \cap E_{n+1}.$$ If $x \in E_1 \cap \cdots \cap E_{n+1}$, then for $1 \leq k \leq n + 1$ there is an $F_k \in \mathcal{E}_k$ with $x \in F_k \subseteq E_k$; then $F_1 \cap \cdots \cap F_{n+1} \neq \emptyset$, and the $F_k$ are all distinct since each $F \in \mathcal{F}$ is in exactly one $\mathcal{E}_k$.

**XI.20.1.25.** The Face Partition Theorem and the Lebesgue Covering Theorem are versions of the statements $\text{ind}(\mathbb{R}^n) = n$ ($\sim$) and $\text{dim}(\mathbb{R}^n) = n$ ($\sim$) respectively; cf. [Eng95].

1277
XI.20.2. The Case \( n = 2 \)

The Brouwer Fixed-Point Theorem for \( n = 2 \) is not as easy as the case \( n = 1 \) (XI.20.1.6.), but is relatively simple.

XI.20.2.1. The argument uses the map \( p : \mathbb{R} \to S^1 \) defined by

\[
p(t) = (\cos 2\pi t, \sin 2\pi t).
\]

This map is surjective, but far from injective; however, if \( s_0 \in \mathbb{R} \) and \( z_0 = p(s_0) \in S^1 \), the restriction of \( p \) to the open interval \((s_0 - \frac{1}{2}, s_0 + \frac{1}{2})\) is a homeomorphism from \((s_0 - \frac{1}{2}, s_0 + \frac{1}{2})\) onto \( S^1 \setminus \{ -z_0 \} \). We will write \( p^{-1}_{s_0} \) for the inverse map from \( S^1 \setminus \{ -z_0 \} \) onto \((s_0 - \frac{1}{2}, s_0 + \frac{1}{2})\).

XI.20.2.2. Lemma. [Path-Lifting Lemma] Let \( \gamma : [0,1] \to S^1 \) be a path (continuous function), with \( \gamma(0) = z_0 \). If \( s_0 \in \mathbb{R} \) is fixed with \( p(s_0) = z_0 \), then there is a unique path \( \tilde{\gamma} : [0,1] \to \mathbb{R} \) with \( \tilde{\gamma}(0) = s_0 \) and \( \gamma = p \circ \tilde{\gamma} \).

Proof: A partition \( \mathcal{P} = \{0 = t_0, t_1, \ldots, t_n = 1\} \) of \([0,1]\) will be called sufficiently fine if, for each \( k \), \( \|\gamma(t) - \gamma(s)\| < 2 \) for all \( t, s \in [t_{k-1}, t_k] \). There is a sufficiently fine partition since \( \gamma \) is uniformly continuous (\( \cdot \)). Suppose \( \mathcal{P} \) is a sufficiently fine partition. There is a unique path \( \beta : [0,t_1] \to \mathbb{R} \) with \( \beta(0) = s_0 \) and \( \gamma|_{[0,t_1]} = p \circ \beta \), namely \( \beta(t) = p^{-1}_{s_0}(\gamma(t)) \) for \( 0 \leq t \leq t_1 \) [to show uniqueness, note that the range of \( \beta \) must be contained in a connected subset of \( p^{-1}(\gamma([0,t_1])) \subseteq p^{-1}(S^1 \setminus \{ -z_0 \}) \), so \( \beta([0,t_1]) \subseteq (s_0 - \frac{1}{2}, s_0 + \frac{1}{2}) \).] In particular, \( s_1 = \beta(t_1) \) is uniquely determined by \( \gamma \) and the choice of \( s_0 \). Define \( \tilde{\gamma}(t) \) for \( t \in [0,t_1] \) to be \( \beta(t) \).

Now let \( z_1 = p(s_1) = \gamma(t_1) \), and repeat the construction to define \( \tilde{\gamma} \) on \([t_1,t_2]\), and inductively extend to all of \([0,1]\). We then have \( \tilde{\gamma}(0) = s_0 \) and \( \gamma = p \circ \tilde{\gamma} \).

To show uniqueness, suppose \( \tilde{\gamma} \) is another lift of \( \gamma \), i.e. \( \tilde{\gamma}(0) = s_0 \) and \( \gamma = p \circ \tilde{\gamma} \) (e.g. \( \tilde{\gamma} \) could be a lift defined by the same process using a different sufficiently fine partition). By the uniqueness shown above, we must have \( \tilde{\gamma} = \gamma \) on \([0,t_1]\), then on \([t_1,t_2]\), and ultimately on all of \([0,1]\).

XI.20.2.3. The lift \( \tilde{\gamma} \) depends on the choice of \( s_0 \). But if the \( s_0 \) is changed, necessarily by addition of an integer \( n \), then the lift is simply translated by \( n \) (the translation by \( n \) is obviously a lift with the right properties, so must be the unique one).

XI.20.2.4. We will want a similar result for homotopies, i.e. maps from \([0,1]^2\) to \( S^1 \). If \( h \) is a map from \([0,1]^2\) to \( S^1 \), and \( z_0 = h(0) \), and \( s_0 \in \mathbb{R} \) with \( p(s_0) = z_0 \), then by XI.20.2.2. there is a unique lifting \( \tilde{h} : [0,1]^2 \to \mathbb{R} \) with \( \tilde{h}(0) = s_0 \) which is continuous on each line segment in \([0,1]^2\) beginning at \( 0 \), defined for each \( x \in [0,1]^2 \) by lifting the path \( \gamma(t) = h(tx) \). However, it is not obvious that this map is continuous on \([0,1]^2\) (this is roughly the same question as whether the same value for \( \tilde{h}(x) \) is obtained by lifting any other path in \([0,1]^2\) from \( 0 \) to \( x \).) The lifted map \( \tilde{h} \) is continuous in a neighborhood of \( 0 \) since all the lifts are done using \( p^{-1}_{s_0} \), which is continuous; it is possible, but tricky, to expand successively through larger regions to the whole square (cf. \( \cdot \)).

We will take an alternate approach, first due to A. W. Tucker [Tuc46] (cf. [Spa81]).

1278
XI.20.2.5. There is a “multiplication” in \( S^1 \): if \( z = (\cos 2\pi t, \sin 2\pi t) \), write \( z \) symbolically as \( e^{2\pi it} \) (this is actually more than symbolic; cf. (1)). The \( t \) is not unique, but for a given \( z \) any two such \( t \) differ by an integer. If \( w = e^{2\pi is} \), define \( zw = e^{2\pi i(t+s)} \). Although \( t \) and \( s \) are only determined up to adding an integer, and thus \( t+s \) is only determined up to an integer, the point \( e^{2\pi i(t+s)} \) is well defined in \( S^1 \). This multiplication is associative and commutative. The point \( 1 = (1,0) = p(0) \) is an identity for this multiplication, and the point \( z^{-1} = e^{-2\pi it} \) is an inverse for \( z = e^{2\pi it} \). Multiplication is continuous as a function from \( S^1 \times S^1 \) to \( S^1 \), inversion (which geometrically is just reflection across the \( x \)-axis) is also continuous, and \( p \) has the property that \( p(t+s) = p(t)p(s) \) for any \( t, s \in \mathbb{R} \) (\( p \) is a homomorphism).

XI.20.2.6. Now suppose \( h : [0,1]^2 \to S^1 \) is a continuous function, with \( h(0) = z_0 \), and \( s_0 \in \mathbb{R} \) with \( p(s_0) = z_0 \). By uniform continuity there is an \( \epsilon > 0 \) such that \( \|h(x) - h(y)\| < 2 \) whenever \( x, y \in [0,1]^2 \) and \( \|x - y\| < \epsilon \). Fix \( n \in \mathbb{N} \) with \( n > \sqrt{\frac{2}{\epsilon}} \); then \( \|\frac{x}{n}\| < \epsilon \) for all \( x \in [0,1]^2 \). For \( x \in [0,1]^2 \) and \( 1 \leq k \leq n \), define

\[
g_k(x) = h \left( \frac{k}{n} x \right) h \left( \frac{k-1}{n} x \right)^{-1}.
\]

Then \( g_k \) is a continuous function from \( [0,1]^2 \) to \( S^1 \), and

\[
h(x) = z_0 g_1(x) g_2(x) \cdots g_n(x).
\]

The range of \( g_k \) is contained in \( S^1 \setminus \{1\} \): since \( \|\frac{k}{n} x - \frac{k-1}{n} x\| < \epsilon \),

\[
\left\| h \left( \frac{k}{n} x \right) - h \left( \frac{k-1}{n} x \right) \right\| = \left\| h \left( \frac{k}{n} x \right) h \left( \frac{k-1}{n} x \right)^{-1} - 1 \right\| < 2.
\]

So there is a lift \( \tilde{g}_k : [0,1]^2 \to \mathbb{R} \) defined by

\[
\tilde{g}_k(x) = p^{-1}_0(g_k(x))
\]

which is continuous. Set

\[
\tilde{h}(x) = s_0 + \tilde{g}_1(x) + \cdots + \tilde{g}_n(x).
\]

then \( \tilde{h} \) is a finite sum of continuous functions, hence continuous, and is a lift of \( h \). By the uniqueness described in XI.20.2.4., this is the unique continuous lift of \( h \) with \( h(0) = s_0 \). Thus we have proved:

XI.20.2.7. Lemma. [Homotopy Lifting Lemma] Let \( h : [0,1]^2 \to S^1 \) be a continuous function, with \( h(0) = z_0 \), and \( s_0 \in \mathbb{R} \) with \( p(s_0) = z_0 \). Then there is a unique continuous function \( \tilde{h} : [0,1]^2 \to \mathbb{R} \) such that \( \tilde{h}(0) = s_0 \) and \( h = p \circ \tilde{h} \).

Note that the proof actually shows that the same is true for functions from \( [0,1]^n \) to \( S^1 \) for any \( n \).

XI.20.2.8. A loop in \( S^1 \) is a path \( \gamma : [0,1] \to S^1 \) with \( \gamma(1) = \gamma(0) \). A loop in \( S^1 \) is effectively the same thing as a continuous function from \( S^1 \) to \( S^1 \): the restriction \( q \) of \( p \) to \( [0,1] \) is a bijection, and although the inverse map \( q^{-1} \) is not continuous, if \( \gamma \) is a loop in \( S^1 \) the map \( f = \gamma \circ q^{-1} \) is a continuous function from \( S^1 \) to \( S^1 \), and conversely if \( f : S^1 \to S^1 \) is continuous, \( \gamma = f \circ q \) (extended by setting \( \gamma(1) = \gamma(0) \)) is a loop in \( S^1 \).
XI.20.2.9. If \( \gamma \) is a loop in \( S^1 \) with \( \gamma(0) = \gamma(1) = z_0 \), and \( s_0 \in \mathbb{R} \) with \( p(s_0) = z_0 \), and \( \tilde{\gamma} \) is the lift of \( \gamma \) to \( \mathbb{R} \), then it is not generally true that \( \tilde{\gamma}(1) = \tilde{\gamma}(0) \). But \( \tilde{\gamma}(1) - \tilde{\gamma}(0) \) is an integer which does not depend on the choice of \( s_0 \) by XI.20.2.3., called the index or degree of \( \gamma \). Thus each continuous function from \( S^1 \) to \( S^1 \) has a well-defined index.

XI.20.2.10. Proposition. Homotopic maps from \( S^1 \) to \( S^1 \) have the same index.

Proof: Let \( f_0 \) and \( f_1 \) be homotopic maps from \( S^1 \) to \( S^1 \) via maps \( f_s \), and \( \gamma_s \) the loop corresponding to \( f_s \). Then \( h(t, s) = \gamma_s(t) \) is a continuous map from \([0, 1]^2 \) to \( S^1 \). Take a lift \( \tilde{h} \) of \( h \) to a continuous function from \([0, 1]^2 \) to \( \mathbb{R} \) (XI.20.2.7.); then

\[ \phi(s) = \tilde{h}(1, s) - \tilde{h}(0, s) \]

is the index of \( f_s \), and is a continuous function of \( s \). Since it takes only integer values, it must be constant, i.e. the index of \( f_0 \) equals the index of \( f_1 \).

XI.20.2.11. Theorem. The circle \( S^1 \) is not contractible; thus the Brouwer Fixed-Point Theorem holds for \( n = 2 \).

Proof: The identity map on \( S^1 \) has index 1, and a constant map has index 0, so they cannot be homotopic.

XI.20.2.12. The converse of XI.20.2.10. is true (): maps from \( S^1 \) to \( S^1 \) with the same index are homotopic; so we get a parametrization of the homotopy classes of maps from \( S^1 \) to \( S^1 \). It is easy to get a loop with arbitrary index: set \( \gamma_n(t) = p(nt) \). Thus the index map from homotopy classes of maps to \( \mathbb{Z} \) is a bijection. This set of homotopy classes can be made into a group (the fundamental group) \( \pi_1(S^1) \) via concatenation, and \( \pi_1(S^1) \cong \mathbb{Z} \). See () for the general theory of fundamental groups.

XI.20.2.13. The map \( p : \mathbb{R} \to S^1 \) is called the universal covering map, and \( \mathbb{R} \) is the universal cover of \( S^1 \). See () for the general theory of covering maps.

XI.20.3. The General Case

If \( n \geq 3 \), the Brouwer Fixed-Point Theorem for \( n \) is more difficult than for \( n = 2 \) since there is no map from \( \mathbb{R}^{n-1} \) onto \( S^{n-1} \) analogous to the map \( p \) (\( S^{n-1} \) is simply connected ())). So one must proceed differently. One method of proof amounts to again defining a degree (index) which is an integer for every map from \( S^{n-1} \) to \( S^{n-1} \), and proving that homotopic maps have the same degree, and that the identity map has degree 1 and a constant map has degree 0.

The proof must have a combinatorial component of some sort. The standard argument requires working with triangulations (()) and can be phrased in several ways which are all more or less equivalent:

(1) The most direct argument involves a combinatorial result called Sperner’s Lemma. See e.g. (), (), [Spa81, p. 151], . . . for expositions of this argument.
(2) One can develop abstract homology theory up through the Mayer-Vietoris sequence, and use this sequence to give a proof of the degree formula and therefore the No-Retraction Theorem by induction. See e.g. (), (), (), ... for this approach.

(3) The homology argument of (2) can be written out directly in the case of spheres without explicit use of the term “homology.” See [Dug78] or () for this approach.

The Sperner’s Lemma argument actually proves the following more general result (cf. [Spa81, p. 151]):

**XI.20.3.1. Theorem.** Let $X$ be a compact manifold with boundary which can be triangulated (e.g. a smooth compact manifold with boundary). Then there is no retraction of $X$ onto $\partial X$.

As a variation of this result, the following version follows immediately from the Brouwer Fixed-Point Theorem:

**XI.20.3.2. Theorem.** Let $U$ be a bounded open set in $\mathbb{R}^n$. Then there is no retraction from $\bar{U}$ onto $\partial U$.

**Proof:** Suppose $r$ is a retraction of $\bar{U}$ onto $\partial U$. Fix $a \in U$, and $m$ so that $B = B_m(a)$ contains $\bar{U}$. Let $s$ be radial retraction of $B \setminus \{a\}$ onto $\partial B \cong S^{n-1}$. Define, for $x \in B$,

$$f(x) = \begin{cases} s(r(x)) & \text{if } x \in \bar{U} \\ s(x) & \text{if } x \in B \setminus \bar{U} \end{cases}.$$  

It is easy to check that $f$ is continuous, since $\partial (B \setminus \bar{U}) \subseteq \partial U \cup \partial B$. Then $f$ is a retraction of $B$ onto $\partial B$, contradicting the No-Retraction Theorem.

**XI.20.3.3.** This result can fail if $U$ is not bounded, e.g. if $U$ is the open upper half-plane in $\mathbb{R}^2$.

**XI.20.3.4.** We will not give a direct proof of the Brouwer Fixed-Point Theorem for $n \geq 3$ here. We will deduce the theorem from some analysis results, including Sard’s Theorem and the Implicit Function Theorem ().

**XI.20.4. Exercises**

**XI.20.4.1. Fundamental Theorem of Algebra.** Here is a winding-number proof of the Fundamental Theorem of Algebra (X.1.4.2., X.8.2.3., X.8.2.4.); cf. [vM89]. Suppose

$$f(z) = a_0 + a_1 z + \cdots + a_n z^n$$

is a nonconstant polynomial of degree $n$ (i.e. $a_n \neq 0$) with complex coefficients, with no roots in $\mathbb{C}$. Then $a_n \neq 0$.

(a) Set

$$g(z) = a_0 z^n + a_1 z^{n-1} + \cdots + a_{n-1} z + a_n.$$  

1281
Show that $g(z) = z^n f\left(\frac{1}{z}\right)$ for $z \neq 0$ and $g(0) = a_n$. Thus $g$ also has no roots in $\mathbb{C}$.

(b) Let $r$ be radial retraction of $\mathbb{C} \setminus \{0\}$ onto $S^1$, and define $h : [0,1] \times S^1 \to S^1$ by

$$h(t, z) = r\left(\frac{f(tz)}{g\left(\frac{1}{z}\right)}\right).$$

Show that $h$ is a homotopy between a constant function and $\phi(z) = z^n$, a contradiction since $n > 0$. 

1282
XI.20.5. Proof of the No-Retraction Theorem

In this section, we give two nice analysis proofs of the No-Retraction Theorem, which give a proof of the general Brouwer Fixed-Point Theorem. The first proof was found by Milnor [Mil78] and simplified by Rogers [Rog80]. The second proof is due to Hirsch [Hir94].

We first reduce the problem to the smooth case. For the first proof, we will only need the following result (and not even all of it) for $C^1$, but it is no harder to prove for $C^\infty$, and the second proof needs the $C^\infty$ result. We use the notation $B^n$ for the closed unit ball in $\mathbb{R}^n$, $S^{n-1}$ its boundary, the $(n-1)$-sphere, and $\mathbb{D}^n$ the open unit ball in $\mathbb{R}^n$.

XI.20.5.1. Lemma. If there is a (continuous) retraction of $B^n$ onto $S^{n-1}$, then there is a $C^\infty$ retraction. In fact, there is a $C^\infty$ retraction which is radial projection on a neighborhood of $S^{n-1}$.

Proof: Let $s$ be a retraction. Since $B^n$ is compact, $s$ is uniformly continuous, so there is a $\delta$, $0 < \delta < \frac{1}{4}$, such that $\|s(x) - s(y)\| < \frac{1}{4}$ whenever $x, y \in B^n$ and $\|x - y\| < \delta$. Then if $x \in B^n$ and $\|x\| > 1 - \delta$, we have

$$\|s(x) - x\| \leq \|s(x) - s\left(\frac{x}{\|x\|}\right)\| + \|s\left(\frac{x}{\|x\|}\right) - x\|$$

$$= \left\|s(x) - \frac{x}{\|x\|}\right\| + \left\|\frac{x}{\|x\|} - x\right\| < \frac{1}{4} + \delta < \frac{1}{2}.$$ 

By the General Weierstrass Approximation Theorem (XV.8.3.3.), or () , there is a $C^\infty$ function $f : B^n \to \mathbb{R}^n$ (in fact the coordinate functions can be polynomials) with $\|f - s\|_\infty < \frac{1}{4}$. Then, for $x \in B^n$, $\|x\| > 1 - \delta$, we have

$$\|f(x) - x\| \leq \|f(x) - s(x)\| + \|s(x) - x\| < \frac{1}{4} + \frac{1}{2} = \frac{3}{4}.$$ 

Let $h$ be a $C^\infty$ function from $[0,1]$ to $[0,1]$ which is identically 0 on $[0,1 - \delta]$ and identically 1 on $[1 - \delta,1]$ (). For $x \in B^n$, define

$$g(x) = h(\|x\|) x + (1 - h(\|x\|)) f(x).$$

Then $g$ is $C^\infty$, $g(x) = x$ if $\|x\| \geq 1 - \frac{\delta}{2}$, and $g(x) = f(x)$ if $\|x\| \leq 1 - \delta$.

If $\|x\| \leq 1 - \delta$, we have $\|g(x) - s(x)\| = \|f(x) - s(x)\| < \frac{1}{4}$, and since $\|s(x)\| = 1$, we have $\|g(x)\| > \frac{3}{4}$, and in particular $g(x) \neq 0$. And if $\|x\| > 1 - \delta$, then $g(x)$ lies on the line segment between $x$ and $f(x)$; since

$$\|f(x) - x\| < \frac{3}{4} < 1 - \delta < \|x\|$$

we again have that $g(x) \neq 0$. Thus

$$r(x) = \frac{g(x)}{\|g(x)\|}$$

is a $C^\infty$ retraction of $B^n$ onto $S^{n-1}$ (note that $\phi(x) = \|x\|$ is $C^\infty$ on $\mathbb{R}^n \setminus \{0\}$). We have $r(x) = \frac{x}{\|x\|}$ if $\|x\| \geq 1 - \frac{\delta}{2}$.

Thus the No-Retraction Theorem reduces to:

1283
XI.20.5.2. **Theorem.** Let $n \in \mathbb{N}$. Then there is no $C^\infty$ retraction from $B^n$ to $S^{n-1}$ which is radial projection on a neighborhood of $S^{n-1}$.

The First Proof

XI.20.5.3. **To prove the theorem, suppose $r$ is a $C^1$ retraction.** Set $g(x) = r(x) - x$ and, for $0 \leq t \leq 1$ set

$$f_t(x) = (1-t)x + tr(x) = x + tg(x)$$

for $x \in B^n$. Then $g$ and each $f_t$ is $C^1$, $f_t(x) \in B^n$ for all $t$ and $x \in B^n$, and $f_1(x) = x$ for all $t$ and $x \in S^{n-1}$.

Since $B^n$ is compact, $Dg$ is bounded on $B^n$, and hence there is a constant $K > 0$ such that

$$\|g(x) - g(y)\| \leq K\|x - y\|$$

for all $x, y \in B^n$. If $0 \leq t < \frac{1}{K}$ and $x, y \in B^n$ with $f_t(x) = f_t(y)$, then

$$x - y = t(g(x) - g(y))$$

and since $Kt < 1$, $x = y$. Thus $f_t$ is one-to-one if $0 \leq t < \frac{1}{K}$.

We have $Df_t(x) = I + tDg(x)$ for all $t$ and $x$. Since $Dg$ is bounded on $B^n$, there is a constant $t_0 > 0$, which we may take to be $< \frac{1}{K}$, such that $\text{Det}(Df_t(x)) > 0$ for all $t$, $0 \leq t \leq t_0$, and all $x \in B^n$.

By the Inverse Function Theorem, $f_t$ is an injective open mapping on $\mathbb{D}^n$ for $0 \leq t \leq t_0$. Let $U_t = f_t(\mathbb{D}^n)$; then $U_t$ is an open set in $\mathbb{R}^n$ contained in $B^n$, hence $U_t \subseteq \mathbb{D}^n$.

XI.20.5.4. **Lemma.** Let $f$ be a continuous function from $B^n$ to $B^n$. Suppose $f(S^{n-1}) \subseteq S^{n-1}$ and that $f|_{\mathbb{D}^n}$ is an open mapping (as a map to $\mathbb{R}^n$). Then $f$ maps $\mathbb{D}^n$ onto $\mathbb{D}^n$ and $B^n$ onto $B^n$.

**Proof:** Since $f$ is an open mapping on $\mathbb{D}^n$, we have $f(\mathbb{D}^n) \subseteq \mathbb{D}^n$. If $f(\mathbb{D}^n)$ is a proper subset of $\mathbb{D}^n$, there is a $y \in \mathbb{D}^n$ which is in $f(\mathbb{D}^n) \setminus f(\mathbb{D}^n)$. But $f(B^n)$ is a compact set containing $f(\mathbb{D}^n)$, so $y \in B^n$, and hence $y = f(x)$ for some $x \in B^n \setminus \mathbb{D}^n = S^{n-1}$. But $f(S^{n-1}) \subseteq S^{n-1}$, a contradiction. Thus $f(\mathbb{D}^n) = \mathbb{D}^n$. Then $f(B^n)$ is a closed set containing $\mathbb{D}^n$, so $f(B^n) = B^n$.

XI.20.5.5. Continuing with the proof of the theorem, we conclude from the lemma that $U_t = \mathbb{D}^n$ and $f_t(B^n) = B^n$ for $0 \leq t \leq t_0$.

Now consider the function

$$\phi(t) = \int_{B^n} \text{Det}(Df_t(x)) \, dx = \int_{B^n} \text{Det}(I + tDg(x)) \, dx.$$ 

This $\phi(t)$ is a polynomial (of degree $\leq n$) in $t$. If $0 \leq t \leq t_0$, then $f_1$ is a $C^1$ diffeomorphism from $B^n$ to itself, and thus by the change-of-variables theorem () we have $\phi(t) = \text{Vol}(B^n)$ for $0 \leq t \leq t_0$. Thus $\phi$ is constant on $[0, t_0]$, and therefore constant everywhere, and nonzero.

However, $f_1$ maps $B^n$ into $S^{n-1}$ and thus has rank $\leq n - 1$ at every point, so $\text{Det}(Df_1(x))$ is zero for all $x$, and hence $\phi(1) = 0$, a contradiction.

This completes the proof of Theorem XI.20.5.2. ✇

1284
The Second Proof

The second proof is much shorter (given XI.20.5.1.), but uses Sard’s Theorem, and thus is not as elementary as the first proof.

XI.20.5.6. Let $r$ be a $C^\infty$ retraction from $B^n$ to $S^{n-1}$ which is radial projection on a neighborhood of $S^{n-1}$. By Sard’s Theorem (the version in XI.23.6.3. suffices), there is a regular value $y \in S^{n-1}$ (in fact a dense set of regular values, but we only need one!) Let $X = r^{-1}(\{y\})$. Then $X$ consists of regular points of $r$, hence is a one-dimensional compact manifold with boundary consisting of a radial line segment in from $y$ and possibly some additional points in $D^n$ (cf. VIII.6.7.1.), and $X \cap D^n$ is a manifold without boundary, i.e. $\partial X = \{y\}$. But a compact 1-manifold with boundary is a finite separated union of copies of $[0, 1]$ and $S^1$, and thus has an even number of boundary points, a contradiction.

This completes the proof of Theorem XI.20.5.2..
XI.21. Topological Dimension Theory

It has been a long and occasionally painful process to give a good definition of the “dimension” of a topological space. There are many reasonable definitions of dimension, and it is a remarkable and significant fact that they all give the same numerical value for “reasonable” topological spaces, including separable metrizable spaces. In this section, we describe some of the principal definitions and their properties. Although we give definitions applicable to all topological spaces, we will concentrate on their properties only in the separable metrizable case.

One obvious property any reasonable dimension theory must have is that the dimension of $\mathbb{R}^n$ should be $n$. This is true for all the definitions we will consider, but it is surprisingly hard to prove for most of them.

Some standard references for Dimension Theory are [Men28], [HW41], [Nag65], [Nag70], [AP73], [Pea75], [Eng95]. The first is mainly just of historical value today, but the others are worth reading for content, especially the last. Of course, newer references contain more complete results.

XI.21.1. Essential Dimension

XI.21.1.1. Definition. Let $X$ be a topological space. The essential dimension $ed(X)$ of $X$ is the largest $n$ such that there is an essential map () from $X$ to $B^n$. We say $ed(X) = 1$ if there is an essential map from $X$ to $B^n$ for all $n$, and $ed(X) = 0$ if every map from $X$ to $B^1 = [-1, 1]$ is inessential. Set $ed(\emptyset) = 1$.

The relevance of this definition is the following result, which is essentially equivalent to the Brouwer Fixed-Point Theorem:

XI.21.1.2. Theorem. We have $ed(\mathbb{R}^n) = ed(B^n) = ed(S^n) = n$.

See XI.21.1.5. for a more general result.

The next fact also justifies the form of the definition.

XI.21.1.3. Proposition. Let $X$ be a topological space. If there is an essential map from $X$ to $B^n$, then there is an essential map from $X$ to $B^m$ for any $m < n$.

Proof: Let $f : X \to B^n$ be an essential map, with coordinate functions $(f_1, \ldots, f_n)$. Fix $m < n$, and define $\tilde{f} : X \to B^m$ by

$$\tilde{f}(x) = (f_1(x), \ldots, f_m(x)).$$

Suppose $\tilde{f}$ is inessential. For $\epsilon > 0$, let $\tilde{g} : X \to B^m$ with $\|\tilde{g} - \tilde{f}\|_\infty < \epsilon$ and $0 \notin \tilde{g}(X)$. Let $(g_1, \ldots, g_m)$ be the coordinate functions of $\tilde{g}$. Define $g : X \to \mathbb{R}^n$ by

$$g(x) = (g_1(x), \ldots, g_m(x), f_{m+1}(x), \ldots, f_n(x)).$$

Then $\|g - \tilde{f}\|_\infty < \epsilon$ and $0 \notin g(X)$. The function $g$ does not necessarily map $X$ into $B^n$, but we can retract the part that does not: define $h$ by

$$h(x) = \begin{cases} g(x) & \text{if } \|g(x)\| \leq 1 \\ \frac{g(x)}{\|g(x)\|} & \text{if } \|g(x)\| > 1 \end{cases}.$$
Then $h$ is a map from $X$ to $B^n$, $\|h - f\|_\infty < \epsilon$, and $0 \notin h(X)$. Since $\epsilon > 0$ is arbitrary, this contradicts that $f$ is essential. Thus $f$ is essential.

**XI.21.1.4.** Proposition. Let $X$ be a topological space, and $f : X \rightarrow B^n$ a map. Then $f$ is essential if and only if there is an $\alpha > 0$ such that for every $g : X \rightarrow B^n$ sufficiently uniformly close to $f$, $g(X)$ contains the ball $B^n_\alpha$ of radius $\alpha$ around $0$.

**Proof:** It is obvious that any $f$ with this property is essential. Conversely, suppose $f$ is essential. Fix $0 < \epsilon < 1$ for which there is no $h$ with $\|f - h\|_\infty < \epsilon$ and $0 \notin h(X)$. Let $g : X \rightarrow B^n$ with $\|g - f\| < \frac{\epsilon}{2}$, and suppose there is an $x_0$ with $\|x_0\| < \frac{\epsilon}{2}$ and $x_0 \notin g(X)$. Define $h : B^n \rightarrow B^n$ by

$$h(x) = \begin{cases} x - x_0 & \text{if } \|x - x_0\| \leq 1 \\ \frac{x - x_0}{\|x - x_0\|} & \text{if } \|x - x_0\| > 1 \end{cases}.$$ 

Then $h(x_0) = 0$, and $x_0$ is the only $x$ with $h(x) = 0$; and $\|h - i\|_\infty < \frac{\epsilon}{2}$, where $i$ is the identity map on $B^n$, so $\|h \circ g - f\|_\infty < \epsilon$ and $0 \notin h \circ g(X)$, a contradiction.

We now prove a general result that includes XI.21.1.2..

**XI.21.1.5.** Theorem. Let $X$ be a smooth $n$-manifold with boundary. Then $ed(X) = n$.

**Proof:** $X$ contains a closed subset $Y$ homeomorphic to $B^n$, and there is a retraction $r$ from $X$ onto $Y$ (this requires the Tietze Extension Theorem () in general, but if $X = B^n$, $\mathbb{R}^n$, or $S^n$, such a $Y$ and $r$ can be given explicitly without resort to the Tietze Extension Theorem). Let $f$ be a homeomorphism from $Y$ onto $B^n$. Then $f$ is an essential map by XI.20.1.16., so $f \circ r$ is an essential map from $X$ to $B^n$ [if $g$ approximates $f \circ r$, and $i$ is the embedding of $Y$ into $X$, then $g \circ i$ approximates $f \circ r \circ i = f$] and $ed(X) \geq n$.

On the other hand, suppose $m > n$ and $f$ is a map from $X$ to $B^m$. To show that $f$ is inessential, it suffices to show that the restriction of $f$ to each component of $X$ is inessential, since the components are clopen and $f$ can be modified independently on each component. Thus we may assume $X$ is connected, and in particular second countable. Then $f$ can be arbitrarily closely approximated by a smooth function $g$, and by () the range of $g$ has dense complement. Thus $f$ is inessential by XI.21.1.4. and $ed(X) < m$.

**XI.21.1.6.** The smooth structure was used only to prove $ed(X) \leq n$; the first half of the proof applies to any topological $n$-manifold with boundary (and in fact to any normal topological space $X$ containing a copy of $B_n$) to give $ed(X) \geq n$. Note that the conclusion is purely topological, and the smooth structure is used only to give a simple way of approximating continuous functions by continuous functions whose range is “small.” The result also holds for manifolds which do not have differentiable structures, but requires a different proof in this case (Exercise XI.21.8.3.). An alternate proof that $ed(B^n) \leq n$ can be given using XI.21.4.14. and Exercise XI.21.8.2.

**XI.21.1.7.** Corollary. Let $X$ be a smooth $n$-manifold with boundary, and $Y$ a smooth $m$-manifold with boundary. If $n \neq m$, then $X$ and $Y$ are not homeomorphic. In particular, if $n \neq m$, $\mathbb{R}^n$ is not homeomorphic to $\mathbb{R}^m$, or to any open subset of $\mathbb{R}^m$.

1287
Extending Maps to Spheres

Essential dimension can be characterized also by an extension property for maps to spheres:

**XI.21.1.8. Theorem.** Let $X$ be a completely regular space. Then $\text{ed}(X) \leq n$ if and only if, whenever $Y$ is a closed subset of $X$ and $f : Y \to S^n$ is continuous, then $f$ extends to a continuous map $g : X \to S^n$.

**Proof:** Suppose $\text{ed}(X) \leq n$, $Y$ is a closed subspace of $X$, and $f : Y \to S^n$. Regard $f$ as a map from $Y$ to $B^{n+1}$. By the Tietze Extension Theorem (), $f$ extends to a map $h$ from $X$ to $B^{n+1}$. Then $h$ is inessential, so by an argument almost identical to the proof of (), there is a $\phi : B^{n+1} \to B^{n+1}$ which is the identity on a neighborhood of $S^n$ and for which $h = \phi \circ h$ satisfies $0 \notin h(X)$. Then $h|_Y = h|_Y$, so $h$ is also an extension of $f$. If $r$ is the radial retraction of $B^{n+1} \setminus \{0\}$ onto $S^n$, then $g = r \circ h$ is an extension of $f$ to $g : X \to S^n$.

Conversely, suppose $X$ has the extension property, and suppose $f : X \to B^{n+1}$. Fix $\epsilon > 0$, and let $Y = f^{-1}(S^n)$ (where $S^n = \{x \in B^{n+1} : \|x\| = \epsilon \}$). Then $Y$ is a closed subset of $X$, so $f|_Y$ extends to a map $h$ from $X$ to $S^n$. Define $g : X \to B^{n+1}$ by

$$g(x) = \begin{cases} h(x) & \text{if } \|f(x)\| \leq \epsilon \\ f(x) & \text{if } \|f(x)\| \geq \epsilon \end{cases}.$$  

Then $g$ is continuous, $\|g - f\|_{\infty} \leq 2\epsilon$, and $0 \notin g(X)$. Thus $f$ is inessential and $\text{ed}(X) \leq n$. 

A trick gives the following interesting and useful variant:

**XI.21.1.9. Corollary.** Let $X$ be a normal space, $Y$ a closed subspace, and $f : Y \to S^n$ a map. If $\text{ed}(X \setminus Y) \leq n$, then $f$ extends to a map from $X$ to $S^n$.

**Proof:** By (), $f$ extends to a neighborhood $U$ of $Y$ in $X$. Since $X$ is normal, there is a neighborhood $V$ of $Y$ in $X$ with $\bar{V} \subseteq U$. Thus $f$ extends to $\tilde{f} : \bar{V} \to S^n$. Then $Z = (X \setminus Y) \cap \bar{V}$ is a closed subspace of $X \setminus Y$, and $g = \tilde{f}|_Z$ is a map from $Z$ to $S^n$. By **XI.21.1.8.**, $g$ extends to $\tilde{g} : X \setminus Y \to S^n$. Then $\tilde{f}$ and $\tilde{g}$ define a map from $X$ to $S^n$ extending $f$.

**Essential Dimension of Subspaces**

**XI.21.1.10.** If $X$ is a topological space and $Y$ is a subspace of $X$, one would expect that $\text{ed}(Y) \leq \text{ed}(X)$. However, this turns out to be false in general, even if $X$ is a compact Hausdorff space (). The problem is that a map from $Y$ to $B^n$ need not extend to $X$ in general. It is true in general that $\text{ed}(Y) \leq \text{ed}(X)$ if $X$ is separable and metrizable (). And if $Y$ is closed, it is always true, and an immediate consequence of **XI.21.1.8.**:

**XI.21.1.11. Corollary.** Let $X$ be a completely regular space, and $Y$ a closed subspace of $X$. Then $\text{ed}(Y) \leq \text{ed}(X)$.

**Proof:** Suppose $\text{ed}(X) = n$. Let $Z$ be a closed subset of $Y$, and $f : Z \to S^n$ a map. Then $Z$ is closed in $X$, so by **XI.21.1.8.** $f$ extends to a map $g : X \to S^n$. Then $g|_Y$ is an extension of $f$ to $Y$. Thus $\text{ed}(Y) \leq n$ by the other direction of **XI.21.1.8.**.

1288
XI.21.1.12. PROPOSITION. Let $X$ be a completely regular space. Then $ed(X) = ed(\beta X)$, where $\beta X$ is the Stone–Čech compactification () of $X$.

PROOF: Let $f$ be a map from $X$ to $B^n$, and $\bar{f}$ its extension to $\beta X$. If $g : X \to B^n$, then $\|\bar{g} - \bar{f}\|_{\infty} = \|g - f\|_{\infty}$; thus if $f$ is essential, $\bar{f}$ is also essential. On the other hand, if $f$ is inessential, then for every $\epsilon > 0$ there is a $g : X \to B^n$ with $\|g - f\|_{\infty} < \epsilon$ and $g(X)$ bounded away from $0$ (XI.21.1.4); thus $0 \notin \bar{g}(\beta X)$, so $\bar{f}$ is also inessential.

Essential Dimension of Subspaces of $\mathbb{R}^n$

XI.21.1.13. THEOREM. Let $X$ be a subset of $\mathbb{R}^n$. Then $ed(X) \leq n$, and $ed(X) = n$ if and only if $X$ has nonempty interior.

XI.21.2. Invariance of Domain

We can now prove Brouwer’s Invariance of Domain Theorem:

XI.21.2.1. THEOREM. [INVARIANCE OF DOMAIN] Let $U$ be a nonempty open subset of $\mathbb{R}^n$, and $f$ a one-to-one continuous function from $U$ to $\mathbb{R}^m$. Then

(i) $m \geq n$.

(ii) If $m = n$, then $f(V)$ is open in $\mathbb{R}^n$ for every open subset $V$ of $U$ (in particular, $f(U)$ is open in $\mathbb{R}^n$), i.e. $f$ is an open mapping and a homeomorphism onto its range.

This will be a consequence of the following:

XI.21.2.2. THEOREM. Let $X$ be a subset of $\mathbb{R}^n$, and $f$ a one-to-one continuous function from $X$ onto a subset $Y$ of $\mathbb{R}^n$. If $x$ is an interior point of $X$, then $f(x)$ is an interior point of $Y$.

XI.21.2.3. A point $x \in X$ is an interior point of $X$ if and only if it is an interior point of a compact subset of $X$: if $x$ is an interior point of $X$, then $x$ is an interior point of a sufficiently small closed ball around $x$ which is contained in $X$, and the converse is obvious. Thus it suffices to prove XI.21.2.2. for $X$ compact. And in this case, the map $f$ is automatically a homeomorphism.

Thus it suffices to prove that interior points of a compact subset $X$ of $\mathbb{R}^n$ can be characterized topologically, which is the substance of the next result:
**XI.21.2.4. Lemma.** Let $X$ be a compact subset of $\mathbb{R}^n$, and $x \in X$. Then $x \in \partial X$ if and only if, whenever $U$ is a neighborhood of $x$ in $X$, there is an open neighborhood $V$ of $x$ in $X$ contained in $U$ such that every map from $X \setminus V$ to $S^{n-1}$ extends to a map from $X$ to $S^{n-1}$.

**Proof:** Suppose $x \in \partial X$, and $U$ is a neighborhood of $x$ in $X$. Then there is an open ball $W$ around $x$ in $\mathbb{R}^n$ such that $W \cap X \subseteq U$. Set $V = W \cap X$. Let $f$ be a map from $X \setminus V$ to $S^{n-1}$. Then $\partial W$ is homeomorphic to $S^{n-1}$, and $X \setminus V$ is compact and hence closed in $(X \setminus V) \cup \partial W$. The complement $Z = [(X \setminus V) \cup \partial W] \setminus (X \setminus V)$ is an open subset of $\partial W$, hence an $(n-1)$-manifold with a smooth structure, and thus $ed(Z) = n-1$ by XI.21.1.5. (only the “easy” part $ed(Z) \leq n-1$ is needed). So by XI.21.1.9. $f$ extends to a map $\tilde{f}$ from $(X \setminus V) \cup \partial W$ to $S^{n-1}$. Since $x \in \partial X$, there is an $x_0 \in W$ with $x_0 \notin X$, and there is a retraction $r$ from $W \setminus \{x_0\}$ to $\partial W$. Define $g : X \to S^{n-1}$ by

$$g(y) = \begin{cases} \tilde{f}(r(y)) & \text{if } y \in V \\ f(y) & \text{if } y \in X \setminus V \end{cases}.$$  

Then $g : X \to S^{n-1}$ is an extension of $f$ to $X$.

Conversely, suppose $x$ is an interior point of $X$, and $\epsilon$ is small enough that the closed ball $B$ of radius $\epsilon$ around $x$ is contained in $X$. Let $U$ be the open ball of radius $\epsilon$ centered at $x$; then $\partial U = \partial B$ is homeomorphic to $S^{n-1}$, and $X \setminus U$ can be radially projected onto $\partial U$. Call this map $f$. If $V$ is any neighborhood of $x$ contained in $U$, then $f$ can be extended to a map from $X \setminus V$ to $\partial W$ using radial projection from $x$. But $f$ cannot be extended to a map $g$ from $X$ to $\partial U$, since the restriction of $g$ to $B$ would be a retraction of $B$ onto $\partial B$. 

---

**XI.21.3. Other Dimension Functions**

For analysis purposes, essential dimension seems to be the most useful dimension function on spaces. However, it is not commonly used by topologists. There are three standard dimension functions used by topologists: small inductive dimension, large inductive dimension, and covering dimension.

**Small Inductive Dimension**

**XI.21.3.1.** Small inductive dimension $\text{ind}$ is the earliest and probably still the most-used dimension function on spaces. The definition is motivated by the idea that the boundary of a “nice” region of $\mathbb{R}^n$ should have dimension $n-1$. The definition is (surprise!) an inductive one: we successively define what it means for a space to have dimension $\leq n$.

**XI.21.3.2. Definition.** Let $X$ be a topological space. Then

(i) $\text{ind}(X) = -1$ if and only if $X = \emptyset$.

(ii) $\text{ind}(X) \leq n$ if and only if, whenever $x \in X$ and $U$ is an open neighborhood of $x$ in $X$, there is an open neighborhood $V$ of $x$ contained in $U$ with $\text{ind}(\partial V) \leq n - 1$.

(iii) $\text{ind}(X) = n$ if $\text{ind}(X) \leq n$ and it is false that $\text{ind}(X) \leq n - 1$.

(iv) $\text{ind}(X) = \infty$ if for every $n$ it is false that $\text{ind}(X) \leq n$.
XI.21.3.3. Thus, for example, a topological space \( X \) satisfies \( \text{ind}(X) = 0 \) if and only if it is nonempty and, for each \( x \in X \) and each open neighborhood \( U \) of \( x \), there is an open neighborhood \( V \) of \( x \) contained in \( U \) with \( \partial V = \emptyset \). But a subset of \( X \) has empty boundary if and only if it is clopen; so \( \text{ind}(X) = 0 \) if and only if for each \( x \in X \) and each open neighborhood \( U \) of \( x \), there is a clopen neighborhood \( V \) of \( x \) contained in \( U \), i.e. if and only if \( X \) is nonempty and there is a base for the topology of \( X \) consisting of clopen sets. (Thus if \( X \) is \( T_0 \) and \( \text{ind}(X) = 0 \), \( X \) must be completely regular.)

XI.21.3.4. Proposition. Let \( X \) be a regular topological space. Then \( \text{ind}(X) \leq n \) if and only if, whenever \( A \) is a closed set in \( X \) and \( x \in X \setminus A \), there is a partition \( P \) between \( \{x\} \) and \( A \) with \( \text{ind}(P) \leq n-1 \).

Proof: There is an open neighborhood \( U \) of \( x \) with \( \bar{U} \subseteq X \setminus A \). There is an open neighborhood \( V \) of \( x \) contained in \( U \) with \( \text{ind}(\partial V) \leq n-1 \). Then \( P = \partial V \) is a partition between \( \{x\} \) and \( A \).

XI.21.3.5. Proposition. Let \( X \) be a topological \( n \)-manifold with boundary \((n \geq 1)\). Then \( 1 \leq \text{ind}(X) \leq n \). In particular, if \( X \) is a topological 1-manifold with boundary, then \( \text{ind}(X) = 1 \). So \( \text{ind}(\mathbb{R}) = \text{ind}([0,1]) = \text{ind}(S^1) = 1 \).

Proof: By induction on \( n \). If \( n = 1 \), a point of \( X \) has arbitrarily small neighborhoods whose boundary consists of either one or two points, hence of inductive dimension 0. Thus \( \text{ind}(X) \leq 1 \). But \( X \) is locally connected and thus \( \text{ind}(X) = 0 \) is false. And if \( X \) is an \((n+1)\)-manifold with boundary, each point of \( X \) has arbitrarily small neighborhoods whose boundary is homeomorphic to either \( S^n \) or \( B^n \), hence with inductive dimension \( \leq n \); thus \( \text{ind}(X) \leq n + 1 \). Also, \( \text{ind}(X) = 0 \) is false for the same reason as before.

XI.21.3.6. In fact, if \( X \) is a topological \( n \)-manifold with boundary, then \( \text{ind}(X) = n \), but it is much harder to prove equality, even if \( X = B^n \) or \( X = \mathbb{R}^n \). Actually, it is hard to prove that there is any topological space \( X \) with \( \text{ind}(X) > 1 \).

One simple but important property of small inductive dimension is monotonicity:

XI.21.3.7. Proposition. Let \( X \) be a topological space, and \( Y \) a subspace of \( X \). Then \( \text{ind}(Y) \leq \text{ind}(X) \).

Proof: By induction on \( n = \text{ind}(X) \). If \( n = -1 \) there is nothing to prove. Suppose the result is true whenever \( \text{ind}(X) \leq n \). If \( \text{ind}(X) \leq n + 1 \) and \( Y \subseteq X \), and \( y \in Y \), let \( U \) be an open neighborhood of \( y \) in \( Y \). Then there is an open neighborhood \( U \) of \( y \) in \( X \) with \( U = U \cap Y \). There is an open neighborhood \( V \) of \( y \) in \( X \) with \( \partial V \subseteq U \) and \( \text{ind}(\partial V) \leq n \). Set \( V = V \cap Y \); then \( V \) is an open neighborhood of \( y \) in \( Y \) with \( V \subseteq U \). We have \( \partial V \subseteq \partial V \) (\( \subseteq \)), so by the inductive hypothesis \( \text{ind}(\partial V) \leq n \). Thus \( \text{ind}(Y) \leq n + 1 \).

XI.21.3.8. Small inductive dimension is a good notion for separable metrizable spaces, but turns out to have pathological properties outside this class and is regarded by topologists as of little use or interest for more general spaces.
**Large Inductive Dimension**

The small inductive dimension is strictly a local concept. There is a technical variation, called the *large inductive dimension* (Ind), which is more of a global condition.

**XI.21.3.9. Definition.** Let $X$ be a topological space. Then

(i) $\text{Ind}(X) = -1$ if and only if $X = \emptyset$.

(ii) $\text{Ind}(X) \leq n$ if and only if, whenever $Y$ is a closed subset of $X$ and $U$ is an open neighborhood of $Y$ in $X$, there is an open neighborhood $V$ of $Y$ contained in $U$ with $\text{Ind}(\partial V) \leq n - 1$.

(iii) $\text{Ind}(X) = n$ if $\text{Ind}(X) \leq n$ and it is false that $\text{Ind}(X) \leq n - 1$.

(iv) $\text{Ind}(X) = \infty$ if for every $n$ it is false that $\text{Ind}(X) \leq n$.

**XI.21.3.10. Proposition.** Let $X$ be a normal topological space. Then $\text{Ind}(X) \leq n$ if and only if, whenever $A$ and $B$ are disjoint closed sets in $X$, there is a partition $P$ between $A$ and $B$ with $\text{Ind}(P) \leq n - 1$.

The proof is nearly identical to the proof of XI.21.3.4..

**XI.21.3.11. Proposition.** Let $X$ be a $T_1$ topological space. Then $\text{ind}(X) \leq \text{Ind}(X)$.

Proof: It is easily proved by induction that if $\text{Ind}(X) \leq n$, then $\text{ind}(X) \leq n$.

**XI.21.3.12. Theorem.** If $X$ and $Y$ are metrizable, then

$$\text{Ind}(X \times Y) \leq \text{Ind}(X) + \text{Ind}(Y).$$

Equality does not hold in general. For example, the space $X$ of the irrationals satisfies $\text{Ind}(X) = 1$ and $\text{Ind}(X \times X) = 1$ also, since $X \times X$ is homeomorphic to $X$. (This space is separable metrizable, so $\text{ind}(X) = \text{Ind}(X) = \dim(X)$. ) There are compact metrizable spaces for which equality fails []. It is unknown whether equality can fail for ANR’s; for well-behaved ANR’s equality does hold [Bor36].

The inequality holds in somewhat greater generality, but does not even hold for all compact Hausdorff spaces: there are compact Hausdorff spaces $X$ and $Y$ with $\text{Ind}(X) = 1$, $\text{Ind}(Y) = 2$, and $\text{Ind}(X \times Y) = 4$ [Fil72]. Compare with XI.21.3.37..

**Sum and Decomposition Theorems**

We now obtain some moderately complicated but crucial results about dimensions of unions, and decompositions into sets of smaller dimension.

It is clear that if $X$ is a union of two subspaces of dimension $n$, then the dimension of $X$ might be larger than $n$: for example, $\mathbb{R}$ can be decomposed into the rational and irrational numbers, each of which has dimension 0. There is only an inequality in general (). In fact, any sufficiently nice space of dimension $n$ can be written as a union of $n + 1$ subspaces of dimension 0 (). But if the space is nice and the subspaces are closed, the dimension of the union does not grow, even with countably many subspaces:
**XI.21.3.13. Theorem.** [Sum Theorem for ind] Let $X$ be a separable metrizable space. If $X = \bigcup_{j=1}^{\infty}X_j$, with each $X_j$ closed in $X$ and $\text{ind}(X_j) \leq n$ for all $j$, then $\text{ind}(X) = \text{Ind}(X) \leq n$.

The name “Sum Theorem,” which has become standard, comes from the practice in older references on set theory and topology to use sum as a synonym for union. Similarly, product was used to mean intersection.

To prove this theorem, we first prove a zero-dimensional version for $\text{Ind}$ which is valid in much greater generality:

**XI.21.3.14. Theorem.** Let $X$ be a normal space. If $X = \bigcup_{j=1}^{\infty}X_j$, with each $X_j$ closed in $X$ and $\text{Ind}(X_j) = 0$ for all $j$, then $\text{Ind}(X) = 0$.

Before proving XI.21.3.13., we need two lemmas, the first of which includes a useful construction:

**XI.21.3.15. Lemma.** Let $X$ be a topological space and $\mathcal{V}$ a base for the topology of $X$ (consisting of open sets). Set

$$Y = \bigcup_{V \in \mathcal{V}} \partial V$$

and $Z = X \setminus Y$. Then $\text{ind}(Z) \leq 0$.

**Proof:** Let $z \in Z$ and $U$ an open neighborhood of $z$ in $Z$. Then there is an open set $W$ in $X$ with $U = W \cap Z$. There is a $V \in \mathcal{V}$ with $z \in V$ and $V \subseteq U$. Since $\partial V \subseteq Y$, we have that $V \cap Z = V \cap Z$, so $V \cap Z$ is relatively clopen in $Z$ and $z \in V \cap Z \subseteq U$.

The second lemma is a variant of XI.20.1.23. (cf. [Eng95, 1.29]).

**XI.21.3.16. Lemma.** Let $X$ be a metrizable space, or more generally a completely normal space $\langle \rangle$, and $Z$ a subspace of $Z$ with $\text{Ind}(Z) = 0$. If $A$ and $B$ are disjoint closed subsets of $X$, then there are open sets $V_1$, $V_2$ in $X$ with $A \subseteq V_1$, $B \subseteq V_2$, $V_1 \cap V_2 = \emptyset$, and

$$[X \setminus (V_1 \cup V_2)] \cap Z = \emptyset.$$

**Proof:** Let $V_1'$ and $V_2'$ be open neighborhoods of $A$ and $B$ whose closures are disjoint. Let $U_1$ be a relatively clopen subset of $X$ containing $V_1' \cap Z$ (all closures are closures in $X$) and disjoint from $V_2 \cap Z$, and $U_2 = Z \setminus U_1$. Note that $V_1'$ is disjoint from $U_2$ and hence from $U_2$ since $V_1'$ is open; thus $A \cap U_2 = \emptyset$. Similarly, $B \cap U_1 = \emptyset$.

Since $U_1 \cap Z = U_1$ and $U_2 \cap Z = U_2$, the sets $U_1$ and $U_2$ are completely separated in $X$, and hence the sets $A \cup U_1$ and $B \cup U_2$ are also completely separated in $X$. Thus they have disjoint neighborhoods $V_1$ and $V_2$ in $X$. Since $Z \subseteq V_1 \cup V_2$, $[X \setminus (V_1 \cup V_2)] \cap Z = \emptyset$.

We now give the proof of XI.21.3.13.:

**Proof:** By induction on $n$. The case $n = 0$ follows immediately from XI.21.3.14. and the fact that if $Y$ is a $T_0$ Lindelöf space with $\text{ind}(Y) = 0$, then $\text{Ind}(Y) = 0$ (XI.13.6.5. and the proof of XI.13.6.7.((iv) $\Rightarrow$ (iii))). Now suppose $n > 0$ and the statement holds for $n - 1$ (including the statement that $\text{ind}(Y) = \text{Ind}(Y)$ for $Y$).
if \( \text{ind}(Y) \leq n - 1 \). There is a countable base \( \mathcal{V} \) for the topology of \( X \) consisting of open sets \( V \) with \( \text{ind}(\partial V) \leq n - 1 \). Set

\[
Y = \bigcup_{V \in \mathcal{V}} \partial V
\]

and \( Z = X \setminus Y \). Then \( \text{ind}(Z) \leq 0 \) by Lemma XI.21.3.15., so \( \text{Ind}(Z) \leq 0 \) since \( Z \) is Lindelöf. We have that \( \text{ind}(Y) \leq n - 1 \) by the inductive assumption. Let \( A \) and \( B \) be disjoint closed subsets of \( X \). By Lemma XI.21.3.16. there are disjoint neighborhoods \( V_1 \) and \( V_2 \) of \( A \) and \( B \) with \( Z \subseteq V_1 \cup V_2 \). Hence \( P = X \setminus (V_1 \cup V_2) \) is a partition between \( A \) and \( B \). Since \( P \subseteq Y \), \( \text{ind}(P) \leq n - 1 \), so \( \text{Ind}(P) \leq n - 1 \) by the inductive assumption. Thus \( \text{Ind}(X) \leq n \) by XI.21.3.10. So we have for this \( n \) that if each \( X_k \) satisfies \( \text{ind}(X_k) \leq n \), then \( \text{Ind}(X) \leq n \). In particular, if \( \text{ind}(X) = n \), set \( X_k = X \) for all \( k \) to conclude that \( \text{Ind}(X) \leq n \). Since \( \text{ind}(X) \leq \text{Ind}(X) \) (XI.21.3.11.), we have \( \text{Ind}(X) = n \).

We now obtain some corollaries of XI.21.3.13.

**XI.21.3.17.** *Corollary.* Let \( X \) be a separable metrizable space. Then \( \text{ind}(X) = \text{Ind}(X) \).

**XI.21.3.18.** *Corollary.* If \( X \) is a countable regular space, then \( \text{Ind}(X) = \text{ind}(X) = \text{dim}(X) = 0 \).

**Proof:** A countable topological space is Lindelöf, so a countable regular space is normal. Each singleton set \( \{x\} \) has \( \text{Ind} \{x\} = 0 \), thus \( \text{Ind}(X) = 0 \). We then have \( \text{ind}(X) = 0 \), so \( \text{dim}(X) = 0 \) by XI.13.6.7. (iii) \( \Rightarrow \) (iv)).

The regularity assumption is necessary: there exist connected countable Hausdorff spaces ().

**XI.21.3.19.** *Corollary.* [First Decomposition Theorem] Let \( X \) be a separable metrizable space, and \( n \geq 0 \). If \( \text{ind}(X) = n \), then \( X \) can be written as \( Y \cup Z \), where \( \text{ind}(Y) = n - 1 \) and \( \text{ind}(Z) = 0 \). Conversely, if \( X \) can be so written, then \( n - 1 \leq \text{ind}(X) \leq n \).

**Proof:** Since \( \text{ind}(X) = n \), there is an \( x \in X \) and an open neighborhood \( U \) of \( x \) such that no open neighborhood \( V \) of \( x \) contained in \( U \) has \( \text{ind}(\partial V) \leq n - 2 \). There is a countable base \( \mathcal{V} \) for \( X \) with \( \text{ind}(\partial V) \leq n - 1 \) for all \( V \in \mathcal{V} \). Set

\[
Y = \bigcup_{V \in \mathcal{V}} \partial V
\]

and \( Z = X \setminus Y \). Then \( \text{ind}(Z) \leq 0 \) by Lemma XI.21.3.15.. We have \( \text{ind}(Y) \leq n - 1 \) by XI.21.3.13.. But if \( V \in \mathcal{V} \) with \( x \in V \subseteq U \), then \( \text{ind}(\partial V) = n - 1 \), so \( \text{ind}(Y) = n - 1 \) by XI.21.3.7.. For the converse, suppose \( X = Y \cup Z \), where \( \text{ind}(Y) = n - 1 \) and \( \text{ind}(Z) = 0 \). Then \( \text{ind}(X) \geq n - 1 \) by XI.21.3.7.. Let \( x \in X \) and \( U \) an open neighborhood of \( x \). Then by Lemma XI.21.3.16. there are disjoint neighborhoods \( V_1 \) of \( x \) and \( V_2 \) of \( X \setminus U \) such that \( Z \subseteq V_1 \cup V_2 \). Then \( \partial V_1 \subseteq Y \), so \( \text{ind}(\partial V_1) \leq n - 1 \); and \( V_1 \subseteq U \). Thus \( \text{ind}(X) \leq n \).

Applying this result repeatedly, we obtain:

1294
XI.21.3.20. Corollary. [Second Decomposition Theorem] Let $X$ be a separable metrizable space. Then $\text{ind}(X) \leq n$ if and only if $X$ can be written as a union of $n + 1$ subspaces $X_1, \ldots, X_{n+1}$ with $\text{ind}(X_k) \leq 0$ for all $k$.

Covering Dimension
This is perhaps the most generally useful notion of dimension. The idea is due to Lebesgue, but the actual definition was given by Čech.

XI.21.3.21. The idea behind covering dimension is that $\mathbb{R}$ can be covered with small open intervals in such a way that only consecutive intervals overlap, i.e. no three of the intervals have nonempty intersection; however, since it is connected, it cannot be covered by pairwise disjoint bounded open intervals. Similarly, $\mathbb{R}^2$ can be covered by small open sets in such a way that no four of the sets have nonempty intersection (e.g. tile the plane with hexagons, or consider a brick wall, and slightly expand the tiles or bricks to open sets), but it appears that in any covering by bounded open sets at least three of the sets must have a nonempty intersection (although this turns out to be not so easy to prove). It is a little harder, but possible, to cover $\mathbb{R}^3$ with small open sets in such a way that no five of the sets have nonempty intersection (try it!), but in any open cover by bounded sets at least four of the sets must have nonempty intersection.

XI.21.3.22. Definition. Let $X$ be a topological space, and $\mathcal{U} = \{U_i : i \in I\}$ an open cover of $X$. Then $\mathcal{U}$ has order $\leq n$ if, whenever $i_1, \ldots, i_{n+2}$ are distinct elements of $I$, then

$$U_{i_1} \cap \cdots \cap U_{i_{n+2}} = \emptyset$$

(i.e. every point of $X$ is contained in at most $n + 1$ of the sets). $\mathcal{U}$ has order $n$ if it has order $\leq n$ but not order $\leq n - 1$, i.e. there are distinct $i_1, \ldots, i_{n+1}$ in $I$ such that

$$U_{i_1} \cap \cdots \cap U_{i_{n+1}} \neq \emptyset.$$

XI.21.3.23. Definition. Let $X$ be a nonempty topological space. The covering dimension $\text{dim}(X)$ of $X$ is $\leq n$ if every finite open cover of $X$ has a refinement of order $\leq n$. Say $\text{dim}(X) = n$ if $\text{dim}(X) \leq n$ and it is false that $\text{dim}(X) \leq n - 1$. If $\text{dim}(X) \leq n$ is false for all $n$, then $\text{dim}(X) = \infty$. Set $\text{dim}(\emptyset) = -1$.

XI.21.3.24. Most, but not all, authors use $\text{dim}(X)$ to denote covering dimension, as we will; the notation $\text{cov}(X)$ is also sometimes used. But in some references such as [HW41], $\text{dim}(X)$ means something else ($\text{ind}(X)$ in [HW41]); some references on geometric measure theory such as [Edg98] use $\text{dim}(X)$ to denote the Hausdorff dimension of a metric space $X$ (a metric, but not a topological, invariant).

XI.21.3.25. An open cover $\mathcal{V}$ of a topological space $X$ is order zero if and only if $X$ is nonempty and $\mathcal{V}$ is a partition of $X$ into clopen sets. Thus $\text{dim}(X) = 0$ if and only if $X$ is nonempty and every finite open cover of $X$ has a refinement consisting of a partition of $X$ into clopen sets.

1295
XI.21.3.26. Covering dimension can be alternately be defined using open shrinkings (XI.7.6.7.), a special kind of refinement. A refinement $V$ of an open cover $U = \{U_i : i \in I\}$ can be converted to an open shrinking using consolidation. A consolidation of $V$ under $U$ consists of, for each $V \in V$, choosing an $i \in I$ with $V \subseteq U_i$ and calling this $i k(V)$. Then for each $i$ set $W_i = \bigcup \{V \in V : k(V) = i\}$. Then $W_i$ is an open set contained in $U_i$ for each $i$, and $W = \{W_i : i \in I\}$ is an open cover of $X$ since each $V \in V$ is contained in some $W_i$. Thus $W$ is an open shrinking of $U$. If $U$ is a finite open cover, then $W$ is also a finite cover.

A consolidation of $V$ under $U$ is highly nonunique in general, and requires the AC to define.

It is easy to check that if $V$ has order $\leq n$, then any consolidation of $V$ under another open cover $U$ also has order $\leq n$. Thus we obtain:

XI.21.3.27. **Proposition.** Let $X$ be a topological space, and $n \geq 0$. The following are equivalent:

(i) $\dim(X) \leq n$.

(ii) Every finite open cover of $X$ has a finite refinement of order $\leq n$.

(iii) Every finite open cover of $X$ has an open shrinking of order $\leq n$.

The following sharpening is useful:

XI.21.3.28. **Theorem.** Let $X$ be a normal space, and $n \geq 0$. Then $\dim(X) \leq n$ if and only if, whenever $U = \{U_1, \ldots, U_{n+2}\}$ is an open cover of $X$ with $n + 2$ elements, there is an open shrinking of $U$ of order $\leq n$.

**Proof:** If $\dim(X) \leq n$, the condition trivially follows. Conversely, suppose $\dim(X) > n$, and let $V = \{V_1, \ldots, V_m\}$ be a finite open cover of $X$ with no refinement of order $\leq n$ (so $m \geq n + 2$). If $i_1, \ldots, i_k$ are distinct natural numbers $\leq m$, with $V_{i_1} \cap \cdots \cap V_{i_k} \neq \emptyset$, and $W = \{W_1, \ldots, W_m\}$ is an open shrinking of $V$ with $W_{i_1} \cap \cdots \cap W_{i_k} = \emptyset$, replace $V$ by $W$. Doing this process successively for each such $i_1, \ldots, i_k$ (there are only finitely many such sets), we may assume $V$ has the property that whenever $i_1, \ldots, i_k \leq m$ and $V_{i_1} \cup \cdots \cup V_{i_k} \neq \emptyset$, and $W = \{W_1, \ldots, W_m\}$ is an open shrinking of $V$, then $W_{i_1} \cap \cdots \cap W_{i_k} \neq \emptyset$.

The reduction does not change the fact that the order of $V$ is at least $n+1$, so reordering $V$ if necessary we may assume $\cap_{j=1}^{n+2} V_j \neq \emptyset$. Now set $U_j = V_j$ if $1 \leq j \leq n + 1$ and $U_{n+2} = \bigcup_{j=n+2}^m V_j$. If $W = \{W_1, \ldots, W_{n+2}\}$ is an open shrinking of $U$, then

$$\{W_1, \ldots, W_{n+1}, W_{n+2} \cap V_{n+2}, \ldots, W_{n+2} \cap V_m\}$$

is an open shrinking of $V$, and hence

$$\emptyset \neq (\cap_{j=1}^{n+2} W_j) \cap (W_{n+2} \cap V_{n+2}) \subseteq \cap_{j=1}^{n+2} W_j.$$

\(\Box\)

XI.21.3.29. **Proposition.** Let $X$ be a normal space, and $n \geq 0$. If, for every pair $A, B$ of disjoint closed sets of $X$ there is a partition $P$ between $A$ and $B$ with $\dim(P) \leq n-1$, then $\dim(X) \leq n$. 3.1.27

1296
XI.21.3.30. Why finite open covers, and not general open covers? Mainly, the theory just turns out to work well this way. But note that any open cover of finite order is locally finite, and there are spaces, even normal spaces, with open covers which have no locally finite (even no point-finite) refinements. But for paracompact spaces, there is no difference:

XI.21.3.31. Theorem. [Dowker’s Theorem] Let $X$ be a topological space with $\dim(X) \leq n$, and $\mathcal{U}$ a locally finite open cover of $X$. Then $\mathcal{U}$ has a refinement of order $\leq n$.

XI.21.3.32. Corollary. Let $X$ be a paracompact space. The following are equivalent:

(i) $\dim(X) \leq n$.

(ii) Every finite open cover of $X$ has a shrinking of order $\leq n$.

(iii) Every open cover of $X$ has a refinement of order $\leq n$.

(iv) Every open cover of $X$ has an open shrinking of order $\leq n$.

XI.21.3.33. Definition. Let $X$ be a topological space. An open cover $\mathcal{U}$ of $X$ is $n$-decomposable if $\mathcal{U}$ is a disjoint union $\mathcal{U} = \mathcal{U}_1 \cup \cdots \cup \mathcal{U}_{n+1}$ of $n + 1$ subcollections, each of which consists of pairwise disjoint sets.

XI.21.3.34. It is obvious that an $n$-decomposable open cover has order $\leq n$. The converse is false: consider a cover of a circle by three arcs. (A cover is 0-decomposable if and only if it has order zero, i.e. consists of a partition into clopen subsets.) However, we do have:

XI.21.3.35. Proposition. Let $X$ be a normal topological space, and $0 \leq n < \infty$. Then every open cover of $X$ of order $n$ has an $n$-decomposable refinement. Every finite open cover of $X$ of order $n$ has a finite $n$-decomposable refinement.

**Proof:** Let $\mathcal{V}$ be an open cover of $X$ of order $n$. Since $\mathcal{V}$ is locally finite, there is a partition of unity $\{f_i\}$ subordinate to $\mathcal{V}$ ( ), which defines a continuous function $\phi$ from $X$ to $|K|$ for a simplicial complex $K$ of dimension $\leq n$ ( ). Let $K'$ be the barycentric subdivision of $K$. Then each vertex $\sigma$ of $K'$ is the barycenter of a unique simplex $\Delta_\sigma$ of $K$; let $d(\sigma) \in \{0, \ldots, n\}$ be the dimension of $\Delta_\sigma$.

Since $|K'|$ can be identified with $|K|$, $\phi$ may be regarded as a map from $X$ to $|K'|$. For each vertex $\sigma$ of $K'$, let $U_\sigma$ be the preimage under $\phi$ of the star of $\sigma$, the points of $|K'|$ whose $\sigma$-coordinate is positive. Then $\mathcal{U} = \{U_\sigma\}$ is an open cover of $X$ which refines $\mathcal{V}$. For each $k$, $0 \leq k \leq n$, let

$$\mathcal{U}_k = \{U_\sigma : d(\sigma) = k\}.$$
Then \( U \) is the disjoint union of the \( U_k \). If \( \sigma, \tau \) are vertices of \( K' \) with \( d(\sigma) = d(\tau) = k \), then \( \sigma \) and \( \tau \) are the barycenters of distinct \( k \)-simplexes in \( K \), so the stars of \( \sigma \) and \( \tau \) are disjoint, and thus \( U_\sigma \) and \( U_\tau \) are disjoint. So \( U \) is \( n \)-decomposable. If \( V \) is finite, \( K' \) (hence \( K' \)) is finite, so \( U \) is also finite.

XI.21.3.36. **Corollary.** Let \( X \) be a normal topological space, and \( n \geq 0 \). Then \( \dim(X) \leq n \) if and only if every finite open cover of \( X \) has an \( n \)-decomposable refinement.

XI.21.3.37. **Theorem.** [Hem46] Let \( X \) and \( Y \) be compact Hausdorff spaces. Then \( \dim(X \times Y) \leq \dim(X) + \dim(Y) \).

Compare with XI.21.3.12.

XI.21.3.38. **Covering dimension is not well behaved for spaces which are not normal.** There is a technical variation which works somewhat better for completely regular spaces (dimension theory is of almost no use or interest for spaces which are not at least completely regular). Recall that a set \( U \) in a topological space \( X \) is a *cozero set* if there is a continuous function \( f : X \to \mathbb{R} \) with \( U = \{ x \in X : f(x) \neq 0 \} \). A cozero set is an open \( F \); if \( X \) is normal, the converse is also true. Some references use the term *functionally open* for cozero sets.

XI.21.3.39. **Definition.** Let \( X \) be a topological space. Then \( \zdim(X) \leq n \) if every finite open cover of \( X \) by cozero sets has a finite refinement by cozero sets which is of order \( \leq n \).

XI.21.3.40. **There is no obvious relation between \( \dim(X) \) and \( \zdim(X) \) for general (even completely regular) spaces \( X \).** But every open cover of a normal space has a shrinking consisting of cozero sets (Exercise XI.21.8.1.); hence if \( X \) is normal, \( \zdim(X) = \dim(X) \). Some authors define the covering dimension of a space \( X \) to be \( \zdim(X) \).

**Partition Dimension**

In analogy with the Lebesgue Covering Theorem (.), we make another definition:

XI.21.3.41. **Definition.** Let \( X \) be a nonempty topological space. The *partition dimension* \( pd(X) \) is the smallest \( n \geq 0 \) such that, whenever \((A_1, B_1), \ldots, (A_{n+1}, B_{n+1})\) are \( n + 1 \) pairs of disjoint closed sets in \( X \), there are partitions \( P_k \) of \((A_k, B_k)\) for \( 1 \leq k \leq n + 1 \) with \( P_1 \cap \cdots \cap P_{n+1} = \emptyset \). If there is no such \( n \), set \( pd(X) = \infty \). Set \( pd(\emptyset) = -1 \).

XI.21.3.42. **If \( X \) is a topological space, then \( pd(X) \leq n \) if and only if, whenever \((A_1, B_1), \ldots, (A_{n+1}, B_{n+1})\) are \( n + 1 \) pairs of disjoint closed sets in \( X \), there are partitions \( P_k \) of \((A_k, B_k)\) for \( 1 \leq k \leq n + 1 \) with \( P_1 \cap \cdots \cap P_{n+1} = \emptyset \). If \( X \) is normal and this condition holds for one \( n \), it holds for all larger \( n \) (and if the condition holds for some \( n \), then \( X \) is normal). The Lebesgue Covering Theorem implies that \( pd(B_n) \geq n \).
Decomposition Dimension

We define one more notion of dimension:

**XI.21.3.43. Definition.** Let \( X \) be a nonempty topological space. The *decomposition dimension* \( \text{dd}(X) \) is the smallest \( n \) such that \( X \) can be written

\[
X = X_1 \cup \cdots \cup X_{n+1}
\]

where \( \text{ind}(X_k) \leq 0 \) for \( 1 \leq k \leq n+1 \). If there is no such \( n \), then \( \text{dd}(X) = \infty \). Set \( \text{dd}(\emptyset) = -1 \).

**XI.21.3.44.** The Second Decomposition Theorem (XI.21.3.20.) says that \( \text{dd}(X) = \text{ind}(X) \) for any separable metrizable \( X \).

**XI.21.4. Comparing the Dimensions**

All the dimensions defined so far agree for separable metric spaces:

**XI.21.4.1. Theorem.** Let \( X \) be a topological space which is separable and metrizable (equivalently, second countable and regular). Then \( \text{ind}(X) = \text{Ind}(X) = \text{dim}(X) = \text{ed}(X) = \text{pd}(X) = \text{dd}(X) \).

This result not only confirms that for “nice” spaces there is an unambiguous notion of topological dimension, but is also useful since some properties of dimension are proved easily for some of the dimension functions and not so easily for others. Proofs of the theorem can be found in [HW41] and [Eng95].

For general spaces, even for metrizable spaces or compact Hausdorff spaces, the dimension functions do not always agree. We state without proof some of the principal relations between them; see e.g. [HW41], [Pea75], [Eng95].

**XI.21.4.2. Theorem.** ([Kat52], [Mor54b]) If \( X \) is a metrizable space (not necessarily separable), then \( \text{Ind}(X) = \text{dim}(X) \).

**XI.21.4.3.** There is a completely metrizable space \( X \) with \( \text{ind}(X) = 0 \) and \( \text{Ind}(X) = \text{dim}(X) = 1 \) [Roy68]. There are first countable compact Hausdorff spaces \( X \) with \( \text{ind}(X) < \text{Ind}(X) \) ([Fil69], [Pas70]). More examples can be found in [Nag70] and [Pea75].

**XI.21.4.4. Theorem.** [?] If \( X \) is a compact Hausdorff space, then \( \text{dim}(X) \leq \text{ind}(X) \).

The result extends to strongly paracompact spaces, but not even to completely metrizable spaces as ROY’S example shows. There is a compact Hausdorff space \( X \) with \( \text{dim}(X) < \text{ind}(X) \) ([Lun49]; cf. [Eng95, 3.1.31]).
**XI.21.4.5.** THEOREM. [Ale47] If $X$ is completely regular, then $ed(X) = zdim(X)$. If $X$ is normal, then $ed(X) = dim(X)$.

The next result is a corollary of XI.21.3.7. and XI.21.4.1:

**XI.21.4.6.** COROLLARY. Let $X$ be a separable metrizable space and $Y$ a subset of $X$. Then $dim(Y) \leq dim(X)$.

**XI.21.4.7.** There is an example of a compact Hausdorff space $X$ and a normal subspace $Y$ such that $dim(X) = Ind(X) = 0$ and $dim(Y) = Ind(Y) = 1$ ([Dow55]; cf. [Eng95, 2.2.11], [GJ76, 16M]).

**XI.21.4.8.** PROPOSITION. Let $X$ be a normal topological space. Then $dim(X) \leq Ind(X)$.

PROOF: This is an easy induction from XI.21.3.29., using XI.21.3.10. and the fact that if $Ind(X) = 0$, then $dim(X) = 0$ (XI.21.3.28.).

For separable metrizable spaces, we obtain a stronger result:

**XI.21.4.9.** PROPOSITION. Let $X$ be a separable metrizable space (or, more generally, a completely normal hereditarily Lindelöf space). Then $dim(X) \leq dd(X) (= ind(X))$.

PROOF: Suppose $dd(X) \leq n$, i.e. $X = X_1 \cup \cdots \cup X_{n+1}$ with $ind(X_k) \leq 0$ for all $k$. Let $\mathcal{U} = \{U_1, \ldots, U_m\}$ be a finite open cover of $X$. For each $k$, we have $dim(X_k) \leq 0$, so the cover $\{U_1 \cap X_k, \ldots, U_m \cap X_k\}$ of $X_k$ has a shrinking $\{F_1, \ldots, F_m\}$ consisting of relatively clopen subsets of $X_k$. Since $X$ is completely normal, there are disjoint open neighborhoods $\{V_{1,k}, \ldots, V_{m,k}\}$ of $F_1, \ldots, F_m$ in $X$. Consider the open cover $W$ of $X$ consisting of all sets of the form $U_j \cap V_{j,k}$. Then $W$ refines $\mathcal{U}$, and has order $\leq n$ since for any $n+2$ distinct sets $U_j \cap V_{j,k}$ in $W$ there must be some $k$ with $k_i = k$ for two distinct $i$. Thus $dim(X) \leq n$.

This result also follows from XI.21.4.8. and the fact that $dd(X) = ind(X) = Ind(X)$ for separable metrizable spaces (XI.21.3.17., XI.21.3.44.), but this requires the Sum Theorem for $ind$; the inequality $dim(X) \leq dd(X)$ for separable metrizable spaces does not require the Sum Theorem.

**XI.21.4.10.** PROPOSITION. Let $X$ be a normal topological space. Then $pd(X) \leq dim(X)$.

PROOF: Suppose $dim(X) \leq n$, and let $\{(A_1, B_1), \ldots, (A_{n+1}, B_{n+1})\}$ be a set of $n+1$ pairs of disjoint closed subsets of $X$. Then the open cover

$$\left\{ X \setminus A_1, \ldots, X \setminus A_{n+1}, X \setminus \bigcup_{k=1}^{n+1} B_k \right\}$$

has a shrinking $V = \{V_1, \ldots, V_{n+2}\}$ of order $\leq n$. Let $\{F_1, \ldots, F_{n+2}\}$ be a closed shrinking of $V$. For $1 \leq k \leq n+1$ define

$$\tilde{A}_k = A_k \cup (F_{n+2} \setminus V_k), \quad \tilde{B}_k = B_k \cup F_{n+2}.$$
Since $A_k \cap F_k = \emptyset$ and $B_k \cap F_{n+2} = \emptyset$ for each $k$, we have $\tilde{A}_k \cap \tilde{B}_k = \emptyset$. Also,

$$\bigcup_{k=1}^{n+1} F_k \subseteq \bigcup_{k=1}^{n+1} \tilde{B}_k.$$  

We have that

$$F_{n+2} \cap \left( \bigcap_{k=1}^{n+1} V_k \right) \subseteq V_{n+2} \cap \left( \bigcap_{k=1}^{n+1} V_k \right) = \emptyset$$

since $\mathcal{V}$ has order $\leq n$. Thus $F_{n+2} \subseteq \bigcup_{k=1}^{n+1} \tilde{A}_k$. Since $\bigcup_{k=1}^{n+2} F_k = X$, we have

$$\bigcup_{k=1}^{n+1} (\tilde{A}_k \cup \tilde{B}_k) = X.$$

Let $P_k$ be a partition between $\tilde{A}_k$ and $\tilde{B}_k$ for each $k$. Then $P_k$ is a partition between $A_k$ and $B_k$, and $\bigcap_{k=1}^{n+1} P_k = \emptyset$ since it is disjoint from $\bigcup_{k=1}^{n+1} (\tilde{A}_k \cup \tilde{B}_k) = X$.

**XI.21.4.11.  PROPOSITION.** Let $X$ be a normal space. Then $\dim(X) = pd(X)$.

**PROOF:** Because of XI.21.4.10., we need to show that $\dim(X) \leq pd(X)$. Assume $pd(X) \leq n$, and let $\mathcal{U} = \{U_1, \ldots, U_{n+2}\}$ be an open cover of $X$. There is a closed shrinking $\{A_1, \ldots, A_{n+2}\}$ of $\mathcal{U}$. Set $B_k = X \setminus U_k$.

Then $\{(A_1, B_1), \ldots, (A_{n+1}, B_{n+1})\}$ is a family of pairs of disjoint closed sets in $X$, so there are partitions $P_k$ between $A_k$ and $B_k$ for $1 \leq k \leq n+1$ with $\bigcap_{k=1}^{n+1} P_k = \emptyset$, i.e. for each $k \leq n+1$ there are disjoint open sets $V_k, W_k$ containing $A_k$ and $B_k$ respectively with

$$\bigcap_{k=1}^{n+1} X \setminus (V_k \cup W_k) = \emptyset.$$  

Set

$$V_{n+2} = U_{n+2} \cap \left( \bigcup_{k=1}^{n+1} W_k \right).$$

Then $V_k \subseteq U_k$ for all $k$, and

$$\bigcup_{k=1}^{n+2} V_k = \left( \bigcup_{k=1}^{n+1} V_k \right) \cup \left( U_{n+2} \cap \left[ \bigcup_{k=1}^{n+1} W_k \right] \right)$$

$$= \left( \bigcup_{k=1}^{n+1} V_k \cup U_{n+2} \right) \cap \left( \left[ \bigcup_{k=1}^{n+1} V_k \right] \cup \left[ \bigcup_{k=1}^{n+1} W_k \right] \right)$$
$$= \left( \bigcup_{k=1}^{n+1} V_k \cup U_{n+2} \right) \cap X = \bigcup_{k=1}^{n+1} V_k \cup U_{n+2} \supseteq \bigcup_{k=1}^{n+2} A_k = X$$
We need only show \( \mathcal{V} = \{V_1, \ldots, V_{n+2}\} \) is a shrinking of \( \mathcal{U} \). We also have
\[
\bigcap_{k=1}^{n+2} V_k = \left( \bigcap_{k=1}^{n+1} V_k \right) \cap \left( U_{n+2} \cup \bigcup_{k=1}^{n+1} W_k \right) 
\subseteq \left( \bigcap_{k=1}^{n+1} V_k \right) \cap \left( \bigcup_{k=1}^{n+1} W_k \right) = \emptyset
\]
so \( \mathcal{V} \) has order \( \leq n \). By XI.21.3.28., \( \dim(X) \leq n \). \( \Diamond \)

**XI.21.4.12.** Proposition. Let \( X \) be a completely regular space. Then \( pd(X) \leq ed(X) \).

**Proof:** We will use XI.21.1.8.. Suppose \( ed(X) \leq n \), and let \( (A_1, B_1), \ldots, (A_{n+1}, B_{n+1}) \) be \( n+1 \) pairs of disjoint closed sets in \( X \). Let \( Y \) be the union of all the \( A_k \) and \( B_k \). Then \( Y \) is a closed subset of \( X \). For each \( k \), \( 1 \leq k \leq n+1 \), set \( f_k(x) = 0 \) if \( x \in A_k \) and \( f_k(x) = 1 \) if \( x \in B_k \). If \( f = (f_1, \ldots, f_{n+1}) \), then \( f \) is a map from \( Y \) to \( \partial I^{n+1} \approx S^n \). By XI.21.1.8., \( f \) extends to a map \( g \) from \( X \) to \( \partial I^{n+1} \). Let \( g_k (1 \leq k \leq n+1) \) be the \( k \)'th coordinate function of \( g \); then \( g_k \) extends \( f_k \) to \( X \). Set \( P_k = g_k^{-1}(1/2) \). Then \( P_k \) is a partition between \( A_k \) and \( B_k \), and \( P_1 \cap \cdots P_{k+1} = \emptyset \) since \((1/2, \ldots, 1/2) \notin \partial I^{n+1}". Thus \( pd(X) \leq n \). \( \Diamond \)

**XI.21.4.13.** Proposition. Let \( X \) be a normal space. Then \( ed(X) = pd(X) \).

**Proof:** We need only show \( ed(X) \leq pd(X) \). We again use XI.21.1.8.. Suppose \( pd(X) \leq n \), \( Y \) is a closed subset of \( X \), and \( f \) is a map from \( Y \) to \( \partial I^{n+1} \). For \( 1 \leq k \leq n+1 \), let \( A_k \) [resp. \( B_k \)] be the set of \( x \in X \) such that the \( k \)'th coordinate of \( f(x) \) is \( 0 \) [resp. \( 1 \)]. Then there are partitions \( P_k \) between \( A_k \) and \( B_k \) for each \( k \), with \( \bigcap_{k=1}^{n+1} P_k = \emptyset \) since \( pd(X) \leq n \), i.e. for each \( k \leq n+1 \) there are disjoint open sets \( V_k, W_k \) containing \( A_k \) and \( B_k \) respectively with
\[
\bigcap_{k=1}^{n+1} X \setminus (V_k \cup W_k) = \emptyset
\]
Let \( \{U_1, \ldots, U_{n+1}\} \) be a swalling of \( \{P_1, \ldots, P_{n+1}\} \) (XI.7.6.10.), so \( P_k \subseteq U_k \) and \( \bigcap_{k=1}^{n+1} U_k = \emptyset \). Then \( V_k \cup P_k \) and \( W_k \cup P_k \) are closed in \( X \), hence normal, so by Urysohn’s Lemma there is a map \( \phi_k : V_k \cup P_k \to [0,1/2] \) with \( \phi_k(V_k \setminus U_k) = \{0\} \) and \( \phi_k(P_k) = \{1/2\} \), and a map \( \psi_k : W_k \cup P_k \to [1/2,1] \) with \( \psi_k(P_k) = \{1/2\} \) and \( \psi_k(W_k \setminus U_k) = \{1\} \). Then \( \phi_k \) and \( \psi_k \) define a map \( f_k \) from \( X \) to \([0,1]\) since they agree on the closed set \( P_k = (V_k \cup P_k) \cap (W_k \cup P_k) \). We have \( g_k(A_k) = \{0\} \) and \( g_k(B_k) = \{1\} \). The \( g_k \) define a map \( g : X \to I^n \). Since \( g_k^{-1}(\{1/2\}) \subseteq U_k \) for each \( k \) and \( \bigcap_{k=1}^{n+1} U_k = \emptyset \), \( g \) never takes the value \( p = (1/2, \ldots, 1/2) \). If \( r \) is a retraction from \( I^n \setminus \{p\} \) to \( \partial I^n \), then \( r \circ g \) is an extension of \( f \) to \( X \). \( \Diamond \)

Combining XI.21.4.13. with XI.21.4.11., we obtain:

**XI.21.4.14.** Corollary. Let \( X \) be a normal space. Then \( \dim(X) = pd(X) = ed(X) \).
XI.21.4.15. In fact, by an extension of the same methods it can be shown that \( ed(X) = zdim(X) \) for any completely regular \( X \).

The hardest of the inequalities in XI.21.4.1. is that \( ind(X) \leq dim(X) \). We now work on this.

XI.21.4.16. We have \( Ind(X) \leq dim(X) \) (and hence \( Ind(X) = dim(X) \) by XI.21.4.8.) if \( X \) is metrizable.

XI.21.5. More Dimension Theories

Analytic Dimension

XI.21.5.1. Let \( X \) be a completely regular topological space. We will give a characterization due to Katětov of \( zdim(X) \) in terms of the ring (algebra) \( BC_{\mathbb{R}}(X) \) of bounded real-valued continuous functions on \( X \). (This ring is denoted \( C^*(X) \) in many references such as [GJ76], which is a thorough study of topology via these rings. We have adopted different notation since \( C(X) \) is too easily confused with C*-algebra notation.) \( BC_{\mathbb{R}}(X) \) has a norm

\[
\| f \| = \sup_{x \in X} |f(x)|
\]

under which it is a real Banach space. The norm is determined by the algebraic structure since it can be defined using the order structure, and a function is nonnegative if and only if it is a square. Note that every subring of \( BC_{\mathbb{R}}(X) \) containing the constant functions is a subalgebra (all subrings we consider will contain the constant functions).

XI.21.5.2. If \( X \) is compact, or more generally countably compact, then \( BC_{\mathbb{R}}(X) = C_{\mathbb{R}}(X) \), the set of all real-valued continuous functions on \( X \) if \( f : X \to \mathbb{R} \) is continuous, then \( \{ f^{-1}((-n, n)) : n \in \mathbb{N} \} \) is a countable open cover of \( X \) which has a finite subcover. A space \( X \) with \( BC_{\mathbb{R}}(X) = C_{\mathbb{R}}(X) \) is called pseudocompact; there exist pseudocompact spaces which are not countably compact, but every normal pseudocompact space is countably compact [GJ76, 3D]. In general, we have a natural identification \( BC_{\mathbb{R}}(X) \cong C_{\mathbb{R}}(\beta X) \), where \( \beta X \) is the Stone-Čech compactification of \( X \).

XI.21.5.3. The idea behind Katětov’s characterization is that if \( X \) is a compact subset of \( \mathbb{R}^n \), then polynomials in the coordinate functions are dense in \( C_{\mathbb{R}}(X) \), i.e. \( C_{\mathbb{R}}(X) \) has a dense unital subalgebra generated by \( n \) elements (the coordinate functions). This turns out to be the minimum number of generators of a dense unital subalgebra if \( dim(X) = n \), e.g. if \( X \) has nonempty interior.

XI.21.5.4. Simply taking the minimum number of generators of a dense unital subalgebra does not work as a satisfactory notion of dimension for a general \( X \), however. For one thing, \( BC_{\mathbb{R}}(X) \) can easily be nonseparable, and will be if \( \beta X \) is not metrizable, e.g. if \( X \) is not compact; then even no countably generated subalgebra can be dense. And the wrong answer is obtained even for a space as simple as a circle \( S^1 \): the minimum number of generators of a dense unital subalgebra of \( C_{\mathbb{R}}(S^1) \) is two, since no real-valued continuous function on \( S^1 \) separates points.

The key trick is to consider analytic subrings:
XI.21.5.5. Definition. Let $X$ be a completely regular space. An analytic subring of $BC_R(X)$ is a closed unital subalgebra $A$ with the property that if $f^2 \in A$, then $f \in A$. The smallest analytic subring containing a set $F$ of functions is called the analytic subring generated by $F$.

Note that any intersection of analytic subrings is an analytic subring, so there is always a smallest analytic subring containing any given set of functions.

XI.21.5.6. Examples. (i) The example of the unit circle $S^1 = \{(x, y) \in \mathbb{R}^2 : x^2 + y^2 = 1\}$ nicely illustrates the idea. Let $f(x, y) = x$. Then the unital subalgebra generated by $f$ is not dense in $C_R(S^1)$. However, if $A$ is the analytic subring of $C_R(S^1)$ generated by $f$, then $A$ contains $g = 1 - f^2$. We have $g(x, y) = 1 - x^2 = y^2$. Thus $A$ also contains $h(x, y) = y$ since $g = h^2$, and it follows from the Stone-Weierstrass Theorem that $A$ is all of $C_R(S^1)$. Thus $C_R(S^1)$ is generated as an analytic subring by one function, i.e. “$S^1$ is one-dimensional.”

(ii) Let $X$ be compact. Consider the analytic subring $A$ generated by the empty set, i.e. the smallest analytic subring of $C_R(X)$. Then $A$ contains the constant function 1 by definition, so it also contains every function taking exactly the values $\pm 1$, and thus the indicator function of every clopen subset of $X$. So all continuous functions with finite range are in $A$. $A$ is just the closure of this set, i.e. $A$ is the closed subalgebra of $C_R(X)$ generated by the indicator functions of clopen sets in $X$. So $A$ is all of $C_R(X)$ if and only if $X$ is totally disconnected, i.e. zero-dimensional.

XI.21.5.7. If $F$ is a subset of $BC_R(X)$, a subset $Y$ of $X$ is a stationary set for $F$ if every $f \in F$ is constant on $Y$. If $Y$ is a stationary set for $F$, so is $\bar{Y}$, so we need consider only closed stationary sets. Of course, each singleton is a stationary set, and the converse is true if and only if $F$ separates points of $X$. The Stone-Weierstrass Theorem can be rephrased:

XI.21.5.8. Theorem. Let $X$ be a compact Hausdorff space, and $F$ a subset of $C_R(X)$. Then the closed unital subalgebra of $C_R(X)$ generated by $F$ consists of all functions in $C_R(X)$ which are constant on each stationary set of $F$.

A variation of this, due to Katětov, is the key result:

XI.21.5.9. Theorem. Let $X$ be a compact Hausdorff space, and $F$ a subset of $C_R(X)$. Then the analytic subring of $C_R(X)$ generated by $F$ consists of all functions in $C_R(X)$ which are constant on each connected stationary set of $F$.

One can restrict attention to maximal connected stationary sets: every connected stationary set is contained in a maximal connected stationary set (XI.13.3.2.), which is automatically closed (XI.13.1.9.).

XI.21.5.10. We can provisionally define the analytic dimension of $X$ to be the smallest $n$ such that $BC_R(X)$ is generated as an analytic subring by $n$ elements. This is a good definition if $BC_R(X)$ is separable, which occurs if and only if $X$ is compact and metrizable. In general, we make the following definition:
XI.21.5.11. Definition. Let $X$ be a completely regular space. The *analytic dimension* $ad(X)$ is the smallest $n$, $0 \leq n \leq \aleph_0$, such that every countably generated (i.e. separable) closed subalgebra of $BC_\mathbb{R}(X)$ is contained in an analytic subring generated by $n$ elements.

The analytic dimension $ad(X)$ is the smallest $n$ such that every finite subset of $BC_\mathbb{R}(X)$ is contained in an analytic subring generated by $n$ elements. If $X$ is compact and metrizable, then $ad(X)$ is the smallest $n$ such that $BC_\mathbb{R}(X)$ is generated as an analytic subring by $n$ elements. Note that the analytic subring generated by even finitely many elements need not be separable: if $X$ is the product of uncountably many two-point spaces, then $X$ is compact and zero-dimensional, and the analytic subring of $C_\mathbb{R}(X)$ generated by $\emptyset$ is all of $C_\mathbb{R}(X)$, which is nonseparable since $X$ is not metrizable.

The main theorem of Katětov is:

XI.21.5.12. Theorem. Let $X$ be a completely regular space. Then $ad(X) = zdim(X)$. Thus, if $X$ is normal, $ad(X) = dim(X)$.

See [GJ76] for a complete discussion and proof, which is fairly involved. Since $ad(X)$ is transparently equal to $ad(\beta X)$ for any $X$, we obtain:

XI.21.5.13. Corollary. Let $X$ be a completely regular space. Then $zdim(X) = zdim(\beta X) = dim(\beta X)$. If $X$ is normal, then $dim(X) = dim(\beta X)$.

The corollary can be proved directly without introducing analytic dimension (cf. XI.21.1.12., XI.21.4.5.; [GJ76, 16.11]).

Affine Dimension
Homological Dimension

XI.21.6. Embedding in Euclidean Space

In this subsection, we prove two important theorems about embedding of topological spaces in Euclidean space.

If $X$ is a topological space of dimension $n$, we want to embed $X$ in $\mathbb{R}^p$ for some $p$ which is a function of $n$. Of course, for $X$ to embed in any Euclidean space it is necessary that $X$ be separable and metrizable, so we make an assumption that all spaces in this section are separable and metrizable. Thus all standard dimension functions agree on such an $X$, so “dimension $n$” is unambiguous.

XI.21.6.1. Theorem. Let $X$ be a subset of $\mathbb{R}^n$. Then $X$ has dimension $n$ if and only if the interior of $X$ is nonempty, i.e. if and only if $X$ contains a nonempty open set in $\mathbb{R}^n$.

The proof is deferred to XI.21.6.14..

XI.21.6.2. If a (separable metrizable) space $X$ has dimension $n$, it cannot be embedded in $\mathbb{R}^n$ in general (consider a circle). It cannot even generally be embedded in $\mathbb{R}^{n+1}$: a graph cannot always be embedded in $\mathbb{R}^2$, and the projective plane and the Klein bottle are closed 2-manifolds which cannot be embedded in $\mathbb{R}^3$. The $n$-skeleton of a $2n + 2$-simplex cannot be embedded in $\mathbb{R}^{2n}$[]. The best which can be done in general is the following:
XI.21.6.3. Theorem. Let $X$ be a separable metrizable space with $\dim(X) \leq n$. Then $X$ embeds in $\mathbb{I}^{2n+1}$. In fact, every continuous function from $X$ to $\mathbb{I}^{2n+1}$ is a uniform limit of embeddings.

To prove XI.21.6.3. (and in fact to prove a slightly better result), we introduce notation for some useful subsets of $\mathbb{R}^n$:

XI.21.6.4. Definition. Let $0 \leq n \leq m$. Then

- $\mathcal{P}_n^m$ is the set of points in $\mathbb{R}^m$ with precisely $n$ rational coordinates.
- $\mathcal{M}_n^m$ is the set of points in $\mathbb{R}^m$ with at most $n$ rational coordinates.
- $\mathcal{L}_n^m$ is the set of points in $\mathbb{R}^m$ with at least $n$ rational coordinates.
- $\mathcal{N}_n = \mathcal{M}_n^{2n+1}$ is the Nöbeling universal space of dimension $n$.

Note that $\mathcal{M}_n^m \cup \mathcal{L}_n^m = \mathbb{R}^m$ and $\mathcal{M}_n^m \cap \mathcal{L}_n^m = \mathcal{P}_n^m$ for any $n$ and $m$.

XI.21.6.5. Proposition. For any $0 \leq n \leq m$, $\dim(\mathcal{P}_n^m) = 0$, $\dim(\mathcal{M}_n^m) = n$, $\dim(\mathcal{L}_n^m) = m - n$, $\dim(\mathcal{N}_n) = n$.

Proof: $\mathcal{P}_n^m$ is a countable union of (relatively) closed subsets where $n$ specified coordinates are specified fixed rational numbers and the other $m - n$ coordinates are irrational. Such a set is homeomorphic to $\mathbb{I}^{m-n}$, which has dimension 0. Thus $\dim(\mathcal{P}_n^m) = 0$ by the Sum Theorem (the zero-dimensional version XI.21.3.14. suffices).

The observations

$$\mathcal{M}_n^m = \mathcal{P}_0^m \cup \mathcal{P}_1^m \cup \cdots \cup \mathcal{P}_n^m$$

$$\mathcal{L}_n^m = \mathcal{P}_n^m \cup \mathcal{P}_{n+1}^m \cup \cdots \cup \mathcal{P}_m^m$$

and the Sum Theorem imply that $\dim(\mathcal{M}_n^m) \leq n$ and $\dim(\mathcal{L}_n^m) \leq m - n$. But $\mathcal{M}_n^m$ contains a subspace homeomorphic to $\mathbb{R}^n$ (say the set of all points with the first $m - n$ coordinates $\pi$), and $\mathcal{L}_n^m$ similarly contains a copy of $\mathbb{R}^{m-n}$, so $\dim(\mathcal{M}_n^m) \geq n$ and $\dim(\mathcal{L}_n^m) \geq m - n$ by XI.21.3.7..

The theorem we will prove is:

XI.21.6.6. Theorem. Let $X$ be a separable metrizable space of dimension $\leq n$. Then there is an embedding $f : X \to \mathcal{N}_n$ such that the closure of $f(X)$ in $\mathcal{N}_n$ is compact. In fact, any bounded continuous function from $X$ to $\mathbb{R}^{2n+1}$ can be uniformly approximated arbitrarily closely by such a function.

This result justifies the name “Nöbeling universal space.” Theorem XI.21.6.3. is an immediate corollary. Another important corollary is:
XI.21.6.7. **Corollary.** Let $X$ be a separable metrizable space of dimension $n$. Then $X$ has a metrizable compactification of dimension $n$. In fact, there is a compact subset $K_n$ of $\mathbb{R}^{2n+1}$ with $\dim(K_n) = n$ such that every separable metrizable space of dimension $\leq n$ embeds in $K_n$.

**Proof:** There is an embedding $f: \mathfrak{M}_n \to \mathfrak{M}_n$ such that $K_n = f(\mathfrak{M}_n)$ is a compact subset of $\mathfrak{M}_n$.

Actually, the Menger Universal Space $M_n^{2n+1}$ is such a space (XI.18.4.12.).

XI.21.6.8. The strategy of the proof of XI.21.6. will be to show that the set $E$ of embeddings of $X$ into $\mathfrak{M}_n$ such that the closure of $f(X)$ in $\mathfrak{M}_n$ is compact is a countable intersection of dense open sets in $BC(X, \mathbb{R}^{2n+1})$. The theorem will then follow from the Baire Category Theorem (XI.21.6.6).

We fix a totally bounded metric $\rho$ on $X$. There is such a metric since $X$ embeds in the Hilbert cube (XI.21.6.6). Actually, the Menger Universal Space $M_n^{2n+1}$ is such a space (XI.18.4.12.).

Let $\mathcal{F}$ be the set of all tuples of the form

$$\mathcal{F} = \{ (i_1, \ldots, i_{n+1}; q_1, \ldots, q_{n+1}) : 1 \leq i_1 < i_2 < \cdots < i_{n+1} \leq 2n+1, \ q_k \in \mathbb{Q} \}.$$ 

Then $\mathcal{F}$ is countable. For each $F \in \mathcal{F}$, define

$$L_F = \{ (x_1, \ldots, x_{2n+1}) \in \mathbb{R}^{2n+1} : x_{ik} = q_k \text{ for } 1 \leq k \leq n+1 \}.$$ 

Then $L_F$ is a hyperplane in $\mathbb{R}^{2n+1}$ of dimension $n$, $L_F \cap \mathfrak{M}_n = \emptyset$, and

$$\bigcup_{F \in \mathcal{F}} L_F = \mathfrak{M}_{n+1} = \mathbb{R}^{2n+1} \setminus \mathfrak{M}_n.$$ 

For each $F \in \mathcal{F}$ and $m \in \mathbb{N}$, let $W_{F,m}$ be the set of all $f \in BC(X, \mathbb{R}^{2n+1})$ such that $f(X)$ is disjoint from $L_F$ and $f$ is an $\mathcal{U}_m$-map, i.e. for every $y \in f(X)$ there is an open neighborhood $V$ of $y$ such that $f^{-1}(V) \subseteq U$ for some $U \in \mathcal{U}_m$. We will show that $W_{F,m}$ is a dense open set in $BC(X, \mathbb{R}^{2n+1})$. This will prove the theorem since

$$E = \bigcap_{F,m} W_{F,m}.$$ 

XI.21.6.9. To show that $W_{F,m}$ is open in $BC(X, \mathbb{R}^{2n+1})$, fix $f \in W_{F,m}$. Since $f(X)$ is compact and disjoint from $L_F$, the distance from $f(X)$ to $L_F$ is a positive number $\eta$. For each $y \in f(X)$, there is an open neighborhood $V_y$ in $\mathbb{R}^{2n+1}$ such that $f^{-1}(V_y)$ is contained in some $U \in \mathcal{U}_m$. Let $\gamma$ be the Lebesgue number of the cover $V = \{ V_y : y \in f(X) \}$ of $f(X)$, i.e. if $B$ is a ball of radius $\leq \gamma$ in $\mathbb{R}^n$ intersecting $f(X)$, then $B \subseteq V_y$ for some $y \in f(X)$, and thus $f^{-1}(B)$ is contained in some $U \in \mathcal{U}_m$.

Set $\delta = \min(\gamma/3, \eta/2)$. If $g \in BC(X, \mathbb{R}^{2n+1})$ with $\|f-g\| < \delta$, then for any $x \in X$ and $a \in L_F$ we have

$$\|g(x) - a\| \geq \|f(x) - a\| - \|f(x) - g(x)\| > \frac{\eta}{2}$$

so $g(X) \cap L_F = \emptyset$. 1307
Let \( y \in \overline{g(X)} \). There is a \( z \in X \) with \( \|y - g(z)\| < \delta \). If \( B \) is the open ball of radius \( \delta \) around \( y \), and \( x \in g^{-1}(B) \), then
\[
\|g(x) - f(z)\| \leq \|g(x) - g(z)\| + \|g(z) - f(z)\| < 3\delta \leq \gamma 
\]
since \( g(x) \) and \( g(z) \) are both in \( B \) and \( \|f - g\| < \delta \). Thus \( g(x) \) is in the open ball \( C \) around \( f(z) \) of radius \( \gamma \), i.e. \( g^{-1}(B) \subseteq f^{-1}(C) \), which is contained in some \( U \in \mathcal{U}_m \). Thus \( g \in W_{F,m} \). So \( W_{F,m} \) is open.

Showing that \( W_{F,m} \) is dense in \( BC(X, \mathbb{R}^{2n+1}) \) takes more work. We need to approximate using vectors in general position.

**XI.21.6.10.** **Proposition.** If \( S \) is a finite union of affine subspaces of \( \mathbb{R}^n \) of dimension \( \leq n - 1 \), then the complement of \( S \) is dense (and open) in \( \mathbb{R}^n \).

**Proof:** The complement of an affine subspace of \( \mathbb{R}^n \) of dimension \( \leq n - 1 \) is dense and open, and in any topological space a finite intersection of dense open sets is dense and open.

In fact, by the Baire Category Theorem, a countable union of affine subspaces of \( \mathbb{R}^n \) of dimension \( \leq n - 1 \) has dense (but usually not open) complement. This also follows from the Sum Theorem XI.21.3.13.

**XI.21.6.11.** **Corollary.** If \( G = \{x_1, \ldots, x_p\} \) is a subset of \( \mathbb{R}^n \) in general position, \( y \in \mathbb{R}^n \), and \( \epsilon > 0 \), then there is an \( x_{p+1} \in \mathbb{R}^n \) with \( \|y - x_{p+1}\| < \epsilon \) and \( \{x_1, \ldots, x_p, x_{p+1}\} \) in general position.

**Proof:** If \( \{x_{i_1}, \ldots, x_{i_r}\} \) is a subset of \( G \) with \( r \leq n \), and \( x \in \mathbb{R}^n \), then \( \{x_{i_1}, \ldots, x_{i_r}, x\} \) span an \( r \)-dimensional affine subspace if and only if \( x \) is not in the \((r-1)\)-dimensional affine subspace spanned by \( \{x_{i_1}, \ldots, x_{i_r}\} \). So we need only choose \( x_{p+1} \) to not be in any of these finitely many affine subspaces.

Applying this result repeatedly, we obtain:

**XI.21.6.12.** **Corollary.** If \( \{x_1, \ldots, x_p\} \) is a subset of \( \mathbb{R}^n \) in general position, \( y_1, \ldots, y_q \in \mathbb{R}^n \), and \( \epsilon > 0 \), then there are \( x_{p+1}, \ldots, x_{p+q} \in \mathbb{R}^n \) such that \( \|x_{p+k} - y_k\| < \epsilon \) for \( 1 \leq k \leq q \) and \( \{x_1, \ldots, x_p, x_{p+1}, \ldots\} \) is in general position.

In fact, if \( \{x_1, \ldots, x_p\} \) is in general position, \( (y_k) \) is any sequence in \( \mathbb{R}^n \), and \( (\epsilon_k) \) is any sequence of positive numbers, there is a sequence \( (x_{p+k}) \) in \( \mathbb{R}^n \) such that \( \|x_{p+k} - y_k\| < \epsilon_k \) for every \( k \) and the infinite set \( \{x_1, \ldots, x_p, x_{p+1}, \ldots\} \) is in general position.

**XI.21.6.13.** Now fix \( F \) and \( m \), and let \( f \in BC(X, \mathbb{R}^{2n+1}) \) and \( \epsilon > 0 \). Let \( \{x_0, \ldots, x_n\} \) be a set of points in general position spanning \( L_F \) as an affine subspace. Cover \( f(X) \) by finitely many open balls of diameter \( \leq \frac{\epsilon}{2} \); by increasing \( m \) if necessary, we may assume \( \mathcal{U}_m \) refines the cover of \( X \) consisting of inverse images of these balls, i.e. that the diameter of \( f(U) \) is less than \( \frac{\epsilon}{2} \) for all \( U \in \mathcal{U}_m \). Let
\[
\mathcal{V} = \{V_1, \ldots, V_q\}
\]
be a shrinking of \( \mathcal{U}_m \) of order \( \leq n \). For each \( k, 1 \leq k \leq q \), fix \( z_k \in V_k \). Choose \( x_{n+1}, \ldots, x_{n+q} \in \mathbb{R}^{2n+1} \) such that \( \|x_{n+k} - f(z_k)\| < \frac{\epsilon}{2} \) for each \( k \) and \( \{x_0, \ldots, x_{n+q}\} \) is in general position.
Let \( \{ h_k : 1 \leq k \leq q \} \) be a partition of unity on \( X \) subordinate to \( V \), e.g. the standard partition of unity from \( \rho (\cdot) \). For \( x \in X \), set

\[
g(x) = \sum_{k=1}^{q} h_k(x) x_{n+k}.
\]

We claim \( g \in W_{F,m} \) and \( \| f - g \| \leq \epsilon \). If \( x \in X \), then for each \( k \) for which \( h_k(x) > 0 \), we have \( x \in V_k \), so \( \| f(x) - f(z_k) \| < \frac{\epsilon}{2} \) and thus \( \| f(x) - x_{n+k} \| < \epsilon \). We thus have

\[
\| f(x) - g(x) \| = \left\| \sum_{k=1}^{q} h_k(x) f(x) - \sum_{k=1}^{q} h_k(x) x_{n+k} \right\|
\]

\[
= \left\| \sum_{k=1}^{q} h_k(x) [f(x) - x_{n+k}] \right\| \leq \sum_{k=1}^{q} h_k(x) \| f(x) - x_{n+k} \| \leq \epsilon h_k(x) = \epsilon
\]

so \( \| f - g \| < \epsilon \).

To show \( g \in W_{F,m} \), we first show \( g(X) \cap L_F = \emptyset \). If \( x \in X \), then since \( V \) has order \( \leq n \), \( g(x) \) is a convex combination of at most \( n + 1 \) of the \( x_{n+k} \), say \( x_{n+i_0}, \ldots, x_{n+i_n} \). Since

\[
\{ x_0, \ldots, x_n, x_{n+i_0}, \ldots, x_{n+i_n} \}
\]

is a set of at most \( 2n + 2 \) vectors in \( \mathbb{R}^{2n+1} \) which is in general position, it is affinely independent; thus the affine subspaces generated by \( \{ x_0, \ldots, x_n \} \) (which is \( L_F \)) and \( \{ x_{n+i_0}, \ldots, x_{i_n} \} \) do not intersect (\( \cdot \)). In particular, the convex hull of \( \{ x_{n+i_0}, \ldots, x_{i_n} \} \) (which is a simplex) does not intersect \( L_F \). There are finitely many such simplexes as \( x \) ranges over \( X \); the union of these simplexes is a compact subset (polyhedron) \( P \) of \( \mathbb{R}^{2n+1} \) containing \( g(X) \) which does not meet \( L_F \). Thus \( g(X) \) does not meet \( L_F \).

If \( y \in P \), let \( \phi_k(y) \) be the barycentric coordinate of \( y \) with respect to \( x_{n+k} \). Then \( \phi_k \) is a continuous function from \( P \) to \( [0,1] \), and \( h_k = \phi_k \circ g \). If \( y \in g(X) \), then since the \( \phi_k(y) \) sum to 1, there is a \( k \) with \( \phi_k(y) > 0 \). Fix such a \( k \), and let \( Z = \{ z \in P : \phi_k(z) > 0 \} \). Then \( Z \) is a neighborhood of \( y \), and \( g^{-1}(Z) \subseteq V_k \).

Thus \( g \in W_{F,m} \).

This completes the proof of Theorem XI.21.6.6.

**XI.21.6.14.** We now turn to the proof of Theorem XI.21.6.1. If \( X \) contains an open subset of \( \mathbb{R}^{n} \), it obviously has dimension \( n \). The proof of the converse involves a somewhat delicate construction, and uses the following functions. If \( a \in \mathbb{R}^{n} \) and \( \epsilon > 0 \), let \( h_{a,\epsilon} \) be the function from \( \mathbb{R}^{n} \setminus \{ a \} \) to \( \mathbb{R}^{n} \) which moves each point of \( \mathbb{R}^{n} \setminus \{ a \} \) radially away from \( a \) a distance \( \epsilon \). This function has the following properties for all \( x, y \in \mathbb{R}^{n} \setminus \{ a \} \), as is easily verified:

(i) \( h_{a,\epsilon} \) is a homeomorphism from \( \mathbb{R}^{n} \setminus \{ a \} \) onto \( \mathbb{R}^{n} \setminus B_\epsilon(a) \).

(ii) \( \| h_{a,\epsilon}(x) - x \| = \epsilon \).

(iii) \( \| x - y \| \leq \| h_{a,\epsilon}(x) - h_{a,\epsilon}(y) \| \leq \| x - y \| + 2\epsilon \).

We will actually prove the following stronger result:
XI.21.6.15. Theorem. Let \( X \) be a subset of \( \mathbb{R}^n \) with empty interior. Then \( X \) is homeomorphic to a subset \( Y \) of \( \mathbb{R}^n \) with empty interior. In particular, \( Y \) is nowhere dense in \( \mathbb{R}^n \) and \( \dim(Y) = \dim(X) \leq n - 1 \).

Proof: By XI.21.2.2., any subset of \( \mathbb{R}^n \) homeomorphic to \( X \) has empty interior. The complement of \( M^n_{n-1} \) in \( \mathbb{R}^n \) is the set of points with all rational coordinates, hence is countable. Let \( \{a_k : k \in \mathbb{N}\} \) be an enumeration of this complement. Set \( Y_1 = X \), and inductively define a sequence \( Y_k \) of subsets of \( \mathbb{R}^n \) and homeomorphisms \( h_k : Y_k \to Y_{k+1} \) as follows. \( Y_k \) has empty interior, so there is a \( b_k \in \mathbb{R}^n \setminus Y_k \) with

\[ \|b_k - a_k\| < \frac{3^{-k}}{4}. \]

Define \( h_k \) to be the restriction of \( h_{b_k,3^{-k}} \) to \( Y_k \), and \( Y_{k+1} = h_k(Y_k) \). We have

\[ \|h_k(y) - a_k\| \geq \|h_k(y) - b_k\| - \|b_k - a_k\| > 3^{-k} - \frac{3^{-k}}{4} = \frac{3^{-k+1}}{4} \]

for all \( y \in Y_k \).

For each \( k \) set \( f_k = h_k \circ \cdots \circ h_1 \). Then \( f_k \) is a homeomorphism from \( X \) onto \( Y_{k+1} \). By XI.21.14.(ii) and the triangle inequality we have, for \( j < k \) and \( x \in X \),

\[ \|f_k(x) - f_j(x)\| \leq \sum_{m=j+1}^{k} 3^{-m} < \sum_{m=j+1}^{\infty} 3^{-m} = \frac{3^{-j}}{2}. \]

Thus the \( f_k \) form a uniform Cauchy sequence and converge uniformly to a continuous function \( f : X \to \mathbb{R}^n \). Set \( Y = f(X) \). For \( x, z \in X \), we have \( \|f(x) - f(z)\| \geq \|x - z\| \) by XI.21.14.(iii), so \( f \) is injective and \( f^{-1}|_Y \) is a contraction, hence continuous; thus \( f \) is a homeomorphism from \( X \) onto \( Y \).

For any \( k \) we have, for any \( x \in X \),

\[ \|f(x) - f_k(x)\| \leq \frac{3^{-k}}{2} \]

and hence

\[ \|f(x) - a_k\| \geq \|f_k(x) - a_k\| - \|f(x) - f_k(x)\| > \frac{3^{-k+1}}{4} - \frac{3^{-k}}{2} = \frac{3^{-k}}{4}. \]

Thus \( a_k \) is not in \( \hat{Y} \), i.e. \( \hat{Y} \subseteq M^n_{n-1} \).

XI.21.7. Infinite-Dimensional Spaces

XI.21.7.1. A topological space can be infinite-dimensional in any of the above senses. There are in fact examples of (normal) spaces which are infinite-dimensional in some senses but not others. For separable metrizable spaces the notion of infinite-dimensionality is unambiguous.

XI.21.7.2. There are degrees of infinite-dimensionality, however. One might expect, for example, that \([0,1]^\kappa\) should be “\(\kappa\)-dimensional.” A more important distinction, however, at least for metrizable spaces, is between “countable-dimensional” and “uncountable-dimensional” spaces:
XI.21.7.3. Definition. Let $X$ be a topological space. Then $X$ is countable-dimensional if it is a countable union of finite-dimensional subspaces. $X$ is countably infinite-dimensional if it is countable-dimensional but not finite-dimensional.

This definition can be made for any of the dimension functions; we will be imprecise as to the meaning of “finite-dimensional” but note this is well-defined for separable metrizable spaces.

XI.21.7.4. By (), a normal space $X$ is countable-dimensional (in the sense of $\text{Ind}$) if and only if it can be written as a countable union of subspaces $X_n$ with $\text{Ind}(X_n) = 0$ for all $n$. $X$ is countably infinite-dimensional if and only if it can be written as a countable union of zero-dimensional subspaces, but not as a finite union of zero-dimensional subspaces.

XI.21.7.5. It is easy to give examples of countably infinite-dimensional separable metrizable spaces: the disjoint union $\sqcup_{n} [0,1]^n$ works. For a compact metrizable example, take the one-point compactification of the disjoint union, or the infinite join if a connected compact metrizable example is desired. It is only slightly harder to string together the cubes to get a compact AR which is countably infinite-dimensional.

Another distinction comes from considering a strengthening of the partition dimension concept:

XI.21.7.6. Definition. Let $X$ be a normal topological space. Then $X$ is strongly infinite-dimensional if there is a sequence of pairs $(A_k, B_k)$ of disjoint closed sets in $X$ such that, if $P_k$ is any partition between $A_k$ and $B_k$ for each $k$, then $\bigcap_{k=1}^{\infty} P_k \neq \emptyset$.

$X$ is weakly infinite-dimensional if $\text{pd}(X) = \infty$ but $X$ is not strongly infinite-dimensional, i.e. for every sequence of pairs $(A_k, B_k)$ of disjoint closed sets in $X$, there are partitions $P_k$ such that $\bigcap_{k=1}^{\infty} P_k = \emptyset$, but for each $n$ there are pairs $(A_1, B_1), \ldots, (A_n, B_n)$ such that, if $P_k$ is any partition between $A_k$ and $B_k$ for each $k$, then $\bigcap_{k=1}^{n} P_k \neq \emptyset$.

XI.21.7.7. Proposition. Every countably infinite-dimensional completely normal space is weakly infinite-dimensional.

Proof: This is a simple adaptation of (). Write $X = \bigcup_{n=1}^{\infty} X_n$, where $X_n$ is zero-dimensional. If $\{ (A_n, B_n) : n \in \mathbb{N} \}$ is a sequence of pairs of disjoint closed sets in $X$, then by XI.21.3.16 there is for each $n$ a partition $P_n$ between $A_n$ and $B_n$ with $P_n \cap X_n = \emptyset$. Then $\bigcap_{n=1}^{\infty} P_n = \emptyset$.

On the contrary, we have:

XI.21.7.8. Theorem. The Hilbert cube $\mathbb{H}$ is strongly infinite-dimensional.

Proof: (cf. [HW41, p. 49]) In $\mathbb{H} = [0,1]^{\mathbb{N}}$, let $A_k$ be the set of all points with $k$’th coordinate 0, and $B_k$ the set of points with $k$’th coordinate 1. Then $A_k$ and $B_k$ are disjoint closed sets in $X$. Suppose $P_k$ is a partition between $A_k$ and $B_k$ for each $k$. For each $n$ let $f_n : [0,1]^n \to \mathbb{H}$ be defined by

$$f_n(x_1, \ldots, x_n) = (x_1, \ldots, x_n, 0, 0, \ldots) .$$
Fix $n$. If $\tilde{A}_k = f_n^{-1}(A_k)$, $\tilde{B}_k = f_n^{-1}(B_k)$, $\tilde{P}_k = f_n^{-1}(P_k)$ for $1 \leq k \leq n$, then $\tilde{A}_k$ and $\tilde{B}_k$ are just the opposite $k$-faces of $[0,1]^n$, and $\tilde{P}_k$ is a partition in $[0,1]^n$ between $\tilde{A}_k$ and $\tilde{B}_k$, so by the Face Partition Theorem (XI.20.1.19.), $\cap_{k=1}^n \tilde{P}_k \neq \emptyset$; thus $\cap_{k=1}^n \tilde{P}_k \neq \emptyset$ in $X$. This is true for all $n$, so the $P_k$ have the Finite Intersection Property, and thus $\cap_{k=1}^\infty P_k \neq \emptyset$ since the $P_k$ are compact.

**XI.21.7.9.** Corollary. The Hilbert cube is not countable-dimensional.

Since the Hilbert cube is separable and metrizable, it is unambiguous what dimension function we use.

**XI.21.7.10.** It is thus highly questionable whether we should say that $\dim ([0,1]^\aleph_0) = \aleph_0$.

There is a theory of transfinite dimension for (some) countable-dimensional spaces (Exercise XI.21.8.7.).

**XI.21.7.11.** There are many pathologies in infinite-dimensional spaces. For example, if $X$ is $n$-dimensional for finite $n$, then $X$ has closed subspaces of dimension $k$ for all $0 \leq k \leq n$ (cf. the proof of XI.21.3.19.). But there are examples of an infinite-dimensional compact metrizable space $X$ such that every subspace of $X$ is either zero-dimensional or infinite-dimensional (such a space is called hereditarily infinite-dimensional). Using the CH, an $X$ can be constructed with the property that every uncountable subspace is infinite-dimensional (the CH is necessary; existence of such a space cannot be proved in ZFC). Note that every (regular) space has zero-dimensional subspaces, e.g. any countable subspace (XI.21.3.18.).

Examples of the following types of spaces (and many more) can be found in [vM89]:

- A weakly infinite-dimensional compact space which is not countable-dimensional.
- A strongly infinite-dimensional compact space which is hereditarily infinite-dimensional.
- A strongly infinite-dimensional totally disconnected space (XI.21.8.6.; there can be no such compact example by XI.13.6.7.).

All these examples are separable and metrizable.

**XI.21.7.12.** Until quite recently, the structure theory of infinite-dimensional spaces lagged far behind that of finite-dimensional spaces. But there has been a lot of recent progress. See [vM01] and [Eng95] for more details.

**XI.21.8.** Exercises

**XI.21.8.1.** Let $X$ be a normal space.

(a) Use XI.7.6.8. and Urysohn’s Lemma to show that any open cover $\mathcal{U}$ of $X$ has an open shrinking consisting of cozero sets.

(b) Show that $zdim(X) = dim(X)$.
XI.21.8.2. \([vM89]\) This problem gives a direct proof that \(pd(B^n) \leq n\) (cf. XI.21.1.5., XI.21.4.14.): we actually show that if \(X\) is any compact subset of \(\mathbb{R}^n\), then \(pd(X) \leq n\).

(a) Show that if \(D\) is a dense subset of \(\mathbb{R}\), and

\[
D^{(n)} = \{(x_1, \ldots, x_n) \in \mathbb{R}^n : x_k \in D \text{ for at least one } k\}
\]

and if \(A\) and \(B\) are disjoint compact subsets of \(\mathbb{R}^n\), then there is a partition between \(A\) and \(B\) in \(\mathbb{R}^n\) contained in \(D^{(n)}\). [Cover \(A\) with finitely many open rectangular solids which are products of intervals with endpoints in \(D\), whose closures are disjoint from \(B\).]

(b) Show that if \((A_1, B_1), \ldots, (A_{n+1}, B_{n+1})\) are \(n + 1\) pairs of disjoint closed sets in \(X\), then there are partitions \(P_k\) between \(A_k\) and \(B_k\) in \(X\) with \(\bigcap_{k=1}^{n+1} P_k = \emptyset\). [Let \(D_1, \ldots, D_{n+1}\) be \(n + 1\) disjoint dense subsets of \(\mathbb{R}\), and choose \(P_k \subseteq D_k^{(n)}\).]

XI.21.8.3. Show that every topological \(n\)-manifold \(X\) with boundary has \(dim(X) = n\). [Write each component of \(X\) as a countable union of subsets homeomorphic to \(B_n\), and apply \(??\).]

XI.21.8.4. (Local Dimension.) If \(X\) is a topological space and \(x \in X\), define \(ind_x(X)\) inductively: 

\[ind_x(X) \leq n\] if and only if, whenever \(U\) is an open neighborhood of \(x\) in \(X\), there is an open neighborhood \(V\) of \(x\) contained in \(U\) with \(ind(\partial V) \leq n - 1\). Let \(dim_x(X)\) be the minimum of \(dim(U)\) for neighborhoods \(U\) of \(x\).

(a) Show that \(\sup_{x \in X} ind_x(X)\) and, if \(X\) is separable and metrizable, \(\dim(X) = \sup_{x \in X} \dim_x(X)\). [For the second, use the Sum Theorem for \(dim\).]

(b) Show that \(ind_x(X)\) and \(dim_x(X)\) can differ, even if \(X\) is a compact metrizable space. [Consider the one-point compactification of a disjoint union of a sequence of compact metrizable spaces of positive dimension.]

(c) \([?]\) Let \(X\) be a separable metrizable space of dimension \(n\). The \(n\)-dimensional kernel of \(X\) is

\[DK(X) = \{x \in X : ind_x(X) = n\}.
\]

Show that \(DK(X)\) is an \(F_n\) and \(ind(DK(X)) \geq n - 1\). [Write the complement as a union of a set of dimension \(\leq n - 2\) and a set of dimension \(0\). Use the Sum Theorem and the argument of XI.21.3.15.\] Of course, \(ind(DK(X)) \leq n\) by XI.21.3.7.. For “most” \(X\), \(ind(DK(X)) = n\).

(d) \(X\) is \(\text{weakly } n\text{-dimensional} if \(\text{ind}(DK(X)) = n - 1\). Show that the space of \((X)\) is weakly 1-dimensional.

For every \(n\) there exist \(n\)-dimensional spaces. A compact metrizable space cannot be weakly \(n\)-dimensional; in fact, a weakly \(n\)-dimensional space cannot contain a compact subset of dimension \(n\) [HW41, p. 95].

XI.21.8.5. Let \(X\) be a topological space and \(Y\) a (nonempty) subspace of \(X\).

(a) Show that \(\text{ind}(Y) = 0\) if and only if there is a base \(\mathcal{B}\) for the topology of \(X\) such that \(Y \cap \partial U = \emptyset\) for all \(U \in \mathcal{B}\).

(b) Apply XI.1.2.10. to show that if \(X\) is second countable and \(\text{ind}(Y) = 0\), there is a countable base \(\mathcal{B}\) for the topology of \(X\) such that \(Y \cap \partial U = \emptyset\) for all \(U \in \mathcal{B}\).

(c) Show that if \(X\) is second countable and \(\text{ind}(Y) = 0\), then there is a \(G_\delta\) subset \(Y_\delta\) of \(X\) with \(Y \subseteq Y_\delta\) and \(\text{ind}(Y_\delta) = 0\). [Consider \(X \setminus \cup_{U \in \mathcal{B}} \partial U\), where \(\mathcal{B}\) is a countable base as in (b); cf. XI.21.3.15.]

(d) Using the Second Decomposition Theorem XI.21.3.20., prove the Extension Theorem: if \(X\) is second countable, \(Y \subseteq X\), and \(\text{ind}(Y) = n\), then there is a \(G_\delta\) subset \(Y_\delta\) of \(X\) with \(Y \subseteq Y_\delta\) and \(\text{ind}(Y_\delta) = n\).
XI.21.8.6. ([?]; cf. [Eng95, 1.4.F]) Let $K$ be the Cantor set, and $n \in \mathbb{N} \cup \{\infty\}$. Set $X = [0,1]^n$. Let $G$ be the set of $G_\delta$’s in $K \times X$. Then $\text{card}(G) = 2^{8^n}$. Let $\phi$ be a bijection from $K$ to $G$. Fix a point $x_0 \in X$, and define a function $f : K \to X$ by choosing $f(t)$ to be a point such that $(t,f(t)) \notin \phi(t)$ if there is such a point and $f(t) = x_0$ otherwise. Let $Y = \{(t,f(t)) : t \in K\} \subseteq K \times X$ be the graph of $f$; give $Y$ the subspace topology.

(a) Show that projection onto the first coordinate is an injective continuous function from $Y$ onto $K$. Thus $Y$ is totally disconnected. (So $Y$ may be thought of as $K$ with a topology stronger than the usual topology.)

(b) If $G$ is a $G_\delta$ in $K \times X$ containing $Y$, then $G = \phi(t)$ for some $t \in K$, and hence $G$ contains $\{t\} \times X$. Conclude that $\text{ind}(G) = n$.

(c) Apply the Extension Theorem (XI.21.8.5.(d)) to conclude that $\text{ind}(Y) = n$.

Note that $Y$ is separable and metrizable, so all dimension functions coincide on $Y$. This argument uses the AC. $K$ and $X$ can be replaced in the construction by any separable metrizable spaces of cardinality $2^{8^n}$; thus any separable metrizable space of cardinality $2^{8^n}$ is an injective continuous image of a separable metrizable space of arbitrarily larger dimension, i.e. has a stronger separable metrizable topology of arbitrarily larger dimension. In particular, for any $n \in \mathbb{N} \cup \{\infty\}$ there is a separable metrizable topology $T_n$ on $\mathbb{R}$, or $[0,1]$, stronger than the usual topology, with $\dim(\mathbb{R}, T_n) = n$. [Do the construction with $K$ and $X$ replaced by $\mathbb{R}$ and $\mathbb{R}^n$ respectively. To see that the $Y$ has dimension exactly $n$, note that $Y$ cannot contain any nonempty open set in $\mathbb{R} \times \mathbb{R}^n \cong \mathbb{R}^{n+1}$ by Invariance of Domain, and apply XI.21.6.1.]

There is also such a topology on $\mathbb{R}$ for $n = 0$, obtained by expanding the usual topology by making each rational number an isolated point.

XI.21.8.7. [ ] Extend the definitions of $\text{ind}$ and $\text{Ind}$ transfinitely: if $\alpha$ is an ordinal, then $\text{ind}(X) \leq \alpha$ if and only if, whenever $x \in X$ and $U$ is an open neighborhood of $x$ in $X$, there is an open neighborhood $V$ of $x$ contained in $U$ with $\text{ind}(\partial V) < \alpha$, and similarly for $\text{Ind}$.

(a) If $X$ is a $T_1$ space, and $\text{Ind}(X)$ is defined, then $\text{ind}(X)$ is defined and $\text{ind}(X) \leq \text{Ind}(X)$.

(b) If $X$ is a separable metrizable space, and $\text{ind}(X)$ is defined, then $X$ is countable-dimensional. Thus $\text{ind}(X)$ is not defined even for every compact metrizable space; in particular, $\text{ind}(\mathbb{R})$ is not defined. If $X$ is compact, metrizable, and countable-dimensional, then $\text{ind}(X)$ and $\text{Ind}(X)$ are defined.

(c) If $X$ is a separable metrizable space, and $\text{ind}(X)$ is defined, then $\text{ind}(X)$ is a countable ordinal.

(d) For every countable ordinal $\alpha$, there are compact metrizable spaces $X_\alpha$ and $Y_\alpha$ with $\text{ind}(X_\alpha) = \alpha$ and $\text{Ind}(Y_\alpha) = \alpha$. There are compact metrizable spaces $X$ with $\omega < \text{ind}(X) < \text{Ind}(X)$.

(e) If $\text{ind}_x(X)$ is finite for every $x \in X$, then $\text{ind}(X) \leq \omega$. The converse is false, even for compact metrizable $X$. Define a transfinite version of local dimension $\text{ind}_x$, and show that $\text{ind}(X) = \sup_{x \in X} \text{ind}_x(X)$ for any $X$.  

1314
XI.22. Homotopy and the Fundamental Group

XI.22.1. Homotopy

Homotopy is the careful mathematical formulation of the notion of “continuous deformation,” one of the most important ideas in topology and the basis for the entire subject of algebraic topology. There are several slight variations which we will discuss. If \( f \) and \( g \) are continuous functions between topological spaces \( X \) and \( Y \), we want to describe how \( f \) can be “continuously deformed” to \( g \); the intuitive idea is that there should be a “continuous path” \((f_t)\) (say, for \( 0 \leq t \leq 1 \)) of continuous functions with \( f_0 = f \), \( f_1 = g \). Experience shows that the following definition is the appropriate one:

**XI.22.1.1. Definition.** Let \( X \) and \( Y \) be topological spaces, and \( f_0, f_1 : X \to Y \) continuous functions. A homotopy from \( f_0 \) to \( f_1 \) is a continuous function \( H : X \times [0, 1] \to Y \) with \( H(x, 0) = f_0(x) \) and \( H(x, 1) = f_1(x) \) for all \( x \in X \). Two continuous functions \( f \) and \( g \) from \( X \) to \( Y \) are homotopic, written \( f \simeq g \), if there exists a homotopy from \( f \) to \( g \).

**XI.22.1.2.** We can then define, for fixed \( t \in [0, 1] \), a continuous function \( f_t : X \to Y \) by \( f_t(x) = H(x, t) \) for \( x \in X \). The functions \( f_t \) “vary continuously” from \( f_0 \) to \( f_1 \) as \( t \) varies from 0 to 1. The \( f_t \) are “jointly continuous” in \( x \) and \( t \). We often think of the homotopy \( H \) as being the family \((f_t)\) of deformations of \( f_0 \) to \( f_1 \).

**XI.22.1.3.** The choice of \([0, 1]\) for the parametrizing interval is arbitrary, as is the specification that \( H \) goes from \( X \times [0, 1] \) to \( Y \) instead of from \([0, 1] \times X \) to \( Y \) (the opposite convention is also common in references). To add to the potential notational confusion, in many applications the space \( X \) will also be \([0, 1]\).

**XI.22.1.4.** In considering homotopies, the target space \( Y \) must be carefully specified or understood. If \( Y \) is a subspace of a larger space \( Z \), and \( f, g : X \to Y \), then \( f \) and \( g \) can well be homotopic as maps from \( X \) to \( Z \) but not as maps from \( X \) to \( Y \), i.e. a homotopy might necessarily pass through points of \( Z \) outside \( Y \). Thus we should really write \( f \simeq g \) in \( Y \) (although we usually don’t).

**XI.22.1.5.** If \( f \simeq g \) via a homotopy \( H \), then for any \( x \in X \) the function \( \gamma_x : [0, 1] \to Y \) defined by \( \gamma_x(t) = H(x, t) \) is a continuous path in \( Y \) from \( f(x) \) to \( g(x) \). In particular, if \( f \simeq g \), then for every \( x \in X \), \( f(x) \) and \( g(x) \) must be in the same path component of \( Y \).

**XI.22.1.6.** Examples. (i) Two constant functions from \( X \) to \( Y \) with values \( y_0 \) and \( y_1 \) are homotopic if and only if \( y_0 \) and \( y_1 \) are in the same path component of \( Y \). Necessity comes from XI.22.1.5. Conversely, if \( \gamma : [0, 1] \to Y \) is a path from \( y_0 \) to \( y_1 \), set \( H(x, t) = \gamma(t) \); then \( H \) is a homotopy (via constant functions). In particular, if \( Y \) is path-connected, any two constant functions from any \( X \) to \( Y \) are homotopic.

(ii) A very special but important case is when the space \( Y \) is a convex subset of \( \mathbb{R}^n \) or, more generally, of a topological vector space. If \( X \) is any topological space, then any two continuous functions \( f \) and \( g \) from \( X \) to \( Y \) are homotopic by a homotopy of the form

\[
H(x, t) = tg(x) + (1 - t)f(x).
\]
Such a homotopy is called a \textit{linear homotopy}, and is defined only when \( Y \) has additional structure from a topological vector space.

The first fundamental property of homotopy is:

\textbf{XI.22.1.7. PROPOSITION.} Let \( X \) and \( Y \) be topological spaces. Then homotopy is an equivalence relation on the set of maps (continuous functions) from \( X \) to \( Y \).

\textbf{Proof:} Reflexivity and symmetry are very simple, but transitivity, although it is relatively simple also, involves an important notion of concatenation for homotopies.

If \( f : X \rightarrow Y \), define \( H(x,t) = f(x) \) for all \( x, t \). Then \( H \) is a homotopy from \( f \) to \( f \), so homotopy is reflexive.

If \( H \) is a homotopy from \( f_0 \) to \( f_1 \), define \( \tilde{H} : X \times [0,1] \rightarrow Y \) by \( \tilde{H}(x,t) = H(x,1-t) \). Then \( \tilde{H} \) is a homotopy from \( f_1 \) to \( f_0 \). Thus homotopy is symmetric.

Let \( H_1 \) be a homotopy from \( f_0 \) to \( f_1 \), and \( H_2 \) a homotopy from \( f_1 \) to \( f_2 \). Define \( H : X \times [0,1] \rightarrow Y \) by

\[
H(x,t) = \begin{cases} 
H_1(x,2t) & \text{if } 0 \leq t \leq \frac{1}{2} \\
H_2(x,2t-1) & \text{if } \frac{1}{2} < t \leq 1
\end{cases}
\]

Then \( H \) is continuous since \( H_1(x,1) = H_2(x,0) = f_1(x) \) for all \( x \), and is a homotopy from \( f_0 \) to \( f_2 \).

Homotopy respects compositions:

\textbf{XI.22.1.8. PROPOSITION.} Let \( X, Y, Z \) be topological spaces, and let \( f, f_0, f_1 : X \rightarrow Y \) and \( g, g_0, g_1 : Y \rightarrow Z \) with \( f_0 \simeq f_1 \) and \( g_0 \simeq g_1 \). Then \( g_0 \circ f_0 \simeq g_1 \circ f_1 \). In particular, \( g \circ f_0 \simeq g \circ f_1 \) and \( g_0 \circ f \simeq g_1 \circ f \).

\textbf{Proof:} We need only prove the last statement, since then \( g_0 \circ f_0 \simeq g_0 \circ f_1 \) and \( g_0 \circ f_1 \simeq g_1 \circ f_1 \), so \( g_0 \circ f_0 \simeq g_1 \circ f_1 \) by \textbf{XI.22.1.7.}.

If \( H \) is a homotopy from \( f_0 \) to \( f_1 \), define \( \tilde{H}(x,t) = g(H(x,t)) \); then \( \tilde{H} \) is a homotopy from \( g \circ f_0 \) to \( g \circ f_1 \).

If \( H \) is a homotopy from \( g_0 \) to \( g_1 \), define \( \tilde{H}(x,t) = H(f(x),t) \); then \( \tilde{H} \) is a homotopy from \( g_0 \circ f \) to \( g_1 \circ f \).

\textbf{Contractible Spaces}

\textbf{XI.22.1.9. DEFINITION.} If \( X \) and \( Y \) are topological spaces, and \( f : X \rightarrow Y \) is a map, then \( f \) is \textit{nullhomotopic} if it is homotopic to a constant function.

A topological space \( X \) is \textit{contractible} if the identity map on \( X \) is nullhomotopic, i.e. homotopic to a constant function from \( X \) to \( X \).

\textbf{XI.22.1.10.} If \( X \) is contractible and \( H \) is a homotopy from the identity map \( \iota_X \) to a constant function with value \( p \), then the functions \( f_t \) “contract” the space down to the point \( p \), and we say \( X \) is \textit{contractible} to \( p \). But a contractible space is path-connected since every point of \( X \) can be connected to \( p \) by a path, so if \( X \) is contractible to \( p \) it is also contractible to \( q \) for any other point \( q \).
XI.22.1.11. **Examples.** (i) If $X$ is a convex subset of $\mathbb{R}^n$, or more generally of a topological vector space, then $X$ is contractible to any point via a linear homotopy (XI.22.1.6.(ii)). In particular, $[0,1]$ is contractible, as is any ball in $\mathbb{R}^n$.

(ii) Let $X$ be the infinite comb $(\cdot)$. Then $X$ is contractible by first moving all points down to the $x$-axis and then moving them to $0$.

(iii) It is a fundamental theorem of topology, equivalent to the Brouwer fixed-point theorem, that $S^n$ is not contractible for any $n$ $(\cdot)$. Note that $S^n$ is path-connected for $n > 0$.

The next result is a special case of XI.22.1.8.

XI.22.1.12. **Proposition.** Let $X$ and $Y$ be topological spaces. If either $X$ or $Y$ is contractible, then every map from $X$ to $Y$ is nullhomotopic. If $Y$ is path-connected, any two maps from $X$ to $Y$ are homotopic.

**Homotopy Relative to a Subspace**

An important variation is homotopy relative to a subspace:

XI.22.1.13. **Definition.** Let $X$ and $Y$ be topological spaces, and $A \subseteq X$, $B \subseteq Y$. Let $f_0, f_1$ be maps from $X$ to $Y$ for which $f_0(A), f_1(A) \subseteq B$. Then a *homotopy from $f_0$ to $f_1$ relative to $(A,B)$* is a continuous function $H : X \times [0,1] \to Y$ such that $H(x,0) = f_0(x)$ and $H(x,1) = f_1(x)$ for all $x \in X$ and $H(x,t) \in B$ for all $x \in A$ and all $t$. If there is such a homotopy, write $f_0 \simeq f_1 \text{ rel } (A,B)$.

XI.22.1.14. A homotopy relative to a subspace is a homotopy. But the notion is much more restrictive, since the image of the set $A$ must remain within $B$ under the entire homotopy. In many applications, $A$ and $B$ are sets with only one or two points, and the restriction that $f$ take $A$ into $B$ amounts to specifying the value of $f$ at the point(s) of $A$.

XI.22.1.15. An important example of relative homotopy is when $X = [0,1]$ and $A = \{0,1\}$. A map $\gamma$ from $[0,1]$ to $Y$ is a path in $Y$. If $\gamma_0$ and $\gamma_1$ are paths in $Y$ with the same initial point $p$ and final point $q$, then $\gamma_0$ and $\gamma_1$ are always homotopic since they are both homotopic to the constant map with value $p$; but if $B = \{p,q\}$ a homotopy rel $(A,B)$ is one in which all intermediate paths also go from $p$ to $q$ (as long as $p$ and $q$ have disjoint neighborhoods in $Y$), so $\gamma_0$ and $\gamma_1$ may not be homotopic rel $(A,B)$. For example, if $Y$ is the unit circle in $\mathbb{R}^2$ and $\gamma_0$ and $\gamma_1$ are paths in $Y$ from $p = (-1,0)$ to $q = (1,0)$ via the upper and lower semicircles respectively, then $\gamma_0$ and $\gamma_1$ are not homotopic rel $(\{0,1\},\{p,q\})$ (this seems intuitively obvious, but requires a nontrivial proof, and is equivalent to the Brouwer fixed-point theorem in the plane). In this case we often notationally suppress the $B$ (if $\gamma_0$ and $\gamma_1$ have the same endpoints) and simply write $\gamma_0 \simeq \gamma_1$ rel $\{0,1\}$. Even the $A$ is often understood in this context, but a reader must carefully understand whether it is assumed (as it most commonly is) that homotopies of paths fix endpoints.

XI.22.1.16. An especially important special case of XI.22.1.15. comes when $p = q$, i.e. $B$ is a singleton $p$. We thus consider *loops with basepoint $p$*, maps $\gamma : [0,1] \to Y$ with $\gamma(0) = \gamma(1) = p$. Two such loops are *homotopic rel $p$* if they are homotopic rel $(\{0,1\},\{p\})$, i.e. homotopic via loops $\gamma_t$ with basepoint $p$ for all $t$. These will be discussed in detail in (\cdot).
XI.22.1.17. Here is another interesting special case. If $X$ is a topological space and $p \in X$, then $X$ is contractible to $p$ relative to $p$ (rel $p$) if the identity map is homotopic to the constant map with value $p$ relative to $(\{p\}, \{p\})$, i.e. if the space can be contracted to $p$ in a way leaving $p$ fixed. A convex set $X$ in a topological vector space is contractible to $p$ rel $p$ for any $p \in X$, but if $X$ is the infinite comb and $p$ is a point on the $y$-axis other than $0$, then $X$ is not contractible to $p$ rel $p$ since all points must move through $0$ in any contraction to $p$ (XI.22.5.1.).

A slight variation of the proofs of XI.22.1.7. and XI.22.1.8. (left to the reader) show:

XI.22.1.18. **Proposition.** Let $X, Y, Z$ be topological spaces, and $A \subseteq X$, $B \subseteq Y$, $C \subseteq Z$. Then

(i) Homotopy rel $(A, B)$ is an equivalence relation on the set of maps from $X$ to $Y$.

(ii) If $f_0, f_1 : X \to Y$, $f_0 \simeq f_1$ rel $(A, B)$, and $g_0, g_1 : Y \to Z$, $g_0 \simeq g_1$ rel $(B, C)$, then $g_1 \circ f_1 \simeq g_0 \circ f_0$ rel $(A, C)$.

**Homotopy Equivalence**

XI.22.1.19. **Definition.** Let $X$ and $Y$ be topological spaces. Then $X$ and $Y$ are homotopy equivalent if there are maps $f : X \to Y$ and $g : Y \to X$ with $g \circ f \simeq \iota_X$ and $f \circ g \simeq \iota_Y$. $X$ homotopically dominates $Y$ if there are maps $f : X \to Y$ and $g : Y \to X$ with $f \circ g \simeq \iota_Y$.

XI.22.1.20. It is an easy consequence of XI.22.1.8. that homotopy dominance is transitive and homotopy equivalence is an equivalence relation. Homotopy dominance is a sort of “homotopy retraction” ()

XI.22.1.21. **Examples.** (i) Every topological space homotopically dominates any contractible space. A topological space is homotopy equivalent to a contractible space if and only if it is contractible. Any two contractible spaces are homotopy equivalent.

(ii) A circle in $\mathbb{R}^2$ is not homotopy equivalent to $\mathbb{R}^2$ since $\mathbb{R}^2$ is contractible. But a circle is homotopy equivalent to $\mathbb{R}^2$ with a point removed.

(iii) The greek letter $\theta$ and a figure 8 are homotopy equivalent.

(iv) A cylinder and a Möbius strip are homotopy equivalent since each is homotopy equivalent to a circle.

(v) If $X$ and $Y$ are homotopy equivalent, they each homotopy dominate the other. But the converse is false in general:

XI.22.1.22. Homotopy equivalence is much weaker than homeomorphism in general: for example, every contractible space is homotopy equivalent to a one-point space. (Homeomorphism can be concluded from homotopy equivalence in some special cases.) Most methods and results of algebraic topology do not distinguish between homotopy equivalent spaces, i.e. algebraic topology describes and studies topological spaces up to homotopy equivalence.
XI.22.1.23. We can also define relative homotopy equivalence. If \( A \subseteq X \) and \( B \subseteq Y \), a homotopy equivalence between \( X \) and \( Y \) rel \((A, B)\) is a pair of maps \( f : X \to Y \) and \( g : Y \to X \) with \( f(A) \subseteq B \), \( g(B) \subseteq A \), and \( g \circ f \simeq \iota_X \) rel \((A, A)\) and \( f \circ g \simeq \iota_Y \) rel \((B, B)\). Relative homotopy dominance can be defined similarly.

Smooth Homotopy

XI.22.1.24. In situations where there is a notion of differentiability, one also wants to consider smooth homotopies. For example, if \( X \) and \( Y \) are \( C^r \)-manifolds and \( f, g \) are \( C^r \) maps from \( X \) to \( Y \), we say \( f \) and \( g \) are \( C^r \)-homotopic if there is a homotopy \( H \) which is a \( C^r \) function from \( X \times [0, 1] \) to \( Y \). The relation between ordinary homotopies and smooth homotopies in this context is somewhat subtle, but in good cases an ordinary homotopy can be “smoothed” to a smooth one.

Isotopy

In some applications in topology, such as knot theory, it is important not to allow the image to “pass through itself” during the deformation. This is accomplished by the notion of isotopy.

XI.22.1.25. Definition. Let \( X \) and \( Y \) be topological spaces, and \( f_0, f_1 \) topological embeddings of \( X \) into \( Y \) (homeomorphisms onto their images). An isotopy from \( f_0 \) to \( f_1 \) is a homotopy \( H = (f_t) \) from \( f_0 \) to \( f_1 \) in which each \( f_t \) (\( 0 \leq t \leq 1 \)) is a topological embedding.

Isotopic maps are obviously homotopic, but the converse is false:

XI.22.1.26. Examples. (i) Let \( X = \{0, 1\}, Y = \{0, 1\} \) (or \( Y = \mathbb{R} \)). Let \( f_0(t) = t \), and \( f_1(t) = 1 - t \). Then \( f_0 \simeq f_1 \) (any two maps from \( X \) to \( Y \) are homotopic). But \( f_0 \) and \( f_1 \) are not isotopic: if \( (f_t) \) is a homotopy from \( f_0 \) to \( f_1 \), there is a \( t \) such that \( f_t(0) = f_t(1) \), so \( f_t \) is not injective [set \( \phi(t) = f_t(1) - f_t(0) \) and apply the Intermediate Value theorem].

(ii) Any two knots are homotopic as maps from \( S^1 \) to \( \mathbb{R}^3 \). But a nontrivial knot like the trefoil is not isotopic to an unknot. In fact, two knots are isotopic if and only if they are equivalent as knots.

(iii) The Fox-Artin wild arc is isotopic to an ordinary arc as maps from \( [0, 1] \) into \( \mathbb{R}^3 \). But the more complicated embedding of \( [0, 1] \) into \( \mathbb{R}^3 \) outlined at the end of (i) which is wild at every point is not isotopic to an ordinary arc.

Ambient Isotopy

XI.22.2. The Fundamental Group

XI.22.3. Covering Spaces

XI.22.4. Other Homotopy Groups

XI.22.5. Exercises

XI.22.5.1. Let \( X \) be the infinite comb, and \( p \) a point of \( X \) on the \( y \)-axis with positive \( y \)-coordinate. Then \( X \) is contractible to \( p \). Show that \( X \) is not contractible to \( p \) rel \( p \).
(a) If \( q \) is a point of \( X \) with positive \( x \)-coordinate, then any path in \( X \) from \( q \) to \( p \) must pass through \( 0 \).

(b) Let \( (p_n) \) be a sequence in \( X \) of points with positive \( x \)-coordinate with \( p_n \to p \). If \( H \) is a contraction of \( X \) to \( p \), then for each \( n \) there must be a \( t_n \) with \( H(p_n, t_n) = 0 \).

(c) If \( t_0 \) is a limit point of the sequence \( (t_n) \), then \( H(p, t_0) = 0 \). Thus we cannot have that \( H \) is a contraction of \( X \) to \( p \) rel \( p \).
XI.22.6. Fubini’s Differentiation Theorem

Although even uniformly convergent infinite series of functions cannot be differentiated term-by-term in general, there are a few types of series for which term-by-term differentiation is valid. The most notable example is convergent power series. Another example is convergent series of nondecreasing functions, the topic of this subsection.

The main theorem is due to Fubini. The name “Fubini’s Theorem” is, however, normally reserved for another of Fubini’s results on interchanging the order of multiple integration. This result is sometimes called “Fubini’s Differentiation Theorem,” a name we will use. This theorem can be stated for sequences (as can any result about infinite series, since the theories of sequences and series are formally equivalent), but the hypotheses are clumsy to state in the sequence setting (cf. Exercise XI.22.7.1.).

XI.22.6.1. Theorem. [Fubini’s Differentiation Theorem] Let \( \sum_{k=1}^{\infty} f_k(x) \) be an infinite series of nondecreasing functions on an interval \([a,b]\), converging pointwise to a (nondecreasing) function \( f \). Then

(i) The series converges uniformly to \( f \) on \([a,b]\).

(ii) The series \( \sum_{k=1}^{\infty} f'_k(x) \) converges pointwise a.e. on \([a,b]\) to \( f'(x) \).

In particular, \( f'_k(x) \to 0 \) for almost all \( x \in [a,b] \).

(Conclusion (ii) is the main part of the theorem; (i) is an easy observation.)

Proof: Begin with (i). For any \( x \in [a,b] \), we have

\[
f(x) = [f(x) - f(a)] + f(a) = \sum_{k=1}^{\infty} [f_k(x) - f_k(a)] + \sum_{k=1}^{\infty} f_k(a)
\]

with both series convergent. If \( \epsilon > 0 \), choose \( N \) such that for all \( n \geq N \),

\[
\left| \sum_{k=n+1}^{\infty} [f_k(b) - f_k(a)] \right| < \frac{\epsilon}{2} \quad \text{and} \quad \left| \sum_{k=n+1}^{\infty} f_k(a) \right| < \frac{\epsilon}{2}.
\]

Then, for any \( n \geq N \) and any \( x \in [a,b] \), we have

\[
\left| f(x) - \sum_{k=1}^{n} f_k(x) \right| = \left| \sum_{k=n+1}^{\infty} [f_k(x) - f_k(a)] + \sum_{k=n+1}^{\infty} f_k(a) \right|
\]

\[
\leq \left| \sum_{k=n+1}^{\infty} [f_k(x) - f_k(a)] \right| + \left| \sum_{k=n+1}^{\infty} f_k(a) \right| \leq \left| \sum_{k=n+1}^{\infty} [f_k(b) - f_k(a)] \right| + \sum_{k=n+1}^{\infty} f_k(a) < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon
\]

(the middle inequality on the last line holds because \( f_k \) is nondecreasing) and thus the series converges uniformly to \( f \) on \([a,b]\).
We now turn to (ii). First assume all the \( f_k \) are nonnegative. There is a subset \( A \) of \([a, b]\) whose complement has measure 0 and such that \( f \) and all the \( f_k \) are differentiable at all \( x \in A \). Let \( s_n(x) = \sum_{k=1}^{n} f_k(x) \) be the \( n \)'th partial sum and \( r_n(x) = f(x) - s_n(x) = \sum_{k=n+1}^{\infty} f_k(x) \) the remainder. Then \( s_n \) and \( r_n \) are nonnegative, nondecreasing, and differentiable on \( A \), with \( s'_n(x) \geq 0 \) and \( r'_n(x) \geq 0 \) for all \( x \in A \). Since \( s'_n(x) \leq s'_n(x) + r'_n(x) = f'(x) \) for all \( x \in A \), we have that \( \sum_{k=1}^{\infty} f'_k(x) \) converges for all \( x \in A \) since it is a nonnegative series with bounded partial sums, and

\[
\sum_{k=1}^{\infty} f'_k(x) \leq f'(x)
\]

for all \( x \in A \).

To show that equality holds a.e. on \([a, b]\), it suffices to find a subsequence \((s'_{n_j})\) which converges to \( f' \) a.e. on \([a, b]\). Since \( s_n(b) \to f(b) \), for each \( j \) there is an \( n_j > n_j-1 \) such that \( r_{n_j}(b) = f(b) - s_{n_j}(b) < 2^{-j} \) and hence, for each \( x \in [a, b] \), we have

\[
0 \leq \sum_{j=1}^{\infty} r_{n_j}(x) = \sum_{j=1}^{\infty} (f(b) - s_{n_j}(b)) < \infty
\]

and thus the series \( \sum_{j=1}^{\infty} r_{n_j}(x) \) satisfies the hypotheses in the preceding paragraph, so there is a subset \( B \) of \([a, b]\) such that \([a, b] \setminus B \) has measure 0 and

\[
0 \leq \sum_{j=1}^{\infty} r'_{n_j}(x) = \sum_{j=1}^{\infty} [f'(x) - s'_{n_j}(x)] < \infty
\]

for all \( x \in B \). Thus, for every \( x \in B \), we have \( \lim_{j \to \infty} [f'(x) - s'_{n_j}(x)] = 0 \), so

\[
\lim_{j \to \infty} s'_{n_j}(x) = f'(x)
\]

for almost all \( x \in [a, b] \).

Now drop the assumption that the \( f_k \) are nonnegative. (The only place this assumption was used was to obtain that the \( r_n \) were nonnegative.) Set \( g(x) = f(x) - f(a) \) and \( g_k(x) = f_k(x) - f_k(a) \) for each \( k \) and each \( x \in [a, b] \). Then the \( g_k \) are nonnegative and nondecreasing, \( g' = f' \), \( g'_k = f'_k \) for all \( k \), and \( g(x) = \sum_{k=1}^{\infty} g_k(x) \) for all \( k \). Thus the previous argument applies to \( g \) and the \( g_k \), and shows that

\[
f'(x) = g'(x) = \sum_{k=1}^{\infty} g'_k(x) = \sum_{k=1}^{\infty} f'_k(x) \text{ a.e.}
\]
XI.22.7. Exercises

XI.22.7.1. Give a correct restatement of the Fubini Differentiation Theorem for sequences. Show that the following is not a correct statement:

“Let \((f_n)\) be a nondecreasing sequence of nondecreasing functions on an interval \([a, b]\) converging uniformly on \([a, b]\) to a (nondecreasing) function \(f\). Then \(f'_n \to f'\) pointwise a.e. on \([a, b]\).”

Consider a strictly increasing sequence \((f_n)\) of nondecreasing step functions converging uniformly to \(f(x) = x\) on \([0, 1]\). Modify this example to make the \(f_n\) continuous by connecting the steps by line segments of large slope. In these examples, there is no \(x \in [0, 1]\) for which \(f_n'(x) \to f'(x)\).

XI.22.7.2. Let \(g\) be the Cantor function \((\)\). Regard \(g\) as a function on \(\mathbb{R}\) by setting \(g(x) = 0\) for \(x < 0\) and \(g(x) = 1\) for \(x > 1\). Then \(g\) is nonnegative, continuous, nondecreasing, \(g(0) = 0\), \(g(1) = 1\), and \(g' = 0\) a.e. Let \([a_k, b_k] : k \in \mathbb{N}\) be an enumeration of the closed bounded intervals with rational endpoints \(a_k < b_k\).

(a) For each \(k\) let \(f_k\) be a scaled copy of \(g\) transferred to \([a_k, b_k]\):

\[
f_k(x) = 2^{-k} f\left(\frac{x - a_k}{b_k - a_k}\right).\]

Show that \(f_k\) is nonnegative, continuous, nondecreasing, \(f_k(x) = 0\) for \(x \leq a_k\), \(f_k(x) = 2^{-k}\) for \(x \geq b_k\), and \(f'_k = 0\) a.e.

(b) Set \(f(x) = \sum_{k=1}^{\infty} f_k(x)\). Show that the series converges uniformly on all of \(\mathbb{R}\), and that \(f\) is continuous and strictly increasing on \(\mathbb{R}\).

(c) Apply XI.22.6.1. to conclude that \(f' = 0\) a.e.

XI.22.7.3. Move to section on series of functions

(a) Let \(\{a_k : k \in \mathbb{N}\}\) be an enumeration of \(\mathbb{Q} \cap [0, 1]\). Show that the infinite series \(\sum_{k=1}^{\infty} \frac{3}{k!} \sqrt{x - a_k}\) converges uniformly on \([0, 1]\) to a function \(g\) which is continuous and strictly increasing.

(b) Let \([a, b]\) be the range of \(g\), and \(f = g^{-1} : [a, b] \to [0, 1]\). Show that \(f\) is continuous, strictly increasing, and that \(f' = 0\) on the dense set \(g(\mathbb{Q})\).

(c) Show that \(g\) is differentiable at every irrational number \(x\) in \([0, 1]\) and that \(g'(x) > 1\). Thus \(f\) is differentiable at every point of \([a, b]\) and \(0 \leq f'(x) < 1\) for all \(x \in [a, b]\).

This example is due to D. Pompeiu (cf. [vRS82, 13.3] or [Str81, p. 215-216]). For this \(f\), the set \(\{x \in [a, b] : f'(x) = 0\}\), while dense in \([a, b]\), is countable. There are more dramatic examples, e.g. there is a strictly increasing continuous function \(f\) on \([a, b]\) such that \(f' = 0\) a.e. (Exercise XI.22.7.2.).

XI.22.7.4. Let \(K \subseteq [0, 1]\) be a Cantor set of positive measure, and let \(g\) be a nonnegative real-valued continuous function on \([0, 1]\) which is zero precisely on \(K\), e.g. \(g(x)\) is the distance from \(x\) to \(K\). Set

\[
f(x) = \int_0^x g(t) \, dt.\]

Then \(f\) is strictly increasing on \([0, 1]\), differentiable everywhere with \(f' = g\) (\(), i.e. \(C^1\), and \(f' = 0\) on a set of positive measure.

1323
XI.22.7.5. Does there exist a strictly increasing differentiable function \( f \) on an interval \([a, b]\) such that the set
\[
S = \{ x \in [a, b] : f'(x) = 0 \}
\]
satisfies that \( S \cap [c, d] \) has positive measure for all \( a \leq c < d \leq b \)? (Compare XI.22.7.3., XI.22.7.4.)

XI.22.7.6. Let \( f_k(x) = \frac{1}{k} \tan^{-1} kx - \frac{1}{k+1} \tan^{-1}(k+1)x \).
(a) Show that \( f_k \) is strictly increasing on \([-1, 1]\).
(b) Show that \( \sum_{k=1}^{\infty} f_k(x) \) converges (uniformly) on \([-1, 1]\) to a differentiable function \( f \).
(c) Although \( f \) and each \( f_k \) are differentiable everywhere, it is not true that \( f'(x) = \sum_{k=1}^{\infty} f'_k(x) \) everywhere (we do not have \( f'(0) = \sum_{k=1}^{\infty} f'_k(0) \)).
XI.23. Sard’s Theorem

Sard’s Theorem in its various forms is one of the most remarkable properties of Euclidean space with its differentiable structure, and is perhaps the fundamental result of the subject of differential topology.

Consider a smooth map $f$ from $\mathbb{R}^n$ to $\mathbb{R}^m$, or, more generally, from a smooth $n$-manifold $N$ to a smooth $m$-manifold $M$. Then, for any $x_0 \in \mathbb{R}^n$, $Df(x_0)$ is a linear transformation from $\mathbb{R}^n$ to $\mathbb{R}^m$. The point $x_0$ is singular if $Df(x_0)$ has rank strictly smaller than $m$; otherwise, $x_0$ is regular. The image in $M$ of the set of singular points of $f$ is called the set of singular values of $f$; a $y_0$ in the range of $f$ which is not a singular value is called a regular value of $f$. (The image of a regular point can be a singular value if it is also the image of a singular point.) The names reflect the fact that $f$ is well-behaved in a neighborhood of a regular point but can be quite pathological near a singular point (cf. ()). Points of $M$ not in the range of $f$ are also (rather perversely) usually called regular values of $f$. Every critical value of $f$ is a singular value; the converse is not necessarily true if $m > 1$.

Although the set of singular points of $f$ can be a large subset of $\mathbb{R}^n$ ($f$ could even be a constant function!), Sard’s Theorem states that the set of singular values of $f$ is a “negligibly small” subset of $\mathbb{R}^m$ (or $M$), in a certain precise sense (measure zero and meager). Thus, in many situations, it can be concluded that “almost all” values of $f$ are regular values; even the existence of one regular value for $f$ can sometimes have important consequences (cf. ()).

Sard’s Theorem is intuitively quite plausible, and relatively easy to prove, if $n \leq m$, and only quite mild differentiability assumptions on $f$ are needed. In the case $n < m$, where every point of $N$ is a singular point (since the rank of $Df(x_0)$ is always $\leq n$ for any $x_0$), it simply says that the range of $f$ is a “small” subset of $M$ (intuitively it has dimension $\leq n$); although the existence of “space-filling curves” (cf.) can shake one’s confidence about this, Sard’s Theorem in the case $n < m$ says that there can be no smooth space-filling curve or lower-dimensional surface. And in the case $n = m = 1$, the statement says that for a continuously differentiable function, “most” horizontal lines are not tangent to the graph.

In the case $n > m$, or $n = m > 1$, the result is also intuitively plausible: if $x_0$ is a singular point, then near $x_0$ the function $f$ is approximately a linear function whose range is a proper subspace of $\mathbb{R}^m$, and such a subspace is negligibly small in a measure or category sense, and thus a small neighborhood of $x_0$ should have an image of “much smaller” size in $\mathbb{R}^m$. However, this intuitive idea turns out not to be directly translatable into a proof in this case, and is even false in general unless some delicate smoothness conditions are assumed (the underlying intuitive reason for the smoothness conditions is closely related to $V.10.6.11.$). The fact that the conclusion holds in the case $n > m$ is rather subtle and quite remarkable, and has all sorts of important consequences, e.g. it easily implies the Brouwer Fixed-Point Theorem, which is the most fundamental fact about the topology of Euclidean space, as well as underlying transversality, the fundamental technical tool of differential topology.

Sard’s Theorem is often called the Morse-Sard Theorem since the case $m = 1$ was proved by A. P. Morse in 1939 [Mor39]; the general theorem was proved by A. Sard in 1942 [Sar42]. Sard, a student of Marston Morse, obtained some of the results independently of A. P. Morse in his Ph.D. dissertation of 1936. Note that A. P. Morse was not the same person as Marston Morse (they were apparently unrelated). Sard states in [Sar42] that Marston Morse previously proved the theorem of A. P. Morse in the cases $n \leq 6$, in part jointly with Sard (unpublished). A closely related result was obtained in [Bro35]. There have been various generalizations and refinements, cf. [Fed69], [Yom83], [Bat93].
XI.23.1. Sets of Measure Zero

The notion of a set of measure zero is really a concept from measure theory (). But little if any actual measure theory is needed to develop the definition and basic properties needed in this section.

XI.23.1.1. Definition. A subset $A \subseteq \mathbb{R}^n$ has measure zero in $\mathbb{R}^n$ if, for every $\epsilon > 0$, there is a sequence $(B_k)$ of open balls in $\mathbb{R}^n$ such that $A \subseteq \bigcup_k B_k$ and

$$
\sum_{k=1}^{\infty} r_k^n < \epsilon
$$

where $r_k$ is the radius of $B_k$. We allow empty balls, i.e. open balls of radius 0; thus the collection $\{B_k\}$ may be finite or countably infinite.

Note that up to a constant factor, the sum $\sum_{k=1}^{\infty} r_k^n$ is just the sum of the $n$-dimensional volumes $\sum_{k=1}^{\infty} V_n(B_k)$ of the $B_k$. By adjusting $\epsilon$, the sum of the volumes can be used instead in the definition.

XI.23.1.2. We should properly say “$A$ has $n$-dimensional Lebesgue measure zero” instead of “$A$ has measure zero in $\mathbb{R}^n$.” Note that the “$in \mathbb{R}^n$” is a crucial part of the terminology: it does not make sense to simply say that a subset of Euclidean space has measure zero without specifying which Euclidean space it is with respect to. For example, the interval $[0, 1]$ does not have measure zero in $\mathbb{R}^1$, but if it is regarded as a segment on the $x$-axis it does have measure zero in $\mathbb{R}^2$. The term null set is often used for a set of measure zero.

XI.23.1.3. A ball of radius $r$ in $\mathbb{R}^n$ is contained in a cube of side length $2r$ with sides parallel to the coordinate axes; conversely, a cube of side length $2s$ is contained in the ball of radius $s / \sqrt{n}$ around its center. So the definition can be equivalently rephrased replacing “open ball” with “open cube” and “radius” with “side length.” The cubes can be restricted to ones with sides parallel to the axes, or not.

An open ball intersecting $A$ is contained in an open ball of twice the radius centered at a point of $A$. Thus all the balls in the definition may be taken with centers in $A$. The same consideration can be made with cubes.

There is much more flexibility. If $B$ is a ball, there is a ball with rational radius with the same center whose radius is less than twice the radius of $B$; thus we may restrict to using open balls with rational radius. Similarly, open cubes with rational edges can be used. In a similar manner, we may restrict to using only open balls or cubes whose centers have rational coordinates (and rational radii or sides).

Another especially useful variation is to use open rectangular solids. For if $R$ is an open rectangular solid, $R$ can be covered by a finite number of open cubes whose total volume is less than $2V_n(R)$. Thus we obtain:

XI.23.1.4. Proposition. Let $A \subseteq \mathbb{R}^n$. Then $A$ has measure zero in $\mathbb{R}^n$ if and only if, for every $\epsilon > 0$, there is a sequence $(R_k)$ of open rectangular solids in $\mathbb{R}^n$ with $A \subseteq \bigcup_k R_k$ and

$$
\sum_{k=1}^{\infty} V_n(R_k) < \epsilon
$$

As before, some of the $R_k$ may be empty, i.e. there may be either a finite or countably infinite number of $R_k$. 
XI.23.1.5. **Proposition.** (i) Any subset of a subset of \( \mathbb{R}^n \) of measure zero in \( \mathbb{R}^n \) has measure zero in \( \mathbb{R}^n \).

(ii) A countable union of subsets of \( \mathbb{R}^n \) of measure zero in \( \mathbb{R}^n \) has measure zero in \( \mathbb{R}^n \).

**Proof:** Part (i) is obvious. For (ii), let \( (A_j) \) be a sequence of subsets of \( \mathbb{R}^n \) of measure zero in \( \mathbb{R}^n \), and \( A = \bigcup_j A_j \). Let \( \epsilon > 0 \). For each \( j \) let \( (B_{jk}) \) be a sequence of open balls in \( \mathbb{R}^n \) covering \( A_j \) for which the sum of the volumes is less than \( 2^{-j} \epsilon \). Then the \( B_{jk} \) cover \( A \) and the sum of the volumes is less than \( \epsilon \).

XI.23.1.6. **Corollary.** Let \( A \subseteq \mathbb{R}^n \). Then \( A \) has measure zero in \( \mathbb{R}^n \) if and only if every \( x_0 \in A \) has a neighborhood \( U \) such that \( A \setminus U \) has measure zero in \( \mathbb{R}^n \).

**Proof:** This is really the Lindelöf property of \( \mathbb{R}^n \). If \( x_0 \in A \) and \( U \) is any neighborhood of \( x_0 \), then there is a ball \( V \) of rational radius, whose center has rational coordinates, with \( x_0 \in V \subseteq U \). If \( A \cap U \) has measure zero in \( \mathbb{R}^n \), so does \( A \cap V \). There are only countably many distinct such \( V \), so \( A \) is a countable union of sets of measure zero in \( \mathbb{R}^n \). The converse is trivial.

XI.23.1.7. **Examples.** (i) Let \( S \) be the \((n - 1)\)-dimensional subspace
\[
\{(x_1, \ldots, x_{n-1}, 0) : x_1, \ldots, x_{n-1} \in \mathbb{R}\}
\]
of \( \mathbb{R}^n \). Then \( S \) is a countable union of bounded subsets. Each bounded subset can be contained in a single open rectangular solid whose thickness is so small that its volume is arbitrarily small. Thus \( S \) has measure zero in \( \mathbb{R}^n \).

(ii) No (nonempty) open rectangle in \( \mathbb{R}^n \) can have measure zero in \( \mathbb{R}^n \). This fact, while intuitively quite plausible, is somewhat tricky to prove; see (). Since any nonempty open set in \( \mathbb{R}^n \) contains an open rectangle, no nonempty open set can have measure zero, i.e. every set of measure zero in \( \mathbb{R}^n \) has empty interior.

XI.23.1.8. **Proposition.** Let \( U \) be a subset of \( \mathbb{R}^n \), \( f : U \rightarrow \mathbb{R}^n \) a Lipschitz function (). If \( A \subseteq U \) has measure zero in \( \mathbb{R}^n \), so does \( f(A) \). In particular, isometries and affine functions preserve sets of measure zero.

**Proof:** Suppose \( A \subseteq U \) has measure zero in \( \mathbb{R}^n \). Let \( M \) be the Lipschitz constant of \( f \). Let \( \epsilon > 0 \), and let \( (B_k) \) be a sequence of open balls with centers \( x_k \in A \) covering \( A \) with total volume less than \( \frac{\epsilon}{M} \). If \( \rho_k \) is the radius of \( B_k \), then \( f(B_k \cap U) \) is contained in the open ball of radius \( M \rho_k \) around \( f(x_k) \); thus \( f(A) \) is contained in the union of these open balls, which have total volume \( < \epsilon \).

XI.23.1.9. **Corollary.** Let \( U \) and \( V \) be open subsets of \( \mathbb{R}^n \), and \( f \) a \((C^1)\) diffeomorphism from \( U \) to \( V \). If \( A \subseteq U \), then \( A \) has measure zero in \( \mathbb{R}^n \) if and only if \( f(A) \) does.

**Proof:** Every point of \( U \) has a compact neighborhood \( V \) contained in \( U \), on which \( f \) is Lipschitz (); thus if \( A \cap V \) has measure zero in \( \mathbb{R}^n \), so does \( f(A \cap V) \).
XI.23.1.10. Sets of measure zero are not preserved under homeomorphisms in general (). Thus having measure zero is a metric concept but not a topological concept.

The next result is a special case of Tonelli’s Theorem (), needed for the proof of Sard’s Theorem. This proof appears in [Ste83, p. 51] and is attributed to H. FURSTENBERG. An \( F_{\sigma} \) is a countable union of closed sets. Since every closed set in \( \mathbb{R}^n \) is a countable union of compact sets, a subset of \( \mathbb{R}^n \) is an \( F_{\sigma} \) if and only if it is \( \sigma \)-compact. Of course, every closed set in \( \mathbb{R}^n \) is an \( F_{\sigma} \). See ().

XI.23.1.11. Theorem. [Baby Tonelli Theorem] Let \( K \) be an \( F_{\sigma} \) in \( \mathbb{R}^n \). Suppose, for each \( t \in \mathbb{R} \), we have that
\[
K_t := \{(x_1, \ldots, x_{n-1}) : (x_1, \ldots, x_{n-1}, t) \in K\} \subseteq \mathbb{R}^{n-1}
\]
has measure zero in \( \mathbb{R}^{n-1} \). Then \( K \) has measure zero in \( \mathbb{R}^n \).

Informally, if each horizontal cross-section of \( K \) has \((n-1)\)-dimensional measure zero, then \( K \) has \( n \)-dimensional measure zero.

We need two lemmas for the proof. The first is a variation of () (note that this result is not quite correctly stated in [Ste83]):

XI.23.1.12. Lemma. Let \([a, b]\) be a closed bounded interval in \( \mathbb{R} \) \( c > 0 \), and \( \mathcal{U} \) a cover of \([a, b]\) by open intervals of length \( \leq c \). Then there is a finite subcover \( \{I_1, \ldots, I_n\} \) of \( \mathcal{U} \) for which
\[
\sum_{k=1}^n \ell(I_k) \leq 2(b - a + c).
\]

Proof: Since \([a, b]\) is compact there is a finite subcover. Any finite subcover contains a minimal subcover \( \mathcal{V} \) (i.e. \( \mathcal{V} \) is a cover but no proper subset of \( \mathcal{V} \) is a cover). Number the intervals in \( \mathcal{V} \) in increasing order of left endpoint (no two can have the same left endpoint by minimality), i.e. \( \mathcal{V} = \{I_1, \ldots, I_n\} \) where \( I_k = (a_k, b_k) \) with \( a_k < a_{k+1} \) for \( 1 \leq k < n \). These endpoints necessarily satisfy
\[
a_1 < a \leq a_2 < b_1 \leq a_3 < b_2 \leq \cdots \leq a_n < b_{n-1} \leq b < b_n
\]
(if one of these inequalities is violated, the collection of intervals is not minimal). We then have
\[
\sum_{k=1}^n \ell(I_k) = \sum_{k=1}^n (b_k - a_k) = (a - a_1) + (b - a) + (b_n - b) + \sum_{k=1}^{n-1} (b_k - a_{k+1}).
\]
The last sum is the total length of the overlaps of the intervals; since the overlaps are disjoint and contained in \([a, b]\), this total length is \( \leq b - a \). Also, \( a - a_1 \leq c \) and \( b_n - b \leq c \). Thus we have
\[
\sum_{k=1}^n \ell(I_k) \leq c + (b - a) + c + (b - a) = 2(b - a + c).
\]

\(\triangleright\)

1328
**XI.23.1.13. Lemma.** Let $K$ be a compact subset of $\mathbb{R}^n \cong \mathbb{R}^{n-1} \times \mathbb{R}$, and $t \in \mathbb{R}$. Set

$$K_t := \{(x_1, \ldots, x_{n-1}) : (x_1, \ldots, x_{n-1}, t) \in K\} \subseteq \mathbb{R}^{n-1}.$$ 

If $U$ is an open set in $\mathbb{R}^{n-1}$ containing $K_t$, then there is a $\delta > 0$ such that

$$K \cap \left[\mathbb{R}^{n-1} \times (t - \delta, t + \delta)\right] \subseteq U \times (t - \delta, t + \delta).$$ 

**Proof:** Suppose there is no such $\delta$. Then there is a sequence $(x_k, t_k)$ of points of $K$ with $t_k \to t$ and $x_k \not\in U$ for all $k$. Passing to a subsequence, we may assume $(x_k, t_k) \to (x, t) \in K$ for some $x$ by compactness of $K$. But then $x \in K_t$, and $x_k \to x$ in $\mathbb{R}^{n-1}$, contradicting that $U$ is an open neighborhood of $x$. \(\Box\)

**XI.23.1.14.** We now prove Theorem XI.23.1.11. It suffices to assume that $K$ is compact. Then there is an interval $[a, b]$ such that $K \subseteq \mathbb{R}^{n-1} \times [a, b]$. Fix $\epsilon > 0$. For each $t \in [a, b]$ there is a countable (even finite) collection $\mathcal{R}_t$ of open rectangular solids in $\mathbb{R}^{n-1}$ covering $K_t$ whose total $(n-1)$-dimensional volume is

$$v_t \leq \frac{\epsilon}{2(b - a + 1)}.$$ 

Let $U_t$ be the union of the rectangular solids in $\mathcal{R}_t$. By XI.23.1.13, there is a $\delta_t > 0$ such that

$$K \cap \left[\mathbb{R}^{n-1} \times (t - \delta_t, t + \delta_t)\right] \subseteq U_t \times (t - \delta_t, t + \delta_t).$$ 

We may assume $\delta_t \leq 1/2$ for all $t$. The intervals $\{(t - \delta_t, t + \delta_t) : t \in [a, b]\}$ form an open cover of $[a, b]$, so by Lemma XI.23.1.12, there is a subcover

$$\{(t_1 - \delta_{t_1}, t_1 + \delta_{t_1}), \ldots, (t_m - \delta_{t_m}, t_m + \delta_{t_m})\}$$

whose total length $\sum_{k=1}^m 2\delta_{t_k}$ is $\leq 2(b - a + 1)$. If $\mathcal{R}$ is the collection of open rectangular solids of the form

$$R \times (t_k - \delta_{t_k}, t_k + \delta_{t_k})$$

for $R \in \mathcal{R}_{t_k}, 1 \leq k \leq m$, then the collection $\mathcal{R}$ covers $K$ and the total $n$-dimensional volume is

$$\sum_{k=1}^m 2\delta_{t_k} v_{t_k} \leq \frac{\epsilon}{2(b - a + 1)} \sum_{k=1}^m 2\delta_{t_k} \leq \epsilon.$$ 

Since $\epsilon > 0$ is arbitrary, $K$ has measure zero in $\mathbb{R}^n$. This completes the proof of Theorem XI.23.1.11. \(\Box\)

**XI.23.1.15.** This theorem extends (XIV.6.1.12) from $F_\alpha$'s to a much larger class of subsets of $\mathbb{R}^n$ (Lebesgue measurable subsets), but not to arbitrary subsets. See XIV.6.3.1..

**Sets of Measure Zero in a Manifold**

We can extend the notion of subset of measure zero to smooth manifolds:
XI.23.1.16.  **Definition.** Let $M$ be a $C^r$ $n$-manifold ($r \geq 1$). A subset $A$ of $M$ has measure zero in $M$ if, for every $x \in A$, there is a coordinate chart $(U, \phi)$ for $M$ with $x \in U$ such that $\phi(A \cap U)$ has measure zero in $\mathbb{R}^n$.

XI.23.1.17.  It follows easily from XI.23.1.9. that if $A \subseteq M$ has measure zero in $M$, and $(U, \phi)$ is any coordinate chart for $M$, then $\phi(A \cap U)$ has measure zero in $\mathbb{R}^n$. This could have been taken as the definition of a subset of measure zero, but the condition of XI.23.1.16. is easier to check.

If $M$ is not second countable, what we have technically defined is a locally null subset of $M$. (This technicality may be safely ignored as irrelevant in our applications.) There is no analogous reasonable definition of a subset of measure zero in a topological manifold ($\ast$).

The next result is a straightforward corollary of XI.23.1.8.:

XI.23.1.18.  **Proposition.** Let $N$ and $M$ be $C^r$ $n$-manifolds ($r \geq 1$), with $N$ separable, and $f : N \to M$ a $C^r$ function. If $A$ is a subset of $N$ which has measure zero in $N$, then $f(A)$ has measure zero in $M$.

XI.23.1.19.  This result holds also if $N$ is $n$-dimensional and $M$ is $m$-dimensional with $n < m$ ($\ast$), but not necessarily if $m < n$.

**XI.23.2. Statement of Sard’s Theorem**

XI.23.2.1.  **Theorem.** [Sard’s Theorem] Let $N$ be a separable $C^r$ $n$-manifold, and $M$ a $C^r$ $m$-manifold, with $r \geq \max(n - m + 1, 1)$, and let $f : N \to M$ be a $C^r$ function. Then the set of singular values of $f$ is a subset of $M$ of measure zero in $M$.

XI.23.2.2.  We will prove special cases of the theorem separately before turning to the most general version. The special cases are written separately because the proof simplifies in these cases and sometimes a more general result holds. The cases we discuss are:

(i) $n < m$.

(ii) $n = m = 1$.

(iii) $n = m > 1$.

(iv) $n > m$, $r$ large.

(v) $n > m$, sharp $r$ bound.

Our proof is adapted from [Ste83] and [Hir94].

XI.23.2.3.  The first reduction in all cases is to note that $N$ can be covered by countably many coordinate charts, each of which is contained in the preimage of a coordinate chart in $M$, and since the union of countably many null sets is a null set and null sets are preserved under diffeomorphisms, it suffices to prove the theorem for $N = \mathbb{R}^n$ and $M = \mathbb{R}^m$. In fact, since $N$ is $\sigma$-compact, it suffices to prove the theorem for the set of singular values in the image of an arbitrary compact subset of $\mathbb{R}^n$. 1330
XI.23.2.4. The restriction that \( N \) be separable, i.e. that it has only countably many components, is necessary in general: if \( N \) has \( 2^{\aleph_0} \) components, a function from \( N \) to \( M \) can be surjective even if it is constant on each component of \( N \); such a function has identically zero derivative, and hence every point of \( M \) is a singular value.

XI.23.3. The Case \( n < m \)

XI.23.4. The Case \( n = m = 1 \)

XI.23.4.1. The simplest case is \( n = m = 1 \). Suppose \( f \) is a \( C^1 \) function from \( \mathbb{R} \) (or an open interval in \( \mathbb{R} \)) to \( \mathbb{R} \). The singular points of \( f \) are just the critical numbers (the \( x_0 \) for which \( f'(x_0) = 0 \)). It suffices to show that the image of the critical numbers in any closed bounded subinterval of the domain has measure zero in \( \mathbb{R} \).

So suppose \([a,b]\) is such an interval. Since \( f' \) is continuous on \([a,b]\), it is uniformly continuous there \((\ast)\). Fix \( \epsilon > 0 \). Then there is a \( \delta > 0 \) such that \(|f'(x) - f'(y)| < \epsilon \) whenever \( x, y \in [a,b], |x - y| < \delta \). Partition \([a,b]\) into subintervals \( I_k = [x_{k-1}, x_k] \) with \( \ell(I_k) = x_k - x_{k-1} < \delta \) for all \( k \). For every \( I_k \) containing a singular point of \( f \), we have \(|f'(x)| < \epsilon \) for all \( x \in I_k \). Thus by the Mean Value Theorem we have \(|f(x) - f(y)| < \epsilon \ell(I_k)\) for all \( x, y \in I_k \), for any such \( k \). Thus \( f(I_k) \) is contained in an interval \( J_k \) of length \( < \epsilon \ell(I_k) \) for any such \( k \) (actually \( f(I_k) \) is itself such an interval). Thus the set of singular values of \( f \) in \([a,b]\) is contained in a finite number of intervals of total length

\[
\sum_{k=1}^{n} \ell(J_k) < \epsilon \sum_{k=1}^{n} \ell(I_k) = \epsilon (b - a)
\]

and since \( \epsilon > 0 \) is arbitrary, this set of singular values has measure zero (in fact zero content) in \( \mathbb{R} \).

This completes the proof in the case \( n = m = 1 \). \( \diamond \)

The \( C^1 \) assumption on \( f \) can be weakened and even eliminated in this case. The following result is due to LUZIN (XIV.17.1.14.); we give an alternate proof due to S. IVANOV (http://mathoverflow.net/questions/113991/counterexample-to-sard-theorem-for-a-not-c1-map/114000#114000):

XI.23.4.2. Theorem. Let \( f \) be a function from \( \mathbb{R} \) (or an interval in \( \mathbb{R} \)) to \( \mathbb{R} \). Set

\[
\mathcal{C} = \{ x \in \mathbb{R} : f'(x) \text{ exists and equals 0} \}
\]

and let \( S = f(\mathcal{C}) \). Then \( S \) has measure zero in \( \mathbb{R} \).

Proof: We will use the Vitali Covering Theorem \((\ast)\). It suffices to show that the part of \( \mathcal{C} \) in \((a,b)\) has image of zero measure, for any bounded open interval \((a,b)\) in the domain of \( f \), so we may assume the domain of \( f \) is \((a,b)\) and hence that \( \mathcal{C} \) has finite outer measure. Fix \( \epsilon > 0 \). For every \( x_0 \in \mathcal{C} \), there is a \( \delta_0 \) such that \((x_0 - \delta_0, x_0 + \delta_0) \subseteq (a,b)\) and

\[
\left| \frac{f(x) - f(x_0)}{x - x_0} \right| < \frac{\epsilon}{5}
\]

for all \( x \) with \( |x - x_0| < \delta_0 \). Set

\[
\mathcal{I}_{x_0} = \left\{ \left( x - \delta, x + \frac{\delta}{5} \right) : 0 < \delta \leq \delta_0 \right\}
\]

1331
and let $I = \bigcup_{x_0 \in \mathbb{C}} I_{x_0}$. Then $\mathcal{I}$ is a Vitali covering of $\mathbb{C}$.

For each $I = (x_0 - \frac{\delta}{5}, x_0 + \frac{\delta}{5}) \in \mathcal{I}$, let $I'$ be the interval $(x_0 - \delta, x_0 + \delta)$ with the same midpoint as $I$ of five times the length. By (i) there is a sequence $(I_n)$ of disjoint sets in $\mathcal{I}$ such that the $I_n'$ cover $\mathbb{C}$. If $x \in I_n'$, and $x_n$ is the midpoint of $I_n$, then

$$|f(x) - f(x_n)| < \frac{\epsilon}{5} |x - x_n| < \frac{\epsilon}{5} \ell(I_n') = \frac{\epsilon}{5} \ell(I_n)$$

and thus, if $x, y \in I_n'$ we have

$$|f(x) - f(y)| \leq |f(x) - f(x_n)| + |f(x_n) - f(y)| < \epsilon \ell(I_n)$$

and so $f(I_n')$ is contained in an interval $J_n$ of length $\epsilon \ell(I_n)$. The $J_n$ cover $\mathcal{S}$.

Since the $I_n$ are disjoint, we have $\sum_n \ell(I_n) \leq b - a$, so

$$\sum_{n=1}^{\infty} \ell(J_n) = \epsilon \sum_{n=1}^{\infty} \ell(I_n) \leq \epsilon (b - a)$$

and since $\epsilon > 0$ is arbitrary, we have that $\mathcal{S}$ has measure zero in $\mathbb{R}$. 

XI.23.5. The Case $n = m > 1$

XI.23.6. The Case $n > m$, $r$ Large

We now show that the theorem holds for general $n$ and $m$ if $r$ is sufficiently large. Most importantly, this result applies for all $n$ and $m$ if $f$ is $C^\infty$. The estimate on the minimum $r$ from this argument is not sharp in general (it is quadratic in $n - m$, not linear). This proof is adapted from [Hir94].

XI.23.6.1. For $n, m \in \mathbb{N}$, define $s(n, m) \in \mathbb{N}$ as follows:

$$s(n, m) = \begin{cases} 1 & \text{if } n \leq m \text{ and } m + 1 \text{ divides } (n - m + 1)(n - m + 2) \\ \frac{1}{2} & \text{if } n > m \end{cases}.$$ 

The following properties needed for the proof of the theorem are easily verified:

XI.23.6.2. Proposition. The numbers $s(n, m)$ have the following properties:

(i) $s(n, m) > \frac{n}{m}$ if $n > m$.

(ii) $s(n, m) - k \geq s(n - 1, m)$ if $1 \leq k \leq \frac{n}{m}$.

(iii) $s(n, m) = s(n - 1, m - 1)$ if $m > 1$.

XI.23.6.3. Theorem. Let $n, m \in \mathbb{N}$. Then if $r \geq s(n, m)$, $N$ is a separable $C^r$ manifold, $M$ a $C^r$ $m$-manifold, and $f : N \to M$ is a $C^r$ function, then the set of singular values of $f$ is a subset of $M$ of measure zero in $M$. 

1332
XI.23.6.4. The proof will be by double induction: induction on \( m \), and for fixed \( m \) induction on \( n \). The cases \( n \leq m \) have already been proved (), so fix \( n \) and \( m \) and assume that \( n > m \) and that the theorem is proved for \((n - 1, m)\), and for \((n - 1, m - 1)\) if \( m > 1 \). If \( \Sigma \) is the set of singular points of \( N \), it suffices to show that every \( x_0 \in \Sigma \) has a neighborhood \( U \) such that \( f(\Sigma \cap U) \) has measure 0 in \( M \). Write

\[
\Sigma = \Sigma_1 \cup \Sigma_2 \cup \Sigma_3
\]

where

\( \Sigma_1 \) is the set of \( x_0 \in \Sigma \) for which all partial derivatives of \( f \) of orders \( \leq \frac{n}{m} \) vanish at \( x_0 \).

\( \Sigma_2 \) is the set of \( x_0 \in \Sigma \) such that the first-order partials of \( f \) vanish at \( x_0 \) but some partial derivative of \( f \) of order \( k \), \( 2 \leq k \leq \frac{n}{m} \), is nonzero at \( x_0 \).

\( \Sigma_3 \) is the set of \( x_0 \in \Sigma \) such that some first-order partial of \( f \) is nonzero at \( x_0 \).

XI.23.6.5. First suppose \( x \in \Sigma_1 \).

XI.23.6.6. Now suppose \( x_0 \in \Sigma_2 \), \( y_0 = f(x_0) \). For each multiindex \( \alpha \) of order \( k \), \( 2 \leq k < \frac{n}{m} \), set

\[
g_{\alpha,i} = \frac{\partial^n f_i}{\partial x_\alpha}
\]

where \( f_i \) is the \( i \)th coordinate function of \( f \). Then \( g_{\alpha,i} \) is \( C^q \), where

\[
q = r - k \geq s(n, m) - \frac{n}{m} \geq s(n - 1, m)
\]

For each multiindex \( \alpha \) of order \( k \), \( 2 \leq k < \frac{n}{m} \), and each \( i \) and \( j \), let \( X_{\alpha,i,j} \) be the set of points \( x \in \Sigma_2 \) such that \( g_{\alpha,i}(x) = 0 \) and \( \frac{\partial g_{\alpha,i}}{\partial x_j}(x) \neq 0 \). Then \( x_0 \in X_{\alpha,i,j} \) for some \( \alpha, i, j \).

Fix \( \alpha, i, j \) with \( x_0 \in X_{\alpha,i,j} \). Then, since \( g_{\alpha,i}(x_0) = 0 \) and \( \frac{\partial g_{\alpha,i}}{\partial x_j}(x_0) \neq 0 \), \( x_0 \) is a regular point of \( g_{\alpha,i} \). Thus there is a neighborhood \( U \) of \( x_0 \) such that 0 is a regular value of \( h_{\alpha,i} = g_{\alpha,i}|U \) and therefore \( Z_{\alpha,i} = h_{\alpha,i}^{-1}(\{0\}) \) is a \( C^q \)-submanifold of \( N \) of dimension \( n - 1 \) containing \( x_0 \). Since \( q \geq s(n - 1, m) \) and \( f|Z_{\alpha,i} \) is \( C^q \), the inductive hypothesis applies. Any point of \( \Sigma_2 \) which is in \( Z_{\alpha,i} \) is a singular point of \( f|Z_{\alpha,i} \); since its differential is zero, so we conclude that the measure of \( f(\Sigma_2 \cap Z_{\alpha,i}) \) is zero. Since \( X_{\alpha,i,j} \cap U \subseteq Z_{\alpha,i} \), we have that the measure of \( X_{\alpha,i,j} \cap U \) is zero. There is a neighborhood of \( x_0 \) in \( \Sigma_2 \) contained in a finite union of such sets for various \( \alpha, i, j \), so we conclude that the measure of \( f(\Sigma_2) \) is zero.

XI.23.6.7. If \( m = 1, \Sigma_3 = \emptyset \) so the proof is finished. If \( m > 1 \), suppose \( x_0 \in \Sigma_3 \), \( y_0 = f(x_0) \). By (), there are neighborhoods \( U \) of \( x_0 \) and \( V \) of \( y_0 \), and diffeomorphisms \( g : \mathbb{R}^{n-1} \times \mathbb{R} \to U \) and \( h : V \to \mathbb{R}^{m-1} \times \mathbb{R} \) with \( g(0, 0) = x_0 \), \( h(y_0) = (0, 0) \), such that \( \phi = h \circ f \circ g \) is of the form

\[
\phi(z, t) = (\psi(z, t), t)
\]

for some \( C^r \)-function \( \psi : \mathbb{R}^{n-1} \times \mathbb{R} \to \mathbb{R}^{m-1} \). The singular values of \( f \) in \( V \) are precisely the images under \( h^{-1} \) of the singular values of \( \phi \), so it suffices to show that the set \( S \) of singular values of \( \phi \) has measure 0. Fix \( t \), and let \( \omega_t : \mathbb{R}^{n-1} \to \mathbb{R}^{m-1} \) be defined by \( \omega_t(z) = \psi(z, t) \). Then \( \omega \) is \( C^r \), so by the inductive hypothesis
the set \( S_t \) of singular values of \( \omega_t \) has measure 0 in \( \mathbb{R}^{m-1} \). We have that \( z \) is a singular point of \( \omega_t \) if and only if \((z,t)\) is a singular point of \( \phi \), so

\[
S = \{(z,t) : t \in \mathbb{R}, z \in S_t \}.
\]

Thus by the Baby Tonelli Theorem (XI.23.1.11) \( S \) has measure zero in \( \mathbb{R}^m \times \mathbb{R} \).

This completes the proof of Theorem XI.23.6.3.

XI.23.7. The Case \( n > m \), Sharp \( r \) Bound

We now turn to the final and most delicate part of the theorem, establishing the sharp bound on \( r \). It is questionable whether it is worth proving this version, since the softer result XI.23.6.3. suffices for almost all applications. But the conceptual reason behind the sharp bound on \( r \) is important and instructive.

The reason for the sharp bound \( r \geq n - m + 1 \) is a higher-dimensional version of the following one-dimensional fact (cf. ()): XI.23.7.1. Proposition. Let \( f : \mathbb{R} \to \mathbb{R} \) be a \( C^r \) function (\( r \geq 0 \)). If \( f \) has a nonisolated zero at \( x_0 \), then \( f(x_0) = f'(x_0) = \cdots = f^{(r)}(x_0) = 0 \). It follows that \( f \) vanishes at \( x_0 \) at least to order \( r^+ \), i.e.

\[
\lim_{x \to x_0} \frac{f(x)}{(x - x_0)^r} = 0.
\]

Proof: If \( r = 0 \) there is nothing to prove. If \( r \geq 1 \), let \((x_n)\) be a sequence of zeroes of \( f \) converging to \( x_0 \). By Rolle’s Theorem, for each \( n \) there is a \( y_n \) between \( x_0 \) and \( x_n \) with \( f'(y_n) = 0 \). We have \( y_n \to x_0 \) by the Squeeze Theorem, so \( f'(x_0) = 0 \) since \( f' \) is continuous. If \( r > 1 \), repeat the argument using \( f' \) in place of \( f \) and the \( y_n \) in place of the \( x_n \) to conclude that \( f''(x_0) = 0 \), and continue inductively. The last statement follows from V.10.1.3.

XI.23.7.2. This result is sharp. If \( f(x) = \frac{|x|}{(\log |x|)^r} \sin(\log |x|) \) for \( x \neq 0 \) and \( f(0) = 0 \), then \( f \) is \( C^1 \) and has a nonisolated zero at 0, but vanishes only to order \( 1^+ \) at 0. There are similar counterexamples for larger \( r \).

XI.23.8. The Category Version

The following result is a simple corollary of the measure-theoretic version of Sard’s Theorem (cf. [Bro35]).

XI.23.8.1. Theorem. Let \( N \) be a separable \( C^r \) \( n \)-manifold, \( M \) a \( C^r \) \( m \)-manifold, and \( f : N \to M \) a \( C^r \) function, where \( r \geq \max(n - m + 1, 1) \). Then the set of singular values of \( f \) is a meager set in \( M \).

Proof: First note that the set of singular points of \( f \) is closed in \( N \): it is the set of \( x_0 \in N \) such that \( \text{Det}(Df(x_0)Df(x_0)^t) = 0 \). Thus, although the set of singular values of \( f \) need not be closed in \( M \), it is an \( F_\alpha \) (XI.11.7.11.), and has measure zero by XI.23.2.1.; thus it has empty interior (\( \) ), i.e. its complement in \( M \) is a dense \( G_\delta \).
**XI.23.8.2.** Corollary. Let $N$ be a separable $n$-manifold, $M$ an $m$-manifold, and $f : N \to M$ a $C^1$ function. If $n < m$, then the range of $f$ is a meager subset of $M$.

**XI.23.8.3.** These results apply to the case where $N$ and $M$ are Euclidean spaces. They imply that manifolds of different dimensions cannot be diffeomorphic; in particular, $\mathbb{R}^n$ and $\mathbb{R}^m$ are not diffeomorphic if $n \neq m$ (actually more is true: they cannot even be homeomorphic, cf. (i)).

**XI.23.9.** Counterexamples

The differentiability restrictions in Sard’s theorem are sharp (as long as only $C^r$ functions are considered for $r \in \mathbb{N}$; some relaxation is possible if more delicate degrees of differentiability are allowed, cf. [Bat93]). Even before any of the publications of A. P. Morse or Sard, H. Whitney [Whi35] described counterexamples to stronger statements.

**XI.23.9.1.** Whitney described a (highly nondifferentiable) parametrized curve $\gamma : [0, 1] \to \mathbb{R}^2$, with $\gamma$ injective, such that

$$\lim_{t \to t_0} \frac{|t - t_0|}{\|\gamma(t) - \gamma(t_0)\|} = 0$$

for every $t_0 \in [0, 1]$. Then the function $\gamma^{-1} : C = \gamma([0, 1]) \to [0, 1]$ has “zero derivative” at each point $a$ of $C$ in the sense that

$$\lim_{x \to a} \frac{\|\gamma^{-1}(x) - \gamma^{-1}(a)\|}{\|x - a\|} = 0$$

where the limit is taken within $C$. By Whitney’s Extension Theorem (i), $\gamma^{-1}$ extends to a $C^1$ function $f$ from $\mathbb{R}^2$ to $\mathbb{R}$; every point of $C$ is a critical point of $f$, so every number in $[0, 1]$ is a critical value.

As described in [Hir94], “This example leads to the following paradox: the graph of $f$ is a surface $S \subset \mathbb{R}^3$ on which there is an arc $A$, at every point of which the surface has a horizontal tangent plane, yet $A$ is not at a constant height. To make this more vivid, imagine that $S$ is a hill and $A$ a path on the hill. The Hill is level at every point of the path, yet the path goes up and down.” In fact, the path can be made to go monotonically up from bottom to top. We should point out that such a path would not be a very good route to follow to ascend the hill, since it has infinite arc length; in fact, its projection into the $xy$-plane has positive Lebesgue measure (the curve has Hausdorff dimension 2 and positive 2-dimensional Hausdorff measure). There cannot be a smooth path with this property because of the Chain Rule.

Whitney briefly described a higher-dimensional version, giving a $C^{n-1}$ function $f_n$ ($n \geq 2$) from $\mathbb{R}^n$ to $\mathbb{R}$ for which the set of critical values contains an interval. If $f_n$ is such a function, then for any $m$ the function $g_{n,m} : \mathbb{R}^{n+m-1} \to \mathbb{R}^m$ given by

$$g_{n,m}(x_1, \ldots, x_n, x_{n+1}, \ldots, x_{n+m-1}) = (f_n(x_1, \ldots, x_n), x_{n+1}, \ldots, x_{n+m-1})$$

is a $C^{n-1}$ function whose singular values contain an entire rectangle in $\mathbb{R}^m$.

**XI.23.9.2.** Here is a simpler example from [Gri85] for the case $n = 2$, $m = 1$.

We need a $C^1$ function $f$ from $\mathbb{R}$ to $\mathbb{R}$ for which every point of the Cantor set $K$ is a singular value. Here is one construction. Fix $\gamma$, $2 < \gamma < 3$, and let $\alpha = (\alpha_1, \alpha_2, \ldots)$ with $\alpha_n = \gamma^{-n}$. Construct the Cantor set $K_\alpha$ as in XI.17.2.1., i.e. subintervals of length $\gamma^{-n}$ are removed at each step. Let $(I_k)$ be a list of the removed
intervals. Let $\phi$ be a mesa function () on $[0,1]$ and $\beta = \int_0^1 \phi(t) \, dt$; then $0 < \beta < 1$. If the length of $I_k$ is $\gamma^{-n}$, let $h_k$ be a translated and scaled version of $\phi$ on $I_k$ whose integral is $3^{-n}$, i.e. scaled horizontally by $\gamma^{-n}$ and vertically by $\frac{1}{\beta} \left( \frac{2}{3} \right)^n$. Since

$$\lim_{n \to \infty} \left( \frac{2}{3} \right)^n = 0$$

we have that $\sum_{k=1}^{\infty} h_k$ converges uniformly to a continuous function $h$. Then $h(t) \geq 0$ for all $t \in \mathbb{R}$ and $h(t) = 0$ for all $t \in K_\alpha$, and for $t < 0$, $t > 1$.

Set $g(x) = \int_{-\infty}^x h(t) \, dt$. Then $g$ is a nondecreasing $C^1$ function on $\mathbb{R}$, $g(x) = 0$ for $x \leq 0$ and $g(x) = 1$ for $x \geq 1$, and $g(x) \in K$ for $x \in K_\alpha$. For each such $x$, $g'(x) = h(x) = 0$. Thus every point of $K$ is a critical value of $g$ (the converse holds too).

Let $f : \mathbb{R}^2 \to \mathbb{R}$ be defined by $f(x,y) = g(x) + g(y)$. Then $f$ is $C^1$, and if $x$ and $y$ are in $K_\alpha$, then $Df(x,y) = 0$. If $z \in [0,2]$, then there are $c,d \in K$ such that $z = c + d$ (Exercise XI.17.3.1). There are $x,y \in K_\alpha$ with $g(x) = c$ and $g(y) = d$; so $f(x,y) = z$ and $z$ is a critical value, hence singular value, of $f$. Thus the set of singular values of $f$ does not have measure zero in $\mathbb{R}$. (Actually $[0,2]$ is the entire range of $f$, and consists of singular values.)

Note that $h$ is not differentiable everywhere, hence $g$, and therefore $f$, are not $C^2$; of course a $C^2$ function with this property cannot exist by Sard’s Theorem.

### XI.23.10. Applications

#### XI.23.10.1. Theorem. Let $X$ be a compact subset of $\mathbb{R}^n$. Then for any $\epsilon > 0$ there is an open neighborhood $U$ of $X$ in $\mathbb{R}^n$ with $\partial U$ a smooth submanifold of $\mathbb{R}^n$ (i.e. $\partial U$ is a compact smooth submanifold with boundary), such that $\rho(y,X) < \epsilon$ for all $y \in U$, $U$ contains all $y \in \mathbb{R}^n$ with $\rho(y,X) < \frac{\epsilon}{4}$, and, for every $y \in \partial U$, $\frac{\epsilon}{4} \leq \rho(y,X) < \epsilon$.

**Proof:** Let $V = \{ y \in \mathbb{R}^n : \rho(y,X) < \epsilon \}$. Then $V$ is a neighborhood of $X$ in $\mathbb{R}^n$ with compact closure. Define $g : \mathbb{R}^n \to \mathbb{R}$ by $g(y) = \rho(y,X)$; then $g$ is continuous. Let $f$ be a $C^\infty$ function from $\mathbb{R}^n$ to $\mathbb{R}$ (e.g. a polynomial in the coordinates) uniformly approximating $g$ within $\frac{\epsilon}{4}$ on $\bar{V}$; there is such an $f$ by the Stone-Weierstrass Theorem (). There is a regular value $\alpha$ for $f$ with $\frac{\epsilon}{2} < \alpha < \frac{4\epsilon}{3}$ by Sard’s Theorem. Set

$$U = \{ y \in V : f(y) < \alpha \} .$$

Then $U$ is open. Since for $y \in \bar{V}$ we have $f(y) - \frac{\epsilon}{4} < \rho(y,X) < f(y) + \frac{\epsilon}{4}$, we have that $\bar{U} \subseteq V$, so

$$\partial U = \{ y \in V : f(y) = \alpha \}$$

is a smooth closed submanifold of $\mathbb{R}^n$, and the desired inequalities follow.

#### XI.23.10.2. In fact the $\frac{\epsilon}{4}$ can be replaced by any $\eta < \epsilon$ by a suitable modification of the proof.

#### XI.23.10.3. In the case $n = 2$, if $X$ is a compact subset of the plane there is for any $\epsilon > 0$ an $\epsilon$-neighborhood $U$ of $X$ in $\mathbb{R}^2$ whose boundary consists of finitely many disjoint smooth closed curves. (Such a neighborhood is not necessarily homeomorphic to a disjoint union of closed disks, however, e.g. if $X$ is a circle.) See XI.23.11.3. for a constructive proof not using Sard’s Theorem.
XI.23.11. Exercises

XI.23.11.1. Carefully justify all the assertions in XI.23.1.3., i.e. show that adding each of the various restrictions or modifications to the definition does not change the class of null sets.

XI.23.11.2. Show that if $C$ is any Cantor set in $\mathbb{R}$ of Lebesgue measure 0, there is a $C^1$ function $f : \mathbb{R} \to \mathbb{R}$ whose set of critical values is $C$. [Write $C = C_\lambda$ as in XI.17.2.9., and mimic the argument of XI.23.9.2., using IV.2.16.5.]

XI.23.11.3. Give a constructive proof of the case $n = 2$ of XI.23.10.1., as follows.
(a) Show that the diameter of a regular hexagon of side $s$ is $2s$. [Write the hexagon as a union of six equilateral triangles.]
(b) If $X$ is a compact subset of $\mathbb{R}^2$ and $V$ is an open neighborhood of $X$, there is a bounded open neighborhood $W$ of $X$ contained in $V$. Let $\epsilon$ be the distance between $X$ and $\partial W$. Show that $\epsilon > 0$.
(c) Cover the plane with a hexagonal honeycomb with sides of length $s < \frac{\epsilon}{4}$, and let $A$ be the union of all the closed hexagons which are contained in $W$. Show that $X$ is contained in the interior $U$ of $A$.
(d) Show that $\partial A = \partial U$ consists of finitely many disjoint simple closed polygonal curves.
(e) If desired, the corners of these boundary curves can be rounded off to give smooth boundary curves.
(f) Try to do the same argument using squares (try staggering the squares so no four edges meet at a point), and try generalizing to $\mathbb{R}^n$. 

1337
XI.24. Piecewise-Linear Topology

The idea behind piecewise-linear (PL) topology is to reduce the study of the topology of “reasonable” subsets of Euclidean space, and eventually all “reasonable” (e.g. compact metrizable) topological spaces, to the affine structure of $\mathbb{R}^n$. This is clearly possible in principle since the affine structure on $\mathbb{R}^n$ determines its topological structure, and it turns out in practice to be a slick and clever way to express many topological notions in essentially combinatorial language.

PL topology has somewhat passed out of fashion. However, the basic setup (which is all we will do here, what topologists would consider to be “preliminaries”) consisting of polyhedra and simplicial complexes and their maps, is material every mathematician should be familiar with.

The standard reference for PL topology is [RS72], on which much of our exposition is based.

XI.24.1. Polyhedra, Cells, and Simplexes

The term “polyhedron” traditionally refers to a three-dimensional figure made up of a finite number of vertices, edges, and faces; it is the three-dimensional analog of a polygon. We will use the term in a somewhat different sense, applying to objects of arbitrary dimension; thus (most) polyhedra in the traditional sense will be polyhedra in our sense, as will be polygons in the plane, closed intervals, points, and analogous higher-dimensional figures.

There is an ambiguity in the usual use of terms like “polyhedron,” “polygon,” “triangle,” “square,” etc.: do we include the “interior” or just the “surface”? Our definition of polyhedron will include both cases, although when a specific polyhedron is considered we must carefully specify which we mean. For example, a solid triangle (homeomorphic to a disk) and a triangle not including the interior (homeomorphic to a circle) will both be polyhedra; the first is a 2-dimensional polyhedron and the second a 1-dimensional polyhedron.

Cells

XI.24.1.1. Definition. A cell in $\mathbb{R}^n$ is a compact convex set with only finitely many extreme points. An extreme point of a cell is called a vertex of the cell. (The plural of vertex is vertices.) The dimension of a cell is the dimension of the affine subspace it generates.

XI.24.1.2. Since a compact convex subset of $\mathbb{R}^n$ is the convex hull of its extreme points ($\{\}$), a cell is precisely the convex hull of a finite set $S$ of points in $\mathbb{R}^n$. (Note, however, that not all the points of $S$ are necessarily vertices of the cell defined by $S$, although each vertex of the cell is in $S$.)

XI.24.1.3. Example. A rectangle (product of intervals) is a cell. A rectangle whose sides all have the same length is called a cube.

It is convenient in PL-topology to use the $\rho_{\infty}$ metric on $\mathbb{R}^n$. The closed balls in this metric are cubes, hence cells. A closed ball in the usual $\rho_2$ metric, or the $\rho_p$ metric for $1 < p < \infty$, is not a cell except in $\mathbb{R}^1$, since it has infinitely many extreme points.

XI.24.1.4. If a cell $C$ in $\mathbb{R}^m$ has $n + 1$ vertices $v_0, v_1, \ldots, v_n$, then the affine subspace it generates is parallel to the subspace spanned by $\{v_1 - v_0, \ldots, v_n - v_0\}$, hence the dimension of $C$ is the dimension of this subspace, which is $\leq n$. It can be strictly less than $n$ (e.g. for a convex polygon in $\mathbb{R}^2$).
XI.24.1.5. Recall () that a face of a convex set \( C \) is a subset \( F \) such that, whenever an interior point of a line segment in \( C \) is in \( F \), the endpoints of the segment are in \( F \). We have easily from () (or with an elementary proof):

XI.24.1.6. Proposition. Let \( C \) be a cell in \( \mathbb{R}^n \), and \( F \) a face of \( C \). Then \( F \) is also a cell, and the vertices of \( F \) are a subset of the vertices of \( C \). The dimension of \( F \) is strictly smaller than the dimension of \( C \) if \( F \) is a proper face of \( C \).

XI.24.1.7. Not every set of vertices of a cell \( C \) determines a face: for example, if \( C \) is a (solid) square in \( \mathbb{R}^2 \), the faces are just the vertices, the edges, and the whole square. Two opposite vertices do not determine a face.

XI.24.1.8. Proposition. Let \( C \) be a cell in \( \mathbb{R}^n \) and \( y \in C \). Let \( F_y \) be the smallest face of \( C \) containing \( y \). Then \( F_y \) is either \( \{y\} \) or the union \( F \) of all line segments in \( C \) containing \( y \) in the interior.

Proof: If \( F \) is empty, then \( y \) is an extreme point of \( C \) and \( F_y = \{y\} \). Suppose \( F \neq \emptyset \). By definition, any face containing \( y \) contains \( F \), so we need only show that \( F \) is a face of \( C \). To show \( F \) is convex, suppose \( a \) and \( b \) are in \( F \), and that \( c \) is a convex combination of \( a \) and \( b \). There are line segments \( \overline{ad} \) and \( \overline{be} \) in \( C \) containing \( y \) in their interior. Let \( Q \) be the quadrilateral in the plane generated by \( \overline{bd} \) and \( \overline{be} \) with vertices \( a, b, d, \) and \( e \); then \( Q \subseteq C \) by convexity. Let \( L \) be the line through \( c \) and \( y \). Then \( L \cap C \) contains \( L \cap Q \), which is a line segment with \( y \) in its interior. Thus \( c \in F \) and \( F \) is convex.

Now suppose \( a, b \in C \), and \( c \) is a (nontrivial) linear combination of \( a \) and \( b \) which is in \( F \). Then there is a line segment \( \overline{cd} \) in \( C \) containing \( y \) in its interior. Let \( T \) be the triangle (in the plane generated by \( \overline{ab} \) and \( \overline{cd} \) with vertices \( a, b, \) and \( d \); then \( T \subseteq C \) by convexity. If \( L \) is the line through \( a \) and \( y \), then \( L \cap C \) contains \( L \cap T \), which is a line segment containing \( y \) in its interior. Thus \( a \in F \). Similarly \( b \in F \). So \( F \) is a face of \( C \).

XI.24.1.9. If \( C \) is a cell in \( \mathbb{R}^n \), let \( \hat{C} \) be the set of all points of \( C \) not contained in any proper face of \( C \), and \( \hat{C} \) the union of the proper faces of \( C \). Then \( C \) and \( \hat{C} \) are called the interior and boundary of \( C \) respectively (they are the topological interior and topological boundary of \( C \) in the affine subspace it generates with the relative topology). The interior \( C \) is nonempty: if \( v_1, \ldots, v_m \) are the vertices of \( C \), then \( \hat{C} \) contains all points of the form \( \sum_{k=1}^m \lambda_k v_k \) where all \( \lambda_k > 0 \) (and \( \sum_{k=1}^m \lambda_k = 1 \)). In fact, \( C \) is precisely this set. \( \hat{C} \) is a relatively open subset of \( C \), and \( \hat{C} = C \setminus \hat{C} \) is compact.

XI.24.1.10. Proposition. Let \( C \) be a cell in \( \mathbb{R}^n \), and \( f : \mathbb{R}^n \rightarrow \mathbb{R}^m \) an affine function. Then \( f(C) \) is a cell in \( \mathbb{R}^m \).

Proof: If \( v_1, \ldots, v_m \) are the vertices of \( C \), then \( f(C) \) is exactly the convex hull of \( \{f(v_1), \ldots, f(v_m)\} \), hence a cell. (But \( f(v_k) \) is not necessarily a vertex of \( f(C) \) for every \( k \)).

1339
XI.24.1.11. PROPOSITION. Let $C$ be a convex subset of $\mathbb{R}^n$. Then $C$ is a cell if and only if $C$ is a finite intersection of (closed) half-spaces.

One direction of this is proved in XI.24.1.31., and the converse in Exercise XI.24.5.1.

Simplexes

XI.24.1.12. DEFINITION. An $n$-simplex is an $n$-dimensional cell with exactly $n + 1$ extreme points. A simplex is an $n$-simplex for some $n$.

The plural of simplex should properly be simplices, but (unlike with vertex) the anglicized plural simplexes has come into general use.

XI.24.1.13. PROPOSITION. Let $C$ be a cell in $\mathbb{R}^m$ with vertices $v_0, \ldots, v_n$. Then the following are equivalent:

(i) $C$ is an $n$-simplex.

(ii) The set $\{v_1 - v_0, \ldots, v_n - v_0\}$ is linearly independent in $\mathbb{R}^m$.

(iii) Every $a \in C$ can be uniquely written as a convex combination $a = \sum_{k=0}^{n} \lambda_k v_k$

with all $\lambda_k \geq 0$ and $\sum_{k=0}^{n} \lambda_k = 1$.

PROOF: (i) $\iff$ (ii): This follows immediately from XI.24.1.4., since $C$ is $n$-dimensional if and only if $\{v_1 - v_0, \ldots, v_n - v_0\}$ spans an $n$-dimensional subset of $\mathbb{R}^m$.

(ii) $\Rightarrow$ (iii): Since $C$ is a cell, every element of $C$ can be written as a convex combination of the $v_k$. So if (iii) is false, there are $(\lambda_0, \ldots, \lambda_n) \neq (\mu_0, \ldots, \mu_n)$ satisfying the conditions of (iii) with

$$0 = \sum_{k=0}^{n} \lambda_k v_k = \sum_{k=0}^{n} \mu_k v_k$$

$$0 = \sum_{k=0}^{n} (\lambda_k - \mu_k) v_k = \sum_{k=1}^{n} (\lambda_k - \mu_k) (v_k - v_0) + \sum_{k=0}^{n} (\lambda_k - \mu_k) v_0 = \sum_{k=1}^{n} (\lambda_k - \mu_k) (v_k - v_0)$$

since $\sum_{k=0}^{n} (\lambda_k - \mu_k) = 0$ because $\sum_{k=0}^{n} \lambda_k = \sum_{k=0}^{n} \mu_k = 1$. So $\{v_1 - v_0, \ldots, v_n - v_0\}$ is not linearly independent.

(iii) $\Rightarrow$ (ii):

XI.24.1.14. If $C$ is a simplex, the numbers $\lambda_k$ for which $a = \sum_{k=0}^{n} \lambda_k v_k$ are called the barycentric coordinates of $a$ in $C$. These are indexed by the vertices of $C$, i.e. $\lambda_k$ is the barycentric coordinate of $a$ with respect to $v_k$ (in $C$). If $C$ is not a simplex, then barycentric coordinates are not well defined since some points can be written in more than one way as convex combinations of the vertices.
XI.24.1.15. In $\mathbb{R}^{n+1}$, let $\Sigma_n$ be the convex hull of the set of standard basis vectors $\{e_0, \ldots, e_n\}$ (it is convenient here to index the coordinates from 0 to $n$ rather than from 1 to $n+1$). Then

$$\Sigma_n = \left\{ (\lambda_0, \ldots, \lambda_n) \in \mathbb{R}^{n+1} : \lambda_k \geq 0, \sum_{k=0}^{n} \lambda_k = 1 \right\}$$

is called the standard $n$-simplex. If $S$ is any $n$-simplex in $\mathbb{R}^m$ with vertices $v_0, \ldots, v_n$, then there is a unique affine map $\phi : \mathbb{R}^{n+1} \to \mathbb{R}^m$ with $\phi(e_k) = v_k$ for each $k$, which maps $\Sigma_n$ homeomorphically onto $S$. Thus every $n$-simplex “looks the same” and is affinely homeomorphic to the standard $n$-simplex.

We sometimes regard the simplex in $\mathbb{R}^n$ with vertices $0, e_1, \ldots, e_n$, i.e.

$$\left\{ (\lambda_1, \ldots, \lambda_n) : \lambda_k \geq 0, \sum_{k=1}^{n} \lambda_k \leq 1 \right\}$$

as the standard $n$-simplex. There is an obvious affine homeomorphism between this simplex and $\Sigma_n$.

A 0-simplex is a single point. A 1-simplex is a (closed) line segment. A 2-simplex is a (solid) triangle. A 3-simplex is a (solid) tetrahedron.

XI.24.1.16. If $S$ is an $n$-simplex with vertices $v_0, \ldots, v_n$, and $w_0, \ldots, w_n$ are any $n+1$ points in $\mathbb{R}^m$, then there is a unique affine function $f$ from $S$ onto the convex hull of $\{w_0, \ldots, w_n\}$ with $f(v_k) = w_k$ for all $k$. The obvious formula is

$$f \left( \sum_{k=0}^{n} \lambda_k v_k \right) = \sum_{k=0}^{n} \lambda_k w_k$$

for $\lambda_k \geq 0$, $\sum_{k=0}^{n} \lambda_k = 1$.

XI.24.1.17. Proposition. Every simplex is a finite intersection of (closed) half-spaces.

Polyhedra

XI.24.1.18. Definition. A polyhedron is a subset of some $\mathbb{R}^n$ which is a finite union of cells.

This is not the way the definition of a polyhedron is usually expressed in PL topology, but is equivalent (in the compact case). The PL definition (XI.24.1.34.) is hard to motivate geometrically, so we have chosen this alternative definition.

XI.24.1.19. Definition. Let $B$ be a (usually compact) subset of $\mathbb{R}^n$, and $a$ a point of $\mathbb{R}^n$ not in $B$. The join $aB$ of $a$ and $B$ is the union of all line segments in $\mathbb{R}^n$ between $a$ and a point of $B$. The join is a cone with vertex $a$ and base $B$ if every $x \in aB \setminus \{a\}$ can be uniquely written as $\lambda a(1 - \lambda)b$ for some $b \in B$ and $0 \leq \lambda < 1$.

XI.24.1.20. It is easily seen that $aB$ is a cone if and only if every ray beginning at $a$ intersects $B$ in at most one point. A cone $aB$ is compact if $B$ is compact.
XI.24.1.21. Definition. Let $X$ be a subset of $\mathbb{R}^n$, $a \in X$, and $\epsilon > 0$. Set

$$N_\epsilon(a, X) = \{ x \in X : \rho_\infty(a, x) \leq \epsilon \}$$

$$\hat{N}_\epsilon(a, X) = \{ x \in X : \rho_\infty(a, x) = \epsilon \}$$

$$\check{N}_\epsilon(a, X) = \{ x \in X : \rho_\infty(a, x) < \epsilon \} .$$

Then $\hat{N}_\epsilon(a, X)$ is an open neighborhood of $a$ in $X$, and $N_\epsilon(a, X)$ is a closed neighborhood of $a$ in $X$. If $N_\epsilon(a, X)$ is a cone with vertex $a$ and base $\hat{N}_\epsilon(a, X)$, $\check{N}_\epsilon(a, X)$ is called the $\epsilon$-star of $a$ in $X$; if not, the $\epsilon$-star of $a$ in $X$ is not defined. $X$ is locally conical if for every $a \in X$ there is an $\epsilon$-star of $a$ in $X$ for some $\epsilon > 0$.

The set $N_\epsilon(a, X)$ is the intersection of $X$ with a cube of side $2\epsilon$ centered at $a$, and $\check{N}_\epsilon(a, X)$ is the intersection of $X$ with the boundary of this cube.

If $a$ has an $\epsilon$-star in $X$, it also has an $\epsilon'$-star for any $\epsilon' < \epsilon$.

Roughly speaking, a set $X$ in $\mathbb{R}^n$ is locally conical if every point $a$ of $X$ has a neighborhood $U$ in $\mathbb{R}^n$ such that $X \cap U$ is a union of ray segments with endpoint $a$ with lengths bounded away from zero.

XI.24.1.22. Examples. (i) Any open set in $\mathbb{R}^n$ is locally conical: if $U$ is open and $a \in U$, then for sufficiently small $\epsilon > 0$ $N_\epsilon(a, U)$ is an entire closed cube centered at $a$.

(ii) Any affine subspace or half-space in $\mathbb{R}^n$ is locally conical: in fact, any point in such a subset has an $\epsilon$-star for every $\epsilon > 0$.

(iii) A polygon in $\mathbb{R}^2$, with or without interior, is locally conical.

(iv) A circle is not locally conical: in fact, no point has an $\epsilon$-star for any $\epsilon > 0$. Similarly, a closed disk is not locally conical.

The important fact justifying our nonstandard definition of polyhedron is:

XI.24.1.23. Theorem. Let $X$ be a compact subset of $\mathbb{R}^m$. The following are equivalent:

(i) $X$ is a polyhedron.

(ii) $X$ is a finite union of simplexes.

(iii) $X$ is locally conical.

The theorem will be proved using some lemmas.

XI.24.1.24. Lemma. Let $X_1, \ldots, X_n$ be subsets of $\mathbb{R}^m$, $X = \bigcap_{k=1}^n X_k$, and $a \in X$. If $N_{\epsilon_k}(a, X_k)$ is an $\epsilon_k$-star of $a$ in $X_k$ for each $k$, and $\epsilon = \min(\epsilon_1, \ldots, \epsilon_n)$, then $N_\epsilon(a, X) = \bigcap_{k=1}^n N_\epsilon(a, X_k)$ is an $\epsilon$-star of $a$ in $X$.

Proof: Obvious from the fact that $N_\epsilon(a, X_k)$ is an $\epsilon$-star of $a$ in $X_k$ for all $k$. ☐
Let $a \in X$. By renumbering, suppose $a \in \cap_{k=1}^r X_k$ and $x \notin \cup_{k=r+1}^n X_k$. Let $N_{\epsilon_k}(a, X_k)$ be an $\epsilon_k$-star of $a$ in $X_k$ for $1 \leq k \leq r$. Choose $\epsilon > 0$ so that $\epsilon \leq \epsilon_k$ for $1 \leq k \leq r$ and $\epsilon < \rho_{\infty}(a, \cup_{k=r+1}^n X_k)$. Then it is easily checked that $N_\epsilon(a, X)$ is an $\epsilon$-star of $a$ in $X$.

**Lemma.** Every simplex is locally conical.

Proof: A half-space is locally conical (XI.24.1.22.(ii)); thus any simplex is locally conical by XI.24.1.17. and XI.24.1.25.

**Lemma.** Let $C$ be a cell in $\mathbb{R}^n$, and $a \in C$. Then $C$ is the union of cones of the form $aF$, where $F$ is a face of $C$ not containing $a$.

Proof: Let $x \in C$, $x \neq a$. If $R$ is the ray starting at $a$ through $x$, then $R \cap C$ is a segment from $a$ to a point $y$. The face $F_y$ (XI.24.1.8.) cannot contain $a$ since there is no line segment in $C$ through $a$ and $y$ containing $y$ in its interior (and $y \neq a$). Thus $x$ is in the union of the sets $aF$. Such a set is a cone, since if a ray from $a$ intersects a face $F$ in points $z$ and $z'$ with $z$ between $a$ and $z'$, by definition of a face $F$ must contain $a$.

**Proof of XI.24.1.23:** We have (ii) $\Rightarrow$ (iii) by XI.24.1.27. and XI.24.1.26., and (ii) $\Rightarrow$ (i) is trivial.

(i) $\Rightarrow$ (ii): By XI.24.1.26., it suffices to show that every cell is a finite union of simplexes. We prove this by induction on the dimension of the cell. If $C$ is a cell of dimension $\leq 1$, then $C$ is a point or line segment, hence a simplex. Now suppose all cells of dimension $< n$ are unions of simplexes, and let $C$ be a cell of dimension $n$. If $a \notin C$, then by XI.24.1.28. $C$ is a (finite) union of cones of the form $aF$, where $F$ is a face of $C$ not containing $a$. Each such $F$ is a cell of dimension $< n$, hence a finite union of simplexes $S_1, \ldots, S_r$. Then $aF$ is the union of $aS_1, \ldots, aS_r$, each of which is a simplex by (i).

It remains to show (iii) $\Rightarrow$ (ii). This will be shown by induction on the dimension of the Euclidean space containing the set. A compact locally conical subset of $\mathbb{R}^1$ is a finite union of points and closed line segments, each of which is a simplex. Now suppose all compact locally conical subsets of Euclidean spaces of dimension less than $n$ are finite unions of simplexes. Let $X$ be a compact locally conical subset of $\mathbb{R}^n$. To show that $X$ is a finite union of simplexes, it suffices to show that for every $a \in X$, an $\epsilon$-star of $a$ in $X$ is a finite union of simplexes for some $\epsilon = \epsilon_a$. For then the sets $N_{\epsilon_a}(a, X)$ form an open cover of $X$ which has a finite subcover. So suppose $N_\epsilon(a, X)$ is an $\epsilon$-star. Let $F$ be a proper face of the closed cube $\{x \in \mathbb{R}^n : \rho(a, x) \leq \epsilon\}$. Then $F$ is compact and locally conical, and thus $X \cap F$ is compact and locally conical by XI.24.1.25. Since $X \cap F$ is contained in a Euclidean space of dimension less than $n$, it is a finite union of simplexes. Then $N_\epsilon(a, X)$,
which is a finite union of the $X \cap F$, is a finite union of simplexes $S_1, \ldots, S_r$. But then $N_\epsilon(a, X)$ is the union of $aS_1, \ldots, aS_r$, each of which is a simplex by ()

This completes the proof of XI.24.1.23.

Here is a consequence which is not at all obvious directly from the definition:

**XI.24.1.29. Corollary.** A finite intersection of polyhedra is a polyhedron.

**Proof:** A finite intersection of polyhedra is compact, and locally conical by XI.24.1.25.

**XI.24.1.30. Proposition.** Let $X$ be a polyhedron in $\mathbb{R}^n$. Then the convex hull of $X$ is a cell. In particular, a convex polyhedron is a cell.

**Proof:** $X$ is a finite union of cells $C_1, \ldots, C_r$. Let $S$ be the set of all extreme points of $C_1, \ldots, C_r$. Then $S$ is a finite set and the convex hull of $S$ is the convex hull of $X$.

We then obtain one direction of XI.24.1.11.:

**XI.24.1.31. Corollary.** Let $X$ be a compact set in $\mathbb{R}^n$ which is a finite intersection of half-spaces. Then $X$ is a cell.

**Proof:** By XI.24.1.25., $X$ is locally conical, hence a polyhedron, and $X$ is also convex.

**XI.24.1.32.** Let $X$ be a subset of $\mathbb{R}^n$. If $a \in X$, a star of $a$ in $X$ is a closed neighborhood of $a$ in $X$ which is a cone of the form $aL$, where $L$ is a compact subset of $X$ not containing $a$ ($L = \emptyset$ is allowed, in which case $aL = \{a\}$). An $\epsilon$-star of $a$ in $X$ is a star with $L = N_\epsilon(a, X)$ provided this set is compact (e.g. if $X$ is compact).

**XI.24.1.33. Proposition.** Let $X \subseteq \mathbb{R}^n$. Then every point of $X$ has a star if and only if $X$ is locally compact and locally conical.

**Proof:** If $X$ is locally compact and locally conical, and $a \in X$, then $\mathcal{N}_\epsilon(a, X)$ is compact for sufficiently small $\epsilon$, so $a$ has a star. Conversely, if $aL$ is a star of $a$, it is a compact neighborhood of $a$, and $N_\epsilon(a, X)$ is an $\epsilon$-star for any $\epsilon < \rho_\infty(a, L)$, so if every point of $X$ has a star, then $X$ is locally compact and locally conical.

**XI.24.1.34.** In PL topology, a polyhedron is defined to simply be a subset of $\mathbb{R}^n$ in which every point has a star, i.e. a locally compact locally conical subset. While it is useful in PL topology to consider locally conical sets (polyhedra) which are not compact, we will not need to do so, so to avoid having to constantly write “compact polyhedron" we will require polyhedra to be compact.
XI.24.2. Complexes

XI.24.2.1. Definition. A cell complex in $\mathbb{R}^n$ is a finite collection $\mathcal{K}$ of cells in $\mathbb{R}^n$ with the following properties:

(i) If $C \in \mathcal{K}$ and $F$ is a face in $C$, then $F \in \mathcal{K}$.

(ii) If $C_1, C_2 \in \mathcal{K}$ then $C_1 \cap C_2$ is a face of both $C_1$ and $C_2$ (we make the convention that $\emptyset$ is a face of every cell, so $C_1 \cap C_2 = \emptyset$ is allowed).

The dimension of $\mathcal{K}$ is maximum of the dimensions of the cells of $\mathcal{K}$.

The vertices of $\mathcal{K}$ are the 0-cells of $\mathcal{K}$ and the edges of $\mathcal{K}$ are the 1-cells.

If $\mathcal{K}$ is a cell complex in $\mathbb{R}^n$, the union of the cells in $\mathcal{K}$ is a polyhedron in $\mathbb{R}^n$ denoted $|\mathcal{K}|$.

A cell complex $\mathcal{K}$ is a collection of cells that fit together nicely. The cell complex $\mathcal{K}$ can be thought of as the polyhedron $|\mathcal{K}|$ with a specified nice subdivision of $|\mathcal{K}|$ into cells. The vertices of $\mathcal{K}$ are the extreme points of the cells in $\mathcal{K}$.

Infinite cell complexes are often used in topology, but for simplicity we will make the convention that cell complexes are finite.

XI.24.2.2. Definition. A simplicial complex in $\mathbb{R}^n$ is a cell complex in which every cell is a simplex.

A triangulation of a polyhedron $X$ is a simplicial complex $\mathcal{K}$ with $|\mathcal{K}| = X$.

A simplicial complex in $\mathbb{R}^n$ is often called a geometric simplicial complex to distinguish it from an abstract simplicial complex (XI.24.2.12.), which is a combinatorial object.

We will work almost exclusively with simplicial complexes.

XI.24.2.3. Examples. (i) Any cell $C$ can be regarded as a cell complex $\mathcal{C}$ consisting of all faces of $C$. Then $\mathcal{C} = |\mathcal{C}|$. In particular, any simplex $S$ can be regarded as a simplicial complex $\mathcal{S}$ consisting of the faces of $S$. $\mathcal{S}$ is a triangulation of $S$.

(ii) Let $X$ be a finite union of line segments in $\mathbb{R}^n$, such that any two of the line segments are either disjoint or have only an endpoint in common. Then $X$ is a polyhedron which is the underlying space of a simplicial complex $\mathcal{K}$ consisting of the line segments and their endpoints (plus $\emptyset$); $\mathcal{K}$ is a triangulation of $X$. In particular, any (simple) polygon in $\mathbb{R}^2$, not including interior, is the underlying space of a simplicial complex. (A simple closed polygon including interior is also the underlying space of a simplicial complex, although this is somewhat harder to show (i).)

Subcomplexes

XI.24.2.4. Definition. Let $\mathcal{K}$ be a cell complex. A subcomplex of $\mathcal{K}$ is a subset of $\mathcal{K}$ which is itself a cell complex.

A subset $\mathcal{K}'$ of a complex $\mathcal{K}$ is a subcomplex if and only if, whenever $C \in \mathcal{K}'$, then all faces of $C$ are also in $\mathcal{K}'$. A subcomplex of a simplicial complex is a simplicial complex.

There are important special subcomplexes of any complex:
XI.24.2.5. Definition. Let $K$ be a cell complex, and $d \in \mathbb{N} \cup \{0\}$. The collection $K_d$ of all cells in $K$ of dimension $\leq d$ is a subcomplex of $K$ called the $d$-skeleton of $K$.

Thus the 0-skeleton consists of the vertices, the 1-skeleton the vertices and edges, etc.

Subdivisions

XI.24.2.6. Definition. Let $K$ and $K'$ be cell complexes. $K'$ is a subdivision of $K$ if $|K'| = |K|$ and every cell in $K'$ is contained in a cell in $K$.

It is easily seen that $K'$ is a subdivision of $K$ if and only if each cell in $K$ is a union of cells in $K'$.

Simplicial Maps

XI.24.2.7. Definition. (i) Let $K$ be a cell complex in $\mathbb{R}^n$. A function $f : |K| \to \mathbb{R}^m$ is simplicial (with respect to $K$), or a simplicial map, if the restriction of $f$ to each cell of $K$ is affine.

(ii) Let $K$ and $K'$ be cell complexes. A function $f : |K| \to |K'|$ is simplicial (with respect to $K$ and $K'$) if the image of each cell in $K$ is contained in a cell of $K'$ and the restriction of $f$ to each cell of $K$ is affine.

A simplicial isomorphism between cell complexes $K$ and $K'$ is a bijection $f$ between $|K|$ and $|K'|$ such that $f$ and $f^{-1}$ are simplicial.

XI.24.2.8. A simplicial map is continuous by (), since each cell is closed in $|K|$ and the restriction to each cell is continuous. A composition of simplicial maps is simplicial.

XI.24.2.9. Examples. (i) If $K'$ is a subcomplex of $K$, the inclusion map from $|K'|$ to $|K|$ is simplicial for $K'$ and $K$.

(ii) If $K'$ is a subdivision of $K$, the identity map on $|K'| = |K|$ is simplicial for $K'$ and $K$. But it is not simplicial for $K$ and $K'$ unless $K' = K$.

(iii) Let $P$ be a (simple closed) polygon in $\mathbb{R}^2$, not including interior, with $n$ sides. Then $P$ can be regarded as a simplicial complex $\mathcal{P}$ with $n$ 0-simplexes (the vertices) and $n$ 1-simplexes (the sides). If $Q$ is another polygon with $n$ sides, regarded as a simplicial complex $\mathcal{Q}$, then $\mathcal{P}$ and $\mathcal{Q}$ are simplicially isomorphic.

But if $P$ and $Q$ are convex polygons with $n$ sides and the interiors are included, regarded as cell complexes $\mathcal{P}$, $\mathcal{Q}$ with one 2-cell and $n$ 1-cells and 0-cells as above, then $\mathcal{P}$ and $\mathcal{Q}$ are not generally simplicially isomorphic, and the conditions for simplicial isomorphism are restrictive: for example, if $P$ is a square, then $\mathcal{P}$ and $\mathcal{Q}$ are simplicially isomorphic if and only if the quadrilateral $Q$ is a parallelogram.

For simplicial complexes, conditions for simplicial isomorphism are much less stringent (XI.24.2.10).

XI.24.2.10. Proposition. Let $K$ and $K'$ be simplicial complexes, and let $\phi$ be a one-one correspondence between the simplexes in $K$ and the simplexes in $K'$ with the property that if $S \in K$ and $F$ is a face of $S$, then $\phi(F)$ is a face of $\phi(S)$. Then there is a unique simplicial isomorphism $f : |K| \to |K'|$ such that $f(S) = \phi(S)$ for every $S \in K$.

Proof: By counting numbers of faces, it follows that $\phi$ must give a bijection between the $d$-simplexes in $K$ and the $d$-simplexes of $K'$ for each $d$. Since the 0-simplexes are just the vertices, $\phi$ gives a one-one
correspondence between the vertices of $\mathcal{K}$ and the vertices of $\mathcal{K}'$. If $v_0, \ldots, v_n$ are the vertices of $\mathcal{K}$, set $w_k = \phi(v_k)$ for each $k$. Then if $S$ is a simplex in $\mathcal{K}$ with vertices $v_{i_1}, \ldots, v_{i_r}$, then $\phi(S)$ must be a simplex in $\mathcal{K}'$ with vertices $w_{i_1}, \ldots, w_{i_r}$, and we may define $f : S \to \phi(S)$ by

$$f \left( \sum_{k=1}^{r} \lambda_k v_{i_k} \right) = \sum_{k=1}^{r} \lambda_k w_{i_k}.$$  

It is easily checked that if $x \in |\mathcal{K}|$, this definition of $f(x)$ is independent of which of the simplexes of $\mathcal{K}$ containing $x$ is used, and thus we obtain a well-defined function $f : |\mathcal{K}| \to |\mathcal{K}'|$ which obviously has the right properties.

\textbf{Barycentric Coordinates}

\textbf{XI.24.2.11.} The construction in the proof of XI.24.2.10. can be thought of in another way. If $\mathcal{K}$ is a simplicial complex and $v_0, \ldots, v_n$ are the vertices of $\mathcal{K}$, and $x \in |\mathcal{K}|$, then for any simplex $S$ of $\mathcal{K}$ containing $x$ with vertices $v_{i_1}, \ldots, v_{i_r}$, $x$ has barycentric coordinates $(\lambda_{i_k})$ with respect to $v_{i_k}$. These barycentric coordinates are defined for any vertex of any simplex of $\mathcal{K}$ containing $x$, and do not depend on which simplex containing $x$ and that vertex is used. If $v_j$ is a vertex of $\mathcal{K}$ and $x$ is not contained in any simplex of $\mathcal{K}$ with $v_j$ a vertex, set the barycentric coordinate $\lambda_j(x)$ equal to 0. Thus the barycentric coordinates $\lambda_0(x), \ldots, \lambda_n(x)$ of $x$ are well defined for every vertex, and satisfy $\lambda_k(x) \geq 0$ for all $k$ and $\sum_{k=0}^{n} \lambda_k(x) = 1$. We may symbolically write

$$x = \sum_{k=0}^{n} \lambda_k(x)v_k$$

interpreted as follows: if the set of vertices $v_k$ for which $\lambda_k(x) > 0$ is $\{v_{i_1}, \ldots, v_{i_r}\}$, then the simplex $S$ with vertices $v_{i_1}, \ldots, v_{i_r}$ is in $\mathcal{K}$ and $x$ is the point of $S$ with barycentric coordinates $\lambda_{i_1}(x), \ldots, \lambda_{i_r}(x)$ with respect to $v_{i_1}, \ldots, v_{i_r}$.

\textbf{Abstract Simplicial Complexes}

The existence of barycentric coordinates (XI.24.2.11.) in any simplicial complex allows the definition of simplicial complexes as combinatorial objects:

\textbf{XI.24.2.12.} \textbf{Definition.} An \textit{abstract simplicial complex} is a collection $\mathcal{K}$ of subsets of a finite set $\{v_0, \ldots, v_n\}$ such that $\{v_k\} \in \mathcal{K}$ for all $k$ and if $S \in \mathcal{K}$, then all subsets of $S$ are also in $\mathcal{K}$. The $v_k$ are called the \textit{vertices} of $\mathcal{K}$.

If $\mathcal{K}$ and $\mathcal{K}'$ are abstract simplicial complexes with sets of vertices $V$ and $V'$ respectively, a \textit{simplicial isomorphism} between $\mathcal{K}$ and $\mathcal{K}'$ is a bijection $\phi$ from $V$ to $V'$ such that $F \subseteq V$ is in $\mathcal{K}$ if and only if $\phi(F) \in \mathcal{K}'$.

A \textit{geometric realization} of an abstract simplicial complex $\mathcal{K}$ is a (geometric) simplicial complex $\mathcal{K}'$ and a bijection $\phi$ from the set $\{v_0, \ldots, v_n\}$ of vertices of $\mathcal{K}$ to the vertices of $\mathcal{K}'$, say $w_k = \phi(v_k)$, such that the simplex with vertices $\{w_{i_1}, \ldots, w_{i_r}\}$ is in $\mathcal{K}'$ if and only if $\{v_{i_1}, \ldots, v_{i_r}\} \in \mathcal{K}$.

The next result is obvious from XI.24.2.10.:
XI.24.2.13. Proposition. Let $\mathcal{K}$ be an abstract simplicial complex. Then there is a unique simplicial isomorphism between any two geometric realizations of $\mathcal{K}$ which extends the identification of the vertices by the realizations. More generally, if $\mathcal{K}$ and $\mathcal{K}'$ are abstract simplicial complexes and $\phi$ is a simplicial isomorphism from $\mathcal{K}$ to $\mathcal{K}'$, then there is a unique simplicial isomorphism from any geometric realization of $\mathcal{K}$ to any geometric realization of $\mathcal{K}'$ extending the identification of the vertices via $\phi$.

XI.24.2.14. Every abstract simplicial complex has a geometric realization. In fact, if an ordering $v_0, v_1, \ldots, v_n$ on the vertices of an abstract simplicial complex $\mathcal{K}$ is fixed, there is a corresponding standard realization of $\mathcal{K}$ as a subcomplex $\mathcal{K}'$ of the standard $n$-simplex $\Sigma_n$: just let $\mathcal{K}'$ be the collection of all faces of $\Sigma_n$ with vertices $\{e_i, \ldots, e_r\}$ for sets $\{v_i, \ldots, v_r\}$ in $\mathcal{K}$.

Thus there is a natural one-one correspondence between simplicial isomorphism classes of abstract simplicial complexes and simplicial isomorphism classes of geometric simplicial complexes.

XI.24.3. Triangulations

Recall (XI.24.2.2) that a triangulation of a polyhedron $P$ is a simplicial complex $\mathcal{K}$ with $|\mathcal{K}| = P$.

XI.24.3.1. Theorem. Every polyhedron has a triangulation.

Triangulations of Topological Spaces

XI.24.3.2. Definition. Let $X$ be a topological space (usually a compact Hausdorff space). A weak triangulation of $X$ is a simplicial complex $\mathcal{K}$ and a continuous function $f : X \to |\mathcal{K}|$ such that every vertex of $\mathcal{K}$ is in the range of $f$. A weak triangulation $f$ of $X$ is a triangulation of $X$ if $f$ is a homeomorphism from $X$ onto $|\mathcal{K}|$.

This terminology is consistent: if $P$ is a polyhedron, then a triangulation of $P$ in the simplicial sense (XI.24.2.2) is a triangulation in the topological sense (XI.24.3.2) when $P$ is regarded as a topological space. The other direction is not well defined, since a polyhedron is more than a topological space: it also has a “local affine structure” (XI.24.4.1) which is not part of the topological structure. See () for further comments.

Note that a topological space with a triangulation must be homeomorphic to a polyhedron, hence a compact metrizable space. But spaces which are not compact and/or metrizable can have weak triangulations: for example, any constant function from a topological space $X$ to $\mathbb{R}^n$ is a weak triangulation.

Triangulations and Partitions of Unity

Weak triangulations of a topological space $X$ are effectively the same thing as finite partitions of unity on $X$.  

1348
XI.24.3.3. Let $X$ be a topological space and \{w_0, \ldots, w_n\} a finite partition of unity on $X$. Define a continuous function $f$ from $X$ to the standard $n$-simplex $\Sigma_n$ by

$$f(x) = \sum_{k=0}^{n} f_k(x) e_k.$$ 

If $\Sigma_n$ is regarded as a simplicial complex, then $f$ is a weak triangulation of $X$. (The requirement that each $f_k$ take the value 1 is precisely the same as the requirement that the range of $f$ contain all vertices of $\Sigma_n$.) Note that the range of $f$ may well be contained in a proper subcomplex of $\Sigma_n$ containing all the vertices.

XI.24.3.4. Conversely, let $f$ be a weak triangulation from $X$ to a simplicial complex $K$, and let $\{w_0, \ldots, w_n\}$ be the vertices of $K$. If $a \in |K|$, let $\lambda_k(a)$ be the barycentric coordinate of $a$ with respect to $w_k$ in $K$. For each $k$ set $f_k = \lambda_k \circ f$, i.e. for $x \in X$ set $f_k(x) = \lambda_k(f(x))$. Then the $f_k$ give a finite partition of unity on $X$.

XI.24.3.5. Suppose $f : X \to |K|$ is a weak triangulation, and let $v_0, \ldots, v_n$ be the vertices of $K$ and $f_0, \ldots, f_n$ the corresponding partition of unity. For each $k$ let $V_k$ be the set of $a \in |K|$ with $\lambda_k(a) > 0$; $V_k$ is the set of points $a$ of $|K|$ such that every simplex in $K$ containing $a$ has $v_k$ as a vertex. Then $V_k$ is open in $|K|$, and if $U_k = f^{-1}(V_k) = \{x \in X : f_k(x) > 0\}$, then $U = \{U_0, \ldots, U_n\}$ is an open cover of $X$, and $\{f_0, \ldots, f_n\}$ is a partition of unity subordinate to $U$.

XI.24.3.6. So if $X$ is a compact Hausdorff space, the theory of partitions of unity assures the existence of “fine” weak triangulations. In fact, we have:

XI.24.3.7. Theorem. Let $X$ be a compact Hausdorff space and $W$ an open cover of $X$. Then there is a surjective weak triangulation $f : X \to |K|$ such that the cover $U$ of XI.24.3.5. is a refinement of $W$.

Proof: By passing to a subcover, we may assume $W$ is finite. Let $V$ be an open star-refinement of $W$, which we may also assume finite, and $\{f_0, \ldots, f_n\}$ a partition of unity subordinate to $V$. The corresponding weak triangulation $f : X \to |K| = \Sigma_n$ works except that $f$ may not be surjective.

We modify $f$ in stages and reduce $K'$ to a subcomplex, beginning with the largest simplex. To do the modification on a simplex $S$ which is not a face of another simplex in $K'$, suppose the interior of $S$ is not entirely contained in the range of $f$ (if it is, no modification for this $S$ is necessary). If $a$ is an interior point of $S$ not contained in the range, there is a retraction $r$ (e.g. radial projection from $a$) from $S \setminus \{a\}$ onto its boundary. Replace $K'$ by $K' \setminus \{S\}$ and $f$ by $r \circ f$. Then the inverse image of the star of any vertex in the reduced complex under $r \circ f$ is contained in the inverse image of the star of that vertex in $K'$ under $f$, so is contained in one of the sets of $W$. The modified $r \circ f$ agrees with $f$ on any $x \in X$ for which $f(x)$ is not in the interior of $S$. Repeat the reduction through all simplexes in $K'$ which are not faces of remaining simplexes after the previous reduction. Since all vertices of $K'$ are in the range of $f$ at every stage, after a finite number of steps a subcomplex $K$ and modified $f$ will be surjective. 

\[\Box\]
XI.24.3.8. **Corollary.** Let $X$ be a compact metrizable space, $\rho$ a fixed metric on $X$, and $\epsilon > 0$. Then there is a surjective weak triangulation $f : X \to |K|$ of $X$, such that for every vertex $v_k$ of $|K|$, the $\rho$-diameter of $f^{-1}(V_k)$ is less than $\epsilon$.

**Proof:** Let $W$ be the open cover of $X$ by balls of $\rho$-diameter $< \epsilon$. 

The Nerve of an Open Cover

XI.24.4. **Piecewise-Linear Maps**

**XI.24.4.1.** If $X$ is a polyhedron and $a \in X$, then for any $b \in X$ sufficiently close to $a$ (within a star of $a$ in $X$) there is an unambiguous notion of the line segment from $a$ to $b$ in $X$, and of $\lambda a + (1 - \lambda)b$ for $0 \leq \lambda \leq 1$, i.e. $X$ has a “local affine structure.” (Existence of such a structure does not characterize polyhedra, however; for example, any convex set also has such a local affine structure.)

The local affine structure is “continuous”:

**XI.24.4.2.** **Proposition.** Let $X$ be a subset of $\mathbb{R}^n$, $a \in X$, and $aL$ a star of $a$ in $X$ (with $L$ compact). If $(\lambda_n a + (1 - \lambda_n)b_n)$ is a sequence in $aL$ (with $0 \leq \lambda_n \leq 1$ and $b_n \in L$ for all $n$), then $\lambda_n a + (1 - \lambda_n)b_n \to \lambda a + (1 - \lambda)b \in \mathbb{R}^n$ with $b \in L$ if and only if $\lambda_n \to \lambda$ and, if $\lambda \neq 1$, $b_n \to b$.

**Proof:** If $\lambda_n \to \lambda$ and $b_n \to b$, then $\lambda_n a + (1 - \lambda_n)b_n \to \lambda a + (1 - \lambda)b$, and $b \in L$ since $L$ is closed in $\mathbb{R}^n$. Conversely, suppose $\lambda_n a + (1 - \lambda_n)b_n \to \lambda a + (1 - \lambda)b$ with $b \in L$. Since $[0, 1]$ and $L$ are compact, any subsequence of $(\lambda_n a + (1 - \lambda_n)b_n)$ has a subsubsequence $(\lambda_{k_n} a + (1 - \lambda_{k_n})b_{k_n})$ such that $(\lambda_{k_n})$ and $(b_{k_n})$ both converge, say to $\mu$ and $c$ respectively, with $0 \leq \mu \leq 1$ and $c \in L$. Then $\lambda_{k_n} a + (1 - \lambda_{k_n})b_{k_n} \to \mu a + (1 - \mu)c$. By uniqueness of limits in $\mathbb{R}^n$, $\mu a + (1 - \mu)c = \lambda a + (1 - \lambda)b$, and by uniqueness of representation of points of $aL$, we must have $\mu = \lambda$ and, if $\lambda \neq 1$, $c = b$. Thus every subsequence of $(\lambda_n)$ has a subsequence converging to $\lambda$, and if $\lambda \neq 1$ every subsequence of $(b_n)$ has a subsubsequence converging to $b$, so $\lambda_n \to \lambda$ and, if $\lambda \neq 1$, $b_n \to b$.

We can use the local affine structure to define piecewise-linear maps between polyhedra:

**XI.24.4.3.** **Definition.** Let $X$ and $Y$ be polyhedra in $\mathbb{R}^n$ and $\mathbb{R}^m$ respectively. A function $f : X \to Y$ is piecewise-linear (PL) if for every $a \in X$ there are $\delta > 0$, $\epsilon > 0$ such that

(i) $a$ has a $\delta$-star in $X$ and $f(a)$ has an $\epsilon$-star in $Y$

(ii) $f(N_\delta(a, X)) \subseteq N_\epsilon(f(a), Y)$

(iii) $f(\lambda a + (1 - \lambda)b) = \lambda f(a) + (1 - \lambda)f(b)$ for all $b \in N_\delta(a, X), 0 \leq \lambda \leq 1$.

Such a function might be more properly called something like *locally affine*, but the name “piecewise-linear” is standard, and is appropriate since $X$ can indeed be broken up into pieces on which $f$ is linear (affine) (XI.24.4.6).

The next fact may seem obvious, but requires proof:

1350
XI.24.4. \textbf{Proposition.} Let $X$ and $Y$ be polyhedra in $\mathbb{R}^n$ and $\mathbb{R}^m$ respectively, and $f : X \to Y$ a PL function. Then $f$ is continuous.

\textbf{Proof:} Let $(c_n)$ be a sequence in $X$ with $c_n \to a$. Let $\delta > 0$ and $\epsilon > 0$ be as in XI.24.4.3. for $a$. Passing to a tail, we may assume $c_n \in N_{\delta}(a, X)$ for all $n$. Write $c_n = \lambda_n a + (1 - \lambda_n) b_n$ for $0 \leq \lambda_n \leq 1$ and $b_n \in N_{\delta}(a, X)$. Since $c_n \to a$, we have $\lambda_n \to 1$ by XI.24.4.2. We have

$$f(c_n) = \lambda_n f(a) + (1 - \lambda_n) f(b_n) \to f(a) + 0 = f(a)$$

since $\lambda_n \to 1$ and $(f(b_n))$ is a bounded sequence. \hfill \(<)

XI.24.4.5. \textbf{Proposition.} Let $X$ and $Y$ be polyhedra in $\mathbb{R}^n$ and $\mathbb{R}^m$ respectively, and $f : X \to Y$ a function. Then $f$ is PL if and only if the graph $\Gamma(f)$ is a polyhedron in $\mathbb{R}^{n+m}$.

\textbf{Proof:} It is easy to verify that $\Gamma(f)$ is compact and locally conical if and only if $f$ is PL. \hfill \(<)

XI.24.4.6. \textbf{Corollary.} Let $X$ and $Y$ be polyhedra in $\mathbb{R}^n$ and $\mathbb{R}^m$ respectively, and $f : X \to Y$ a PL function. Then there is a triangulation of $X$ such that $f$ is simplicial for the triangulation. Conversely, such a map is PL.

\textbf{Proof:} If $f$ is PL, triangulate the polyhedron $\Gamma(f)$. The projection map from $\Gamma(f)$ to $X$ is affine, and is a homeomorphism, so the projections of the simplexes in the triangulation of $\Gamma(f)$ are simplexes in $X$ and give a triangulation of $X$ as desired. The converse is obvious. \hfill \(<)

This result justifies the name “piecewise-linear.”

\textbf{XI.24.5. Exercises}

XI.24.5.1. (a) Show that every affine subspace of $\mathbb{R}^n$ is a finite intersection of (closed) half-spaces.

(b) Let $C$ be a cell in $\mathbb{R}^n$ with vertices $v_1, \ldots, v_m$. Suppose $C$ generates $\mathbb{R}^n$ as an affine subspace. For $1 \leq k \leq m$, let $C_k$ be the cone (in the vector space sense) generated by $C$ with vertex $v_k$, i.e. the union of all rays from $v_k$ passing through other points of $C$. Show that $C = C_1 \cap \cdots \cap C_m$. [Use an argument like the one in the proof of XI.24.1.28.]

(c) Show that each $C_k$ is a finite intersection of half-spaces.

(d) Conclude that every cell is a finite intersection of half-spaces. Use this to give a direct proof of (i) $\Rightarrow$ (iii) of XI.24.1.23.

XI.24.5.2. Let $T$ be an open triangle in $\mathbb{R}^2$ with one vertex added. Show that $T$ is locally conical, but not a polyhedron in the PL sense (XI.24.1.34.) since it is not locally compact.
XI.25. The Metric Space of a Measure Space

If \((X, \mathcal{A}, \mu)\) is a measure space, there is a natural pseudometric on \(\mathcal{A}\) for which the metric quotient is complete.

Recall that if \(A\) and \(B\) are sets, the symmetric difference of \(A\) and \(B\) is

\[A \triangle B = (A \setminus B) \cup (B \setminus A) = (A \cup B) \setminus (A \cap B).\]

\(A\triangle B\) consists of elements which are in either \(A\) or \(B\), but not both. The size of \(A\triangle B\) is a measure of how much the sets \(A\) and \(B\) differ.

If \(\mathcal{A}\) is an algebra of subsets of a set \(X\), and \(A, B \in \mathcal{A}\), then \((A \triangle B) \in \mathcal{A}\).

Here are some important simple properties of symmetric difference:

**Proposition.** Let \(A, B, C\) be sets. Then

1. \((A \triangle B) \triangle C = A \triangle (B \triangle C)\).
2. \(A \triangle C \subseteq (A \triangle B) \cup (B \triangle C)\).
3. \(A \triangle B = B \triangle A\).
4. \(A \triangle \emptyset = \emptyset\).
5. \(A \triangle \emptyset = A\).

**Definition.** Let \((X, \mathcal{A}, \mu)\) be a measure space. If \(A, B \in \mathcal{A}\), set

\[\rho_\mu(A, B) = \min(\mu(A \triangle B), 1)\]

**Proposition.** If \((X, \mathcal{A}, \mu)\) is a measure space, then \(\rho_\mu\) is a pseudometric on \(\mathcal{A}\).

**Proof:** It is obvious from XI.25(iii) that \(\rho_\mu(A, B) = \rho_\mu(B, A) \geq 0\) for any \(A, B \in \mathcal{A}\), and the triangle inequality follows from XI.25(ii) and monotonicity of \(\mu\).

There is inconsistency in the exact way \(\rho_\mu\) is defined in the literature, but the differences are not important since all standard definitions give uniformly equivalent metrics. The “natural” definition is just \(\rho_\mu(A, B) = \mu(A \triangle B)\), but this can take the value \(\infty\), which is not allowed for a pseudometric.

As usual, we can take a quotient of \(\mathcal{A}\) on which \(\rho_\mu\) defines a metric. The equivalence class of a set \(A \in \mathcal{A}\) is

\[[A] = \{B \in \mathcal{A} : \mu(A \triangle B) = 0\}\]

The set of equivalence classes is often written \(\mathcal{A}/\mathcal{N}\), where \(\mathcal{N}\) is the \(\sigma\)-ideal of \(\mu\)-null sets. We will denote the induced metric on \(\mathcal{A}/\mathcal{N}\) also by \(\rho_\mu\).

If \((A_n)\) is a sequence of sets, recall the definition of \(\limsup_{n \to \infty} A_n\) and \(\liminf_{n \to \infty} A_n\) from (i).
Theorem. Let \((X, \mathcal{A}, \mu)\) be a measure space, and \(\mathcal{N}\) the set of \(\mu\)-null sets. Let \((A_n)\) be a Cauchy sequence in \(\mathcal{A}\) for \(\rho_\mu\). Then

\[
\left(\limsup_{n \to \infty} A_n\right) \setminus \left(\liminf_{n \to \infty} A_n\right) \in \mathcal{N}
\]

and \([\limsup A_n] = [\liminf A_n] = \lim_{n \to \infty} [A_n]\) in \(\mathcal{A}/\mathcal{N}\). Thus \((\mathcal{A}/\mathcal{N}, \rho_\mu)\) is a complete metric space.

Note that this result has nothing to do with completeness of \(\mu\). In fact, if \((X, \bar{\mathcal{A}}, \bar{\mu})\) is the completion of \((X, \mathcal{A}, \mu)\), and \(\bar{\mathcal{N}}\) is the set of \(\bar{\mu}\)-null sets, there is a natural bijection between \(\bar{\mathcal{A}}/\bar{\mathcal{N}}\) and \(\mathcal{A}/\mathcal{N}\), and \(\rho_\mu\) agrees with \(\rho_\bar{\mu}\) on this space, so the metric space of \(\bar{\mu}\) is the “same” as for \(\mu\).

The usual set operations are continuous with respect to the topology on \(\mathcal{A}\):

**Theorem.** Let \((X, \mathcal{A}, \mu)\) be a measure space and \((\mathcal{A}/\mathcal{N}, \rho_\mu)\) the corresponding metric space. Then

(i) The functions \(([A], [B]) \mapsto [A \cup B], ([A], [B]) \mapsto [A \cap B], ([A], [B]) \mapsto [A \setminus B],\) and \(([A], [B]) \mapsto [A \Delta B]\)

are well defined and jointly continuous, i.e. continuous functions from \((\mathcal{A}/\mathcal{N}) \times (\mathcal{A}/\mathcal{N})\) to \(\mathcal{A}/\mathcal{N}\).

(ii) The function \([A] \mapsto [X \setminus A]\) is a well-defined continuous function from \(\mathcal{A}/\mathcal{N}\) to \(\mathcal{A}/\mathcal{N}\).

(iii) If \(\mathcal{B}\) is an algebra of sets containing \(\mathcal{N}\), the closure of \(\mathcal{B}/\mathcal{N}\) in \(\mathcal{A}/\mathcal{N}\) is \(\sigma(\mathcal{B})/\mathcal{N}\), where \(\sigma(\mathcal{B})\) is the \(\sigma\)-algebra generated by \(\mathcal{B}\).
Chapter XII

Measurable Spaces and Subset Structures

In this chapter, we will set up the structures on which measures can be naturally defined. While these structures are of interest in their own right, the reader should not lose sight of the primary goal of this work: developing a good notion of measure and integration. In this context, this chapter should be regarded as a set of elaborate and technical preliminary work necessary to obtain a good theory of measure. Strictly speaking, not all of the material of this chapter will be necessary for basic measure theory, but it makes sense to give a reasonably complete study of these topics all at once.

The set structures discussed in this chapter should be compared to topologies, another very important kind of set structure discussed in Chapter (). Although the various kinds of set structures have properties making them useful in different contexts, all are of the same general nature and have many features in common.

XII.1. Algebras and σ-Algebras of Sets
XII.1.1. Rings, Semirings, and Semialgebras

In this subsection, we will discuss various types of collections of subsets of a set $X$ which are important to a greater or lesser extent in measure theory. Throughout the section, $X$ will be a fixed set which we will regard as our “universe.”

XII.1.1.1. We first recall some standard operations on subsets of $X$. If $A, B \subseteq X$, then

- The union $A \cup B$ is $\{x \in X : x \in A \text{ or } x \in B\}$.
- The intersection $A \cap B$ is $\{x \in X : x \in A \text{ and } x \in B\}$.
- The complement of $A$ is $A^c = \{x \in X : x \notin A\}$.
- The difference $A \setminus B$ is $A \cap B^c = \{x \in A : x \notin B\}$.
- The symmetric difference $A \triangle B$ is $\{x \in X : x \in A \text{ or } x \in B \text{ but not both}\} = (A \setminus B) \cup (B \setminus A)$.

More generally, if $\{A_i : i \in I\}$ is an indexed collection of subsets of $X$, then

- $\bigcup_{i \in I} A_i = \{x \in X : x \in A_i \text{ for some } i \in I\}$
- $\bigcap_{i \in I} A_i = \{x \in X : x \in A_i \text{ for all } i \in I\}$

XII.1.1.2. Definition. A nonempty collection $S$ of subsets of $X$ is a semiring if

(i) $S$ is closed under finite intersections.
(ii) If $A, B \in S$, then $A \setminus B$ is a finite disjoint union of sets in $S$.

A semiring $S$ for which $X \in S$ is a semialgebra. A semiring $S$ with the property that $X$ is a countable union of sets in $S$ is of countable type. A semialgebra is a semiring of countable type.

Taking $B = A$ in (ii), it follows that $\emptyset$ is in any semiring.

The definition of a semiring may look strange at first, but many important collections of subsets which naturally arise in analysis turn out to be semirings, and on the other hand semirings have enough structure that important constructions can be done with them.

XII.1.1.3. Examples. (i) Here is perhaps the most important example. Let $I$ be the set of intervals in $\mathbb{R}$, either open, closed, or half-open; include in $I$ the “degenerate” intervals $\emptyset$ and singleton sets $\{x\}$ (intervals of length 0). $I$ is closed under finite intersections (in fact under arbitrary intersections), and the complement of one interval in another is either an interval or the disjoint union of two intervals, so $I$ is a semiring. In fact, $I$ is a semialgebra.

(ii) As a variation of (i), let $I_I$ be the set of bounded intervals in $\mathbb{R}$, including degenerate intervals. By the same argument, $I_I$ is a semiring. It is not a semialgebra, but it is a semiring of countable type.

(iii) Similarly, if $\delta > 0$, let $I_\delta$ be the set of intervals in $\mathbb{R}$ of length $\leq \delta$, again including degenerate intervals. By the same argument, using the Archimedean property of $\mathbb{R}$, $I_\delta$ is a semiring of countable type.

(iv) If $C$ is any semiring (e.g. an algebra or $\sigma$-algebra) on $X$, and $\{A_i : i \in I\}$ is a nonempty collection of sets in $C$, then $S = \{S \subseteq C : S \subseteq A_i \text{ for some } i \in I\}$ is a semiring. More generally, if $P$ is a property of sets inherited by all subsets, then the set of $C \subseteq C$ with property $P$ form a semiring.

1355
XII.1.4. The intersection of two semirings is not necessarily a semiring, and hence if \( \mathcal{C} \) is a collection of subsets of \( X \), there is not necessarily a smallest semiring containing \( \mathcal{C} \). But there is a standard construction of a semiring containing \( \mathcal{C} \), which is particularly important in probability:

XII.1.5. Proposition. Let \( \mathcal{C} \) be any nonempty collection of subsets of \( X \), and let

\[
\mathcal{D} = \{ A \setminus B : A, B \in \mathcal{C} \}.
\]

Let \( \mathcal{S} \) be the set of finite intersections of sets in \( \mathcal{C} \cup \mathcal{D} \). Then \( \mathcal{S} \) is a semiring containing \( \mathcal{C} \).

Note that \( \emptyset \in \mathcal{D} \) since it is \( A \setminus A \) for any \( A \in \mathcal{C} \); if \( \emptyset \in \mathcal{C} \), then \( \mathcal{C} \subseteq \mathcal{D} \) since \( A = A \setminus \emptyset \) for any \( A \).

Proof: (Outline) This is completely routine, but tedious to write out carefully; see XII.1.5.1. The proof consists of repeated applications of the following facts for subsets \( A, B, C \) of \( X \):

\[
(A \setminus B) \setminus C = (A \setminus C) \cap (B \setminus C).
\]

\[
(A \setminus B) \setminus C = (A \setminus C) \cap (A \setminus B).
\]

\( A \setminus (B \setminus C) \) is the disjoint union of \( A \setminus B \) and \( A \setminus B \cap C \).

\( A \setminus (B \cap C) \) is the disjoint union of \( A \setminus B \) and \( (A \setminus B) \setminus C \).

The details of the proof are left to the reader, who should at least verify the above facts.

A similar proof shows the following:

XII.1.6. Proposition. Let \( \mathcal{C} \) be a nonempty collection of subsets of \( X \) with the property that \( A \in \mathcal{C} \) implies \( A^c \in \mathcal{C} \). Let \( \mathcal{S} \) be the collection of finite intersections of sets in \( \mathcal{C} \). Then \( \mathcal{S} \) is a semialgebra.

Collections with more structure behave more nicely and are of central importance in measure theory:

XII.1.7. Definition. A ring of subsets of a set \( X \) is a nonempty collection of subsets of \( X \) which is closed under finite unions and relative complements.

XII.1.8. Proposition. A ring is closed under symmetric difference and finite intersections; in particular, a ring is a semiring.

Proof: If \( A, B \subseteq X \), then \( A \Delta B = (A \setminus B) \cup (B \setminus A) \) and \( A \cap B = (A \cup B) \setminus (A \Delta B) \).

1356
XII.1.1.9. The converse also holds: a nonempty collection of subsets of \( X \) closed under finite intersections and symmetric differences is a ring, because of the relations

\[
A \cup B = (A \oplus B) \Delta (A \cap B), \quad A \setminus B = A \oplus (A \cap B)
\]

for subsets of \( X \). This explains the use of the term “ring”: the operations \( A + B = A \oplus B \) and \( AB = A \cap B \) make \( \mathcal{P}(X) \) into a ring in the algebraic sense of III.3.6.3. (in fact, a special kind of ring called a Boolean algebra); a ring of subsets is precisely a subring of \( \mathcal{P}(X) \) with these operations. This use of ring (of subsets) is apparently due to Halmos [Hal50].

In many references, especially older ones, \( A \cap B \) is written \( AB \), and in many of these \( A \setminus B \) is written \( A - B \). But \( \mathcal{P}(X) \) is not a ring under these algebraic operations. Also, for sets of numbers or subsets of a topological group, these notations are commonly used to denote something quite different (). Thus we will not use the notation \( AB \) or \( A + B \) for set-theoretic operations.

XII.1.1.10. Any intersection of rings is a ring (the intersection is nonempty since \( \emptyset \) is in every ring). Thus if \( \mathcal{C} \) is any collection of subsets of \( X \), there is a smallest ring of subsets containing \( \mathcal{C} \), called the ring generated by \( \mathcal{C} \) (there is at least one ring containing \( \mathcal{C} \), namely \( \mathcal{P}(X) \)). The ring generated by \( \emptyset \) is \( \{ \emptyset \} \).

XII.1.1.11. Proposition. Let \( \mathcal{S} \) be a semiring. The ring generated by \( \mathcal{S} \) is precisely the set of finite disjoint unions of sets in \( \mathcal{S} \).

Proof: Let \( \mathcal{A} \) be the set of finite disjoint unions of sets in \( \mathcal{S} \). We show that \( \mathcal{A} \) is closed under finite intersections, then finite unions and relative complements.

For finite intersections, let \( A \) be the disjoint union of \( A_1, \ldots, A_n \in \mathcal{S} \) and \( B \) the disjoint union of \( B_1, \ldots, B_m \in \mathcal{S} \). Then \( A \cap B \) is the disjoint union of

\[
\{ A_j \cap B_k : 1 \leq j \leq n, 1 \leq k \leq m \}.
\]

For finite unions, it suffices to show that if \( A_1, \ldots, A_n, B \in \mathcal{S} \) with \( A_1, \ldots, A_n \) pairwise disjoint, then \( A_1 \cup \cdots \cup A_n \cup B \) can be written as a finite disjoint union of sets in \( \mathcal{S} \). For each \( j, B \setminus A_j \) can be written as a finite disjoint union of sets in \( \mathcal{S} \). Thus by the previous argument

\[
B \setminus (A_1 \cup \cdots \cup A_n) = (B \setminus A_1) \cap \cdots \cap (B \setminus A_n)
\]

can be written as a finite disjoint union of sets in \( \mathcal{S} \); the union of these sets and the \( A_j \) is \( A_1 \cup \cdots \cup A_n \cup B \).

Now let \( A, B \in \mathcal{A} \), with \( A \) the disjoint union of \( A_1, \ldots, A_n \in \mathcal{S} \) and \( B \) the disjoint union of \( B_1, \ldots, B_m \in \mathcal{S} \). We have

\[
A \setminus B = \bigcup_{j=1}^{n} \bigcap_{k=1}^{m} (A_j \setminus B_k)
\]

and each \( A_j \setminus B_k \) is a finite disjoint union of sets in \( \mathcal{S} \), hence in \( \mathcal{A} \). So \( A \setminus B \) is in \( \mathcal{A} \) by the previous arguments. \( \blacksquare \)

XII.1.1.12. Corollary. A semiring which is closed under finite disjoint unions is a ring.
XII.1.1.13. \textbf{Corollary.} Let $S$ be a semiring, $A, A_1, \ldots, A_n$ sets in $S$ with $A_j \subseteq A$ for all $j$ and the $A_j$ pairwise disjoint. Then there are finitely many sets $B_1, \ldots, B_m \in S$ such that $\{A_1, \ldots, A_n, B_1, \ldots, B_m\}$ are pairwise disjoint and
\[
A = \left( \bigcup_{j=1}^{n} A_j \right) \cup \left( \bigcup_{k=1}^{m} B_k \right).
\]

\textbf{Proof:} Let $\mathcal{A}$ be the ring generated by $S$. If $D = \bigcup_{j=1}^{n} A_j$, then $D \in \mathcal{A}$, so $(A \setminus D) \in \mathcal{A}$, i.e. $A \setminus D$ can be written as a finite disjoint union of sets in $S$.

XII.1.1.14. \textbf{Proposition.} Let $S$ be a semiring of subsets of a set $X$, and let $A, A_1, A_2, \ldots$ be sets in $S$. Suppose $A \subseteq \bigcup_{n=1}^{\infty} A_n$. Then there is a sequence $(B_k)$ of pairwise disjoint sets in $S$ with each $B_k$ contained in a unique $A_n$, only finitely many $B_k$ in each $A_n$, such that $A = \bigcup_{k=1}^{m_1+1} B_k$.

\textbf{Proof:} Set $B_1 = A \cap A_1 \in S$. Write $A \setminus A_1 = C_{11} \cup \cdots \cup C_{1m_1}$ with the $C_{1j}$ pairwise disjoint sets in $S$. Set $B_2 = A_2 \cap C_{11}, \ldots, B_{m_1+1} = A_2 \cap C_{1m_1}$. Then the $B_k$ (for $1 \leq k \leq m_1 + 1$) are in $S$ and are pairwise disjoint, $B_1 \subseteq A_1, B_k \subseteq A_2 \setminus A_1$ for $2 \leq k \leq m_1 + 1$, and
\[
\bigcup_{k=1}^{m_1+1} B_k = A \cap (A_1 \cup A_2).
\]

Write $A \setminus A_2 = C_{21} \cup \cdots \cup C_{2m_2}$ with the $C_{2j}$ pairwise disjoint sets in $S$. The next set of $B_k$’s (for $m_1 + 2 \leq k \leq m_1 + m_1 m_2 + 1$) are of the form $A_3 \cap C_{i1} \cap C_{2j}$ for $1 \leq i \leq m_1$ and $1 \leq j \leq m_2$. The new $B_k$ are pairwise disjoint and contained in $A_3 \setminus (A_1 \cup A_2)$, and
\[
\bigcup_{k=1}^{m_1+m_1 m_2+1} B_k = A \cap (A_1 \cup A_2 \cup A_3).
\]

The process can be continued inductively, although the notation becomes increasingly complicated. At the end we have
\[
\bigcup_{k=1}^{\infty} B_k = A \cap \left( \bigcup_{n=1}^{\infty} A_n \right) = A.
\]

XII.1.2. \textbf{Algebras and $\sigma$-Algebras}

For measure theory purposes, the most important set structures are algebras and especially $\sigma$-algebras.

XII.1.3. \textbf{$\pi$-Systems, $\lambda$-Systems, and Monotone Classes}

We will occasionally have use for some collections of sets with other combinations of closure properties, and it will be convenient to have names for them.
XII.1.3.1. **Definition.** Let \( X \) be a set.

A nonempty collection \( Q \) of subsets of \( X \) is a \( \pi \)-system if it is closed under finite intersections.

A collection \( L \) of subsets of \( X \) is a \( \lambda \)-system if it contains \( X \) and is closed under complements and countable disjoint unions.

A nonempty collection \( \mathcal{N} \) of subsets of \( X \) is a monotone class if it is closed under countable monotone unions and intersections: if \((A_n)\) is an increasing sequence in \( \mathcal{N} \), then \( \bigcup_{n=1}^{\infty} A_n \in \mathcal{N} \), and if \((B_n)\) is a decreasing sequence in \( \mathcal{N} \), then \( \bigcap_{n=1}^{\infty} B_n \in \mathcal{N} \).

XII.1.3.2. **Examples.**

(i) A semiring is a \( \pi \)-system. A \( \sigma \)-algebra is both a \( \lambda \)-system and a monotone class. A \( \pi \)-system contains \( \emptyset \), and is thus also closed under finite disjoint unions.

(ii) A \( \pi \)-system need not be a semiring. For example, a topology on \( X \) is a \( \pi \)-system but usually not a semiring.

(iii) A \( \lambda \)-system need not be closed under even finite unions. For example, let \( X \) be a finite set with an even number of elements (> 2), and \( L \) the collection of all subsets with an even number of elements. Then \( L \) is a \( \lambda \)-system, but is not closed under finite unions. \( L \) is also a monotone class.

(iv) A monotone class need not be closed under either finite unions or finite intersections, or even finite disjoint unions. In fact, any finite collection of subsets of a set \( X \) is a monotone class.

(v) Any intersection of \( \pi \)-systems (on a fixed set \( X \)) is a \( \pi \)-system, and similarly for \( \lambda \)-systems and monotone classes. So if \( S \) is any collection of subsets of a set \( X \), there is a smallest \( \pi \)-system containing \( S \), denoted \( \pi(S) \); similarly there is a smallest \( \lambda \)-system \( \lambda(S) \) and a smallest monotone class \( \nu(S) \) containing \( S \). \( \pi(S) \) just consists of all finite intersections of sets in \( S \), but \( \lambda(S) \) and \( \nu(S) \) do not have simple descriptions in general.

XII.1.3.3. **Proposition.**

(i) A \( \lambda \)-system of subsets of a set \( X \) is closed under relative monotone complements: if \( A, B \in \mathcal{L} \) and \( A \subseteq B \), then \( B \setminus A \in \mathcal{L} \).

(ii) Let \( \mathcal{L} \) be a collection of subsets of a set \( X \) containing \( X \) and closed under relative monotone complements and finite and countable disjoint unions. Then \( \mathcal{L} \) is a \( \lambda \)-system.

**Proof:**

(i): \( B \setminus A = [A \cup B^c]^c \), and \( A \cap B^c = \emptyset \).

(ii): If \( A \in \mathcal{L} \), then \( A^c = X \setminus A \in \mathcal{L} \) since \( X \in \mathcal{L} \).

XII.1.3.4. **Proposition.** A collection \( A \) of subsets of a set \( X \) which is both a \( \pi \)-system and a \( \lambda \)-system is a \( \sigma \)-algebra.

**Proof:** \( A \) is closed under complements and finite intersections, hence an algebra. Thus \( A \) is closed under relative complements. If \( (A_n) \) is a sequence of sets in \( A \), let \( B_1 = A_1 \) and \( B_n = A_n \setminus A_{n-1} \) for \( n > 1 \), then \( (B_n) \) is a pairwise disjoint sequence of sets in \( A \), so \( \bigcup_{n=1}^{\infty} B_n = \bigcup_{n=1}^{\infty} A_n \in A \), so \( A \) is closed under countable unions.

The following variation of this result will be important:
XII.1.3.5.  **Theorem.**  [Dynkin’s $(\pi-\lambda)$-Theorem] Let $X$ be a set, $Q$ a $\pi$-system in $X$, and $L$ a $\lambda$-system in $X$. If $Q \subseteq L$, then $\sigma(Q) \subseteq L$.

**Proof:** By XII.1.3.4., it suffices to show that $\lambda(Q)$ is a $\pi$-system, since $\lambda(Q)$ is a $\lambda$-system contained in $L$ by minimality.

If $A \subseteq X$, let

$$L_A = \{ B \subseteq X : A \cap B \in \lambda(Q) \}.$$ 

If $A \in \lambda(Q)$, then we show that $L_A$ is a $\lambda$-system. $X$ is trivially in $L_A$. If $B, C \in L_A, C \subseteq B$, then $A \cap B$ and $A \cap C$ are in $\lambda(Q)$, so $A \cap (B \setminus C) = (A \cap C) \setminus (A \cap B) \in \lambda(Q)$ by XII.1.3.3. (i), since $\lambda(Q)$ is a $\lambda$-system. Thus $B \setminus C \in L_A$ and $L_A$ is closed under relative monotone complements. If $(B_n)$ is a pairwise disjoint sequence in $L_A$, then $(A \cap B_n)$ is a pairwise disjoint sequence in $\lambda(Q)$, hence $A \cap \bigcup_{n=1}^{\infty} B_n = \bigcup_{n=1}^{\infty} (A \cap B_n) \in \lambda(Q)$, i.e. $\bigcup_{n=1}^{\infty} B_n \in L_A$, and $L_A$ is closed under countable disjoint unions. So $L_A$ is a $\lambda$-system if $A \in \lambda(Q)$, and in particular if $A \in Q$.

Now suppose $A \in Q$. If $B \in Q$, then $A \cap B \in Q$ since $Q$ is a $\pi$-system, and thus $B \in L_A$. So if $A \in Q$, then $Q \subseteq L_A$, and thus $\lambda(Q) \subseteq L_A$ by minimality of $\lambda(Q)$.

Note that if $A, B \subseteq X$, then $B \in L_A$ if and only if $A \in L_B$. If $A \in Q$ and $B \in \lambda(Q)$, then $B \in L_A$ since $\lambda(Q) \subseteq L_A$, and thus $A \in L_B$. Thus, for $B \in \lambda(Q), Q \subseteq L_B$, and hence $\lambda(Q) \subseteq L_B$ by minimality of $\lambda(Q)$. If $B, C \in \lambda(Q)$, we have $C \in L_B$, i.e. $B \cap C \in \lambda(Q)$, so $\lambda(Q)$ is a $\pi$-system.  

We have similar results for monotone classes, due to Halmos, which will be useful:

XII.1.3.6.  **Proposition.**  An algebra of subsets of a set $X$ which is also a monotone class is a $\sigma$-algebra.

**Proof:** Let $A$ be an algebra of subsets of $X$, and suppose $A$ is also a monotone class. Let $(A_n)$ be a sequence of sets in $A$. For each $n$, set $B_n = \bigcap_{k=1}^{n} A_k$. Then $(B_n)$ is a decreasing sequence of sets in $A$ since $A$ is an algebra, and hence $\bigcap_{n=1}^{\infty} B_n = \bigcap_{n=1}^{\infty} A_n \in A$ since $A$ is a monotone class.  

XII.1.3.7.  **Theorem.**  [Monotone Class Theorem] Let $X$ be a set, $A$ an algebra of subsets of a set $X$, and $\mathcal{N}$ a monotone class of subsets of $X$. If $A \subseteq \mathcal{N}$, then $\sigma(A) \subseteq \mathcal{N}$.

XII.1.4.  **Measurable Spaces and Measurable Functions**

XII.1.4.1.  **Definition.**  A measurable space $(X, A)$ is a set $X$ with a specified $\sigma$-algebra $A$ of subsets.

Measurable spaces are the natural setting for measure theory, which will be developed in (). Note the analogy with the definition of a topological space. Measurable spaces are often called Borel spaces, especially (but not necessarily) if they come from a topological space as in ().

As usual with mathematical theories, it is important not only to have sets with a structure, but to have a class of functions which preserve the structure to serve as the morphisms of the theory. Experience shows that the appropriate morphisms between measurable spaces are the measurable functions:

1360
XII.1.4.2. **Definition.** Let \((X, \mathcal{A})\) and \((Y, \mathcal{B})\) be measurable spaces, and \(f : X \to Y\) a function. Then \(f\) is \((\mathcal{A}, \mathcal{B})\)-measurable (or just measurable if the \(\mathcal{A}\) and \(\mathcal{B}\) are understood) if \(f^{-1}(B) \in \mathcal{A}\) for every \(B \in \mathcal{B}\).

Note the close analogy with the definition of a continuous function between topological spaces \((\text{topo})\) (although there is no useful notion of “measurability at a point.”) When measurable spaces are called Borel spaces, measurable functions between them are often called Borel functions, although this terminology can sometimes be slightly ambiguous.

XII.1.4.3. **Proposition.** Let \((X, \mathcal{A}), (Y, \mathcal{B})\), and \((Z, \mathcal{C})\) be measurable spaces, and \(f : X \to Y\) and \(g : Y \to Z\) functions. If \(f\) is \((\mathcal{A}, \mathcal{B})\)-measurable and \(g\) is \((\mathcal{B}, \mathcal{C})\)-measurable, then \(g \circ f\) is \((\mathcal{A}, \mathcal{C})\)-measurable.

The proof is virtually identical to the proof that a composition of continuous functions is continuous.

XII.1.4.4. Thus the measurable spaces and measurable functions form a category. An isomorphism in this category, i.e. a bijection \(f\) such that both \(f\) and \(f^{-1}\) are measurable, is often called a Borel isomorphism.

XII.1.4.5. Just as with continuity, the larger \(\mathcal{A}\) is, or the smaller \(\mathcal{B}\) is, the easier it is for a function to be measurable. Given \(\mathcal{A}\), there is a largest \(\mathcal{B}\) making \(f\) measurable, and similarly, given \(\mathcal{B}\), there is a smallest corresponding \(\mathcal{A}\). These are given by the following construction:

XII.1.4.6. **Definition.** Let \(X\) and \(Y\) be sets, and \(f : X \to Y\) a function. If \(\mathcal{A}\) is a \(\sigma\)-algebra on \(X\), set
\[
\mathcal{f}^{-}(\mathcal{A}) = \{ B \subseteq Y : f^{-1}(B) \in \mathcal{A} \}.
\]
If \(\mathcal{B}\) is a \(\sigma\)-algebra on \(Y\), set
\[
\mathcal{f}^{+}(\mathcal{B}) = \{ f^{-1}(B) : B \in \mathcal{B} \}.
\]

XII.1.4.7. **Proposition.** Let \(X\) and \(Y\) are measurable spaces and \(f : X \to Y\) a function.

(i) If \(\mathcal{A}\) is a \(\sigma\)-algebra on \(X\), then \(\mathcal{f}^{-}(\mathcal{A})\) is a \(\sigma\)-algebra on \(Y\).

(ii) If \(\mathcal{B}\) is a \(\sigma\)-algebra on \(Y\), then \(\mathcal{f}^{+}(\mathcal{B})\) is a \(\sigma\)-algebra on \(X\).

**Proof:** Both parts follow easily from the fact that \(f^{-1}(\emptyset) = \emptyset\), \(f^{-1}(Y) = X\), \(f^{-1}(B^c) = [f^{-1}(B)]^c\), and \(f^{-1}(\bigcup_{n=1}^{\infty} B_n) = \bigcup_{n=1}^{\infty} f^{-1}(B_n)\) for any \(B, B_n \subseteq Y\). \(\square\)

XII.1.4.8. In fact, if \((X, \mathcal{A})\) is a measurable space and \(Y\) is a set, and \(f : X \to Y\) a function, then \(\mathcal{f}^{-}(\mathcal{A})\) is the largest \(\sigma\)-algebra on \(Y\) making \(f\) measurable. Similarly, if \(f : X \to (Y, \mathcal{B})\), then \(\mathcal{f}^{+}(\mathcal{B})\) is the smallest \(\sigma\)-algebra on \(X\) making \(f\) measurable.

Note, however, that \(\mathcal{f}^{-}(\mathcal{A})\) and \(\mathcal{f}^{+}(\mathcal{B})\) can be quite degenerate: for example, if \(f\) is a constant function, then \(\mathcal{f}^{-}(\mathcal{A}) = \mathcal{P}(Y)\) and \(\mathcal{f}^{+}(\mathcal{B}) = \{\emptyset, X\}\). There are examples where \(\mathcal{f}^{-}(\mathcal{A}) = \{\emptyset, Y\}\) even for nondegenerate \(f\) and \(\mathcal{A}\); \(\mathcal{f}^{+}(\mathcal{B})\) is less degenerate in general.

Although it would appear that \(\mathcal{f}^{-}\) and \(\mathcal{f}^{+}\) are “inverse” to each other, this is not the case in general: we always have that \(\mathcal{f}^{+}(\mathcal{f}^{-}(\mathcal{A})) \subseteq \mathcal{A}\) and \(\mathcal{f}^{-}(\mathcal{f}^{+}(\mathcal{B})) \supseteq \mathcal{B}\), but equality does not hold in general.\(\square\)

The next theorem is one of the most useful facts about mappings of \(\sigma\)-algebras.
XII.1.4.9. Theorem. Let $X$ and $Y$ be sets, $f : X \to Y$ a function, and $\mathcal{B}$ a $\sigma$-algebra on $Y$. If $\mathcal{C} \subseteq \mathcal{B}$ is a subset which generates $\mathcal{B}$ as a $\sigma$-algebra, then $f^{-1}(\mathcal{C}) = \{ f^{-1}(C) : C \in \mathcal{C} \}$ generates $f^{-1}(\mathcal{B})$ as a $\sigma$-algebra.

Proof: Let $\mathcal{A}$ be the $\sigma$-algebra on $X$ generated by $f^{-1}(\mathcal{C})$. Then $\mathcal{A} \subseteq f^{-1}(\mathcal{B})$ since by XII.1.4.7, $f^{-1}(\mathcal{B})$ is a $\sigma$-algebra containing $f^{-1}(\mathcal{C})$. Let

$$B_0 = f^{-1}(A) \cap B = \{ B \in \mathcal{B} : f^{-1}(B) \in \mathcal{A} \}.$$  

By XII.1.4.7, $B_0$ is the intersection of two $\sigma$-algebras, hence is a $\sigma$-algebra; and $B_0 \subseteq \mathcal{B}$. Also, $\mathcal{C} \subseteq B_0$. But $\mathcal{C}$ generates $\mathcal{B}$ as a $\sigma$-algebra, so $B_0 = \mathcal{B}$, and hence $f^{-1}(B) \in \mathcal{A}$ for any $B \in \mathcal{B}$, i.e. $f^{-1}(\mathcal{B}) \subseteq \mathcal{A}$, so $\mathcal{A} = f^{-1}(\mathcal{B})$.

XII.1.4.10. Corollary. Let $(X, \mathcal{A})$ and $(Y, \mathcal{B})$ be measurable spaces, $f : X \to Y$ a function, and $\mathcal{C}$ a subset of $\mathcal{B}$ which generates $\mathcal{B}$ as a $\sigma$-algebra. Then $f$ is measurable if and only if $f^{-1}(C) \in \mathcal{A}$ for every $C \in \mathcal{C}$.

Proof: It is obvious that if $f$ is measurable, then $f^{-1}(C) \in \mathcal{A}$ for every $C \in \mathcal{C}$. The converse follows immediately from XII.1.4.9., since by assumption the $\sigma$-algebra on $X$ generated by $f^{-1}(\mathcal{C})$, which by the theorem is $f^{-1}(\mathcal{B})$, is contained in $\mathcal{A}$.

The next simple observation is extraordinarily useful in defining measurable functions piecewise:

XII.1.4.11. Proposition. Let $(X, \mathcal{A})$ and $(Y, \mathcal{B})$ be measurable spaces, and let $(E_n)$ be a sequence in $\mathcal{A}$ with $\bigcup_{n=1}^{\infty} E_n = X$. (Since $\emptyset \in \mathcal{A}$, $(E_n)$ could also be a finite sequence.) Let $f : X \to Y$ be a function, and set $f_n = f|_{E_n} : E_n \to Y$. If each $f_n$ is measurable, then $f$ is measurable.

Proof: Let $B \in \mathcal{B}$. We need to show that $f^{-1}(B) \in \mathcal{A}$. By assumption, $f_n^{-1}(B) = \{ x \in E_n : f_n(x) = f(x) \in B \}$ is in $\mathcal{A}$. But $f^{-1}(B) = \bigcup_{n=1}^{\infty} f_n^{-1}(B)$.

A slight rephrasing is usually used in piecewise definition of functions:

XII.1.4.12. Corollary. Let $(X, \mathcal{A})$ and $(Y, \mathcal{B})$ be measurable spaces, and let $(E_n)$ be a sequence in $\mathcal{A}$ which partitions $X$, i.e. the $E_n$ are pairwise disjoint and $\bigcup_{n=1}^{\infty} E_n = X$. (Since $\emptyset \in \mathcal{A}$, $(E_n)$ could also be a finite sequence.) For each $n$, let $f_n : E_n \to Y$ be a function, and define $f : X \to Y$ by $f(x) = f_n(x)$ if $x \in E_n$. If each $f_n$ is measurable, then $f$ is measurable.

XII.1.4.13. We can also rephrase the last two results in another way. If $(X, \mathcal{A})$ is a measurable space, and $E \in \mathcal{A}$, the restriction of $\mathcal{A}$ to $E$ is

$$\mathcal{A}_E = \{ A \cap E : A \in \mathcal{A} \} = \{ B : B \in \mathcal{A}, B \subseteq E \}.$$  

which can be easily verified to be a $\sigma$-algebra of subsets of $E$. The measurable space $(E, \mathcal{A}_E)$ is called a measurable subspace, or Borel subspace, of $(X, \mathcal{A})$.  

1362
XII.1.4.14. **Definition.** (i) If \((X, \mathcal{A})\) and \((Y, \mathcal{B})\) are measurable spaces, the *sum* or *disjoint union* is the measurable space \((Z, \mathcal{C})\), where \(Z\) is the disjoint union \(X \sqcup Y \) and
\[
\mathcal{C} = \{ A \sqcup B : A \in \mathcal{A}, B \in \mathcal{B} \}
\]
(it is easy to check that \(\mathcal{C}\) is a \(\sigma\)-algebra of subsets of \(X \sqcup Y\)). The sum is denoted \((X, \mathcal{A}) \oplus (Y, \mathcal{B})\).

(ii) Let \((X_n, \mathcal{A}_n)\) be a finite or countable set of measurable spaces. The *sum* or *disjoint union*, denoted \(\bigoplus_n (X_n, \mathcal{A}_n)\), is the measurable space \((Z, \mathcal{C})\), where \(Z = \sqcup_n X_n\) and
\[
\mathcal{C} = \{ \sqcup_n A_n : A_n \in \mathcal{A}_n \text{ for all } n \}
\]
(it is again easy to check that \(\mathcal{C}\) is a \(\sigma\)-algebra of subsets of \(Z\) (Exercise ()).)

Then XII.1.4.11. can be rephrased:

XII.1.5. **Proposition.** Let \((X, \mathcal{A})\) be a measurable space, and let \((E_n)\) be a sequence in \(\mathcal{A}\) which partitions \(X\), i.e. the \(E_n\) are pairwise disjoint and \(\sqcup_{n=1}^\infty E_n = X\). (Since \(\emptyset \in \mathcal{A}\), \((E_n)\) could also be a finite sequence.) Let \(f_n\) be the inclusion map of \(E_n\) into \(X\), and \(f : \sqcup_n E_n \to X\) the induced map. Then \(f\) is a Borel isomorphism from \(\bigoplus_n (E_n, \mathcal{A}_{E_n})\) onto \((X, \mathcal{A})\). In particular, if \(E \in \mathcal{A}\), then \((X, \mathcal{A})\) is Borel isomorphic to \((E, \mathcal{A}_E) \oplus (X \setminus E, \mathcal{A}_{X \setminus E})\).

XII.1.5. **Exercises**

XII.1.5.1. This exercise should convince the reader of (1) the truth of the statement of XII.1.1.5. and (2) the author’s wisdom in not attempting to write out a full proof. Adopt the situation and notation of XII.1.1.5..

(a) Verify the four identities in the proof outline.

(b) Let \(A_i, B_i, C_i, D_i\) \((i = 1, 2)\) be sets in \(\mathcal{C}\). Show that
\[
[(A_1 \setminus B_1) \cap (A_2 \setminus B_2)] \setminus [(C_1 \setminus D_1) \cap (C_2 \setminus D_2)]
\]
is a finite disjoint union of finite intersections of sets in \(\mathcal{C} \cup \mathcal{D}\), using the four identities. [The first step is to use the fourth identity to rewrite the set as
\[
[(A_1 \setminus B_1) \cap (A_2 \setminus B_2)] \setminus (C_1 \setminus D_1) \cup \{(A_1 \setminus B_1) \cap (A_2 \setminus B_2) \cap (C_1 \setminus D_1)\}\setminus (C_2 \setminus D_2)
\]
where \(\sqcup\) denotes disjoint union.]

XII.1.5.2. Let \(\mathcal{E}\) be a collection of subsets of a set \(X\). Set \(\tilde{\mathcal{E}} = \{ X \setminus E : E \in \mathcal{E}\}\).

(a) Show that if \(\mathcal{E}\) is closed under finite unions and finite intersections, and \(\mathcal{E} \cap \tilde{\mathcal{E}}\) is nonempty, then \(\mathcal{E} \cap \tilde{\mathcal{E}}\) is an algebra of subsets of \(X\) and is the largest algebra contained in \(\mathcal{E}\).

(b) Show that if \(\mathcal{E}\) is closed under countable unions and countable intersections, and \(\mathcal{E} \cap \tilde{\mathcal{E}}\) is nonempty, then \(\mathcal{E} \cap \tilde{\mathcal{E}}\) is a \(\sigma\)-algebra of subsets of \(X\) and is the largest \(\sigma\)-algebra contained in \(\mathcal{E}\).

(c) Even if \(\mathcal{E}\) is infinite and closed under countable unions and countable intersections, \(\mathcal{E} \cap \tilde{\mathcal{E}}\) can be empty. [Let \(\mathcal{E}\) be the collection of countable subsets of an uncountable set.]
XII.1.5.3. Prove the Schröder-Bernstein Theorem for measurable spaces: if \((X, \mathcal{A})\) and \((Y, \mathcal{B})\) are measurable spaces, \((X, \mathcal{A})\) is Borel isomorphic to a measurable subspace of \((Y, \mathcal{B})\), and \((Y, \mathcal{B})\) is Borel isomorphic to a measurable subspace of \((X, \mathcal{A})\), then \((X, \mathcal{A})\) and \((Y, \mathcal{B})\) are Borel isomorphic. [Mimic the proof of the Schröder-Bernstein Theorem of set theory (II.5.6.11.).]
XII.1.6. Filters and Ultrafilters

Filters are another important type of subspace structure. Filters are useful in a wide variety of mathematical applications, especially in topology.

XII.1.6.1. Definition. Let $X$ be a set. A filter on $X$ is a nonempty collection $\mathcal{F}$ of subsets of $X$ such that

(i) $\mathcal{F}$ is closed under finite intersections.

(ii) $\mathcal{F}$ has the superset property: if $A \in \mathcal{F}$ and $A \subseteq B \subseteq X$, then $B \in \mathcal{F}$.

(iii) $\emptyset \notin \mathcal{F}$.

A filter on $X$ which is not properly contained in any other filter on $X$ is called an ultrafilter on $X$.

XII.1.6.2. It follows from the superset property that a filter $\mathcal{F}$ is closed under arbitrary unions, and, since $\mathcal{F}$ is nonempty, that $X \in \mathcal{F}$. Thus a filter is somewhat similar to a topology. But property (iii) gives a crucial difference between a filter and a topology (a topology also does not have the superset property in general).

In fact, if $\mathcal{F}$ is a filter on $X$ and $A \subseteq X$, we cannot have both $A$ and $A^c$ in $\mathcal{F}$, since then we would have $A \cap A^c = \emptyset \notin \mathcal{F}$. It can happen, though, that neither $A$ nor $A^c$ is in $\mathcal{F}$. (This cannot happen in an ultrafilter, and in fact gives a characterization of ultrafilters (XII.1.6.12.).)

XII.1.6.3. A useful point of view, which is helpful in determining abstract properties of filters and appropriate for some, but not all, applications, is to regard a filter (especially an ultrafilter) as giving a notion of “size” for subsets of $X$: sets in the filter are regarded as “large” subsets and those not in the filter as “small” subsets.

XII.1.6.4. As with many other subset structures, the intersection of any collection $\{\mathcal{F}_i : i \in I\}$ of filters on $X$ is a filter on $X$ (note that the intersection is a nonempty collection of subsets since $X \in \mathcal{F}_i$ for all $i$). However, the union of two filters is not a filter in general (in fact, see XII.1.6.8.); but the union of a chain (under inclusion) of filters is a filter (Exercise (i)).

XII.1.6.5. If $\mathcal{F}$ is a filter on $X$, the set $\mathcal{I} = \{A^c : A \in \mathcal{F}\}$ is closed under finite unions and subsets, and does not contain the whole set $X$. Such a collection is called an order ideal. Order ideals and hence filters can be defined in general partially ordered sets (i).

XII.1.6.6. Examples. (i) Let $A$ be a fixed nonempty subset of $X$, and let

$$\mathcal{F}_A = \{B \subseteq X : A \subseteq B\}.$$ 

Then $\mathcal{F}_A$ is a filter on $X$, which is an ultrafilter if and only if $A$ is a singleton (note that $\mathcal{F}_A \subseteq \mathcal{F}_B$ if and only if $A \subseteq B$). If $x \in X$, write $\mathcal{F}_x$ to mean $\mathcal{F}_{\{x\}}$. Thus $\mathcal{F}_x = \{B \subseteq X : x \in B\}$.

(ii) Let $X$ be an infinite set, and $\mathcal{F}$ the collection of all subsets of $X$ with finite complement. Then $\mathcal{F}$ is a filter on $X$. This filter is never an ultrafilter (cf. XII.1.6.12.). More generally, if $\kappa$ is an infinite cardinal less
than or equal to $\text{card}(X)$, the set $\mathcal{F}$ of subsets $A$ of $X$ for which $\text{card}(A^c) < \kappa$ is a filter on $X$; in particular, if $X$ is uncountable, the set of cocountable subsets of $X$ is a filter on $X$.

(iii) Let $(X, \mathcal{T})$ be a topological space, and $x \in X$. Let $\mathcal{O}_x$ be the collection of all $\mathcal{T}$-neighborhoods () of $x$. Then $\mathcal{O}_x$ is a filter on $X$ which is contained in $\mathcal{F}_x$; they are not the same in general since $\{x\} \in \mathcal{O}_x$ if and only if $x$ is an isolated point in $X$ (i.e. $\{x\} \in \mathcal{T}$). Thus $\mathcal{O}_x$ is usually not an ultrafilter on $X$. More generally, $x$ can be replaced by any nonempty subset of $X$. (The notation $\mathcal{O}_x$ should really include the topology $\mathcal{T}$ since this filter depends on $\mathcal{T}$ as well as $x$.)

The intersection of all the sets in a filter may be empty (XII.1.6.6.(ii)) or nonempty (XII.1.6.6.(i)). We make the following definition:

XII.1.6.7. Definition. Let $\mathcal{F}$ be a filter on a set $X$. $\mathcal{F}$ is a fixed filter with fixed set $A$ if the intersection of all the sets in $\mathcal{F}$ is the nonempty set $A$. If the intersection of all sets in $\mathcal{F}$ is empty, $\mathcal{F}$ is a free filter on $X$.

An ultrafilter on a set $X$ is either of the form $\mathcal{F}_x$ (XII.1.6.6.(i)) for some $x \in X$, or is free. The ultrafilter $\mathcal{F}_x$ is often called the principal ultrafilter at the point $x$.

XII.1.6.8. If $\mathcal{F}$ and $\mathcal{G}$ are filters on $X$, then there may not be any filter on $X$ at all containing $\mathcal{F} \cup \mathcal{G}$; this will fail if there is a subset $A$ of $X$ with $A \in \mathcal{F}$ and $A^c \in \mathcal{G}$ (XII.1.6.2.), e.g. if $\mathcal{F}$ and $\mathcal{G}$ are $\mathcal{F}_x$ and $\mathcal{F}_y$ as in XII.1.6.6.(i) for distinct $x$ and $y$. If there is such a set $A$, $\mathcal{F}$ and $\mathcal{G}$ are said to be separated (). Thus an arbitrary collection of nonempty subsets of $X$ need not be contained in a filter on $X$. We will characterize when a collection of subsets is contained in a filter.

XII.1.6.9. Definition. A collection $\mathcal{S}$ of subsets of a set $X$ has the finite intersection property if the intersection of any finite number of sets in $\mathcal{S}$ is nonempty.

Any subset of a filter on a set $X$ has the finite intersection property. The converse is also true:

XII.1.6.10. Proposition. Let $\mathcal{S}$ be a collection of subsets of a set $X$, with the finite intersection property. Then there is a filter on $X$ containing $\mathcal{S}$.

Proof: Let $\mathcal{F}$ be the collection of all subsets of $X$ which contain a finite intersection of sets in $\mathcal{S}$. It is easy to verify that $\mathcal{F}$ is a filter containing $\mathcal{S}$, and is the smallest such filter. ☐

We now aim towards the question of whether every filter is contained in an ultrafilter, and along the way we will obtain an important explicit characterization of ultrafilters. We first obtain a fairly simple, but important, one-step extension theorem.

XII.1.6.11. Theorem. [Filter Extension Theorem] Let $\mathcal{F}$ be a filter on a set $X$, and $A \subseteq X$. If $A^c \notin \mathcal{F}$, then there is a filter $\mathcal{G}$ on $X$ containing $\mathcal{F}$ and $A$, i.e. with $\mathcal{F} \subseteq \mathcal{G}$ and $A \in \mathcal{G}$.

Note that the condition $A^c \notin \mathcal{F}$ is necessary for the existence of $\mathcal{G}$, since otherwise both $A$ and $A^c$ would be in $\mathcal{G}$.
Proof: Let
\[ G = \{ C \subseteq X : C \supseteq (B \cap A) \text{ for some } B \in \mathcal{F} \} . \]
If \( B \in \mathcal{F} \), then \( B \supseteq (B \cap A) \), so \( B \in \mathcal{G} \), and thus \( \mathcal{F} \subseteq \mathcal{G} \). We also have \( A \in \mathcal{G} \) since \( A \supseteq (X \cap A) \).

We show that \( \mathcal{G} \) is a filter on \( X \). \( \mathcal{G} \) obviously has the superset property, and is nonempty since \( \mathcal{F} \subseteq \mathcal{G} \).

If \( C_1, C_2 \in \mathcal{G} \), with \( C_1 \supseteq (B_1 \cap A) \) and \( C_2 \supseteq (B_2 \cap A) \) for \( B_1, B_2 \in \mathcal{F} \), then
\[
C_1 \cap C_2 \supseteq (B_1 \cap A) \cap (B_2 \cap A) = (B_1 \cap B_2) \cap A
\]
and \( (B_1 \cap B_2) \in \mathcal{F} \), so \( (C_1 \cap C_2) \in \mathcal{G} \). Hence \( \mathcal{G} \) is closed under finite intersections. Finally, we show \( \emptyset \notin \mathcal{G} \).

If \( \emptyset \in \mathcal{G} \), then \( \emptyset \supseteq (B \cap A) \) for some \( B \in \mathcal{F} \); for this \( B \), we have \( B \cap A = \emptyset \), so \( B \subseteq A^c \) and \( A^c \in \mathcal{F} \) by the superset property, contrary to hypothesis. Thus \( \mathcal{G} \) is the desired filter.

As an immediate consequence, we get a characterization of ultrafilters:

XII.1.6.12. Theorem. [Ultrafilter Characterization Theorem] Let \( \mathcal{F} \) be a filter on a set \( X \). Then \( \mathcal{F} \) is an ultrafilter if and only if, for every subset \( A \) of \( \mathcal{F} \), exactly one of \( A \) and \( A^c \) is in \( \mathcal{F} \).

Proof: We cannot have both \( A \) and \( A^c \) in \( \mathcal{F} \) (XII.1.6.2.). If neither \( A \) nor \( A^c \) is in \( \mathcal{F} \) for some subset \( A \) of \( X \), then the filter \( \mathcal{G} \) of XII.1.6.11. properly contains \( \mathcal{F} \), so \( \mathcal{F} \) is not an ultrafilter. Conversely, if \( \mathcal{F} \) is not an ultrafilter, and \( \mathcal{G} \) is a filter on \( X \) properly containing \( \mathcal{F} \), let \( A \in \mathcal{G} \setminus \mathcal{F} \). Then \( A^c \notin \mathcal{G} \) by XII.1.6.2., so neither \( A \) nor \( A^c \) is in \( \mathcal{F} \).

Here is another useful observation which is a simple corollary:

XII.1.6.13. Corollary. Let \( \mathcal{F} \) be a filter on a set \( X \). Then \( \mathcal{F} \) is an ultrafilter if and only if, whenever \( A, B \subseteq X \) and \( A \cup B \in \mathcal{F} \), we have either \( A \in \mathcal{F} \) or \( B \in \mathcal{F} \).

Proof: A filter with this property is an ultrafilter by setting \( B = A^c \). Conversely, suppose \( \mathcal{F} \) is an ultrafilter and \( A \cup B \in \mathcal{F} \). If \( A \notin \mathcal{F} \) and \( B \notin \mathcal{F} \), we have \( A^c \in \mathcal{F} \) and \( B^c \in \mathcal{F} \), so
\[
A^c \cap B^c = (A \cup B)^c \in \mathcal{F}
\]
which contradicts XII.1.6.2..
XII.1.6.15. Theorem. (AC) Every filter on a set $X$ is contained in an ultrafilter on $X$.

The proof of this theorem is a standard Zorn’s Lemma argument, and is left to the reader (Exercise ()).

XII.1.6.16. This theorem cannot be proved without some form of the Axiom of Choice. But the full AC is not needed: the statement of this theorem is equivalent to the Boolean Prime Ideal Theorem (II.6.3.11.), which is strictly weaker than AC.

We cannot even prove without some form of AC that there is a free ultrafilter on $\mathbb{N}$ (this statement actually follows from the Measure Extension Theorem (), which is strictly weaker than the Boolean Prime Ideal Theorem). With AC (or BPI), this is an immediate application of XII.1.6.15. to the filter of cofinite subsets of $\mathbb{N}$ (XII.1.6.6.(ii)).

It can be shown even without AC that many sets have a large number of pairwise separated filters. To give the best statement possible without AC, we first discuss two key property of at least some cardinals:

XII.1.6.17. If $\kappa$ is a cardinal, and $X$ is a set of cardinality $\kappa$, then we denote by $\kappa^2$ the cardinality of $X \times X$. We always have $\kappa^2 \geq \kappa$. If $1 < \kappa < \aleph_0$, then $\kappa^2 > \kappa$. If $\kappa$ is infinite, then it is conceivable that $\kappa^2$ always equals $\kappa$; this can be proved using AC (and turns out to be equivalent to AC). Without AC the following can be proved:

(i) $\aleph_0^2 = \aleph_0$ ()

(ii) More generally, if $\aleph$ is any aleph (), then $\aleph^2 = \aleph$.

(iii) $(2^{\aleph_0})^2 = 2^{\aleph_0}$ ()

XII.1.6.18. We now turn to the other cardinal property. Let $\kappa$ be a cardinal, and $X$ a set of cardinality $\kappa$. Let $\Phi$ be the set of all finite subsets of $X$. We have $\text{card}(\Phi) \geq \text{card}(X)$. If $\kappa$ is finite, the inequality is strict. For infinite sets, it is conceivable that equality always holds (it holds for $\aleph_0$ by ()); if $\text{card}(\Phi) = \text{card}(X)$, we say $\kappa$ has the finite subset property.

If $\kappa^2 = \kappa \geq \aleph_0$ and $X$ can be totally ordered, it is not difficult to show that $\kappa$ has the finite subset property (II.5.6.12.). Thus $\aleph_0$ (in fact, any $\aleph$) and $2^{\aleph_0}$ have the finite subset property. So it follows from AC that every infinite cardinal has the finite subset property. It cannot be proved in ZF that every infinite cardinal has the finite subset property (), i.e. some type of Choice is necessary.

XII.1.6.19. Theorem. ([?]; cf. [?], [GJ76, 9.2]) Let $\kappa$ be a (necessarily infinite) cardinal with $\kappa^2 = \kappa$ and the finite subset property, and $X$ a set of cardinality $\kappa$. Then there are $2^{2^\kappa}$ pairwise separated filters on $X$. In particular, there are $2^{2^{\aleph_0}}$ pairwise separated filters on $\mathbb{N}$.

Proof: Let $\Phi$ be the set of all finite subsets of $X$, and $\Lambda$ the set of all finite subsets of $\Phi$. Set $\Omega = \Phi \times \Lambda$. Then from $\kappa^2 = \kappa$ and the finite subset property it follows that $\text{card}(\Phi) = \text{card}(\Lambda) = \text{card}(\Omega) = \kappa$.

We will define $2^{2^\kappa}$ pairwise separated filters on $\Omega$, which will suffice since $\text{card}(\Omega) = \text{card}(X)$. First some notation: for $S \subseteq X$, define a subset $\mathcal{B}_S$ of $\Omega$ as follows:

$$\mathcal{B}_S = \{(F, \mathcal{L}) \in \Phi \times \Lambda : S \cap F \in \mathcal{L}\}.$$
Write $C_S$ for the complement of $B_S$ in $\Omega$. Then, for $S \subseteq \mathcal{P}(X)$, define

$$\mathcal{B}_S = \{B_S : S \in S\} \cup \{C_S : S \notin S\} \subseteq \mathcal{P}(\Omega).$$

We claim that $\mathcal{B}_S$ has the finite intersection property (XII.1.6.9.). If $\mathfrak{A}$ is a finite subset of $\mathcal{B}_S$, the distinct sets in $\mathfrak{A}$ can be numbered as follows:

$$B_{S_1}, \ldots, B_{S_k}, C_{S_{k+1}}, \ldots, C_{S_n}$$

where $S_1, \ldots, S_n$ are distinct subsets of $X$. For $i \neq j$ let $x_{ij}$ be an element of $X$ which is in one of $S_i$ and $S_j$ but not the other (note that there are only finitely many choices to be made here, so no form of AC is needed). Let $F$ be the set of all the $x_{ij}$ for $i \neq j$. Then the sets

$$S_i \cap F, \ldots, S_n \cap F$$

are all distinct since if $i \neq j$, $x_{ij}$ is in one of $S_i \cap F$ and $S_j \cap F$ but not the other. Set

$$\mathcal{L} = \{S_1 \cap F, \ldots, S_k \cap F\} \in \mathfrak{A}.$$  

We have that $S_i \cap F \in \mathcal{L}$ for $1 \leq i \leq k$, and $S_j \cap K \notin \mathcal{L}$ for $k + 1 \leq j \leq n$. So $(F, \mathcal{L}) \in \mathcal{B}_S$, for $1 \leq i \leq k$ and $(F, \mathcal{L}) \in \mathcal{C}_S$, for $k + 1 \leq j \leq n$, and hence the intersection of the sets in $\mathfrak{A}$ is nonempty, proving the claim.

Thus, for each $S \subseteq \mathcal{P}(X)$, there is a filter $\mathfrak{F}_S$ on $\Omega$ containing $\mathcal{B}_S$ by XII.1.6.10. If $S_1$ and $S_2$ are distinct subsets of $\mathcal{P}(X)$, let $S$ be a subset of $X$ which is in one of them (say $S_1$) but not the other. Then $B_S \in \mathfrak{F}_{S_1}$ and $C_S \in \mathfrak{F}_{S_2}$, so $\mathfrak{F}_{S_1}$ and $\mathfrak{F}_{S_2}$ are separated. The number of distinct filters constructed is $\text{card}(\mathcal{P}(\mathcal{P}(X))) = 2^{2^n}$.\[\text{\blacksquare}\]

Note that AC is not used in this result. Using AC, the conclusion holds for all infinite cardinals. The full AC is needed here, not just the BPI (since we need $\kappa^2 = \kappa$ for all $\kappa$). Combining this result with XII.1.6.15., we obtain:

**XII.1.6.20.** Theorem. (AC) Let $X$ be an infinite set, of cardinality $\kappa$. Then there are exactly $2^{2^n}$ free ultrafilters on $X$.

**Proof:** By XII.1.6.15., each $\mathfrak{F}_S$ from the proof of XII.1.6.19. is contained in an ultrafilter. These ultrafilters are all distinct since the $\mathfrak{F}_S$ are pairwise separated. Thus there are at least $2^{2^n}$ ultrafilters on $X$. On the other hand, there are at most $2^{2^n}$ filters on $X$ since there are only $2^{2^n}$ sets of subsets of $X$. Thus there are exactly $2^{2^n}$ ultrafilters on $X$. Only $\kappa$ of these are fixed, so there are $2^{2^n}$ free ones.\[\text{\blacksquare}\]

In particular, there are $2^{2^{\aleph_0}}$ distinct free ultrafilters on $\mathbb{N}$ (assuming AC, or at least BPI).

**XII.1.7.** Exercises

**XII.1.7.1.** Verify the assertions in the examples of XII.1.6.6.

**XII.1.7.2.** Verify the assertion in XII.1.6.7. that every ultrafilter which is not free is of the form $\mathcal{F}_x$ for some $x$.  

1369
XII.1.7.3. (a) Verify that the set $F$ defined in the proof of XII.1.6.10. is a filter.
(b) Show that two filters $F$ and $G$ on a set $X$ are separated if and only if $F \cup G$ fails to have the finite intersection property. Thus if $F$ and $G$ are not separated, they are contained in a common larger filter on $X$.

XII.1.7.4. (a) Show that if $\{F_i : i \in I\}$ is a chain (under inclusion) of filters on a set $X$, i.e. $F_i \subseteq F_j$ or $F_j \subseteq F_i$ for all $i, j \in I$, then $\cup_{i \in I} F_i$ is a filter on $X$.
(b) Let $F$ be a filter on a set $X$, and let $\mathcal{Y} \subseteq \mathcal{P}(\mathcal{P}(X))$ be the set of all filters on $X$ containing $F$. Partially order $\mathcal{Y}$ by inclusion. Show that every chain in $\mathcal{Y}$ has an upper bound in $\mathcal{Y}$.
(c) Conclude from Zorn’s Lemma that $\mathcal{Y}$ contains a maximal element $G$. Show that $G$ is an ultrafilter on $X$.

XII.1.7.5. Let $(\mathcal{X}, \leq)$ be a partially ordered set. Define an order ideal in $(\mathcal{X}, \leq)$ to be a subset $I$ which is hereditary, i.e. if $y \in I$, $x \in \mathcal{X}$, and $x \leq y$, then $x \in I$, and such that any two elements (hence any finite set of elements) of $I$ have an upper bound in $I$. Define a filter on $(\mathcal{X}, \leq)$ to be the complement of a nonempty proper order ideal.
(a) Let $X$ be a set. Show that order ideals and filters in $(\mathcal{P}(X), \subseteq)$ under this definition are exactly the order ideals and filters under the definitions of this section.
(b) Extend the results of this section as far as possible to filters in general partially ordered sets.
XII.2. Borel Sets and Borel Measurable Functions

For measure theory purposes, the Borel sets are the most important subsets of $\mathbb{R}$ or $\mathbb{R}^n$. The class of Borel sets is large enough to contain every subset of $\mathbb{R}$ which can be described “naturally”, and small enough that measure-theoretic operations behave well on them. Similarly, the Borel measurable functions are the natural ones to consider for integration theory. (Later we will expand the classes of Borel sets and Borel measurable functions to the larger classes of Lebesgue measurable sets and functions, primarily for technical reasons.)

We will give two characterizations of the Borel sets in this section, and a third important one in the next section, along with corresponding descriptions of the Borel measurable functions. Most of the work can be done in a general topological space, but we will emphasize the most important case of $\mathbb{R}$ in examples.

XII.2.1. Borel Sets

XII.2.1.1. Definition. Let $(X, T)$ be a topological space. Let $\mathcal{B}_T$ be the $\sigma$-algebra on $X$ generated by $T$, i.e. the smallest $\sigma$-algebra containing the open sets of $X$. $\mathcal{B}_T$ is called the class of Borel sets of $(X, T)$.

When a set $X$ such as $\mathbb{R}$ has a natural topology, we will usually just write $\mathcal{B}$ for the class of Borel sets on $X$, suppressing the subscript $T$.

XII.2.1.2. The following sets are Borel sets in $(X, T)$:

(i) All open sets in $X$.

(i') All closed sets in $X$.

(ii) Any countable intersection of open sets in $X$. Such a subset of $X$ is called a $G_\delta$ set.

(ii') Any countable union of closed sets in $X$. Such a subset of $X$ is called an $F_\sigma$ set.

(iii) Any countable union of $G_\delta$ sets in $X$. Such a subset of $X$ is called a $G_\delta\sigma$ set.

(iii') Any countable intersection of $F_\sigma$ sets in $X$. Such a subset of $X$ is called a $F_\sigma\delta$ set.

(iv) $G_{\delta\sigma\delta}, F_{\sigma\delta\sigma}, G_{\delta\sigma\delta\sigma}, \cdots$ sets can be defined analogously.

XII.2.1.3. In most cases, and in particular if $X = \mathbb{R}$, this process never terminates and must be repeated transfinitely (uncountably many times) to obtain all Borel sets (XII.3.5.4.). (It is not obvious that these classes are never $\sigma$-algebras after finitely or countably many steps for $X = \mathbb{R}$; see () for a proof.) The complement of a $G_\delta$ set is an $F_\sigma$ set, the complement of an $F_\sigma\delta$ is a $G_\delta\sigma$, etc. For measure theoretic purposes, it is rarely necessary to consider sets more complicated than $G_\delta$’s or $F_\sigma$’s (which are complicated enough already!)

The notation $F_\sigma, G_\delta, \text{etc.}$, is due to HAUSDORFF. There is a more modern notation, described in XII.3.4., which is used by descriptive set theorists; but HAUSDORFF’S notation is still commonly used by analysts.

It should be obvious that the class of Borel sets in $\mathbb{R}$ includes a great many subsets. For example:
XII.2.1.4.

(i) Every singleton set \( \{x\} \) in \( \mathbb{R} \) (or, more generally, in a \( T_1 \) space \( X \)) is a closed set, hence a Borel set. Every countable subset of \( \mathbb{R} \) is thus an \( F_\sigma \), hence a Borel set, since it is a countable union of singleton sets. In particular, \( \mathbb{Q} \) is an \( F_\sigma \), and hence \( J \) is a \( G_\delta \). (It turns out, although it is not obvious, that \( \mathbb{Q} \) is not a \( G_\delta \), so \( J \) is not an \( F_\sigma \); see XI.12.1.5.)

(ii) Every open interval in \( \mathbb{R} \) is an \( F_\sigma \); \( (a,b) = \bigcup_{n=1}^\infty [a + \frac{1}{n}, b - \frac{1}{n}] \), and similarly for \( (a,\infty) \) or \( (-\infty,b) \). Since every open set in \( \mathbb{R} \) is a countable union of open intervals, every open set in \( \mathbb{R} \) is an \( F_\sigma \), and thus every closed set is a \( G_\delta \). Of course, every open set is a \( G_\delta \), so every closed set is an \( F_\sigma \).

It is not true that every open set in a general topological space \( X \) is an \( F_\sigma \), but it is true if \( X \) is metrizable ().

(iii) A half-open interval in \( \mathbb{R} \) is neither open nor closed, but is both an \( F_\sigma \) and a \( G_\delta \), and hence a Borel set. The proof is very similar to the proof of (ii), and is left as an exercise.

(iv) An arbitrary (not necessarily countable) union of actual intervals can be written as a countable union of possibly different intervals (), hence is a Borel set (in fact, an \( F_\sigma \)).

An interesting and useful consequence of the construction of the Borel sets is:

XII.2.1.5. PROPOSITION. Let \( \mathcal{A} \) be a collection of subsets of \( \mathbb{R} \) (or any metrizable space) such that

1. \( \mathcal{A} \) contains all closed sets.
2. \( \mathcal{A} \) is closed under countable unions and countable intersections.

Then \( \mathcal{A} \) contains all Borel sets.

PROOF: \( \mathcal{A} \) contains all \( F_\sigma \)'s. Since every open set in \( \mathbb{R} \) is an \( F_\sigma \), \( \mathcal{A} \) contains all open sets, and hence all \( G_\delta \)'s. Hence \( \mathcal{A} \) contains all \( F_{\sigma\delta} \)'s, all \( G_{\delta\sigma} \)'s, \ldots, and by transfinite induction all Borel sets. 

XII.2.1.6. Note that such an \( \mathcal{A} \) need not be a \( \sigma \)-algebra, i.e. need not be closed under complements. An example is the collection of analytic sets (). A similar proof shows that a collection of subsets of a metrizable space which contains all open sets and is closed under countable unions and intersections contains all Borel sets.

XII.2.2. Borel Measurable Functions

Along with the Borel sets themselves, the Borel measurable functions are basic objects for study in measure theory.
XII.2.2.1. Definition. Let \((X, \mathcal{A})\) be a measurable space. A real-valued function \(f : X \to \mathbb{R}\) is \(\mathcal{A}\)-measurable if it is a measurable as a function from \((X, \mathcal{A})\) to \((\mathbb{R}, \mathcal{B})\) in the sense of (\(\circ\)), i.e. if \(f^{-1}(B) \in \mathcal{A}\) for every Borel set \(B\) in \(\mathbb{R}\). Denote by \(\mathcal{B}_{\mathcal{A}}\) the set of \(\mathcal{A}\)-measurable functions from \(X\) to \(\mathbb{R}\).

We can similarly define \(\mathcal{A}\)-measurable functions from a measurable space \((X, \mathcal{A})\) to a topological space \((Y, \mathcal{T})\) to be functions which are \((\mathcal{A}, \mathcal{B}_\mathcal{T})\)-measurable in the sense of (\(\circ\)). Thus we may also define \(\mathcal{A}\)-measurable functions from \(X\) to \(\mathbb{R}^n\).

If \((X, \mathcal{T})\) is a topological space, a function \(f : X \to \mathbb{R}\) is Borel measurable if it is \(\mathcal{B}_\mathcal{T}\)-measurable, i.e. the inverse image of every Borel set in \(\mathbb{R}\) is a Borel set in \((X, \mathcal{T})\). Denote by \(\mathcal{B}_\mathcal{T}\) the set of Borel measurable functions from \(X\) to \(\mathbb{R}\). Write \(\mathcal{B}\) for the set of Borel measurable functions from \(\mathbb{R}\) to \(\mathbb{R}\). We may similarly define Borel measurability for functions from \(X\) to \(\mathbb{R}^n\), and more generally for functions from \(X\) to any topological space \((Y, \mathcal{S})\).

XII.2.2.2. We most commonly use the term “Borel measurable” for functions from \(\mathbb{R}\) to \(\mathbb{R}\) (or from \(\mathbb{R}^n\) to \(\mathbb{R}^m\)). We will show that all “reasonable” functions from \(\mathbb{R}\) to \(\mathbb{R}\) are Borel measurable. In fact, roughly speaking, any function from \(\mathbb{R}\) to \(\mathbb{R}\) which can be defined or described without using the Axiom of Choice is Borel measurable; in particular, any function which can be defined by a countable number of algebraic, order, or pointwise limit operations is Borel measurable. (Strictly speaking, the first part of this statement is not true; it is possible, but quite complicated, to explicitly describe a subset of \(\mathbb{R}\) which is not a Borel set, and hence a function which is not Borel measurable; see (\(\circ\)).

The next proposition is a special case of XII.1.4.3.: 

XII.2.2.3. Proposition. (a) Let \((X, \mathcal{A})\) and \((Y, \mathcal{C})\) be measurable spaces, \(f : X \to Y\) an \((\mathcal{A}, \mathcal{C})\)-measurable function, and \(g : Y \to \mathbb{R}\) a \(\mathcal{C}\)-measurable function. Then \(g \circ f : X \to \mathbb{R}\) is \(\mathcal{A}\)-measurable. (Here \(\mathbb{R}\) may be replaced by any topological space.)
(b) Let \((X, \mathcal{T})\), \((Y, \mathcal{S})\), and \((Z, \mathcal{R})\) be topological spaces, \(f : X \to Y\) and \(g : Y \to Z\) Borel measurable functions. Then \(g \circ f : X \to Z\) is Borel measurable.

It is often convenient to use an apparently weaker criterion for measurability of real-valued functions. Here are some of the most useful ones:

XII.2.2.4. Proposition. Let \((X, \mathcal{A})\) be a measurable space and \(f : X \to \mathbb{R}\) a function. Then \(f\) is \(\mathcal{A}\)-measurable if and only if any of the following conditions are satisfied:

- \((i)\) \(f^{-1}(U) \in \mathcal{A}\) for every open set \(U \subseteq \mathbb{R}\).
- \((i)\) \(f^{-1}(E) \in \mathcal{A}\) for every closed set \(E \subseteq \mathbb{R}\).
- \((ii)\) \(f^{-1}(U) \in \mathcal{A}\) for every open interval \(U \subseteq \mathbb{R}\).
- \((iv)\) \(f^{-1}((-\infty, a)) \in \mathcal{A}\) for every \(a \in \mathbb{R}\).
- \((v)\) \(f^{-1}((a, +\infty)) \in \mathcal{A}\) for every \(a \in \mathbb{R}\).
- \((vi)\) \(f^{-1}([a, +\infty)) \in \mathcal{A}\) for every \(a \in \mathbb{R}\).
- \((vii)\) \(f^{-1}((a, +\infty)) \in \mathcal{A}\) for every \(a \in \mathbb{R}\).
- \((viii)\) \(f^{-1}((\infty, a)) \in \mathcal{A}\) for every \(a \in \mathbb{Q}\).
(ix) $f^{-1}((-\infty, a]) \in \mathcal{A}$ for every $a \in \mathbb{Q}$.

(x) $f^{-1}((a, +\infty)) \in \mathcal{A}$ for every $a \in \mathbb{Q}$.

(xi) $f^{-1}([a, +\infty)) \in \mathcal{A}$ for every $a \in \mathbb{Q}$.

These criteria apply to Borel measurability for functions from $\mathbb{R}$ to $\mathbb{R}$ (or from a topological space $(X, \mathcal{T})$ to $\mathbb{R}$), with $\mathcal{A} = \mathcal{B}$.

This proposition is an immediate consequence of XII.1.4.9., since each of the collections of sets listed generates $\mathcal{B}$ as a $\sigma$-algebra.

**XII.2.2.5.** Corollary. Every continuous function from a topological space $(X, \mathcal{T})$ to $\mathbb{R}$ is Borel measurable. In particular, every continuous function from $\mathbb{R}$ to $\mathbb{R}$ is Borel measurable.

**Proof:** Apply (i): if $f$ is continuous and $U \subseteq \mathbb{R}$ is open, then $f^{-1}(U)$ is open in $(X, \mathcal{T})$, and every open set is a Borel set.

The next special case of XII.1.4.11. (using XII.2.2.5.) shows that “piecewise-continuous” functions are Borel measurable.

**XII.2.2.6.** Corollary. Let $(X, \mathcal{T})$ be a topological space, and $(E_n)$ a sequence of Borel subsets of $X$ with $\bigcup_{n=1}^{\infty} E_n = X$. Let $f : X \to \mathbb{R}$ be a function. If $f|_{E_n}$ is continuous (regarding $E_n$ as a topological space with the relative topology) for each $n$, then $f$ is Borel measurable.

Many very discontinuous functions are Borel measurable. For example:

**XII.2.2.7.** Proposition. Let $(X, \mathcal{A})$ be a measurable space, and $A \subseteq X$. Then $\chi_A$ is an $\mathcal{A}$-measurable function if and only if $A \in \mathcal{A}$. In particular, if $B \subseteq \mathbb{R}$, then $\chi_B$ is a Borel measurable function if and only if $B$ is a Borel set in $\mathbb{R}$.

**Proof:** Since $\chi_A$ takes only the values 0 and 1, $\chi_A^{-1}((a, +\infty))$ is either $\emptyset$ (if $a \geq 1$), $A$ (if $0 \leq a < 1$), or $X$ (if $a < 0$). Apply XII.2.2.4.(vi).

More generally, we have:

**XII.2.2.8.** Proposition. Let $(X, \mathcal{A})$ be a measurable space, and $\phi = \sum_{i=1}^{n} \alpha_i \chi_{A_i}$ be a simple function from $X$ to $\mathbb{R}$. Then $\phi$ is $\mathcal{A}$-measurable if and only if each $A_i$ is in $\mathcal{A}$.

The proof is almost identical to the proof of XII.2.2.7., and is left as an exercise.

From XII.2.2.3., in combination with XII.2.2.5., we obtain an important property of the set $\mathfrak{B}_A$ of $\mathcal{A}$-measurable functions:
XII.2.2.9. **Proposition.** Let \((X, \mathcal{A})\) be a measurable space, \(f \in \mathcal{B}_A\), and \(g\) a Borel measurable function from \(\mathbb{R}\) to \(\mathbb{R}\). Then \(g \circ f\) is in \(\mathcal{B}_A\). In particular, if \(h : \mathbb{R} \to \mathbb{R}\) is continuous, then \(h \circ f\) is in \(\mathcal{B}_A\).

XII.2.2.10. If \(f\) is a real-valued function, we define the positive and negative parts of \(f\) to be \(f_+\) and \(f_-\), where \(f_+(x) = \max(f(x), 0)\) and \(f_-(x) = \max(-f(x), 0)\). In other words, \(f_+ = f\) wherever \(f\) is nonnegative, and is zero where \(f\) is negative; and \(f_- = |f|\) where \(f\) is negative and zero where \(f\) is nonnegative. Then \(f = f_+ - f_-\), \(|f| = f_+ + f_-\), and \(f_+ f_- = 0\).

XII.2.2.11. **Corollary.** Let \((X, \mathcal{A})\) be a measurable space, and \(f \in \mathcal{B}_A\). Then \(f^2, f_+, f_-\), and \(|f|\) are in \(\mathcal{B}_A\). If \(f \geq 0\), then \(f \in \mathcal{B}_A\).

**Proof:** \(f^2 = g \circ f\), where \(g(t) = t^2\). Similarly, the other functions are the compositions of \(f\) with the functions \(\max(t, 0), \max(-t, 0), |t|, \) and \(\sqrt{|t|}\) respectively.

This corollary can also be easily proved directly from XII.2.4.

Our next goal is to show that \(\mathcal{B}_A\) is closed under the usual algebraic operations: sum, product, and scalar multiple. (We say that \(\mathcal{B}_A\) is an algebra of functions.) The only step which takes some work is showing closure under addition.

XII.2.2.12. **Theorem.** Let \((X, \mathcal{A})\) be a measurable space, \(f, g \in \mathcal{B}_A\). Then \(f + g\) and \(fg\) are in \(\mathcal{B}_A\).

**Proof:** Closure under scalar multiplication is obvious from XII.2.4.(vi)-(viii).

We show closure under addition. Let \(h = f + g\). To show that \(h \in \mathcal{B}_A\), then by XII.2.4.(vi) it suffices to show that \(h^{-1}((a, \infty)) \in \mathcal{A}\) for every \(a \in \mathbb{R}\). But if \(a\) is fixed, then

\[
\begin{align*}
h^{-1}((a, \infty)) &= \{x : f(x) > a - g(x)\} \\
&= \{x : f(x) > r > a - g(x) \text{ for some } r \in \mathbb{Q}\} \\
&= \{x : f(x) > r \text{ and } g(x) > a - r \text{ for some } r \in \mathbb{Q}\} \\
&= \bigcup_{r \in \mathbb{Q}} [f^{-1}((r, \infty)) \cap g^{-1}((a - r, \infty))].
\end{align*}
\]

Since \(f\) and \(g\) are \(\mathcal{A}\)-measurable, and \(\mathbb{Q}\) is countable, the last set is in \(\mathcal{A}\).

A trick using XII.2.2.11. gives closure under multiplication:

\[
fg = \frac{1}{2}((f + g)^2 - f^2 - g^2).
\]
Closure under Pointwise Limits

Measurable Functions to $\mathbb{R}^n$

As previously noted, we can define $\mathcal{A}$-measurability for functions from a measurable space $(X, \mathcal{A})$ to $\mathbb{R}^n$. We do not get anything essentially new by doing this, however:

**XII.2.2.13. Proposition.** Let $(X, \mathcal{A})$ be a measurable space, and $f : X \to \mathbb{R}^n$ a function. Write $f_k : X \to \mathbb{R}$ $(1 \leq k \leq n)$ for the $k$'th coordinate functions of $f$, i.e. $f(x) = (f_1(x), \ldots, f_n(x))$ for $x \in X$. Then $f$ is an $\mathcal{A}$-measurable function from $X$ to $\mathbb{R}^n$ if and only if each $f_k$ is an $\mathcal{A}$-measurable function from $X$ to $\mathbb{R}$.

**Proof:** We have $f_k = \pi_k \circ f$, where $\pi_k : \mathbb{R}^n \to \mathbb{R}$ is the projection onto the $k$'th coordinate. Since $\pi_k$ is continuous, $f_k$ is $\mathcal{A}$-measurable if $f$ is $\mathcal{A}$-measurable by XII.2.2.9. Conversely, suppose each $f_k$ is $\mathcal{A}$-measurable. Let $B_1, \ldots, B_n$ be Borel sets in $\mathbb{R}$, and $B = B_1 \times B_2 \times \cdots \times B_n$ the corresponding measurable rectangle in $\mathbb{R}^n$. Then $f^{-1}(B) = f_1^{-1}(B_1) \cap \cdots \cap f_n^{-1}(B_n)$. Since $f_k^{-1}(B_k) \in \mathcal{A}$ for each $k$, $f^{-1}(B) \in \mathcal{A}$. Measurable rectangles generate the $\sigma$-algebra of Borel sets in $\mathbb{R}^n$, so $f$ is $\mathcal{A}$-measurable by XII.1.4.9.

**XII.2.3. Another Characterization of Borel Sets and Borel Measurable Functions**

It turns out that the Borel measurable functions have a simple and useful alternate characterization as the “sequential completion” of the class of continuous functions. The results of this section can be generalized to functions on arbitrary topological spaces, but we will stick to functions from $\mathbb{R}$ to $\mathbb{R}$ for simplicity.

**XII.2.3.1. Definition.** Let $\mathcal{C}$ be the set of continuous functions from $\mathbb{R}$ to $\mathbb{R}$. Let $\mathcal{C}$ be the smallest class of functions from $\mathbb{R}$ to $\mathbb{R}$ containing $\mathcal{C}$ and which is closed under pointwise sequential limits, i.e. such that if $(f_n)$ is a sequence in $\mathcal{C}$ and $f_n \to f$ pointwise, then $f \in \mathcal{C}$.

A subset $A$ of $\mathbb{R}$ is a $BC$ set if $\chi_A \in \mathcal{C}$.

The abbreviation $BC$ stands for “Baire class.”

The definition of $\mathcal{C}$ makes sense as the intersection of all classes of functions with the two properties. This collection of classes is nonempty since the class of all functions from $\mathbb{R}$ to $\mathbb{R}$ has the properties.

We will show that the functions in $\mathcal{C}$ are precisely the Borel measurable functions, and the $BC$ sets are precisely the Borel sets. Such sets and functions are very natural to consider in measure and integration, where pointwise limits often arise.

**XII.2.3.2. Caution:** It is not true that $\mathcal{C}$ is just the set $\mathcal{BC}_1$ of pointwise limits of sequences of continuous functions. This set $\mathcal{BC}_1$ is contained in $\mathcal{C}$, but is not closed under pointwise sequential limits (although this is not obvious; see Exercise ()). Let $\mathcal{BC}_2$ be the set of pointwise limits of sequences of functions in $\mathcal{BC}_1$, and inductively for each ordinal $\alpha$ let $\mathcal{BC}_{\alpha+1}$ be the set of pointwise limits of sequences of functions in $\mathcal{BC}_\alpha$, with $\mathcal{BC}_\alpha = \cup_{\beta < \alpha} \mathcal{BC}_\beta$ when $\alpha$ is a limit ordinal. Then $\mathcal{C}$ is the union of the $\mathcal{BC}_\alpha$ over all countable $\alpha$, and it turns out that $\mathcal{C} \neq \mathcal{BC}_\alpha$ for any countable $\alpha$ (Appendix B). The functions in $\mathcal{BC}_\alpha$ are said to be of Baire class $\alpha$. 

1376
XII.2.4. Algebraic Properties of $\mathcal{C}$

We first show that, like $\mathcal{B}_A$ (XII.2.2.12), $\mathcal{C}$ is closed under the usual algebraic operations: sum, product, and scalar multiple (i.e. $\mathcal{C}$ is an algebra of functions.) It is a standard fact from Calculus that $\mathcal{C}$ is closed under these operations. It can be easily shown by transfinite induction that each $\mathcal{B}_\mathcal{C}_n$ is also closed under the operations, and hence so is $\mathcal{C}$. A cleaner and more elementary proof can be given, however:

XII.2.4.1. Proposition. Let $f, g \in \mathcal{C}$ and $\alpha \in \mathbb{R}$. Then $f + g$, $fg$, and $\alpha f$ are all in $\mathcal{C}$.

Proof: First fix $g \in \mathcal{C}$, and let $\mathcal{D} = \{ f \in \mathcal{C} : f + g \in \mathcal{C} \}$. We claim that $\mathcal{D} = \mathcal{C}$. Clearly $\mathcal{D} \subseteq \mathcal{C}$, so we need only show that $\mathcal{C} \subseteq \mathcal{D}$ and that $\mathcal{D}$ is closed under pointwise sequential limits. If $f \in \mathcal{C}$, then $f + g \in \mathcal{C} \subseteq \mathcal{C}$, so $f \in \mathcal{D}$. And if $(f_n)$ is a sequence in $\mathcal{D}$ (i.e. $f_n \in \mathcal{C}$ and $f_n + g \in \mathcal{C}$), and $f_n \to f$ pointwise, then $f_n \in \mathcal{C}$ for all $n$, so $f \in \mathcal{C}$; also, $f_n + g \to f + g$ pointwise, and $f_n + g \in \mathcal{C}$, so $f + g \in \mathcal{C}$, i.e. $f \in \mathcal{D}$. This proves the claim, and therefore the sum of a function in $\mathcal{C}$ and a function in $\mathcal{C}$ is in $\mathcal{C}$.

Now suppose $g \in \mathcal{C}$, and repeat the argument with $\mathcal{E} = \{ f \in \mathcal{C} : f + g \in \mathcal{C} \}$. As before, we show that $\mathcal{C} \subseteq \mathcal{E}$ (by the first part of the proof) and that $\mathcal{E}$ is closed under pointwise sequential limits, and thus $\mathcal{E} = \mathcal{C}$. This shows that $\mathcal{C}$ is closed under addition.

The proof that $\mathcal{C}$ is closed under multiplication is virtually identical, replacing “sum” by “product” everywhere, and is left as an exercise ().

The case of scalar multiplication is a special case of the product, regarding the scalar $\alpha$ as the constant function with value $\alpha$.

XII.2.4.2. Corollary. The class of BC sets in $\mathbb{R}$ is a $\sigma$-algebra.

Proof: Suppose $A$ is a BC set, i.e. $\chi_A \in \mathcal{C}$. Then $\chi_A^c = 1 - \chi_A \in \mathcal{C}$, so $A^c$ is a BC set. If $A$ and $B$ are BC sets, then $\chi_A \cap B = \chi_A \chi_B \in \mathcal{C}$, so $A \cap B$ is a BC set. Finally, if $(A_n)$ is a sequence of BC sets and $A = \cap_{n=1}^\infty A_n$, set $f_n = \chi_{A_1 \cap \cdots \cap A_n} = \chi_{A_1} \chi_{A_2} \cdots \chi_{A_n}$. Then $f_n \in \mathcal{C}$ and $f_n \to \chi_A$ pointwise, so $\chi_A \in \mathcal{C}$ and so $A$ is a BC set. Thus the class of BC sets is closed under complements and countable intersections. It clearly contains $\mathbb{R}$ since $\chi_\mathbb{R}$ is the constant function 1, which is in $\mathcal{C}$.

XII.2.4.3. Proposition. Every open interval in $\mathbb{R}$ is a BC set.

Proof: Let $(a, b)$ be an open interval in $\mathbb{R}$. We need to show that $\chi_{(a, b)} \in \mathcal{C}$; we will find a sequence of continuous functions converging pointwise to $\chi_{(a, b)}$. Let $f_n$ be the function with the following graph:

It is easy to check that $f_n \to \chi_{(a, b)}$ pointwise.

XII.2.4.4. Corollary. Every Borel set is a BC set.

Proof: The class of BC sets is a $\sigma$-algebra (XII.2.4.2.) which contains the open intervals (XII.2.4.3.). The smallest such $\sigma$-algebra is the Borel sets.

Now we show that $\mathcal{C}$ is closed under composition:
XII.2.4.5. Proposition. Let \( f, g \in \mathcal{C} \). Then \( f \circ g \in \mathcal{C} \).

Proof: The proof is very similar to the proof of XII.2.4.1. First fix \( f \in \mathcal{C} \), and let \( \mathcal{D} = \{ g \in \mathcal{C} : f \circ g \in \mathcal{C} \} \). As in XII.2.4.1, \( \mathcal{C} \subseteq \mathcal{D} \) since a composition of continuous functions is continuous. Also, if \( g_n \in \mathcal{D} \) and \( g_n \to g \) pointwise, and \( x \in \mathbb{R} \), if \( y_n = g_n(x) \) and \( y = g(x) \) we have that \( y_n \to y \), and thus \( [f \circ g_n](x) = f(y_n) \to f(y) = [f \circ g](x) \) since \( f \) is continuous; thus \( f \circ g_n \to f \circ g \) and so \( f \circ g \in \mathcal{C} \), \( f \in \mathcal{D} \). Thus \( \mathcal{D} = \mathcal{C} \), i.e. \( f \circ g \in \mathcal{C} \) if \( f \in \mathcal{C} \), \( g \in \mathcal{C} \).

Now fix \( g \in \mathcal{C} \) and let \( \mathcal{E} = \{ f \in \mathcal{C} : f \circ g \in \mathcal{C} \} \). By the first part of the proof, \( \mathcal{C} \subseteq \mathcal{E} \). Also, if \( (f_n) \) is a sequence in \( \mathcal{E} \) converging pointwise to \( f \), then \( f \in \mathcal{C} \), and \( f_n \circ g \to f \circ g \) pointwise (this is true with no restriction on \( g \)), and thus \( f \circ g \in \mathcal{C} \), \( f \in \mathcal{E} \). Thus \( \mathcal{C} = \mathcal{E} \) and the proposition is proved. \( \diamond \)

XII.2.4.6. Corollary. If \( g \in \mathcal{C} \), then \( |g| \in \mathcal{C} \).

Proof: We have that \( |g| = f \circ g \), where \( f(x) = |x| \), which is a continuous function. \( \diamond \)

See problem () for another proof of this result.

A very important consequence of this corollary comes from the following lemma.

XII.2.4.7. Lemma. If \( x, y \in \mathbb{R} \), then \( \max(x, y) = \frac{1}{2}(x + y + |x - y|) \) and \( \min(x, y) = \frac{1}{2}(x + y - |x - y|) \). Thus, if \( f \) and \( g \) are functions from \( \mathbb{R} \) to \( \mathbb{R} \), then \( \max(f, g) = \frac{1}{2}(f + g + |f - g|) \) and \( \min(f, g) = \frac{1}{2}(f + g - |f - g|) \).

Proof: The proof is a straightforward case-by-case verification which is left as an exercise. \( \diamond \)

XII.2.4.8. Corollary. If \( f \) and \( g \) are in \( \mathcal{C} \), then so are \( \max(f, g) \) and \( \min(f, g) \).

XII.2.4.9. A sequence \( (f_n) \) of functions from \( \mathbb{R} \) to \( \mathbb{R} \) is pointwise bounded if, for every \( x \in \mathbb{R} \), the set \( \{ f_n(x) : n \in \mathbb{N} \} \) is bounded in \( \mathbb{R} \). If \( (f_n) \) is pointwise bounded, then \( \sup_n f_n \) and \( \inf_n f_n \) are defined as functions from \( \mathbb{R} \) to \( \mathbb{R} \): \( \sup_n f_n(x) = \sup\{ f_n(x) : n \in \mathbb{N} \} \), \( \inf_n f_n(x) = \inf\{ f_n(x) : n \in \mathbb{N} \} \).

XII.2.4.10. Corollary. Let \( (f_n) \) be a pointwise bounded sequence in \( \mathcal{C} \). Then \( \sup_n f_n \) and \( \inf_n f_n \) are in \( \mathcal{E} \).

Proof: Let \( g_n = \max(f_1, \ldots, f_n) \) and \( h_n = \min(f_1, \ldots, f_n) \). Then \( g_n, h_n \in \mathcal{E} \) by XII.2.4.8., and \( g_n \to \sup_n f_n, h_n \to \inf_n f_n \) pointwise.

In fact, it turns out that any algebra of functions which is closed under pointwise sequential limits is also closed under countable suprema and infima (Problem ()). A clever trick yields a converse to this:

1378
XII.2.4.11. **Proposition.** Let $\mathcal{F}$ be a set of real-valued functions on a set $X$. If $\mathcal{F}$ is closed under suprema and infima of pointwise bounded sequences, then $\mathcal{F}$ is closed under pointwise sequential limits.

**Proof:** Suppose $(f_n)$ is a sequence in $\mathcal{F}$, and $f_n \to f$ pointwise. Then, for each $x \in X$, the sequence $(f_n(x))$ is convergent and therefore bounded; thus $(f_n)$ is pointwise bounded. Also, for $x \in X$,

$$f(x) = \lim_n f_n(x) = \limsup_n f_n(x) = \inf_n \{\sup_{k \geq n} f_k(x)\}$$

and so, if $g_n = \sup_{k \geq n} f_k$, then $g_n \in \mathcal{F}$ for all $n$, and therefore $f = \inf_n [\sup_{k \geq n} f_k] = \inf_n g_n \in \mathcal{F}$. $\Diamond$

This applies in particular to the collection of $\mathcal{A}$-measurable real-valued functions on any measurable space $(X, \mathcal{A})$:

XII.2.4.12. **Proposition.** Let $(X, \mathcal{A})$ be a measurable space, and $\mathcal{B}_A$ the set of $\mathcal{A}$-measurable real-valued functions. Then $\mathcal{B}_A$ is closed under suprema and infima of pointwise bounded sequences, and hence under pointwise sequential limits.

**Proof:** Let $(f_n)$ be a locally bounded sequence in $\mathcal{B}_A$, and let $g = \sup_n f_n$. We will show that $g^{-1}((a, +\infty)) \in \mathcal{A}$ for every $a \in \mathbb{R}$, and use XII.2.4.(vi). If $x \in X$, then $g(x) > a$ if and only if $f_n(x) > a$ for some $n$, and thus $g^{-1}((a, +\infty)) = \bigcup_{n=1}^\infty f_n^{-1}((a, +\infty))$. By assumption, $f_n^{-1}((a, +\infty)) \in \mathcal{A}$ for all $n$, so $g^{-1}((a, +\infty))$ is a countable union of sets in $\mathcal{A}$.

The proof for $\inf_n f_n$ is nearly identical, using XII.2.4.(iv). $\Diamond$

The set of $\mathcal{A}$-measurable functions on $(X, \mathcal{A})$ is also an algebra (XII.2.12.).

As a consequence, we get a relationship between $\mathcal{C}$ and Borel measurability:

XII.2.4.13. **Corollary.** Every function in $\mathcal{C}$ is Borel measurable.

**Proof:** If $\mathcal{B}$ is the set of Borel measurable functions, then $\mathcal{B}$ contains $\mathcal{C}$ by XII.2.5., and is closed under pointwise sequential limits by XII.2.4.12.; thus $\mathcal{B}$ contains $\mathcal{C}$. $\Diamond$

XII.2.4.14. **Corollary.** Every BC set is a Borel set.

**Proof:** If $A$ is a BC set, then $\chi_A \in \mathcal{C}$, and hence $\chi_A$ is Borel measurable. But this implies that $A$ is a Borel set by XII.2.7.. $\Diamond$

Combining XII.2.4.14. with XII.2.4.4., we obtain one of the principal facts we needed to prove:

XII.2.4.15. **Theorem.** A subset of $\mathbb{R}$ is a Borel set if and only if it is a BC set.
**XII.2.4.16. Corollary.** A simple function is Borel measurable if and only if it is a BC function.

It still remains to prove that every Borel measurable function is in $\mathcal{E}$. Since every simple Borel measurable function is in $\mathcal{C}$ (XII.2.4.16.), it suffices to show:

**XII.2.4.17. Lemma.** Every Borel measurable function is a pointwise limit of simple Borel measurable functions.

**Proof:** Suppose $f$ is Borel measurable. Fix $n \in \mathbb{N}$. For each $k \in \mathbb{Z}$, let

$$E_{kn}(f) = f^{-1}\left(\left[\frac{k}{n}, \frac{k+1}{n}\right]\right).$$

Then each $E_{kn}(f)$ is a Borel set since it is the inverse image of a Borel set, and for fixed $n$ we have that $\mathbb{R}$ is the disjoint union of the $E_{kn}(f)$’s. Let $f_n(t) = \frac{k}{n}$ if $t \in E_{kn}(f)$. Since $\frac{k}{n} \leq f(t) < \frac{k+1}{n}$ for $t \in E_{kn}(f)$, we have that $f_n(t) \leq f(t)$ and $f(t) - f_n(t) < \frac{1}{n}$ for every $t$. Thus the sequence $(f_n)$ actually converges uniformly to $f$. However, $f_n$ is not quite simple in general. To obtain simple functions, let $g_n(t) = f_n(t)$ if $t \in E_{kn}(f)$ for $-n \leq k \leq n$ and $g_n(t) = 0$ otherwise. Then $g_n$ is simple, and $g_n \to f$ pointwise on $\mathbb{R}$ (but not uniformly unless $f$ is bounded.)

So we have shown:

**XII.2.4.18. Theorem.** $\mathcal{E} = \mathcal{B}$.

**Egorov’s Theorem**

**XII.2.5. The Multiplicity Function**

In many settings where a function is being analyzed, it is important to consider the “size” of inverse images of points; this provides, among other things, a description of how far the function is from being one-to-one. The most basic way to do this is via the “multiplicity function” (sometimes called the “counting function”):

**XII.2.5.1. Definition.** Let $f : X \to Y$ be a function. The multiplicity function of $f$ is the function $N_f : Y \to \{0\} \cup \mathbb{N} \cup \{+\infty\}$ defined by

$$N_f(y) = \begin{cases} \text{card}(f^{-1}(\{y\})) & \text{if } f^{-1}(\{y\}) \text{ is finite} \\ +\infty & \text{if } f^{-1}(\{y\}) \text{ is infinite} \end{cases}.$$

The Multiplicity Function is most commonly used when $Y = \mathbb{R}$ (or $\mathbb{R}^n$). Note that in this function, we do not distinguish between cases where $f^{-1}(\{y\})$ is countable and cases where it is uncountable. We can sometimes take this into account by a finer invariant; cf. ( ).

1380
XII.2.5.2. **Examples.** (i) \( N_f \) is the constant function 1 if and only if \( f \) is a bijection. If \( f \) is one-to-one, then \( N_f \) takes only the values 0 and 1.

(ii) If \( f : \mathbb{R} \to \mathbb{R} \) is given by \( f(x) = x^2 \), then \( N_f(y) = \begin{cases} 1 & \text{if } y < 0 \\ 1 & \text{if } y = 0 \\ 2 & \text{if } y > 0 \end{cases} \).

(iii) If \( f : [0,1] \to [0,1] \) is a coordinate function of a space-filling curve (.), then \( f \) is continuous and \( N_f(y) = +\infty \) for all \( y \in [0,1] \).

XII.2.5.3. If \((X, A)\) and \((Y, B)\) are measurable spaces and \( f : X \to Y \) is measurable, it is not true in general (cf. XII.2.5.7.) even if \( X = Y = \mathbb{R} \), that \( N_f \) is a measurable function (since its range is a countable set, \( N_f \) will be measurable if and only if, for each \( n \in \{0\} \cup \mathbb{N} \cup \{+\infty\} \) we have that \( \{y \in Y : N_f(y) = n\} \) is in \( B \)). But in some important special cases this can be shown. The next result is the simplest example, and perhaps the most widely used; the proof can be adapted to broader contexts.

XII.2.5.4. **Proposition.** Let \( f \) be a real-valued continuous function on an an interval \( I \) in \( \mathbb{R} \). Then \( N_f \) is an extended real-valued Borel measurable function.

**Proof:** First suppose \( I \) is a bounded interval from \( a \) to \( b \) (with or without endpoints). For each \( n \in \mathbb{N} \), define a function \( \phi_n : \mathbb{R} \to \mathbb{N} \) by taking a partition \( \{x_0 = a, x_1, \ldots, x_{2^n} = b\} \) of \( I \) into \( 2^n \) subintervals \( J_1, \ldots, J_{2^n} \) of equal length, with \( x_k \in J_k \), \( x_k \notin J_{k+1} \) for \( 1 \leq k \leq 2^n - 1 \), \( a \in J_1 \) if \( a \in I \), and \( b \in J_{2^n} \) if \( b \in I \). Then set

\[
\phi_n = \sum_{k=1}^{2^n} \chi_{f(J_k)}.
\]

We have that \( f(J_k) \) is an interval, hence a Borel set; thus \( \phi_n \) is a Borel measurable function from \( \mathbb{R} \) to \( \mathbb{R} \). For any \( y \in \mathbb{R} \), \( \phi_n(y) \) is the number of subintervals whose intersection with \( f^{-1}(\{y\}) \) is nonempty. It is easily seen that \( \phi_n \leq \phi_{n+1} \) for each \( n \), and that \( N_f = \sup_n \phi_n \). Thus \( N_f \) is Borel measurable.

For a general \( I \), write \( I = \cup I_m \), where each \( I_m \) is a bounded interval and \( I_m \subseteq I_{m+1} \). Let \( f_m = f|_{I_m} \). Then \( N_f = \sup_m N_{f_m} \), and each \( f_m \) is Borel measurable, hence so is \( N_f \).

XII.2.5.5. We can try to adapt this argument to a more general setting of a Borel measurable function \( f \) (e.g. a continuous function) between topological spaces \( X \) and \( Y \). There are two things which need to be done:

(i) We need a sequence of finite partitions of \( X \), each refining the previous one, into “nice” subsets (e.g. Borel sets), such that distinct elements of \( X \) are separated by sufficiently fine partitions in the sequence. This can be done systematically using Borel sets in any Polish space (.), hence in any standard Borel space (.), e.g. in any Borel subset of \( \mathbb{R}^n \); for Borel sets in \( \mathbb{R}^n \) there is an obvious approach using grids similar to the approach in the proof of XII.2.5.4..
(ii) We need to know that if \( J_1, \ldots, J_r \) are the sets in the \( n \)'th partition, then \( f(J_k) \) is a Borel subset of \( Y \).
This is false in general (). However, if \( Y \) is a Polish space (e.g. \( \mathbb{R}^n \)), then \( f(J_k) \) is an analytic subset of \( Y \) if \( J_k \) is Borel in \( X \) ()

Combining these observations with (), we obtain the most general result which can be easily stated:

**XII.2.5.6. Theorem.** Let \((X, A)\) be a standard Borel space (e.g. a Borel subset of \( \mathbb{R}^n \)), and \( f : X \to \mathbb{R}^m \) a Borel measurable function. Then \( N_f \) is a Lebesgue measurable extended real-valued function on \( \mathbb{R}^m \).

Lebesgue measurability of \( N_f \) can be replaced by \( \mu \)-measurability, for any measure \( \mu \) which is the completion of a Borel measure on \( \mathbb{R}^m \), e.g. Hausdorff measure \( \mathcal{H}^s \) for any \( s \).

**XII.2.5.7. Example.** This result, which applies to Borel measurable functions from \( \mathbb{R} \) to \( \mathbb{R} \), cannot be extended to Lebesgue measurable functions from \( \mathbb{R} \) to \( \mathbb{R} \):

Let \( K \) be the usual Cantor set, and \( K' \subseteq [0,1] \) a generalized Cantor set of positive measure. Let \( g \) be a strictly increasing continuous function from \([0,1]\) onto \([0,1]\) with \( g(K) = K' \) (). Let \( Y \) be a subset of \( K' \) which is not Lebesgue measurable, and set \( A = g^{-1}(Y) \). Then \( A \) has measure 0 since it is a subset of \( K \).

Define \( f : \mathbb{R} \to \mathbb{R} \) by
\[
f(x) = \begin{cases}  g(x) & \text{if } x \in A \\ 2 & \text{if } x \notin A \end{cases}
\]

Then \( f \) is Lebesgue measurable (it equals the constant function \( 2 \) a.e.), but \( N_f \) is not Lebesgue measurable since \( \{ y \in \mathbb{R} : N_f(y) = 1 \} = Y \).

Note that although \( f = 2 \) a.e., we do not have \( N_f = N_2 \) a.e. In fact, \( N_2 \) (i.e. \( N_h \), where \( h \) is the constant function 2) is Borel measurable (it is constant a.e.)

For continuous real-valued functions on a closed bounded interval, there is a close relationship between the Multiplicity Function and the notion of bounded variation (**XIV.16.3.1.**).

**XII.2.6. Exercises**

**XII.2.6.1.** Let \( \mathfrak{B}_\alpha \) be the set of functions of Baire class \( \alpha \) (). A subset \( A \) of \( \mathbb{R} \) is a **set of Baire class \( \alpha \)** if \( \chi_A \in \mathfrak{B}_\alpha \). Let \( \mathcal{B}_\alpha \) denote the set of subsets of \( \mathbb{R} \) of Baire class \( \alpha \).

(a) Show that \( \cup_{\alpha < \omega_1} \mathcal{B}_\alpha \) is precisely the set of Borel sets.

(b) Show by transfinite induction that \( \mathfrak{B}_\alpha \) is an algebra of functions for each \( \alpha \).

(c) Show that each \( \mathcal{B}_\alpha \) is an algebra of sets. [Hint: \( \chi_{A \cap B} = \chi_A \chi_B \).]

(d) If \( f \in \mathfrak{B}_1 \) and \( U \) is an open set in \( \mathbb{R} \), then \( f^{-1}(U) \) is an \( F_\sigma \). (The converse is also true: if \( f^{-1}(U) \) is an \( F_\sigma \) for every open set \( U \), then \( f \in \mathfrak{B}_1 \)[].) [If \( f_n \to f \) pointwise and \( \alpha \in \mathbb{R} \), then
\[
f^{-1}((\alpha, \infty)) = \bigcup_n \bigcap_{m \geq m} \{ t : f_k(t) \geq \alpha + \frac{1}{n} \}.
\]

(e) Show that \( A \in \mathcal{B}_1 \) if and only if \( A \) is both an \( F_\sigma \) and a \( G_\delta \). [If \( A \) is both an \( F_\sigma \) and a \( G_\delta \), show that there is an increasing sequence \( (F_n) \) of closed sets, and a decreasing sequence \( (U_n) \) of open sets, such that

1382
A = ∪_n F_n = ∩_n U_n. If f_n is a continuous function which is 1 on F_n and 0 outside U_n, then f_n → χ_A. Deduce the converse from (d).] In particular, any open or closed set is in BC_1. In particular, any F_τ or G_δ is in BC_2.

(f) Show that a countable union or countable intersection of sets in BC_α is in BC_{α+1}. In particular, any F_τ or G_δ is in BC_2.

(g) Since Q is not a G_δ, Q ∉ BC_1. But Q ∈ BC_2 since it is an F_τ.

(h) Use the argument of (d) to show that if f ∈ BC_2 and U is open, then f^{-1}(U) is a G_δ. Conclude that if A is in BC_2, then A is both a G_δ and an F_σ. Generalize to BC_n and BC_α.

In fact, if α < β are countable ordinals, then BC_α is a proper subset of BC_β, and hence BC_α is a proper subset of the class of Borel sets (Appendix B).

**XII.2.6.2.** Let f be any function from R to R. Show that the set of points of continuity of f is a G_δ. [For each n, let U_n be the set of all a ∈ R for which there is a δ > 0 such that |f(x) - f(y)| < 1/n whenever |x - a| < δ and |y - a| < δ. Show that U_n is open.]

**XII.2.6.3.** (a) If I is an interval, show that there is a Borel measurable f : R → R such that I is exactly the set of discontinuities for f. [If I is closed, consider χ_QI. If I is open, let g be a continuous function which is nonzero precisely on I, and consider χ_Qg.]

(b) If B is an F_σ containing no interval, show there is a Borel measurable f whose set of discontinuities is precisely B. [Write B = ∪ F_n, with F_n closed, and consider ∑ 2^{-n} χ_{F_n}]

(c) Show that if A is a G_δ, then there is a Borel measurable f : R → R such that A is exactly the set of points where f is continuous.

**XII.2.6.4.** Let f : R → R be continuous. (a) For n, k ∈ N, c ∈ R, let U_{n,k,c} be the set of all a for which there is an x with

0 < |x - a| < 1/n and \[ \frac{f(x) - f(a)}{x - a} > c - \frac{1}{k} \]

Show that U_{n,k,c} is open and ∩_{n,k} U_{n,k,c} is the set

\[ V_c = \left\{ a \in \mathbb{R} : \limsup_{x \to a} \frac{f(x) - f(a)}{x - a} \geq c \right\} \]

So V_c is a G_δ.

(b) Similarly, if d ∈ R, show that

\[ W_d = \left\{ a \in \mathbb{R} : \liminf_{x \to a} \frac{f(x) - f(a)}{x - a} \leq d \right\} \]

is a G_δ.

(c) Show that the set D of points where f is differentiable is an F_σδ. [The complement of D is

\[ \left( \bigcup_{c,d \in \mathbb{Q}} V_c \cap W_d \right) \cup \left( \bigcap_{c \in \mathbb{Q}} V_c \right) \cup \left( \bigcap_{d \in \mathbb{Q}} W_d \right). \]

(d) What if f is not assumed to be continuous? (cf. XII.2.6.2.)
XII.2.6.5. Let $f$ be a real-valued function on an interval $I$ which has only countably many discontinuities. Show that $f$ is Baire class 1. [Let $(x_n)$ be a dense sequence in $I$ containing all discontinuities of $f$, and let $f_n$ be a piecewise-linear continuous function agreeing with $f$ on $\{x_1, \ldots, x_n\}$. Show that $f_n \to f$ pointwise.]

XII.2.6.6. Let $I$ be an interval in $\mathbb{R}$, and $f : I \to \mathbb{R}$. Extend $f$ to $\tilde{f} : \mathbb{R} \to \mathbb{R}$ by setting $\tilde{f}$ identically 0 outside $I$. Show that $\tilde{f}$ is Baire class 1 on $\mathbb{R}$ if and only if $f$ is Baire class 1 on $I$.

XII.2.6.7. Let $I$ be an interval in $\mathbb{R}$. Let $D$ be a vector space of real-valued functions on $I$ containing the constant functions, whose uniform closure $\bar{D}$ has the property that if $f \in D$, then $|f| \in D$, and let $D$ be the set of all pointwise limits of sequences in $\bar{D}$. Show that $D$ is closed under uniform limits, as follows.

(a) If $f$ is a pointwise limit of a sequence in $\bar{D}$, show that $f$ is a pointwise limit of a sequence in $D$. Thus we may, and will, assume $\bar{D}$ is uniformly closed.

(b) If $f \in D$, then $f + = f \vee 0 = \frac{1}{2}(f + |f|) \in D$. Show that if $a \leq b$, then $(f \vee a) \wedge b \in D$.

(c) Let $(f_n)$ a sequence in $D$ which converges uniformly to $f$ on $I$. Passing to a subsequence, we may assume that $|f_{n+1}(x) - f_n(x)| \leq 2^{-n-1}$ for all $n$ and all $x \in I$. Set $g_n = f_1$ and $g_{n+1} = f_{n+1} - f_n$ for $n \geq 1$. For each $n$ let $(h_{nk})$ be a sequence in $D$ with $h_{nk} \to g_n$ pointwise. Use (b) to show that we may assume $|h_{nk}(x)| \leq 2^{-n}$ for all $n > 1$, all $k$, and all $x \in I$.

(d) For each $k$, the infinite series $\sum_{n=1}^{\infty} h_{nk}$ converges uniformly. Let $h_k = \sum_{n=1}^{\infty} h_{nk}$. Then $h_k \in D$. Show that $h_k \to f$ pointwise.

(e) The hypotheses are satisfied if $D$ is an algebra of bounded functions on $I$ and contains the constant functions (XV.8.2.9).

(f) The hypotheses are satisfied if $D = \mathcal{C}(I)$. Conclude that $\mathcal{BC}_1(I)$ is uniformly closed.

(g) Show by induction on $n$ that if $g \in \mathcal{BC}_n(I)$ and $f$ is continuous, then $f \circ g$ is in $\mathcal{BC}_n(I)$. Conclude that $D = \mathcal{BC}_n(I)$ satisfies the hypotheses, and hence that $\mathcal{BC}_{n+1}(I)$ is closed under uniform limits.

(h) Show that the result of the problem holds if “uniform” is replaced by “u.c.” throughout. Thus the class $\mathcal{BC}_n(I)$ is closed under u.c. limits for each $n \in \mathbb{N}$.

XII.2.6.8. Let $I$ be an interval in $\mathbb{R}$.

(a) Show that every step function on $I$ is in $\mathcal{BC}_1(I)$. [Use XII.2.6.5.]

(b) Show that every regulated function (V.8.6.7.) on $I$ is in $\mathcal{BC}_1(I)$. [Use XII.2.6.5. and XII.2.6.7., or XII.2.6.5. and V.8.6.7.(a).]
XII.3. Analytic Sets

There is an important class of subsets of \( \mathbb{R} \) (or more general topological spaces) which is slightly larger than the class of Borel sets.

XII.3.1. Standard Borel Spaces

XII.3.1.1. Recall that a topological space is a Polish space if it is homeomorphic to a separable complete metric space.

The next result says that, although there is an enormous variety of topologically distinct uncountable Polish spaces, they are all “identical” from a measure-theoretic standpoint:

Theorem. Let \( X \) and \( Y \) be uncountable Polish spaces. Then the measurable spaces \((X, B_X)\) and \((Y, B_Y)\) are isomorphic. In particular, \((X, B_X)\) is isomorphic to \((\mathbb{R}, \mathcal{B})\) and to \(([0, 1], B_{[0,1]})\).

This theorem is an easy consequence of the following result of Kuratowski [7], which is a sharpening of XI.10.2.7. The proof is rather involved, although fairly elementary, and we omit it; see, for example, [7, 2.4.1].

XII.3.1.2. Theorem. Let \( X \) be an uncountable Polish space which is dense in itself. Then there is an injective continuous function from \( \mathbb{N} \) onto \( X \) such that the image of every open set is an \( F_\sigma \).

Such a function is obviously a Borel isomorphism. To obtain XII.3.1.2., note that by the Cantor-Bendixson Theorem (XI.2.5.4.) every Polish space is a disjoint union of a countable open subset and a closed subset which is dense-in-itself.

XII.3.1.3. Theorem. Let \( X \) be an uncountable Polish space which is dense in itself. Then there is an injective continuous function from \( \mathbb{N} \) onto \( X \) such that the image of every open set is an \( F_\sigma \).

Since every countable subset of a \( T_1 \)-space is a Borel set, it follows that \((\mathbb{N}, B_\mathbb{N})\) is isomorphic as a Borel space to \((\mathbb{N}, B_\mathbb{N}) \oplus (\mathbb{P}(\mathbb{N}))\). Any uncountable Polish space \( X \) decomposes into a countable set and a Borel subset \( Z \) Borel isomorphic to \( \mathbb{N} \) by XII.3.1.3., so

\[ (X, B_X) \cong (Z, B_Z) \oplus (\mathbb{N}, P(\mathbb{N})) \cong (\mathbb{N}, B_{\mathbb{N}}) \oplus (\mathbb{N}, P(\mathbb{N})) \cong (\mathbb{N}, B_{\mathbb{N}}). \]

See problems (–) for an alternate proof of XII.3.1.2.

In particular, we have

XII.3.1.4. So to finish the proof of XII.3.1.2, note that if \( Y \) is \( \mathbb{N} \) with a countable number of points removed, then \( Y \) is a \( G_\delta \) in \( \mathbb{N} \), hence a Polish space, and \( Y \) is dense in itself; so \( Y \) is Borel isomorphic to \( \mathbb{N} \).

In particular, we have

XII.3.1.5. Corollary. Every uncountable Polish space has cardinality \( 2^{\aleph_0} \).

XII.3.1.6. Definition. A measurable space \((X, B)\) is a standard Borel space if it is isomorphic to \(([0, 1], B_{[0,1]}),\) hence to \((Y, B_Y)\) for any uncountable Polish space \( Y \).

Sometimes measurable spaces of the form \((X, P(X))\) for a countable set \( X \) are also called standard Borel spaces. These are the measurable spaces of the form \((X, B_X)\) for countable Polish spaces \( X \).
Subspaces of Standard Borel Spaces

XII.3.1.7. **Proposition.** Let \((X, \mathcal{A})\) be a measurable space which is countably generated and separates points (i.e. if \(x, y \in X\), there is an \(A \in \mathcal{A}\) with \(x \in A \) and \(y \notin A\)). Then there is a subset \(Y\) of \(\mathcal{C}\) such that \((X, \mathcal{A})\) is Borel isomorphic to \((Y, \mathcal{B}_Y)\).

**Proof:** Let \(\{A_n : n \in \mathbb{N}\}\) generate \(\mathcal{A}\) as a \(\sigma\)-algebra. For \(x \in X\), define \(f(x) \in \mathcal{C}\) by \(f(x)(n) = 1\) if \(x \in A_n\), \(f(x) = 0\) if \(x \notin A_n\). It is easily checked that \(f\) is a Borel isomorphism onto \(f(X)\). \(\Diamond\)

Such an \((X, \mathcal{A})\) is not necessarily a standard Borel space, even if uncountable (). But if the set \(Y\) is an uncountable \(G_{\delta}\) in \(\mathcal{C}\), then it follows from XI.10.3.3. that \((X, \mathcal{A})\) is a standard Borel space; We will extend this to show that \((X, \mathcal{A})\) is a standard Borel space if \(Y\) is merely an uncountable Borel set in \(\mathcal{C}\).

XII.3.1.8. **Theorem.** Let \((X, T)\) be a Polish space and \(A\) a Borel set in \((X, T)\). Then there is a Polish topology \(S\) on \(X\) which is stronger than \(T\), in which \(A\) is a clopen set, and such that every Borel set in \((X, S)\) is a Borel set in \((X, T)\).

**Proof:** Let \(\mathcal{A}\) be the set of all Borel subsets of \(X\) for which such an extension of \(T\) is possible. If \(F\) is closed in \(X\), let \(\mathcal{S} = \{U, U \cap F : U \in T\}\). Then \(\mathcal{S}\) is a topology on \(X\) stronger than \(T\), \(F\) is clopen in \(\mathcal{S}\), and \(\mathcal{S} \subseteq B_T\), so \(B_\mathcal{S} = B_T\). Also, \((X, \mathcal{S})\) is homeomorphic to \((F, T_F) \cup (F^c, T_{F^c})\), and \((F, T_F)\) and \((F^c, T_{F^c})\) are Polish by (), so \((X, \mathcal{S})\) is Polish. Thus all closed sets in \(X\) are in \(\mathcal{A}\). \(\mathcal{A}\) is clearly closed under complements.

To show that \(\mathcal{A}\) is closed under countable unions, suppose \((A_n)\) is a sequence in \(\mathcal{A}\). For each \(n\) let \(S_n\) be a Polish topology on \(X\) stronger than \(T\), with the same Borel sets, in which \(A_n\) is clopen. Let \(S_\infty\) be the topology on \(X\) generated by \(\bigcup_n S_n\); then \(S_\infty \subseteq B_T\), so \(B_{\mathcal{S}_\infty} = B_T\). If \(\sigma_n\) is a \([0, 1]\)-valued complete metric giving \(S_n\), then \(\sigma = \sum_n 2^{-n} \sigma_n\) is a complete metric giving \(S_\infty\). If \(D_n\) is a countable dense subset of \((X, S_n)\), then \(D = \bigcup_n D_n\) is a countable dense subset of \((X, S_\infty)\). Thus \((X, S_\infty)\) is Polish. We have that \(A = \bigcup_n A_n\) is open in \((X, S_\infty)\), so by the first part of the proof there is a Polish topology \(\mathcal{S}\) stronger than \(S_\infty\), with the same Borel sets, such that \(A\) is clopen in \((X, \mathcal{S})\). Thus \(A \in \mathcal{A}\) and \(\mathcal{A}\) is a \(\sigma\)-algebra containing \(T\), hence containing \(B_T\). \(\Diamond\)

XII.3.1.9. **Corollary.** An uncountable measurable subspace of a standard Borel space is a standard Borel space.

An interesting consequence is the following, which “settles” the Continuum Hypothesis for Borel sets:

XII.3.1.10. **Corollary.** Let \(X\) be a Polish space. Any uncountable Borel subset of \(X\) has cardinality \(2^{\aleph_0}\).

XII.3.2. **Analytic Sets**

XII.3.2.1. **Definition.** Let \(X\) be a Polish space. A subset \(Y\) of \(X\) is **analytic** if there is a continuous function from \(\mathcal{N}\) onto \(Y\).
XII.3.2.2. The official definition of an analytic set in a general topological space $X$ is a little different: it is a subset of $X$ of the form $\pi_X(F)$, where $F$ is a closed subset of $X \times \mathcal{N}$. If $Y \subseteq X$ and there is a continuous function $f$ from $\mathcal{N}$ onto $Y$, then $Y$ is analytic (let $F$ be the graph of $f$). Conversely, if $X$ is Polish and $Y = \pi_X(F)$ for a closed subset $F$ of $X \times \mathcal{N}$, then $F$ is Polish, so there is a continuous function $g$ from $\mathcal{N}$ onto $F$ by XI.10.2.7., and $\pi_X \circ g$ is a continuous function from $\mathcal{N}$ onto $Y$. Thus the two definitions are equivalent for $X$ Polish.

By XI.10.2.7., if $X$ is a Polish space, then $X$ itself is analytic in $X$; and the property of being analytic is independent of the containing space.

It is obvious from the definition that continuous images of analytic sets are analytic:

XII.3.2.3. Proposition. If $X$ and $Z$ are Polish spaces, $f : X \to Z$ is continuous, and $Y$ is an analytic subset of $X$, then $f(Y)$ is an analytic subset of $Z$.

One of the most important results about analytic sets is:

XII.3.2.4. Theorem. Let $X$ be a Polish space. The collection of analytic subsets of $X$ is closed under countable unions and countable intersections.

Proof: Closure under unions is fairly simple. Let $E_n$ be an analytic set for each $n$, and $f_n : \mathcal{N} \to E_n$ a surjective continuous function. We can regard $f_n$ as being defined on $\{n\} \times \mathcal{N} \subseteq \mathbb{N} \times \mathcal{N}$. Putting these together, we get a map $f$ from $\mathbb{N} \times \mathcal{N} \cong \mathcal{N}$ onto $\bigcup E_n$.

Closure under intersections is trickier, and cannot be done simply by taking complements because it is not clear (and in fact turns out to be false) that the complement of an analytic set is analytic. So we proceed as follows. Let $\psi$ be a homeomorphism from $\mathcal{N}$ onto $\mathcal{N}^{\mathbb{N}}$, with coordinate functions $\psi_n$. (This $\psi$ is an analog of the “ultimate space-filling curve” of ().) Let $E_n$ be an analytic subset of $X$ for each $n$ and $f_n$ a continuous function from $\mathcal{N}$ onto $E_n$. Let

$$Y = \{ s \in \mathcal{N} : f_n(\psi_n(s)) = f_m(\psi_m(s)) \text{ for all } n, m \in \mathbb{N} \}.$$ 

$Y$ is a closed subset of $\mathcal{N}$. For $s \in Y$, set $f(s) = f_1(\psi_1(s)) = f_n(\psi_n(s))$ for all $n \in \mathbb{N}$. We have that $f(s) \in f_n(\mathcal{N}) = E_n$ for all $n$, hence the range of $f$ is contained in $\bigcap E_n$. If $x \in \bigcap E_n$, then for each $n$ there is an $s_n \in \mathcal{N}$ with $f_n(s_n) = x$. Then there is an $s \in \mathcal{N}$ with $s_n = \psi_n(s)$ for all $n$; then $s \in Y$ and $f(s) = x$. So the range of $f$ is exactly $\bigcap E_n$. Since $Y$ is closed in $\mathcal{N}$, it is analytic, and hence $\bigcap E_n$ is analytic by XII.3.2.3.. $\diamondsuit$

XII.3.2.5. Corollary. Let $X$ be a Polish space. Then every Borel subset of $X$ is analytic.

Proof: Every closed subset of $X$ is a Polish space, hence analytic by XI.10.2.7.. The result then follows from XII.3.2.4. and ({}).

This result also follows easily from XII.3.1.8.: if $B$ is a Borel set in $X$, there is a Polish topology $\mathcal{S}$ on $X$ stronger than the given topology $\mathcal{T}$ for which $B$ is clopen. $B$ is thus Polish in the relative topology from $\mathcal{S}$; hence by XI.10.2.7. there is an $\mathcal{S}$-continuous map from $\mathcal{N}$ onto $B$, which is also $\mathcal{T}$-continuous.

1387
The converse of XII.3.2.5. is not quite true, since we will see that the complement of an analytic set is not necessarily analytic. But the converse is not “too far” from being true. To see this, we first show that disjoint analytic sets can be separated by Borel sets:

XII.3.2.6. Theorem. [Luzin Separation Theorem] Let $X$ be a Polish space, and $E$ and $F$ disjoint analytic subsets of $X$. Then there is a Borel subset $B$ of $X$ such that $E \subseteq B$ and $F \subseteq B^c$.

Proof: First note that if $(Y_n)$ and $(Z_m)$ are sequences of subsets of $X$ which can be separated by Borel sets, i.e. for each $n, m$ there is a Borel set $B_{n,m}$ with $Y_n \subseteq B_{n,m}$ and $Z_m \subseteq B_{n,m}^c$, then there is a Borel set $B$ separating $\cup_n Y_n$ and $\cup_m Z_m$: $B = \cup_n \cap_m B_{n,m}$ works.

Write $E = \phi(N)$ and $F = \psi(N)$ for continuous functions $\phi$, $\psi$. If $(k_1, \ldots, k_n) \in \mathbb{N}^n$, set

$$N_{k_1,\ldots,k_n} = \{(s_1, s_2, \ldots) \in N : s_j = k_j \text{ for } 1 \leq j \leq n\}.$$and put $E_{k_1,\ldots,k_n} = \phi(N_{k_1,\ldots,k_n})$, $F_{k_1,\ldots,k_n} = \psi(N_{k_1,\ldots,k_n})$.

Suppose $E$ and $F$ are not separated by a Borel set. Since $E = \cup_k E_k$ and $F = \cup_k F_k$, by the first part of the proof there must be $s_1, t_1$ such that $E_{s_1}$ and $F_{t_1}$ are not separated by a Borel set. Similarly, since $E_{s_1} = \cup_k E_{s_1,k}$ and $F_{t_1} = \cup_k F_{t_1,k}$, there must be $s_2, t_2$ such that $E_{s_2}$, $s_2$ and $F_{t_2}$, $t_2$ are not separated by Borel sets. Continuing inductively, sequences $s$ and $t$ in $N$ are constructed such that $E_{s_1,\ldots,s_n}$ and $F_{t_1,\ldots,t_n}$ cannot be separated by a Borel set. Let $x = \phi(s)$ and $y = \phi(t)$. Then $x \in E$ and $y \in F$, so $x \neq y$. Let $U$ and $V$ be disjoint neighborhoods of $x$ and $y$ in $X$. By continuity, we must have $E_{s_1,\ldots,s_n} = \phi(N_{s_1,\ldots,s_n}) \subseteq U$ and $F_{t_1,\ldots,t_n} = \psi(N_{t_1,\ldots,t_n}) \subseteq V$, so $U$ separates $E_{s_1,\ldots,s_n}$ and $F_{t_1,\ldots,t_n}$, a contradiction.

Note that no form of Choice is needed in this proof: each $s_j$ and $t_j$ can just be chosen to be the smallest one for which the conditions hold (specifically, choose $s_j$ to be the smallest possible for which there is a $t_j$, and then $t_j$ the smallest possible for this $s_j$).

XII.3.2.7. Corollary. Let $E$ be an analytic subset of a Polish space $X$. Then $E$ is a Borel set if and only if $E^c$ is also analytic.

XII.3.2.8. Example. It is not so easy to construct an analytic set which is not a Borel set. Here is a construction of an analytic subset $A$ of $N$ whose complement in $N$ is not analytic, hence $A$ is not Borel. Since $N$ is homeomorphic to the set of irrational numbers $J$, $A$ may be regarded as an analytic subset of $J$ whose complement in $J$ is not analytic (since if it were, $(J \setminus A) \cap J$ would be analytic by XII.3.2.4.). The construction uses a version of Cantor’s diagonalization argument.

We first construct a “universal” open set $W$ in $N^3$ which is a catalog for open sets in $N^2$, i.e. for every open set $V$ in $N^2$ there is a $t \in N$ such that $(r, s) \in V \iff (r, s, t) \in W$. The basic open sets in $N^2$ (products of sets of the form $N_{s_1,\ldots,s_n}$) can be arranged in a sequence $(U_n)$ (this can be done explicitly without any form of AC; cf. Exercise ??). For each $n \in \mathbb{N}$, define

$$W_n = \{(r, s, t) \in N^3 | (r, s) \in U_n\}$$where as usual we write $t = (t_1, t_2, \ldots)$. Then $W_n$ is open: if $(r, s, t) \in W_n$, then

$$\{(r', s', t') \in N^3 | (r', s') \in U_{t_n}, t_n = t_n\}$$
is a neighborhood of $(r, s, t)$ contained in $W_n$. Set $W = \bigcup_n W_n$. Then $W$ is open in $\mathcal{N}^3$. If $V$ is an open set in $\mathcal{N}^2$, let $t = (t_1, t_2, \ldots)$ be the set of $n$’s (in increasing order) such that $U_n \subseteq V$. Then $V = \bigcup_n U_{t_n}$, so

$$(r, s) \in V \iff (r, s) \in U_{t_n} \text{ for some } n \iff (r, s, t) \in W_n \text{ for some } n \iff (r, s, t) \in W$$

so $W$ is a catalog for open sets in $\mathcal{N}^2$.

Let $G = \mathcal{N}^3 \setminus W$. Then $G$ is a catalog for closed sets if $\mathcal{N}^2$: if $F \subseteq \mathcal{N}^2$ is closed, let $V = \mathcal{N}^2 \setminus F$. Then there is a $t \in \mathcal{N}$ such that

$$(r, s) \in F \iff (r, s) \notin V \iff (r, s, t) \notin W \iff (r, s, t) \in G.$$

Now let $C = \pi_{13}(G) \subseteq \mathcal{N}^2$ be the projection of $G$ onto the first and third coordinates. Then $C$ is an analytic subset of $\mathcal{N}^2$ since $G$ is closed in $\mathcal{N}^2 \times \mathcal{N}$. We claim that $C$ is a catalog for analytic subsets of $\mathcal{N}$. If $B$ is an analytic subset of $\mathcal{N}$, there is a closed set $F \subseteq \mathcal{N}^2$ with $B = \pi_1(F)$. There is then a $t \in \mathcal{N}$ such that $(r, s) \in F \iff (r, s, t) \in G$. We then have, for $r \in \mathcal{N}$,

$$r \in B \iff (r, s) \in F \text{ for some } s \iff (r, s, t) \in G \text{ for some } s \iff (r, t) \in C.$$

Finally, let $D = \{(t, t) | (t, t) \in C\} \subseteq \mathcal{N}^2$ and let $A = \pi_1(D)$. $D$ is the intersection of $C$ with the diagonal in $\mathcal{N}^2$, which is a closed, hence analytic, subset of $\mathcal{N}^2$; hence $D$ is analytic in $\mathcal{N}^2$ by XII.3.2.4., and so $A$ is analytic in $\mathcal{N}$. But $A^c = \mathcal{N} \setminus A$ cannot be analytic, since if it were there would be a $t \in \mathcal{N}$ such that $r \in A^c \iff (r, t) \in C$. But then, for this $t$,

$$t \in A^c \iff (t, t) \in C \iff (t, t) \in D \iff t \in A$$

which is a contradiction.

XII.3.3. Suslin Sets and the Suslin Operation

XII.3.3.1. There is a curious operation on sets called the Suslin operation, which is reminiscent of the construction in the proof of XI.10.2.7. For each finite sequence $(s_1, \ldots, s_n)$ of natural numbers, let $A_{s_1, \ldots, s_n}$ be a subset of a set $X$. The collection of finite sequences in $\mathbb{N}$ is countable, so there are countably many such sets in all. Define

$$S(\{A_{s_1, \ldots, s_n}\}) = \bigcup_{s \in \mathbb{N}} \bigcap_{n=1}^{\infty} A_{s_1, \ldots, s_n}.$$

Although the operation begins with a countable collection of sets, the union is over all sequences (uncountably many) in $\mathcal{N}$.

XII.3.3.2. Definition. Let $X$ be a Polish space. A Suslin set is a subset of $X$ obtained by applying the Suslin operation to a collection of closed subsets of $X$. 1389
XII.3.3.3. **Theorem.** A subset of a Polish space is a Suslin set if and only if it is analytic.

**Proof:** Suppose $A$ is a Suslin set in a Polish space $X$. Let $A = \bigcup_{x \in \mathcal{N}} \cap_n F_{s|n}$, where the $F_{s|n}$ are closed sets. Set

$$F = \{(x, s) \in X \times \mathcal{N} : x \in F_{s|n} \text{ for all } n\} \subseteq X \times \mathcal{N}.$$ 

Then $F$ is a closed subset of $X \times \mathcal{N}$, and $A = \pi_X(F)$, so $A$ is analytic.

Conversely, suppose $A$ is analytic. Fix a complete metric $\rho$ on $X$. Let $\phi : \mathcal{N} \to A$ be continuous. For each $(s_1, \ldots, s_n)$ set $F_{s_1, \ldots, s_n} = \phi_\phi(\mathcal{N}_{s_1, \ldots, s_n})$. Then $F_{s_1, \ldots, s_n}$ is closed and for each $s \in \mathcal{N}$, $F_{s|(n+1)} \subseteq F_{s|n}$ for all $n$, and $\text{diam}(F_{s|n}) \to 0$ as $n \to \infty$ since $\phi$ is continuous. Thus for every $s \in \mathcal{N}$ there is a unique $x_s \in \cap_n F_{s|n}$ since $X$ is complete. Fix $s$ and set $x = x_s$. Then for each $n$ there is an $x_n \in \phi(\mathcal{N}_{s_1, \ldots, s_n})$ with $\rho(x_n, x) < 2^{-n}$, and there is an $s(n) \in \mathcal{N}_{s_1, \ldots, s_n}$ with $\phi(s(n)) = x_n$. We have $s(n) \to s$ since $s(n)|n = s|n$ for all $n$; thus $\phi(s(n)) \to \phi(s)$. But $\phi(s(n)) = x_n \to x$, so $x = \phi(s)$, i.e. $x \in A$. So $S(\{F_{s_1, \ldots, s_n}\}) \subseteq A$. The reverse containment is obvious, so $A = S(\{F_{s_1, \ldots, s_n}\}) \in \mathcal{S}(\mathcal{F})$.  

XII.3.3.4. **Theorem.** Let $(X, \mathcal{A}, \mu)$ be a complete measure space. Then $\mathcal{A}$ is closed under the Suslin operation.

XII.3.3.5. **Corollary.** Let $X$ be a Polish space, and $\mu$ a complete measure defined on a $\sigma$-algebra $\mathcal{A}$ of subsets of $X$ containing the Borel sets. Then $\mathcal{A}$ contains all analytic subsets of $X$.

XII.3.3.6. The history of Suslin sets and the Suslin operation is unfortunate and somewhat murky, and is an important facet of the story of analysis in the Soviet Union. SUSLIN died of typhus in 1919 at age 24, having published only one paper during his lifetime. LUZIN, his mentor, then refined, expanded on, and published some of Suslin’s work (with credit to Suslin). Later, ALEKSEANDROV claimed that he was responsible for the Suslin operation and the notion of analytic set, and that in the original names “A-operation” and “A-set”, used by both Suslin and Luzin, the “A” stood for “Aleksandrov”, not “analytic”, the term eventually used by Luzin (Luzin said this name had been proposed by Lebesgue). There is some (inconclusive) evidence to support Aleksandrov’s claim, but also persuasive evidence to the contrary, and most contemporary scholarship attributes the concept of analytic set to Suslin and Luzin (Hausdorff also played a significant and rather independent role); cf. [Lor01]. The relations between Aleksandrov and Luzin began well but soured early, and contained a lot of personal friction and political intrigue during the Stalin era. Aleksandrov was an active participant in the attempted political persecution of Luzin known as the “Luzin affair.” Accounts of these and related events vary widely in point of view, and it is quite difficult to get an unbiased picture of what really happened. The story is certainly a complicated one, involving (according to references) politics, mysticism, and homosexuality. See [GK09], [ZD07], and [Sin03] for pieces of the story.

There are many fascinating anecdotes about these personalities in these references (many of which involve their fanatical and occasionally tragic swimming adventures). For example, the usually reserved Kolmogorov, a close friend of Aleksandrov, once slapped Luzin in the face during a meeting of the Academy of Sciences (according to [GK09], in response to an insult by Luzin); the incident came to the personal attention of Stalin, who shrugged it off, saying, “Well, such things occur with us as well.” It should be noted that both before and after this incident, Kolmogorov had kind things to say about Luzin, as did Aleksandrov earlier in his career.
XII.3.3.7. Universally measurable sets

XII.3.4. Addison’s Notation and the Projective Hierarchy

In 1958 J. Addison [Add59] introduced coherent new notation not only for the sets in the hierarchy of the construction of the Borel sets, but also for analytic sets and a continuing hierarchy of subsets of $\mathbb{R}$ (or a general topological space). Indexing by ordinals had been part of the subject since the work of Baire, Lebesgue, Hausdorff, and the Russian school.

XII.3.4.1. Fix a topological space $X$, usually $\mathbb{R}$ or $\mathcal{N}$. Define the classes $\Sigma^0_\alpha$ and $\Pi^0_\alpha$ of subsets of $X$ inductively for $0 < \alpha < \omega_1$ as follows:

- $\Sigma^0_0$ is the class of open sets.
- $\Pi^0_0$ is the class of closed sets.
- $\Sigma^0_\alpha$ is the class of countable unions of sets in $\bigcup_{\beta < \alpha} \Pi^0_\beta$.
- $\Pi^0_\alpha$ is the class of countable intersections of sets in $\bigcup_{\beta < \alpha} \Sigma^0_\beta$.

Thus $\Sigma^0_2$ is the class of $F_\sigma$'s, $\Pi^0_2$ the class of $G_\delta$'s, $\Sigma^0_3$ the class of $G_{\delta\sigma}$'s, $\Pi^0_3$ the class of $F_{\sigma\delta}$'s, etc.

A set $A$ is called a $\Sigma^0_\alpha$-set (or $\Pi^0_\alpha$-set) if $A \in \Sigma^0_\alpha$ (or $A \in \Pi^0_\alpha$).

XII.3.4.2. If $X$ is Polish, we have that $\Sigma^0_\alpha \subseteq \Pi^0_\beta$ and $\Pi^0_\beta \subseteq \Sigma^0_\alpha$ if $\beta < \alpha$. The complement of a $\Sigma^0_\alpha$-set is a $\Pi^0_\alpha$-set, and vice versa. Since $\Sigma^0_1 \subseteq \Sigma^0_0$ ( ), by induction we have $\Sigma^0_\beta \subseteq \Sigma^0_\alpha$ and $\Pi^0_\alpha \subseteq \Pi^0_\beta$ for $\beta < \alpha$.

The unions $\bigcup_{\alpha < \omega_1} \Sigma^0_\alpha$ and $\bigcup_{\alpha < \omega_1} \Pi^0_\alpha$ are both equal to the class of Borel sets (the Countable AC is needed to show that these unions form a $\sigma$-algebra and hence contain all Borel sets (XII.3.5.4.)).

XII.3.4.3. It follows easily from the results of ( ) that for $X = \mathbb{R}$, these classes strictly increase in $\alpha$. This was first shown by Lebesgue [?], who proved that $\Sigma^0_{\alpha} \nsubseteq \Pi^0_{\alpha}$ for any $\alpha < \omega_1$ (see ( )).

We also define $\Delta^0_{\alpha} = \Sigma^0_{\alpha} \cap \Pi^0_{\alpha}$.

XII.3.4.4. Now for $n \in \mathbb{N} \cup \{0\}$ define $\Sigma^1_n$ and $\Pi^1_n$ inductively as follows.

- $\Sigma^0_0 = \Sigma^1_0$ is the class of open sets.
- $\Pi^0_0$ is the class of complements of $\Sigma^1_0$-sets.
- $\Sigma^1_n$ is the class of countable unions of $\Pi^1_n$-sets in $X \times \mathcal{N}$.
- $\Delta^1_n = \Sigma^1_n \cap \Pi^1_n$.

Thus $\Pi^1_0$ is the class of closed sets, and $\Sigma^1_1$ is the class of analytic sets ( ). $\Delta^1_1$ is the class of Borel sets ( ). It follows that $\Sigma^1_0 \cup \Pi^1_0 \subseteq \Delta^1_1$ (there is also a simple direct proof of this) and hence by induction $\Sigma^1_n \cup \Pi^1_n \subseteq \Delta^1_{n+1}$ for all $n$.

A set in $\bigcup_n \Sigma^1_n = \bigcup_n \Pi^1_n = \bigcup_n \Delta^1_n$ is called a projective set.
To see why the projection operation is natural, and that this hierarchy is analogous to the Borel sets, note that an $F_\sigma$ ($\Sigma^0_2$-set) in $X$ is a $\pi_X$ projection of a closed set ($\Pi^0_1$-set) in $X \times \mathbb{N}$, and more generally a $\Sigma^0_{\alpha+1}$-set in $X$ is the $\pi_X$ projection of a $\Pi^0_{\alpha}$-set in $X \times \mathbb{N}$.

This hierarchy can be extended transfinitely to define $\Sigma^1_\alpha$ and $\Pi^1_\alpha$ for $\alpha < \omega_1$. What about $\Sigma^n_\alpha$, $\Sigma^2_\alpha$, etc.?

ADDISON’s notation is strongly reminiscent of similar notation used in mathematical logic and model theory, and was in fact inspired by analogies and connections with the logic notation.

**Exercises**

**XII.3.5.1.** Let $\mathcal{C} = \{0,1\}^\mathbb{N}$ ($\mathcal{C}$ is homeomorphic to the Cantor set (\)). Define a map $f : \mathcal{N} \to \mathcal{C}$ by

\[
f(n_1, n_2, \ldots) = (0, \ldots, 0, 1, 0, \ldots, 0, 1, \ldots).
\]

(a) Show that $f$ is a homeomorphism of $\mathcal{N}$ with a subset of $\mathcal{C}$ with countable complement.

(b) Show that $(\mathcal{C}, \mathcal{B}_\mathcal{C})$ is Borel isomorphic to $(\mathcal{N}, \mathcal{B}_\mathcal{N}) \oplus (\mathbb{N}, \mathcal{P}(\mathbb{N}))$.

(c) Since $\mathcal{N}$ is also homeomorphic to the irrational numbers in $[0,1]$, $([0,1], \mathcal{B}_{[0,1]})$ is Borel isomorphic to $(\mathcal{N}, \mathcal{B}_\mathcal{N}) \oplus (\mathbb{N}, \mathcal{P}(\mathbb{N}))$. Thus $([0,1], \mathcal{B}_{[0,1]})$ is Borel isomorphic to $(\mathcal{C}, \mathcal{B}_\mathcal{C})$.

(d) Show that $(\mathcal{C}, \mathcal{B}_\mathcal{C})$ is also Borel isomorphic to $([0,1]^\mathbb{N}, \mathcal{B}_{[0,1]})$. $[\mathcal{C}$ is homeomorphic to $C^{\mathbb{N}}\]$.

(c) Since $(\mathbb{N}, \mathcal{P}(\mathbb{N})) \oplus (\mathbb{N}, \mathcal{P}(\mathbb{N}))$ is Borel isomorphic to $(\mathbb{N}, \mathcal{P}(\mathbb{N}))$, $(\mathcal{C}, \mathcal{B}_\mathcal{C}) \oplus (\mathbb{N}, \mathcal{P}(\mathbb{N}))$ is Borel isomorphic to $(\mathcal{C}, \mathcal{B}_\mathcal{C})$. [Use (b).]

**XII.3.5.2.** If $(X, \rho)$ is a perfect complete metric space, show that there is a homeomorphism from $\mathcal{C}$ onto a (compact) subspace of $X$. Thus $(\mathcal{C}, \mathcal{B}_\mathcal{C})$ is Borel isomorphic to a measurable subspace of $(X, \mathcal{B}_X)$.

(a) Let $X$ be a Polish space. Then $X$ is homeomorphic to a $G_\delta$ in the Hilbert cube (\(\)) and (\(\)). Thus $(X, \mathcal{B}_X)$ is Borel isomorphic to a measurable subspace of $(\mathcal{C}, \mathcal{B}_\mathcal{C})$ by (\(\)) (d).

(b) If $X$ is an uncountable Polish space, then by (\(\)) $(X, \mathcal{B}_X)$ is Borel isomorphic to $(Y, \mathcal{B}_Y) \oplus (\mathbb{N}, \mathcal{P}(\mathbb{N}))$ for some perfect (uncountable) Polish space $Y$. Thus $(X, \mathcal{B}_X)$ is Borel isomorphic to a measurable subspace of $(\mathcal{C}, \mathcal{B}_\mathcal{C})$.

(c) If $X$ is an uncountable Polish space, then $X$ has a (compact) subspace homeomorphic to $C$ (\(\)) and (\(\)), and thus $(\mathcal{C}, \mathcal{B}_\mathcal{C})$ is Borel isomorphic to a measurable subspace of $(X, \mathcal{B}_X)$.

(d) Apply the Schröder-Bernstein Theorem for measurable spaces (XII.1.5.3.) to conclude that if $X$ is any uncountable Polish space, then $(X, \mathcal{B}_X)$ is Borel isomorphic to $(\mathcal{C}, \mathcal{B}_\mathcal{C})$.

**XII.3.5.4.** Explain why the Countable AC is needed to show that the unions $A = \bigcup_{\alpha < \omega_1} \Sigma^0_\alpha = \bigcup_{\alpha < \omega_1} \Pi^0_\alpha$ (XII.3.4.2.) form a $\sigma$-algebra. (See II.8.6.10..)
Chapter XIII

Measure Theory

XIII.1. Measures

It should come as no surprise that the fundamental concept of measure theory is the notion of measure. Measures live on measurable spaces \((X, \mathcal{A})\), and assign to each measurable set a nonnegative extended real-number "size" for the set. The crucial property a measure must have is countable additivity.

XIII.1.1. Definitions

XIII.1.1.1. Definition. Let \((X, \mathcal{A})\) be a measurable space. A measure on \((X, \mathcal{A})\) is a function \(\mu : \mathcal{A} \to [0, \infty]\) satisfying

(i) \(\mu(\emptyset) = 0\).

(ii) If \(A_1, A_2, \ldots\) is a sequence of pairwise disjoint sets in \(\mathcal{A}\), then

\[
\mu \left( \bigcup_{k=1}^{\infty} A_k \right) = \sum_{k=1}^{\infty} \mu(A_k) = \sup_{n} \sum_{k=1}^{n} \mu(A_k) = \lim_{n \to \infty} \sum_{k=1}^{n} \mu(A_k)
\]

(\(\mu\) is countably additive).

A measure space is a triple \((X, \mathcal{A}, \mu)\), where \((X, \mathcal{A})\) is a measurable space and \(\mu\) is a measure on \((X, \mathcal{A})\).

XIII.1.1.2. Note that specification of the \(\sigma\)-algebra is part of the definition of a measure and of a measure space. While we frequently downplay this specification, especially in contexts where there is some natural \(\sigma\)-algebra of measurable sets, it cannot be ignored. Thus, for example, if \((X, \mathcal{A}, \mu)\) is a measure space and \(\mathcal{B}\) is a proper sub-\(\sigma\)-algebra of \(\mathcal{A}\), and \(\nu = \mu|_{\mathcal{B}}\), then \(\nu\) is technically a different measure than \(\mu\), and the measure spaces \((X, \mathcal{A}, \mu)\) and \((X, \mathcal{B}, \nu)\) are different measure spaces. See XIII.1.6.10.

XIII.1.1.3. Condition (i) in the definition is almost redundant: the only function satisfying (ii) but not (i) is the function \(\mu\) with \(\mu(A) = \infty\) for all \(A \in \mathcal{A}\). (To see this, let \(A \in \mathcal{A}\), set \(A_1 = A\) and \(A_n = \emptyset\) for \(n > 1\), and apply (ii).)

By a similar argument, we can see:
XIII.1.1.4. Proposition. Let $\mu$ be a measure on $(X, \mathcal{A})$. Then $\mu$ is finitely additive: if $A_1, \ldots, A_n$ are pairwise disjoint sets in $\mathcal{A}$, then
\[
\mu \left( \bigcup_{k=1}^n A_k \right) = \sum_{k=1}^n \mu(A_k).
\]
In particular, if $A, B \in \mathcal{A}$ are disjoint, then $\mu(A \cup B) = \mu(A) + \mu(B)$.

**Proof:** Set $A_k = \emptyset$ for $k > n$, and apply countable additivity.

XIII.1.1.5. We can define a finitely additive measure on a measurable space $(X, \mu)$ to be a finitely additive function $\mu : \mathcal{A} \to [0, \infty]$ with $\mu(\emptyset) = 0$. (Actually we only need for $\mathcal{A}$ to be an algebra of subsets of $X$ for this definition to make sense.) XIII.1.1.4. says that every measure is a finitely additive measure; but there are many finitely additive measures which are not measures (e.g. XIII.1.1.6.(vii)–(viii)). A few authors call a finitely additive measure a “measure” (measures in our sense are then called “countably additive measures”), but this terminology is nonstandard.

The theory of finitely additive measures is important in some contexts, and the theory of measure and integration can be developed surprisingly far in this generality (cf. [DS88, Chapter 3]). However, countable additivity is really what gives the theory of measure and integration its power. Countable additivity should be regarded as a sort of continuity condition (cf. XIII.1.2.7.).

Although we cannot yet give any really interesting examples of measures (the interesting ones take considerable effort to construct), here are some simple examples which range from uninteresting to moderately interesting:

XIII.1.1.6. Examples. (i) Let $(X, \mathcal{A})$ be any measurable space. Set $\mu(A) = 0$ for all $A \in \mathcal{A}$. Then $\mu$ is a measure on $(X, \mathcal{A})$, called the zero measure.

(ii) Let $X$ be any set. For $A \subseteq X$, set $\mu(A) = 0$ if $A = \emptyset$ and $\mu(A) = \infty$ if $A \neq \emptyset$. Then $\mu$ is a measure on $(X, \mathcal{P}(X))$. (This measure can be restricted to any $\sigma$-algebra on $X$.)

(iii) Let $X$ be an uncountable set. If $A \subseteq X$, set $\mu(A) = 0$ if $A$ is countable and $\mu(A) = \infty$ if $A$ is uncountable. Then $\mu$ is a measure on $(X, \mathcal{P}(X))$.

(iv) Let $X$ be an uncountable set, $\mathcal{A}$ the $\sigma$-algebra of countable/cocountable subsets of $X$. If $A \in \mathcal{A}$, set $\mu(A) = 0$ if $A$ is countable and $\mu(A) = 1$ if $A$ is cocountable. Then $\mu$ is a measure on $(X, \mathcal{A})$.

(v) Let $X$ be any set, and $p$ a fixed element of $X$. For $A \subseteq X$, set $\delta_p(A) = 1$ if $p \in A$ and $\delta_p(A) = 0$ if $p \notin A$. Then $\delta_p$ is a measure on $(X, \mathcal{P}(X))$, called the (unit) point mass (or Dirac measure) at $p$.

(vi) Let $X$ be any set. If $A \subseteq X$, set $\mu(A) = n$ if $A$ is a finite set with $n$ elements, and $\mu(A) = \infty$ if $A$ is infinite. Then $\mu$ is a measure on $(X, \mathcal{P}(X))$, called counting measure on $X$. This measure, while very simple, is important, especially in the case $X = \mathbb{N}$; integration theory for this measure is really exactly the theory of infinite series.

(vii) Let $X$ be an infinite set. If $A \subseteq X$, set $\mu(A) = 0$ if $A$ is finite and $\mu(A) = \infty$ if $A$ is infinite. Then $\mu$ is a finitely additive measure on $(X, \mathcal{P}(X))$ which is not a measure.

(viii) Let $\mathcal{F}$ be a free ultrafilter () on $\mathbb{N}$. For $A \subseteq \mathbb{N}$, set $\mu(A) = 1$ if $A \in \mathcal{F}$ and $\mu(A) = 0$ if $A \notin \mathcal{F}$. Then $\mu$ is a finitely additive measure on $(X, \mathcal{P}(X))$ which is not a measure. The same construction works if $\mathbb{N}$ is replaced by any infinite set whose cardinality is less than the first measurable cardinal.
XIII.1.2. Elementary Properties

Here we develop some of the most basic properties of measures.

XIII.1.2.1. Proposition. Let \((X, \mathcal{A}, \mu)\) be a measure space. Then

(i) \(\mu\) is monotone: if \(A, B \in \mathcal{A}\), \(B \subseteq A\), then \(\mu(B) \leq \mu(A)\).

(ii) \(\mu\) is countably subadditive: if \((A_k)\) is a sequence in \(\mathcal{A}\), then

\[
\mu \left( \bigcup_{k=1}^{\infty} A_k \right) \leq \sum_{k=1}^{\infty} \mu(A_k).
\]

Proof: (i): We have \(A = B \cup (A \setminus B)\), a disjoint union, and \((A \setminus B) \in \mathcal{A}\), so

\[\mu(A) = \mu(B) + \mu(A \setminus B)\]

by finite additivity, and \(\mu(A \setminus B) \geq 0\).

(ii): Disjointize the sequence \((A_n)\) as in (i), i.e. set \(B_1 = A_1\) and \(B_n = A_n \setminus (\bigcup_{k=1}^{n-1} A_k)\) for \(n > 1\). Then the \(B_n\) are in \(\mathcal{A}\) and are pairwise disjoint, \(B_n \subseteq A_n\), and \(\bigcup_{n=1}^{\infty} B_n = \bigcup_{n=1}^{\infty} A_n\). So, by countable additivity and (i),

\[
\mu \left( \bigcup_{n=1}^{\infty} A_n \right) = \mu \left( \bigcup_{n=1}^{\infty} B_n \right) = \sum_{n=1}^{\infty} \mu(B_n) \leq \sum_{n=1}^{\infty} \mu(A_n).
\]

As with XIII.1.1.4., we also have

XIII.1.2.2. Corollary. Let \((X, \mathcal{A}, \mu)\) be a measure space. Then \(\mu\) is finitely subadditive: if \(A_1, \ldots, A_n \in \mathcal{A}\), then

\[
\mu \left( \bigcup_{k=1}^{n} A_k \right) \leq \sum_{k=1}^{n} \mu(A_k).
\]

In particular, if \(A, B \in \mathcal{A}\), then \(\mu(A \cup B) \leq \mu(A) + \mu(B)\).

XIII.1.2.3. Note that by a nearly identical proof, a finitely additive measure is also monotone and finitely subadditive. A finitely additive measure need not be countably subadditive: the measure in XIII.1.1.6.(vii) is a counterexample. In fact, a finitely additive measure which is countably subadditive is countably additive, i.e. a measure (Exercise XIII.1.9.1.).

Decompositions of Measure Spaces

The next observation is an immediate consequence of countable additivity. We will often use this result to break up a measure space into a finite or countable number of pieces.
XIII.1.2.4. PROPOSITION. Let \((X, \mathcal{A}, \mu)\) be a measure space, \(I\) a finite or countable index set, and \(\{X_i : i \in I\}\) a collection of pairwise disjoint measurable subsets of \(X\) with \(X = \bigcup_{i \in I} X_i\). Then for any \(A \in \mathcal{A}\) we have\[
\mu(A) = \sum_{i \in I} \mu(A \cap X_i) .
\]

XIII.1.2.5. Note that countability of the index set \(I\) is essential. In many examples such as in XIII.1.1.6.(iii), or \(\mathbb{R}\) with Lebesgue measure, the entire space \(X\) can be decomposed as a disjoint union of singleton subsets, each of which is measurable and has measure zero.

Measures of Differences

XIII.1.2.6. If \((X, \mathcal{A}, \mu)\) is a measure space, and \(A, B \in \mathcal{A}\) with \(B \subseteq A\), and \(\mu(B) < \infty\) (e.g. if \(\mu(A) < \infty\)), then we have that\[
\mu(A \setminus B) = \mu(A) - \mu(B)
\]where we interpret \(-b = \infty\) for \(b \in \mathbb{R}\). However, if \(\mu(B) = \infty\) (and hence \(\mu(A) = \infty\) also by monotonicity), we cannot draw any conclusion about \(\mu(A \setminus B)\) (cf. Exercise XIII.1.9.2.). Thus we must be careful in subtracting measures of sets when the measures are infinite.

Upward Continuity

The next property is the first instance of how countable additivity can be regarded as a continuity property. It is called the Baby Monotone Convergence Theorem because it is actually the special case of the Monotone Convergence Theorem for indicator functions.

XIII.1.2.7. PROPOSITION. [BABY MONOTONE CONVERGENCE THEOREM] Let \((X, \mathcal{A}, \mu)\) be a measure space, and \((A_n)\) an increasing sequence in \(\mathcal{A}\), i.e. \(A_n \subseteq A_{n+1}\) for all \(n\). Then\[
\mu \left( \bigcup_{n=1}^{\infty} A_n \right) = \sup_n \mu(A_n) = \lim_{n \to \infty} \mu(A_n)
\](\(\mu\) is upward continuous).

PROOF: Disjointize the sequence \((A_n)\) by setting \(B_1 = A_1\) and \(B_n = A_n \setminus A_{n-1}\) for \(n > 1\). Then the \(B_n\) are in \(\mathcal{A}\) and are pairwise disjoint, \(A_n = \bigcup_{k=1}^{n} B_k\) for all \(n\), and \(\bigcup_{n=1}^{\infty} A_n = \bigcup_{k=1}^{\infty} B_k\). Then\[
\mu \left( \bigcup_{n=1}^{\infty} A_n \right) = \mu \left( \bigcup_{k=1}^{\infty} B_k \right) = \sum_{k=1}^{\infty} \mu(B_k) = \lim_{n \to \infty} \sum_{k=1}^{n} \mu(B_k) = \lim_{n \to \infty} \mu(A_n) .
\]
XIII.1.2.8. A finitely additive measure $\mu$ is not upward continuous in general, although if $(A_n)$ is an increasing sequence of measurable sets we always have

$$\mu \left( \bigcup_{n=1}^{\infty} A_n \right) \geq \sup_n \mu(A_n) = \lim_{n \to \infty} \mu(A_n)$$

by monotonicity. Example XIII.1.1.6.(vii) is a counterexample to equality. In fact, it is easily seen that upward continuity is equivalent to countable additivity for a finitely additive measure (Exercise XIII.1.9.1.).

**Downward Continuity**

What about downward continuity? The following example shows that it does not hold in general.

XIII.1.2.9. **Example.** Let $\mu$ be counting measure on $(\mathbb{N}, \mathcal{P}(\mathbb{N}))$. Let $A_n = \{ k \in \mathbb{N} : k \geq n \}$. Then $A_n \supseteq A_{n+1}$ for all $n$. We have $\mu(A_n) = \infty$ for all $n$. But $\cap_{n=1}^{\infty} A_n = \emptyset$, so

$$0 = \mu \left( \bigcap_{n=1}^{\infty} A_n \right) < \inf_n \mu(A_n) = \lim_{n \to \infty} \mu(A_n) = \infty .$$

The difficulty stems from the failure of subtraction for measures of sets (cf. XIII.1.2.6.). In fact, we have:

XIII.1.2.10. **Proposition.** Let $(X, \mathcal{A}, \mu)$ be a measure space, and $(A_n)$ a decreasing sequence in $\mathcal{A}$, i.e. $A_n \supseteq A_{n+1}$ for all $n$. If $\mu(A_1) < \infty$, then

$$\mu \left( \bigcap_{n=1}^{\infty} A_n \right) = \inf_n \mu(A_n) = \lim_{n \to \infty} \mu(A_n)$$

($\mu$ is **downward continuous** on sets of finite measure).

**Proof:** Set $B_n = A_1 \setminus A_n$ for each $n$. Then the $B_n$ are in $\mathcal{A}$ and are increasing. If $A = \cap_{n=1}^{\infty} A_n$ and $B = \cup_{n=1}^{\infty} B_n$, we have $B = A_1 \setminus A$. We thus have, using XIII.1.2.6. and XIII.1.2.7.,

$$\mu(A_1) - \mu(A) = \mu(B) = \lim_{n \to \infty} \mu(B_n) = \lim_{n \to \infty} [\mu(A_1) - \mu(A_n)] = \mu(A_1) - \lim_{n \to \infty} \mu(A_n)$$

and the result follows.

Note that, by passing to a tail of the sequence, it suffices that $\mu(A_n) < \infty$ for some $n$.

The First Borel-Cantelli Lemma

We can obtain various more sophisticated results about measures. For example, the next result is particularly important in probability, where it is called the **first Borel-Cantelli Lemma**. Recall () that if $(A_n)$ is a sequence of subsets of a set $X$, then

$$\limsup_n A_n = \bigcap_{n=1}^{\infty} \left( \bigcup_{k=n}^{\infty} A_k \right)$$

is the set of $x \in X$ which are in infinitely many of the $A_n$. 

1397
XIII.1.2.11. Proposition. [First Borel-Cantelli Lemma] Let \((X, \mathcal{A}, \mu)\) be a measure space, and 
\((A_n)\) a sequence in \(\mathcal{A}\). If
\[
\sum_{k=1}^{\infty} \mu(A_k) < \infty,
\]
then
\[
\mu(\limsup_{n} A_n) = 0.
\]

Proof: Let \(\epsilon > 0\). Then there is an \(m\) such that
\[
\sum_{k=1}^{\infty} \mu(A_k) - \sum_{k=1}^{m} \mu(A_k) = \sum_{k=m+1}^{\infty} \mu(A_k) < \epsilon
\]
(in fact this holds for all sufficiently large \(m\)). For such an \(m\), we have
\[
\limsup_{n} A_n \subseteq \bigcup_{k=m+1}^{\infty} A_k
\]
so by monotonicity and countable subadditivity we have
\[
\mu(\limsup_{n} A_n) \leq \mu \left( \bigcup_{k=m+1}^{\infty} A_k \right) \leq \sum_{k=m+1}^{\infty} \mu(A_k) < \epsilon.
\]
Since \(\epsilon > 0\) is arbitrary, \(\mu(\limsup_{n} A_n) = 0\).

XIII.1.3. Null Sets and Completeness

XIII.1.3.1. Definition. Let \((X, \mathcal{A}, \mu)\) be a measure space. A set \(A \in \mathcal{A}\) is a null set (or \(\mu\)-null set) if
\[
\mu(A) = 0.
\]

XIII.1.3.2. In general mathematics, the term "null set" is often used as a synonym for "empty set"; but in analysis it is more useful to use the definition we have given. Note that the empty set is always a null set by the analysis definition, but many measure spaces also have other null sets which are nonempty. Of course, whether a set is a null set depends on the measure: if \(\mu\) and \(\nu\) are measures on a measurable space \((X, \mathcal{A})\), then a \(\mu\)-null set is not necessarily a \(\nu\)-null set.

The idea behind the terminology is that null sets are "negligibly small" for measure-theoretic purposes. A general philosophy in measure theory is that sets or functions can be modified on a null set with no effect. In fact, we will eventually feel quite free to ignore what happens on null sets, although at least at first one should be careful about this.

Unions of Null Sets

XIII.1.3.3. Proposition. A countable union of null sets is a null set. (In particular, a finite union of null sets is a null set.)

This is an immediate consequence of countable subadditivity.
Subsets of Null Sets and Completeness

XIII.1.3.4. It may be surprising that a subset of a null set is not necessarily a null set. It is a trivial consequence of monotonicity that any measurable subset of a null set is a null set. However, there are many examples of measure spaces containing null sets with nonmeasurable subsets. Here is perhaps the simplest example:

XIII.1.3.5. Example. Let $\mathcal{A}$ be the $\sigma$-algebra of countable/cocountable subsets of $\mathbb{R}$. If $A \in \mathcal{A}$, let $\mu(A) = 1$ if $1 \in A$ and $\mu(A) = 0$ if $1 \notin A$. It is easily checked that $\mu$ is a measure on $(\mathbb{R}, \mathcal{A})$ (it is the restriction to $\mathcal{A}$ of the Dirac measure $\delta_1$ of XIII.1.3.7. (v)). We have that $\mathbb{R} \setminus \{1\}$ is a null set, but $(1, +\infty)$ and $(-\infty, 1)$ are not null sets since they are not measurable, i.e., not in $\mathcal{A}$ (each is an uncountable set with uncountable complement).

This example may seem artificial since we arbitrarily chose a smaller $\sigma$-algebra than the natural one on which $\mu$ is defined (namely $\mathcal{P}(\mathbb{R})$). There are more natural examples such as Lebesgue measure on the Borel sets $\mathcal{B}$, although in a certain sense every example is unnatural (XIII.1.3.7.).

XIII.1.3.6. Definition. Let $(X, \mathcal{A}, \mu)$ be a measure space. Then $(X, \mathcal{A}, \mu)$ is a complete measure space if every subset of a null set is a null set (i.e., measurable).

XIII.1.3.7. Theorem. Let $(X, \mathcal{A}, \mu)$ be a measure space, and let $\mathcal{A}$ be the $\sigma$-algebra of subsets of $X$ generated by $\mathcal{A}$ and all subsets of null sets. Then there is a unique extension $\tilde{\mu}$ of $\mu$ to $(X, \mathcal{A})$, and $(X, \mathcal{A}, \tilde{\mu})$ is complete. In fact, $\mathcal{A}$ is the collection of all subsets of $X$ of the form $A \cup D$, where $A \in \mathcal{A}$ and $D$ is a subset of a null set.

Proof: Let $\mathcal{B}$ be the collection of all subsets of $X$ of the form $A \cup D$, where $A \in \mathcal{A}$ and $D$ is a subset of a null set. Note that $\emptyset$ and $X$ are in $\mathcal{B}$, and it is easy (using XIII.1.3.3.) to check that $\mathcal{B}$ is closed under countable unions. Let $B = A \cup D \in \mathcal{B}$, where $A \in \mathcal{A}$ and $D \subseteq C \subseteq A$ with $\mu(C) = 0$. Then

$$X \setminus B = (X \setminus [A \cup C]) \cup (C \setminus B)$$

and $X \setminus (A \cup C) \in \mathcal{A}$, $C \setminus B \subseteq C$. Thus $\mathcal{B}$ is a $\sigma$-algebra and $A \subseteq B \subseteq \mathcal{A}$; $\mathcal{B}$ contains all subsets of null sets, so $\mathcal{B} = \mathcal{A}$.

For $B = A \cup D$ as above, set $\tilde{\mu}(B) = \mu(A)$. This is well defined: if $B = A_1 \cup D_1 = A_2 \cup D_2$ with $D_j \subseteq C_j$, $\mu(C_j) = 0$, then

$$A_1 \setminus C_2 \subseteq A_2 \subseteq A_1 \cup C_1$$

so $\mu(A_1) = \mu(A_2)$. It is clear that $\tilde{\mu}$ extends $\mu$ and easy to check that $\tilde{\mu}$ is countably additive. For uniqueness, if $\nu$ extends $\mu$ and $B = A \cup D$ with $D \subseteq C$, $\mu(C) = 0$, we must have

$$\mu(A) = \nu(A) \leq \nu(B) \leq \nu(A \cup C) = \mu(A \cup C) \leq \mu(A) + \mu(C) = \mu(A)$$

by monotonicity and subadditivity. Since every subset of a $\tilde{\mu}$-null set is a subset of a $\mu$-null set and hence in $\mathcal{A}$, $(X, \mathcal{A}, \tilde{\mu})$ is complete.

\hfill \Box
XIII.1.3.8. Definition. The measure space \((X, \mathcal{A}, \mu)\) is called the completion of \((X, \mathcal{A}, \mu)\) and, by slight abuse of terminology, \(\bar{\mu}\) is called the completion of \(\mu\).

Almost Everywhere

XIII.1.3.9. It is convenient to use the phrase almost everywhere, abbreviated a.e., to mean “except on a null set.” Thus, for example, if we say “the functions \(f\) and \(g\) agree almost everywhere,” we mean “there is a null set \(A\) such that \(f(x) = g(x)\) for all \(x \notin A\).” When the measure \(\mu\) needs to be specified, we say “\(\mu\)-almost everywhere,” written \(\mu\)-a.e.

However, if we are dealing with an incomplete measure space, there is a subtlety. Saying “the functions \(f\) and \(g\) agree almost everywhere” does not necessarily mean “the set of all \(x\) for which \(f(x) = g(x)\) does not hold (i.e. one or both of \(f(x)\) and \(g(x)\) is undefined, or both are defined but unequal) has measure zero,” because this set could be nonmeasurable (it is only a subset of a set of measure 0). In fact, if \(f\) and \(g\) agree almost everywhere, and \(f\) is measurable, then \(g\) is not necessarily even measurable (consider the case where \(f\) is identically zero and \(g\) is the indicator function of a nonmeasurable subset of a null set). This difficulty disappears when working with complete measure spaces, and is one reason for completing measure spaces (although taking completions also introduces different subtleties; cf. (i) or (ii)).

XIII.1.3.10. We can also say that two measurable sets \(A\) and \(B\) in a measure space \((X, \mathcal{A}, \mu)\) are almost disjoint (or \(\mu\)-almost disjoint) if \(A \cap B\) is a null set.

The next technical result is very useful and is often applied in the later development of measure and integration:

XIII.1.3.11. Proposition. Let \((X, \mathcal{A}, \mu)\) be a measure space, with completion \((X, \bar{\mathcal{A}}, \bar{\mu})\). If \(f\) is an extended real-valued \(\mathcal{A}\)-measurable function, then there is an \(\mathcal{A}\)-measurable function \(g\) with \(g = f\ \mu\)-almost everywhere.

Proof: The proof is a good example of the technique of bootstrapping, proving something for all measurable functions by first proving it for indicator functions, then simple functions, and finally general functions by taking pointwise limits. In this case, suppose \(f = \chi_C\), where \(C \in \mathcal{A}\). Then \(C = A \cup B\), where \(A \in \mathcal{A}\) and \(B \subseteq D\) for some \(\mu\)-null set \(D \in \mathcal{A}\). Then \(\chi_A = \chi_C\) on \(X \setminus B\) and \(a fortiori\) on \(X \setminus D\), and \(\chi_A\) is \(\mathcal{A}\)-measurable. Next, if \(f_1, \ldots, f_n\) are \(\mathcal{A}\)-measurable functions equal a.e. to \(\mathcal{A}\)-measurable functions \(g_1, \ldots, g_n\) respectively, and if \(\alpha_1, \ldots, \alpha_n \in \mathbb{R}\), then \(\alpha_1 f_1 + \cdots + \alpha_n f_n\) is equal a.e. to the \(\mathcal{A}\)-measurable function \(\alpha_1 g_1 + \cdots + \alpha_n g_n\) since a finite union of null sets is a null set. In particular, any \(\mathcal{A}\)-measurable simple function is equal a.e. to an \(\mathcal{A}\)-measurable simple function.

Now let \(f\) be a general \(\mathcal{A}\)-measurable function. There is a sequence \((f_n)\) of \(\mathcal{A}\)-measurable simple functions converging pointwise to \(f\). For each \(n\), there is a \(\mu\)-null set \(D_n\) and an \(\mathcal{A}\)-measurable simple function \(g_n\) such that \(f_n = g_n\) on \(X \setminus D_n\). Let \(D = \bigcup_{n=1}^{\infty} D_n\). Then \(D\) is a \(\mu\)-null set. Let \(h_n = g_n = f_n\) on \(X \setminus D\) and \(h_n = 0\) on \(D\). Then \(h_n\) is \(\mathcal{A}\)-measurable, and \((h_n)\) converges pointwise to a function \(h\) which is \(\mathcal{A}\)-measurable and agrees with \(f\) on \(X \setminus D\) (in fact, \(h_n = g_n \chi_{X \setminus D} = f_n \chi_{X \setminus D}\) and \(h = f \chi_{X \setminus D}\)).

14000
XIII.1.4. Finite, $\sigma$-Finite, and Semifinite Measures

Sets of infinite measure cause difficulties in measure theory. We cannot simply wish them away, however, since many of the most natural and important measure spaces (e.g. $\mathbb{R}$ with Lebesgue measure) have sets of infinite measure. We do want to work with sets of finite measure as much as possible, however. In this subsection we set up some terminology and develop a framework for doing this.

Finite Measure Spaces

The nicest measure spaces are ones with no sets of infinite measure:

XIII.1.4.1. Definition. A measure space $(X, \mathcal{A}, \mu)$ is finite, and the measure $\mu$ is finite, if $\mu(X) < \infty$. The number $\mu(X)$ is the total mass of the measure space. The measure space is a probability measure space, and $\mu$ is a probability measure, if $\mu(X) = 1$.

The term “probability measure” comes of course from probability theory, but the term is used throughout analysis even in contexts unrelated to probability. Any (nonzero) finite measure can be renormalized to a probability measure by taking an appropriate scalar multiple.

XIII.1.4.2. If $(X, \mathcal{A}, \mu)$ is a finite measure space with total mass $m$, then $\mu(A) \leq m$ for any $A \in \mathcal{A}$ by monotonicity. In particular, if $\mu$ is a probability measure, then $\mu(A) \leq 1$ for all $A \in \mathcal{A}$.

$\sigma$-Finite Measures

It turns out to be almost as good for a set to be a countable union of sets of finite measure, and measure spaces which can be decomposed into countably many finite pieces are well behaved.

XIII.1.4.3. Definition. Let $(X, \mathcal{A}, \mu)$ be a measure space. A set $A \in \mathcal{A}$ is of $\sigma$-finite measure if there is a sequence $(A_n)$ of sets in $\mathcal{A}$ with $A = \bigcup_{n=1}^{\infty} A_n$ and $\mu(A_n) < \infty$ for all $n$. The measure space $(X, \mathcal{A}, \mu)$ is $\sigma$-finite, and $\mu$ is a $\sigma$-finite measure, if $X$ is a set of $\sigma$-finite measure, i.e. if there is a sequence $(X_n)$ in $\mathcal{A}$ with $X = \bigcup_{n=1}^{\infty} X_n$ and $\mu(X_n) < \infty$ for all $n$.

Note that in this definition, the sets $A_n$ need not have any relation to each other, except they must of course all be subsets of $A$. In particular, they do not have to be either nested or disjoint. However, if desired it can always be arranged that they are nested or that they are disjoint:

XIII.1.4.4. Proposition. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $A \in \mathcal{A}$. The following are equivalent:

(i) $A$ has $\sigma$-finite measure.

(ii) There is an increasing sequence $(B_n)$ in $\mathcal{A}$ with $A = \bigcup_{n=1}^{\infty} B_n$ and $\mu(B_n) < \infty$ for all $n$.

(iii) There is a pairwise disjoint sequence $(E_n)$ in $\mathcal{A}$ with $A = \bigcup_{n=1}^{\infty} E_n$ and $\mu(E_n) < \infty$ for all $n$.

Proof: This is just a consequence of standard nesting or disjointizing operations. (ii) $\Rightarrow$ (i) and (iii) $\Rightarrow$ (i) are trivial. To show (i) $\Rightarrow$ (ii) and (i) $\Rightarrow$ (iii), set $B_n = \bigcup_{k=1}^{n} A_k$, $E_1 = A_1$, and $E_n = B_n \setminus B_{n-1}$ for $n > 1$. Note that $\mu(E_n) \leq \mu(B_n) \leq \sum_{k=1}^{n} \mu(A_k) < \infty$ by monotonicity and finite subadditivity. ☺
XIII.1.4.5. **Corollary.** Let \((X, \mathcal{A}, \mu)\) be a \(\sigma\)-finite measure space. Then

(i) There is an increasing sequence \((Y_n)\) of sets in \(\mathcal{A}\) with \(X = \bigcup_{n=1}^{\infty} Y_n\) and \(\mu(Y_n) < \infty\) for all \(n\).

(ii) There is a pairwise disjoint sequence \((Z_n)\) of sets in \(\mathcal{A}\) with \(X = \bigcup_{n=1}^{\infty} Z_n\) and \(\mu(Z_n) < \infty\) for all \(n\).

XIII.1.4.6. **Proposition.** Let \((X, \mathcal{A}, \mu)\) be a measure space. Any measurable subset of a set of \(\sigma\)-finite measure has \(\sigma\)-finite measure. In particular, if the measure space is \(\sigma\)-finite, every measurable set in \(X\) has \(\sigma\)-finite measure.

**Proof:** If \(A \in \mathcal{A}\) has \(\sigma\)-finite measure, let \((A_n)\) be a sequence of sets in \(\mathcal{A}\) with \(A = \bigcup_{n=1}^{\infty} A_n\) and \(\mu(A_n) < \infty\) for all \(n\). If \(B \in \mathcal{A}\), \(B \subseteq A\), set \(B_n = B \cap A_n\) for each \(n\). Then \(B = \bigcup_{n=1}^{\infty} B_n\), and \(\mu(B_n) < \infty\) by monotonicity.

**Decomposable Measures**

The essential feature of \(\sigma\)-finite measure spaces is that the whole space can be chopped up into a countable number of disjoint pieces, each of finite measure. For some purposes it is sufficient that the space can be chopped up in a similar way even if there are uncountably many pieces.

XIII.1.4.7. **Definition.** A measure space \((X, \mathcal{A}, \mu)\) is decomposable (sometimes called finitely decomposable) if there is a collection \(\{X_i : i \in I\}\) of pairwise disjoint sets in \(\mathcal{A}\) with \(X = \bigcup_{i \in I} X_i\), \(\mu(X_i) < \infty\) for all \(i\), and

\[
\mu(A) = \sum_{i \in I} \mu(A \cap X_i)
\]

for all \(A \in \mathcal{A}\) (where the sum is the supremum of the sums over finite subsets of \(I\)). By slight abuse of terminology we will also say that \(\mu\) is decomposable.

XIII.1.4.8. It follows immediately from XIII.1.2.4. that a \(\sigma\)-finite measure space is decomposable; in fact, \((X, \mathcal{A}, \mu)\) is \(\sigma\)-finite if and only if it is decomposable with a countable set \(I\). There are decomposable measures which are not \(\sigma\)-finite, e.g. counting measure on an uncountable set \(X\) (where we can take each \(X_i\) to be a singleton). There are also measures which are not decomposable, e.g. the ones in XIII.1.1.6.(ii)–(iii).

XIII.1.4.9. **Caution:** For a measure space to be decomposable, it is not enough that it decompose into a disjoint union of measurable sets of finite measure. The example of XIII.1.6.(iii) is a simple counterexample: the space is a disjoint union of singletons, each measurable and of finite measure. The problem is not that the subsets have measure 0; see XIII.1.9.7.

**Semifinite Measures**

There is a weaker condition than decomposability that is somewhat useful:
XIII.1.4.10. Definition. Let \((X, \mathcal{A}, \mu)\) be a measure space. A set \(E \in \mathcal{A}\) is semifinite, or has semifinite measure, if, whenever \(A \in \mathcal{A}, A \subseteq E,\) and \(\mu(A) = \infty,\) there is a \(B \in \mathcal{A}, B \subseteq A,\) with \(0 < \mu(B) < \infty.\) \((X, \mathcal{A}, \mu)\) is a semifinite measure space if \(X\) has semifinite measure. By slight abuse of terminology we will also say that \(\mu\) is semifinite.

XIII.1.4.11. It is obvious from the definition that every measurable subset of a set of semifinite measure also has semifinite measure. In particular, every measurable set in a semifinite measure space has semifinite measure.

XIII.1.4.12. Proposition. Every decomposable measure space is semifinite. In particular, every \(\sigma\)-finite measure space is semifinite.

Proof: Let \((X, \mathcal{A}, \mu)\) be decomposable. Let \(\{X_i : i \in I\}\) be a pairwise disjoint collection of sets in \(\mathcal{A}\) with \(X = \bigcup_i X_i, \mu(X_i) < \infty\) for all \(i,\) and
\[
\mu(A) = \sum_{i \in I} \mu(A \cap X_i)
\]
for all \(A \in \mathcal{A}.\) If \(\mu(A) = \infty,\) then for any \(M\) there is a finite subset \(F\) of \(I\) such that \(\sum_{i \in F} \mu(A \cap X_i) > M.\) If \(B = \bigcup_{i \in F} (A \cap X_i),\) then \(B \subseteq A\) and by monotonicity
\[
M < \mu(B) = \sum_{i \in F} \mu(A \cap X_i) \leq \sum_{i \in F} \mu(X_i) < \infty.
\]

XIII.1.4.13. There are semifinite measures which are not decomposable (XIII.1.9.3., XIII.1.9.4.). There are also measures which are not semifinite, e.g. the ones in XIII.1.1.6.(ii)–(iii). Measure spaces which do not at least have many subsets of semifinite measure are so pathological that they are rarely useful; for example, integration theory for such measure spaces is completely degenerate.

XIII.1.4.14. Proposition. Let \((X, \mathcal{A}, \mu)\) be a measure space, and \(E \in \mathcal{A}\) of semifinite measure. Then for every \(A \in \mathcal{A}, A \subseteq E,\) we have
\[
\mu(A) = \sup \{ \mu(B) : B \in \mathcal{A}, B \subseteq A, \mu(B) < \infty \}.
\]
Conversely, any \(E\) with this property has semifinite measure.

Proof: The formula is trivial (in any measure space) by monotonicity if \(\mu(A) < \infty,\) so assume \(\mu(A) = \infty.\) Set
\[
M = \sup \{ \mu(B) : B \in \mathcal{A}, B \subseteq A, \mu(B) < \infty \}.
\]
If \(M < \infty,\) for each \(n\) let \(B_n \in \mathcal{A}, B_n \subseteq A,\) and \(M - \frac{1}{n} \leq \mu(B_n) < \infty.\) Set \(D_n = \bigcup_{k=1}^{n} B_k\) for each \(n.\) Then \((D_n)\) is an increasing sequence, \(D := \bigcup_n D_n \subseteq A,\) and
\[
\mu(D_n) \leq \sum_{k=1}^{n} B_k < \infty
\]

1403
and therefore $\mu(D_n) \leq M$ for all $n$. We have $\mu(D) = \sup_n \mu(D_n) \leq M$ by XIII.1.2.7., and since $B_n \subseteq D$ for all $n$, by monotonicity we have 

$$M - \frac{1}{n} \leq \mu(B_n) \leq \mu(D) \leq M$$

for all $n$. It follows that $\mu(D) = M$.

Since $\mu(A) = \infty$ and $\mu(D) < \infty$, we have $\mu(A \setminus D) = \infty$, and thus by semifiniteness of $E$ there is an $C \in A, C \subseteq A \setminus D$, with $0 < \mu(C) < \infty$. But then $C \cup D \subseteq A$, and

$$M < \mu(C \cup D) = \mu(C) + \mu(D) = \mu(C) + M < \infty$$

contradicting the definition of $M$. Thus $M = \infty$.

The converse statement is obvious. 

XIII.1.5. Discrete and Continuous Measures

XIII.1.5.1. Definition. Let $(X, A, \mu)$ be a measure space. An atom in $(X, A, \mu)$ is a set $A \in A$ with the property that $\mu(A) > 0$ and, whenever $B \in A, B \subseteq A$, then either $\mu(B) = 0$ or $\mu(A \setminus B) = 0$.

An atom is a non-null measurable set which is “indivisible” up to null sets. The most obvious examples of atoms are (measurable) singleton subsets of positive measure, when such sets exist, although in general atoms need not be singletons. Measure spaces do not necessarily have any atoms; in fact, most interesting measure spaces do not.

XIII.1.6. Linear Combinations, Restrictions, and Extensions of Measures

We can take sums (finite or infinite) and scalar multiples of measures to obtain new measures, and we can in good circumstances restrict and extend measures. The arguments in this subsection are for the most part virtually trivial, with a few subtleties.

Addition of Measures

XIII.1.6.1. Proposition. Let $\mu$ and $\nu$ be measures on a measurable space $(X, A)$. Then $\mu + \nu$ is a measure on $(X, A)$. [By $\mu + \nu$ we mean the usual pointwise (setwise) sum, i.e. $(\mu + \nu)(A) = \mu(A) + \nu(A)$ for $A \in A$.]

Proof: We have $(\mu + \nu)(\emptyset) = 0 + 0 = 0$. If $(A_k)$ is a sequence of pairwise disjoint sets in $A$, then

$$(\mu+\nu)\left(\bigcup_{k=1}^{\infty} A_k\right) = \mu\left(\bigcup_{k=1}^{\infty} A_k\right) + \nu\left(\bigcup_{k=1}^{\infty} A_k\right) = \sum_{k=1}^{\infty} \mu(A_k) + \sum_{k=1}^{\infty} \nu(A_k) = \sum_{k=1}^{\infty} \left[\mu(A_k) + \nu(A_k)\right] = \sum_{k=1}^{\infty} (\mu+\nu)(A_k)$$

where combining the two infinite sums is justified by () since the terms are nonnegative. 

Note that we can only add measures defined on the same measurable space. We can even add a sequence of measures:
XIII.1.6.2. **Proposition.** Let \( (\mu_n) \) be a sequence of measures on a measurable space \((X, A)\). Define \( \mu = \sum_{n=1}^{\infty} \mu_n \) on \((X, A)\) by

\[
\mu(A) = \left( \sum_{n=1}^{\infty} \mu_n \right)(A) = \sum_{n=1}^{\infty} \mu_n(A)
\]

for \( A \in A \). Then \( \mu \) is a measure on \((X, A)\).

**Proof:** We clearly have \( \mu(\emptyset) = 0 \). If \( (A_k) \) is a sequence of pairwise disjoint sets in \( A \), then

\[
\mu \left( \bigcup_{k=1}^{\infty} A_k \right) = \sum_{n=1}^{\infty} \mu_n \left( \bigcup_{k=1}^{\infty} A_k \right) = \sum_{n=1}^{\infty} \left( \sum_{k=1}^{\infty} \mu_n(A_k) \right)
\]

\[
= \sum_{k=1}^{\infty} \left( \sum_{n=1}^{\infty} \mu_n(A_k) \right) = \sum_{k=1}^{\infty} \mu(A_k)
\]

where the interchange of order in the double summation is justified by () since the terms are nonnegative. \( \diamond \)

In fact, an arbitrary set of measures can be added in the same way. See () for this and more general results about combining measures.

**Scalar Multiples of Measures**

XIII.1.6.3. **Proposition.** Let \( \mu \) be a measure on a measurable space \((X, A)\), and \( 0 \leq \alpha < \infty \). Then \( \alpha \mu \) is also a measure on \((X, A)\). [\( \alpha \mu \) is defined by \( [\alpha \mu](A) = \alpha [\mu(A)] \) for \( A \in A \); here by definition \( 0 \cdot \infty = 0 \).]

**Proof:** We obviously have \( [\alpha \mu](\emptyset) = 0 \). If \( (A_n) \) is a sequence of disjoint sets in \( A \), then

\[
[\alpha \mu] \left( \bigcup_{k=1}^{\infty} A_k \right) = \alpha \left[ \mu \left( \bigcup_{k=1}^{\infty} A_k \right) \right] = \alpha \sum_{k=1}^{\infty} \mu(A_k) = \sum_{k=1}^{\infty} \alpha [\mu(A_k)] = \sum_{k=1}^{\infty} [\alpha \mu](A_k)
\]

where the next-to-last step is justified by (). \( \diamond \)

**Linear Combinations of Measures**

Combining XIII.1.6.1. and XIII.1.6.3., we obtain:

XIII.1.6.4. **Proposition.** Any nonnegative linear combination of measures on a measurable space is a measure. Specifically, if \( \mu_1, \ldots, \mu_n \) are measures on a measurable space \((X, A)\), and \( \alpha_1, \ldots, \alpha_n \) are nonnegative real numbers, then \( \sum_{k=1}^{n} \alpha_k \mu_k \) is a measure on \((X, A)\), where \( [\sum_{k=1}^{n} \alpha_k \mu_k](A) = \sum_{k=1}^{n} \alpha_k \mu_k(A) \) for \( A \in A \).

We have the same for countable sums, using XIII.1.6.2.:
XIII.1.6.5. **Proposition.** If $\mu_1, \mu_2, \ldots$ is a sequence of measures on a measurable space $(X, \mathcal{A})$, and $\alpha_1, \alpha_2, \ldots$ is a sequence of nonnegative real numbers, then $\sum_{k=1}^{\infty} \alpha_k \mu_k$ is a measure on $(X, \mathcal{A})$, where $[\sum_{k=1}^{\infty} \alpha_k \mu_k](A) = \sum_{k=1}^{\infty} \alpha_k \mu_k(A)$ for $A \in \mathcal{A}$.

Restrictions and Compressions of Measures

XIII.1.6.6. **Definition.** Let $\mu$ be a measure on a measurable space $(X, \mathcal{A})$, and $E \in \mathcal{A}$.

(i) The **restriction** of $\mu$ to $E$ is the measure $\mu|_E$ on $(E, \mathcal{A}_E)$ defined by

$$[\mu|_E](A) = \mu(A)$$

for $A \in \mathcal{A}_E$ (i.e. $A \in \mathcal{A}$ and $A \subseteq E$).

(ii) The **compression** of $\mu$ to $E$ is the measure $\mu_{\cdot E}$ on $(X, \mathcal{A})$ defined by

$$[\mu_{\cdot E}](A) = \mu(A \cap E)$$

for $A \in \mathcal{A}$.

The measures $\mu|_E$ and $\mu_{\cdot E}$ are in some sense the “same”, but there is a technical difference: $\mu|_E$ is a measure on $E$, while $\mu_{\cdot E}$ is a measure on all of $X$ which is supported on $E$, i.e. $[\mu_{\cdot E}](X \setminus E) = 0$.

It is a routine exercise (Exercise (i)) to verify that $\mu|_E$ and $\mu_{\cdot E}$ are indeed measures.

Extensions and Dilations of Measures

XIII.1.6.7. **Definition.** Let $(X, \mathcal{A})$ be a measurable space, and $E \in \mathcal{A}$. If $\mu$ is a measure on $(X, \mathcal{A})$, and $\nu$ a measure on $(E, \mathcal{A}_E)$, then $\mu$ is an **extension** of $\nu$ to $X$ if $\nu = \mu|_E$.

There is nothing unique about extensions of measures in general.

There is always a minimal extension of any measure:

XIII.1.6.8. **Definition.** Let $(X, \mathcal{A})$ be a measurable space, and $E \in \mathcal{A}$. If $\nu$ is a measure on $(E, \mathcal{A}_E)$, the **dilation** of $\nu$ to $(X, \mathcal{A})$ is the measure $\nu \uparrow X$ defined by

$$[\nu \uparrow X](A) = \nu(A \cap E)$$

for $A \in \mathcal{A}$.

XIII.1.6.9. It is easily verified that $\nu \uparrow X$ is a measure on $(X, \mathcal{A})$, that $(\nu \uparrow X)$ is an extension of $\nu$ to $X$, that $\nu \uparrow X = (\nu \uparrow X)_{\cdot E}$, and that $\nu \uparrow X$ is the unique measure on $(X, \mathcal{A})$ with these properties and the smallest extension of $\nu$ to $X$ (in the sense that if $\mu$ is any extension, then $\mu \geq (\nu \uparrow X)$.) In fact, if $\mu$ is any measure on $(X, \mathcal{A})$, then $\mu = ([\mu|_E] \uparrow X) + ([\mu|_{X \setminus E}] \uparrow X) = (\mu_{\cdot E}) + (\mu_{\cdot X \setminus E})$.

Restriction of Measures to Sub-$\sigma$-Algebras

There is another type of restriction of measures:
XIII.1.6.10. Definition. Let \((X, \mathcal{A}, \mu)\) be a measure space, and \(\mathcal{B}\) a sub-\(\sigma\)-algebra of \(\mathcal{A}\). Then the restriction of \(\mu\) to \(\mathcal{B}\) is the measure \(\mu|_{\mathcal{B}}\) on \((X, \mathcal{B})\) defined by
\[
[\mu|_{\mathcal{B}}](B) = \mu(B)
\]
for \(B \in \mathcal{B}\).

Note that \(\mu|_{\mathcal{B}}\) is technically a different measure than \(\mu\) since the specification of the \(\sigma\)-algebra of measurable subsets is part of the definition of a measure. There are occasions, however, where making an explicit distinction between \(\mu\) and \(\mu|_{\mathcal{B}}\) seems overly pedantic, and we will occasionally overlook the distinction when no confusion can occur. The most important example is restriction of Lebesgue measure to the Borel sets.

XIII.1.6.11. We can also regard the measure \(\mu\) as an extension of \(\mu|_{\mathcal{B}}\) to the larger \(\sigma\)-algebra \(\mathcal{A}\). Existence of extensions of measures to larger \(\sigma\)-algebras is a very subtle matter and is not possible in general; see II.10.1.1., XIII.1.3.7., () for some instances of extensions and nonexistence of extensions.

Push-Forward of Measures
We can push measures forward by measurable functions:

XIII.1.6.12. Definition. Let \((X, \mathcal{A})\) and \((Y, \mathcal{B})\) be measure spaces, and \(f : X \to Y\) an \((\mathcal{A}, \mathcal{B})\)-measurable function (). If \(\mu\) is a measure on \((X, \mathcal{A})\), then the push-forward of \(\mu\) by \(f\) is the measure \(f_*(\mu)\) on \((Y, \mathcal{B})\) defined by
\[
[f_*(\mu)](B) = \mu(f^{-1}(B))
\]
for \(B \in \mathcal{B}\).

As usual, it is routine to show that \(f_*(\mu)\) is a measure on \((Y, \mathcal{B})\).

XIII.1.6.13. Examples. (i) If \((X, \mathcal{A})\) is a measurable space and \(E \in \mathcal{A}\), and \(f : E \to X\) is the inclusion map, and \(\nu\) is a measure on \((E, \mathcal{A}_E)\), then \(f_*(\nu) = \nu|_E\).

(ii) Let \((X, \mathcal{A}, \mu)\) be a measure space, and \(\mathcal{B}\) a sub-\(\sigma\)-algebra of \(\mathcal{A}\). Let \(f\) be the identity map on \(X\), regarded as a measurable function from \((X, \mathcal{A})\) to \((X, \mathcal{B})\). Then \(f_*(\mu) = \mu|_{\mathcal{B}}\).

XIII.1.6.14. There is no reasonable way to pull back measures from \((Y, \mathcal{B})\) to \((X, \mathcal{A})\) in general, but this can be done under some special circumstances (e.g. ()).

XIII.1.7. Measures Defined on Rings and \(\sigma\)-Rings

XIII.1.8. Egorov’s Theorem

XIII.1.8.1. Theorem. [Egorov’s Theorem] Let \((X, \mathcal{A}, \mu)\) be a finite measure space. Let \((f_n)\) be a sequence of real-valued measurable functions on \(X\) converging pointwise a.e. to a real-valued (measurable) function \(f\). Then for every \(\epsilon > 0\) there is a set \(A \in \mathcal{A}\) with \(\mu(X \setminus A) < \epsilon\) and \(f_n \to f\) uniformly on \(A\).
Proof: Fix \( \epsilon > 0 \). Let \( E \in \mathcal{A} \) with \( f_n(x) \to f(x) \) for all \( x \in E \) and \( \mu(X \setminus E) = 0 \). For each \( n \) and \( m \), set

\[
A_{n,m} = \left\{ x \in X : |f_k(x) - f(x)| < \frac{1}{m} \text{ for all } k \geq n \right\}.
\]

We have \( A_{n,m} \in \mathcal{A} \) for all \( n, m \). For fixed \( m \), we have \( A_{n,m} \subseteq A_{n+1,m} \) for all \( n \) and \( \cup_n A_{n,m} \supseteq E \), i.e. \( \cap_n [X \setminus A_{n,m}] \subseteq X \setminus E \). Thus by (1)

\[
0 \leq \inf_n \mu(X \setminus A_{n,m}) \leq \mu(X \setminus E) = 0
\]

and thus there is an \( n_m \) such that \( \mu(X \setminus A_{n,m}) < \frac{\epsilon}{2m} \).

Let \( A = \cap_{m=1}^{\infty} A_{n,m,m} \). Then

\[
\mu(X \setminus A) = \mu\left( \bigcup_{m=1}^{\infty} [X \setminus A_{n,m,m}] \right) \leq \sum_{m=1}^{\infty} \mu(X \setminus A_{n,m,m}) < \sum_{m=1}^{\infty} \frac{\epsilon}{2m} = \epsilon
\]

and \( f_n \to f \) uniformly of \( A \): if \( \delta > 0 \), fix \( m \) with \( \frac{1}{m} \leq \delta \); then, for all \( k \geq n_m \) and all \( x \in A \subseteq A_{n,m,m} \), we have

\[
|f_k(x) - f(x)| < \frac{1}{m} \leq \delta.
\]

\[\Box\]

XIII.1.9. Exercises

XIII.1.9.1. Let \( \mu \) be a finitely additive measure on a measurable space \((X, \mathcal{A})\). Show that the following are equivalent:

(i) \( \mu \) is countably subadditive (XIII.1.2.1).

(ii) \( \mu \) is upward continuous (XIII.1.2.7).

(iii) \( \mu \) is countably additive, i.e. a measure.

XIII.1.9.2. Let \( \mu \) be counting measure on \((\mathbb{N}, \mathcal{P}([\mathbb{N}]))\). Show that for any \( n \in \{0\} \cup \mathbb{N} \cup \{\infty\} \), there are subsets \( A, B \) of \( \mathbb{N} \) with \( B \subseteq A \), \( \mu(A) = \mu(B) = \infty \), and \( \mu(A \setminus B) = n \).

XIII.1.9.3. Let \( X \) be an uncountable set, and \( x_0 \) a fixed element of \( X \). Let \( \mathcal{A} \) be the collection of all countable subsets of \( X \) not containing \( x_0 \), and their complements.

(a) Show that \( \mathcal{A} \) is a \( \sigma \)-algebra on \( X \).

(b) Let \( \mu \) be the restriction of counting measure to \( \mathcal{A} \). Show that \( \mu \) is semifinite.

(c) The point \( x_0 \) is not contained in any measurable set of finite measure. Conclude that \( \mu \) cannot be decomposable.

(d) If the cardinality of \( X \) is \( \kappa \), then the cardinality of \( \mathcal{A} \) is \( \kappa^{\aleph_0} \). In particular, if \( \text{card}(X) = 2^{\aleph_0} \), then \( \text{card}(\mathcal{A}) = 2^{\aleph_0} \).
XIII.1.9.4.  [Bog07, ] Let $X$ be a set of cardinality $\aleph_1$, $Y$ a set of cardinality $\aleph_2$, and $Z = X \times Y$. If $E \subseteq Z$, $x \in X$, and $y \in Y$, write $E_x$ and $E^y$ for the vertical and horizontal cross sections of $E$ at $x$ and $y$ respectively ().

(a) Let $\mathcal{M}$ be the set of all subsets $E$ of $Z$ such that for every $x \in X$, $E_x$ is either countable or cocountable, and for every $y \in Y$, $E^y$ is either countable or cocountable. Show that $\mathcal{M}$ is a $\sigma$-algebra.
(b) If $E \in \mathcal{M}$, define
\[
\mu(E) = \text{card}\{x \in X : E_x \text{ is cocountable}\} + \text{card}\{y \in Y : E^y \text{ is cocountable}\}
\]
(where $\mu(E) = \infty$ if either set on the right is infinite). Show that $\mu$ is a measure on $(Z, \mathcal{M})$. Every countable subset (in particular, every singleton subset) of $X$ is in $\mathcal{M}$ and has measure $0$.
(c) Show that $\mu$ is semifinite. [If $\mu(E) > 0$, then $E$ contains a set of the form $A \times \{y\}$ for a cocountable subset $A$ of $X$ and some $y \in Y$, or a set of the form $\{x\} \times B$ for cocountable $B \subseteq Y$.]
(d) Suppose $\mu$ is decomposable, and let $\{Z_i : i \in I\}$ be a decomposition. For each $y \in Y$, show that the set $(Z_i)^y$ is cocountable for exactly one $i$.
(e) If $y \in Y$, let $\phi(y)$ be the unique $i$ as in (d). Then $\phi$ is a function from $Y$ to $I$. For any $i \in I$, $\phi^{-1}(\{i\})$ is finite. Conclude that $\text{card}(I) \geq \aleph_2$.
(f) On the other hand, for each $x \in X$ there is an $i$ such that $(Z_i)_x$ is cocountable. Thus there are only countably many $i$ such that $(Z_i)_x$ is nonempty. Conclude that $\text{card}(I) \leq \aleph_1$.
(g) Conclude from (d)–(f) that $\mu$ is not decomposable.

XIII.1.9.5.  Let $I$ be an uncountable set, and for each $i \in I$ let $X_i$ be a copy of $[0, 1]$. Let $X$ be the disjoint union of the $X_i$. Let $\mathcal{M}$ be the $\sigma$-algebra of Lebesgue measurable sets in $[0, 1]$, and let
\[
\mathcal{B} = \{B \subseteq X : B \cap X_i \in \mathcal{M} \text{ for all } i \in I\}
\]
and $\mathcal{A}$ the collection of all $A \in \mathcal{B}$ such that $A \cap X_i$ is either $\emptyset$ or $X_i$ for all but countably many $i$.
(a) Show that $\mathcal{B}$ and $\mathcal{A}$ are $\sigma$-algebras.
(b) For $A \in \mathcal{A}$, set $\mu(A) = \sum_{i \in I} \lambda(A \cap X_i)$, where $\lambda$ is Lebesgue measure on $X_i$. Show that $\mu$ is a complete measure on $(X, \mathcal{A})$.
(c) Show that $\{X_i : i \in I\}$ is a decomposition of $(X, \mathcal{A}, \mu)$, so $\mu$ is decomposable and, in particular, semifinite.
(d) If $B \in \mathcal{B}$, set $\nu(B) = \mu(B)$ if $B \in \mathcal{A}$ and $\nu(B) = \infty$ if $B \in \mathcal{B} \setminus \mathcal{A}$. Show that $\nu$ is a complete measure on $(X, \mathcal{B})$ extending $\mu$.
(e) If $B$ is a subset of $X$ such that $B \cap X_i$ is a singleton for all $i$, then $\nu(B) = \infty$, but $B$ contains no subsets of finite positive $\nu$-measure. Thus $\nu$ is not semifinite.

Note that this problem, including (e), can be done without using the Axiom of Choice by taking $X$ to be the unit square and the $X_i$ to be (say) horizontal cross sections. The set $B$ of (e) can be taken to be a vertical line segment.

XIII.1.9.6.  Let $(X, \mathcal{A}, \mu)$ be a semifinite measure space.
(a) If $\mathcal{A}$ contains only countably many sets of finite measure, show that $\mu$ is $\sigma$-finite.
(b) [R. Israel] If $\mathcal{A}$ contains only $\aleph_1$ sets of finite measure, and every point of $X$ is contained in a measurable subset of finite measure, then $\mathcal{A}$ is decomposable. [Well order the sets of finite measure as $(A_\alpha : \alpha < \omega_1)$, and for each $\alpha$ let $X_\alpha = A_\alpha \setminus (\cup_{\beta < \alpha} A_\beta)$.] The last condition in (b) is not automatic, at least if the continuum hypothesis is assumed (XIII.1.9.3.).

1409
XIII.1.9.7. Let $Y$ be an uncountable set and $\nu$ the measure on $(Y, \mathcal{P}(Y))$ with $\nu(A) = 0$ if $A$ is countable and $\nu(A) = \infty$ if $A$ is uncountable. Let $X = Y \times \{0, 1\}$, and for $A, B \subseteq Y$ set

$$\mu([A \times \{0\}] \cup [B \times \{1\}]) = \nu(A) + |B|$$

where $|B|$ is the number of elements in $B$ (counting measure of $B$).

(a) Show that $\mu$ is a measure on $(X, \mathcal{P}(X))$.

(b) For each $y \in Y$ set $X_y = \{(y, 0), (y, 1)\}$. Then $X$ is the disjoint union of the $X_y$ and $\mu(X_y) = 1$ for all $y$.

(c) Nonetheless, $(X, \mathcal{P}(X), \mu)$ is not decomposable or even semifinite.
XIII.2. Probability

“How can we venture to speak of the laws of chance? Is not chance the antithesis of all law?”

J. Bertrand

XIII.2.1. Introduction

XIII.2.1.1. From its first beginnings, probability theory had some of the flavor of primitive measure theory. In 1933, A. Kolmogorov [1] cemented the connection by giving an axiomatization of probability which serves as the foundation of all modern probability theory. (Of course, Kolmogorov did not come up with this axiomatization out of thin air; the ideas were implicit and in fact increasingly explicit in other work in the field.)

XIII.2.1.2. The two basic ingredients of probability are:

(i) A sample space \( \Omega \), the set of all possible outcomes of a specific process or experiment. A subset of \( \Omega \) is called an event.

(ii) A probability \( P \), an assignment to each event \( E \) a numerical probability or likelihood \( P(E) \) that \( E \) occurs (i.e. that the outcome of the process lies in \( E \)). We should have \( 0 \leq P(E) \leq 1 \) for any \( E \), and \( P(\Omega) = 1 \).

XIII.2.1.3. It is virtually a no-brainer that \( P \) should be finitely additive. Kolmogorov realized that in order to get a satisfactory theory, one needs \( P \) to actually be countably additive.

XIII.2.1.4. Examples show that it is not possible in general to assign a probability to every subset of \( \Omega \) in a countably additive way (the process described in I.3.1.17., along with XIII.3.9.5. and II.10.3.6., is an example where it is not reasonably possible). Thus probability can only be assigned to some collection of well-behaved events. This turns out not to be a serious drawback; indeed, experience shows that it is frequently useful to deliberately restrict the set of events to which a probability is assigned.

Nevertheless, it is important to be able to apply sequences of set-theoretic operations to allowable events and stay within the class of allowable events. This leads naturally to the assumption that the set of allowable events forms a \( \sigma \)-algebra of subsets of \( \Omega \).

Thus Kolmogorov was led to make the following definition:

XIII.2.1.5. Definition. A probability space is a triple \((\Omega, \mathcal{E}, P)\), where

- \( \Omega \) is a set, called the sample space.
- \( \mathcal{E} \) is a \( \sigma \)-algebra of subsets of \( \Omega \), called the set of (allowable) events.
- \( P \) is a function from \( \mathcal{E} \) to \([0, 1]\) satisfying
  
  \[
  (i) \quad P(\Omega) = 1.
  \]

\[\text{References:} \quad [\text{Ber72}]; \text{cf.} \quad [\text{Poi96}, \text{p. 64}].\]

1411
(ii) \( P \) is countably additive, i.e. if \((E_n)\) is a sequence of pairwise disjoint sets in \( \mathcal{E} \), then
\[
P \left( \bigcup_{n=1}^{\infty} E_n \right) = \sum_{n=1}^{\infty} P(E_n) .
\]

Such a \( P \) is called a probability on \((\Omega, \mathcal{E})\). If \( E \in \mathcal{E} \), \( P(E) \) is called the probability of the event \( E \).

**XIII.2.1.6.** If \((\Omega, \mathcal{E}, P)\) is a probability space, then \((\Omega, \mathcal{E})\) is a measurable space. We have
\[
P(\emptyset) = P(\emptyset \cup \emptyset \cup \cdots) = \sum_{n=1}^{\infty} P(\emptyset) = \infty \cdot P(\emptyset)
\]
and thus \( P(\emptyset) = 0 \) (since it is in \([0,1]\)). Therefore \((\Omega, \mathcal{E}, P)\) is a measure space \((\text{XIII.1.1.1.})\), with \( P \) a probability measure. Conversely, any probability measure space is a probability space. Thus probability spaces are precisely the same thing as probability measure spaces, with slightly different notation and terminology.

Therefore, the results of \((\text{XIII.1.2.})\) apply in probability spaces:

**XIII.2.1.7.** Proposition. Let \((\Omega, \mathcal{E}, P)\) be a probability space. Then

1. **(i) \( P \) is finitely additive:** if \( E_1, \ldots, E_n \in \mathcal{E} \) are pairwise disjoint, then
\[
P \left( \bigcup_{k=1}^{n} E_k \right) = \sum_{k=1}^{n} P(E_k) .
\]

In particular, if \( E, F \in \mathcal{E} \) are disjoint, then \( P(E \cup F) = P(E) + P(F) \).

2. **(ii) \( P \) is monotone:** if \( E, F \in \mathcal{E}, E \subseteq F \), then \( P(E) \leq P(F) \).

3. **(iii) \( P \) is countably subadditive:** if \((E_n)\) is a sequence in \( \mathcal{E} \), then
\[
P \left( \bigcup_{n=1}^{\infty} E_n \right) \leq \sum_{n=1}^{\infty} P(E_n) .
\]

\( P \) is thus also finitely subadditive; in particular, if \( E, F \in \mathcal{E} \), then \( P(E \cup F) \leq P(E) + P(F) \). (In fact, we have \( P(E \cup F) = P(E) + P(F) - P(E \cap F) \).)

4. **(iv) \( P \) is upward continuous:** If \((E_n)\) is an increasing sequence in \( \mathcal{E} \), then
\[
P \left( \bigcup_{n=1}^{\infty} E_n \right) = \sup_n P(E_n) = \lim_{n \to \infty} P(E_n) .
\]

5. **(v) \( P \) is downward continuous:** If \((E_n)\) is a decreasing sequence in \( \mathcal{E} \), then
\[
P \left( \bigcap_{n=1}^{\infty} E_n \right) = \inf_n P(E_n) = \lim_{n \to \infty} P(E_n) .
\]

1412
XIII.2.2. The Dictionary

The mathematical setup of probability is thus measure theory, using somewhat different language. Here is a dictionary of the correspondence of basic terminology between measure theory and probability. Some other terminology such as “distribution” is common to both.

<table>
<thead>
<tr>
<th>Measure Theory</th>
<th>Probability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Measurable space</td>
<td>Sample space</td>
</tr>
<tr>
<td>Measure</td>
<td>Probability</td>
</tr>
<tr>
<td>Real-valued measurable function</td>
<td>Random variable</td>
</tr>
<tr>
<td>Integral</td>
<td>Expectation</td>
</tr>
<tr>
<td>Almost everywhere (a.e.)</td>
<td>Almost surely (a.s.)</td>
</tr>
<tr>
<td></td>
<td>Independent</td>
</tr>
</tbody>
</table>

In fact, it is sometimes said that probability is “measure theory plus independence” (although this is clearly somewhat of an oversimplification). It is unfair and not really accurate to say that probability is part of measure theory, although modern probability is certainly built on measure theory.

XIII.2.3. Exercises

XIII.2.3.1. A Conditional Probability Paradox?

(a) You have $n$ red balls, $n$ white balls, and $n$ blue balls ($n \geq 3$) in an urn. Your assistant chooses three balls at random from the urn and puts them in a box. What is the probability $p$ that all three balls in the box have the same color?

(b) While the assistant is choosing the balls, your second assistant comes into the room and sees some of what the first assistant is doing. He tells you that he saw one of the balls the first assistant put in the box and it was red. What now is the conditional probability $q$ that all the balls in the box are the same color, given that at least one of the balls is red? Explain why $q < p$, especially since if the second assistant had said that the ball he saw was white, or blue, the conditional probability is also $q$, and one of these situations must occur, with equal probability since the colors are completely symmetric.

(c) Suppose your second assistant doesn’t speak much English, and you know not a word of his native language. He reports to you that the color of ball he saw was gloop, but can’t remember the English word for this color. What is the conditional probability that the three balls are the same color, given that at least one of the balls is gloop? On the one hand, no matter what gloop means, the conditional probability is $q$; on the other hand, he has given you no information, so the conditional probability should just be the probability $p$. Explain and resolve the paradox.

(d) The first assistant speaks the second assistant’s language fluently, but is temporarily unavailable to translate. Anyway, the first assistant can provide more information than just the meaning of gloop; in fact, he knows what the colors of the three balls are. How does this affect the conditional probabilities, if at all?

(e) Do $p$ and/or $q$ depend on $n$? Explain why or why not.
XIII.3. Measures Defined by Extensions

The most important construction of measures is by the Carathéodory extension process. One begins with a “premeasure” defined on a collection $C$ of subsets of a set $X$, and extends the premeasure to a measure on a $\sigma$-algebra containing $C$. The extension is made via an “outer measure” defined on all subsets of $X$.

Let us informally outline the process and try to give some motivation for the procedure, which can otherwise seem strange and nonintuitive at first glance. First consider how to define the “area” of a region in the plane. If $A$ is a bounded subset of the plane $\mathbb{R}^2$, a reasonable and commonly-used way to define the area of $A$ is to cover it with a rectangular grid $G$, and let $\overline{V}(A,G)$ be the sum of the areas of the rectangles in the grid which contain points of $A$, and $\overline{V}(A,G)$ the sum of the areas of the rectangles in the grid entirely contained in $A$. $\overline{V}(A,G)$ and $\underline{V}(A,G)$ can be regarded as an “upper” or “outer” estimate, and a “lower” or “inner” estimate, respectively, for the area of $A$. As $G$ becomes finer, the outer estimates decrease and the inner estimates increase, and for “nice” $A$ they converge to the same value, which is a reasonable definition of the area of $A$. See XIV.3.2.1. and XIV.3.2.10.

It turns out that not enough subsets of the plane are “nice” enough to have an area defined in this way to give a satisfactory theory of measure and integration (i.e. such sets do not form a $\sigma$-algebra). But the idea of approximating from the outside and inside is one which, with suitable care, gives a good theory. We begin with a collection $C$ of sets which have a reasonable “size” already specified, and, to get an “outer estimate” of the “size” of a general set $A$, consider collections $(C_n)$ of sets in $C$ which cover $A$ (whose union contains $A$); the sum of the “sizes” of the $C_n$ is an upper estimate for the “size” of $A$. There are two differences we allow from the grid covering example, which together give us a notion of “size” with considerably more flexibility:

1. We allow countable collections $(C_n)$, not just finite collections.

2. We do not insist that the $C_n$ are disjoint or even “nonoverlapping.”

The infimum of all such upper estimates will be called the “outer measure” of the set $A$, written $\mu^*(A)$.

For the “inner” estimate, it turns out that the allowance of countably infinite covers is incompatible with truly estimating size from the “inside” as in the grid method. But in the grid example, there is a simple change of point of view which does work in the new setting: if $R$ is a large rectangle which is subdivided to make the grid $G$, it is easily seen that if $V(R)$ is the area of $R$, then $\overline{V}(A,G) = V(R) - \overline{V}(R \setminus A, G)$. So, if we are working within subsets of a fixed set $Y$ of finite measure, we can replace inner estimates for the size of our set $A$ by outer estimates for the size of $Y \setminus A$. The criterion that the inner and outer estimates for the size of $A$ should converge to the same limit as the covers get “finer” translates into the requirement that the sum of the outer measure $\mu^*(A)$ and the outer measure $\mu^*(Y \setminus A)$ should be the measure of $Y$. If the whole set $X$ has finite measure, it turns out that for $A$ to be “measurable” (to have a well-behaved notion of “size”) we need only require this condition for $Y = X$; however, in the general setting we must have a technical strengthening: for every $Y \subseteq X$, we require

$$\mu^*(Y \cap A) + \mu^*(Y \cap A^c) = \mu^*(Y).$$

Roughly speaking, the set $A$ is measurable if, for every $Y \subseteq X$, the sets $Y \cap A$ and $Y \cap A^c$ can be finely covered by “almost disjoint” countable families from $C$.

It turns out then that under reasonable conditions on the size function (“premeasure”) on $C$ we can prove that the collection of “measurable” subsets of $X$ is a $\sigma$-algebra containing $C$, and that $\mu^*$ restricts to a measure on this $\sigma$-algebra which agrees with the premeasure on $C$, and in particular the premeasure on $C$ extends to a measure on a $\sigma$-algebra containing $C$. 

1414
We will do most of the construction for “outer measures” defined abstractly, which have the crucial properties of outer measures induced by premeasures. This is essential since there are important outer measures which are not induced (at least not in any useful way) from premeasures.

XIII.3.1. Outer Measures

Outer measures are a crucial technical tool in measure theory. Almost all interesting measures are constructed (at least indirectly) from outer measures.

XIII.3.1.1. Definition. Let \( X \) be a set. An outer measure on \( X \) is a function \( \mu^* : \mathcal{P}(X) \to [0, \infty] \) such that

1. \( \mu^*(\emptyset) = 0 \)
2. If \( A \subseteq B \), then \( \mu^*(A) \leq \mu^*(B) \) (monotonicity)
3. If \( A = \bigcup_{n=1}^{\infty} A_n \), then \( \mu^*(A) \leq \sum_{n=1}^{\infty} \mu^*(A_n) \) (countable subadditivity).

There are two important differences between measures and outer measures. First, an outer measure is defined on all subsets of \( X \); second, an outer measure is not even finitely additive, let alone countably additive, in general.

XIII.3.1.2. In the case of a measure, monotonicity (condition (ii)) follows from the other properties (i), but (ii) does not follow from (i) and (iii) for outer measures in general (take Example XIII.3.5.14. with \( \alpha < 1 \)). In the presence of (i), both (ii) and (iii) can be replaced by the single condition

4. If \( A \subseteq \bigcup_{n=1}^{\infty} A_n \), then \( \mu^*(A) \leq \sum_{n=1}^{\infty} \mu^*(A_n) \).

[(iii') obviously follows from (ii) and (iii), and (iii') trivially implies (iii); for (iii') \( \Rightarrow \) (ii), if \( A \subseteq B \), set \( A_1 = B \) and \( A_n = \emptyset \) for \( n > 1 \), and use (i).]

XIII.3.1.3. As with measures, countable subadditivity for outer measures implies finite subadditivity: if \( A \subseteq \bigcup_{k=1}^{n} A_k \), then \( \mu^*(A) \leq \sum_{k=1}^{n} \mu^*(A_k) \). This follows from countable subadditivity by taking \( A_k = \emptyset \) for \( k > n \). In particular, if \( A, B \subseteq X \), then \( \mu^*(A \cup B) \leq \mu^*(A) + \mu^*(B) \).

XIII.3.1.4. Note: It must be noted that a substantial number of references, particularly ones concerned with geometric measure theory, call an outer measure a “measure”; in these references, a measure on a set \( X \) is defined on all subsets of \( X \), but is only countably additive on a \( \sigma \)-algebra of “measurable” subsets of \( X \). The distinction is largely a semantic one: every measure has a canonical extension to an outer measure, and conversely every outer measure naturally defines a \( \sigma \)-algebra of measurable subsets on which it is countably additive (a measure in our sense). The two processes are almost, but not quite, inverses of each other, however. The terminology we use is more flexible and superior for most purposes: for example, it is often crucial to keep track of the \( \sigma \)-algebra on which a measure is defined, particularly in probability where it is often necessary to consider and distinguish between two or more \( \sigma \)-algebras.

1415
XIII.3.1.5. Most outer measures are constructed beginning with a “measure” defined on a collection of subsets which is too small to be a \(\sigma\)-algebra, usually a semiring. Suppose \(C\) is a collection of subsets of a set \(X\), with the property that \(\emptyset \in C\). Let \(\iota\) be a function from \(C\) to \([0, \infty]\). We will eventually impose some reasonable measure-like conditions on \(C\) and \(\iota\), but to get an outer measure the only requirement on \(\iota\) is that \(\iota(\emptyset) = 0\).

Define a function \(\mu^*\) from \(\mathcal{P}(X)\) to \([0, \infty]\) as follows. If \(A \subseteq X\), set

\[
\mu^*(A) = \inf \left\{ \sum_{n=1}^{\infty} \iota(C_n) : C_n \in C, \ A \subseteq \bigcup_{n=1}^{\infty} C_n \right\}
\]

(if \(A\) has no countable cover by sets in \(C\), set \(\mu^*(A) = \infty\).)

If \(A \subseteq \bigcup_{n=1}^{\infty} C_n\), we say the sequence \(\{C_n\}\) covers \(A\).

Note that since \(\emptyset \in C\), finite as well as countably infinite covers are allowed in computing \(\mu^*(A)\), since a finite cover \(\{C_1, \ldots, C_m\}\) of \(A\) can be expanded to a countably infinite cover by setting \(C_n = \emptyset\) for \(n > m\) and using \(\iota(\emptyset) = 0\).

XIII.3.1.6. Some authors do not include the requirement that \(\emptyset \in C\) and/or that \(\iota(\emptyset) = 0\), obtaining that \(\mu^*(\emptyset) = 0\) since \(\emptyset\) is covered by the “empty cover” and hence \(\mu^*(\emptyset)\) is less than or equal to the “empty sum,” which is by definition 0. But there is no advantage in this approach (\(\emptyset\) can be added to \(C\) if necessary and \(\iota(\emptyset)\) can be defined or redefined to be 0 with no penalty) and it causes technical problems, e.g. when one wants to use finite covers as well as countable ones.

XIII.3.1.7. Proposition. This function \(\mu^*\) is an outer measure on \(X\).

**Proof:** Since \(\emptyset \in C\), \(\{\emptyset\}\) is a cover of \(\emptyset\), so \(\mu^*(\emptyset) = 0\). If \(A \subseteq B\), any countable cover of \(B\) is a countable cover of \(A\), so the infimum in calculating \(\mu^*(A)\) is over a larger collection of covers, and hence \(\mu^*(A) \leq \mu^*(B)\). Finally, suppose \(A = \bigcup_{n=1}^{\infty} A_n\). If \(\sum_{n=1}^{\infty} \mu^*(A_n) = \infty\), then clearly \(\mu^*(A) \leq \sum_{n=1}^{\infty} \mu^*(A_n)\). In the case that \(\sum_{n=1}^{\infty} \mu^*(A_n) < \infty\), so \(\mu^*(A_n) < \infty\) for all \(n\), let \(\epsilon > 0\), and for each \(n\) let \(\{C_{nk}\}\) be a cover of \(A_n\) with

\[
\sum_{k=1}^{\infty} \iota(C_{nk}) \leq \mu^*(A_n) + 2^{-n} \epsilon.
\]

Then \(\{C_{nk} : n, k \in \mathbb{N}\}\) is a cover of \(A\), so

\[
\mu^*(A) \leq \sum_{n,k} \iota(C_{nk}) \leq \sum_{n=1}^{\infty} \mu^*(A_n) + \epsilon.
\]

Since \(\epsilon\) is arbitrary, \(\mu^*(A) \leq \sum_{n=1}^{\infty} \mu^*(A_n)\).

XIII.3.1.8. Definition. The outer measure \(\mu^*\) is the outer measure induced by \(\iota\).

This construction of an outer measure from a set function is often called **Method I.** See (1) for “Method II.”

Note that \(\mu^*(C) \leq \iota(C)\) for any \(C \in C\), since \(\{C\}\) is a cover of \(C\) by \(C\); but \(\mu^*(C)\) does not equal \(\iota(C)\) in general.
XIII.3.1.9. Example. Let $X = \mathbb{N}$, $C = \mathcal{P}(\mathbb{N})$. Set $\iota(A) = 0$ if $A$ is finite and $\iota(A) = 1$ if $A$ is infinite. Then $\iota$ is monotone and (finitely) subadditive, but $\mu^*(A) = 0$ for all $A \subseteq \mathbb{N}$.

An outer measure induced by such a set function has an outer regularity property. If $C$ is a collection of subsets of $X$ containing $\emptyset$, write $C_\sigma$ for the set of countable unions of sets in $C$, and $C_{\sigma \delta}$ for the set of countable intersections of sets in $C_\sigma$. $C_\sigma$ and $C_{\sigma \delta}$ are contained in the $\sigma$-algebra generated by $C$.

XIII.3.1.10. Proposition. Let $C$ be a set of subsets of $X$ with $\emptyset \in C$, $\iota : C \to [0, \infty]$ with $\iota(\emptyset) = 0$, and $\mu^*$ the induced outer measure on $X$. Let $E \subseteq X$ with $\mu^*(E) < \infty$. Then

(i) For every $\epsilon > 0$, there is an $A \in C_\sigma$ with $E \subseteq A$ and $\mu^*(A) \leq \mu^*(E) + \epsilon$.

(ii) There is a $B \in C_{\sigma \delta}$ with $E \subseteq B$ and $\mu^*(E) = \mu^*(B)$.

Proof: (i) Let $\epsilon > 0$. Take a sequence $(C_n)$ in $C$ with $E \subseteq \bigcup_{n=1}^{\infty} C_n$ and $\sum_{n=1}^{\infty} \iota(C_n) \leq \mu^*(E) + \epsilon$. If $A = \bigcup_{n=1}^{\infty} C_n$, then $A \in C_\sigma$, $E \subseteq A$, and

$$\mu^*(A) \leq \sum_{n=1}^{\infty} \mu^*(C_n) \leq \sum_{n=1}^{\infty} \iota(C_n) \leq \mu^*(E) + \epsilon.$$ 

(ii): For each $n$ let $A_n \in C_\sigma$ with $E \subseteq A_n$ and $\mu^*(A_n) \leq \mu^*(E) + \frac{\epsilon}{n}$. Take $B = \bigcap_{n=1}^{\infty} A_n$. Then $B \in C_{\sigma \delta}$, $E \subseteq B$, and

$$\mu^*(E) \leq \mu^*(B) \leq \mu^*(A_n) \leq \mu^*(E) + \frac{1}{n}$$

for every $n$, so $\mu^*(B) = \mu^*(E)$. 

XIII.3.2. Lebesgue Outer Measure on $\mathbb{R}$

By far the most important example of the process of inducing an outer measure from a function on subsets is Lebesgue outer measure, used to construct Lebesgue measure.

XIII.3.2.1. Definition. Let $C$ be the set of all open intervals in $\mathbb{R}$ (including $\emptyset$). For an open interval $I$, let $\ell(I)$ be the length of $I$. The induced outer measure from $\ell$ is Lebesgue outer measure $\lambda^*$. Specifically: for $A \subseteq \mathbb{R}$,

$$\lambda^*(A) = \inf \left\{ \sum_{n=1}^{\infty} \ell(I_n) : I_n \in C, A \subseteq \bigcup_{n=1}^{\infty} I_n \right\}.$$ 

The use of open intervals is a matter of taste. It is useful to know that the same outer measure is obtained if arbitrary intervals are used:
III.3.2.2. Proposition. Let $\mathcal{I}$ be the set of all intervals in $\mathbb{R}$, including $\emptyset$ and singleton subsets. For $I \in \mathcal{I}$, let $\ell(I)$ be the length of $I \setminus \{a\} = 0$ for a singleton $\{a\}$). Then the outer measure on $\mathbb{R}$ induced by $\ell$ on $\mathcal{I}$ is Lebesgue outer measure.

Proof: Let $\mu^*$ be the outer measure on $\mathbb{R}$ induced by $\ell$ on $\mathcal{I}$. Since $\mathcal{C} \subseteq \mathcal{I}$, any $\mathcal{C}$-cover of a set $A$ is also an $\mathcal{I}$-cover, so the infimum in computing $\mu^*(A)$ is over more covers than for computing $\lambda^*(A)$ and $\mu^*(A) \leq \lambda^*(A)$. To show the opposite inequality, we may assume $\mu^*(A) < \infty$. Let $\epsilon > 0$, and let $\{I_n\}$ be an $\mathcal{I}$-cover of $A$ with $\sum_{n=1}^{\infty} \ell(I_n) \leq \mu^*(A) + \epsilon/2$. Each $I_n$ is an interval (possibly $\emptyset$ or a singleton); for each $n$, let $I'_n$ be an open interval containing $I_n$ of length $\leq \ell(I_n) + 2^{-n-1}\epsilon$. Then $\{I'_n\}$ is a cover of $A$ by open intervals, so we have

$$\lambda^*(A) \leq \sum_{n=1}^{\infty} \ell(I'_n) \leq \sum_{n=1}^{\infty} \ell(I_n) + \frac{\epsilon}{2} \leq \mu^*(A) + \epsilon.$$ 

Since $\epsilon$ is arbitrary, $\lambda^*(A) \leq \mu^*(A)$.

The next corollary can be proved directly in the same way, or by just applying III.3.2.2.

III.3.2.3. Corollary. Let $\mathcal{H}$ be the set of intervals in $\mathbb{R}$ which are open on the left and closed on the right (i.e. of the form $[a, b)$, $(-\infty, b]$, or $(a, +\infty)$), along with the empty set. For $I \in \mathcal{H}$, let $\ell(I)$ be the length of $I$. Then the outer measure on $\mathbb{R}$ induced by $\ell$ on $\mathcal{H}$ is Lebesgue outer measure.

Proof: Let $\nu^*$ be the outer measure induced by $\ell$ on $\mathcal{H}$. Since $\mathcal{H} \subseteq \mathcal{I}$, we have $\mu^*(A) \leq \nu^*(A)$ for any $A \subseteq \mathbb{R}$. If $A \subseteq \mathbb{R}$ and $\{I_n\}$ is a $\mathcal{C}$-cover of $A$, let $I'_n$ be $I_n$ with right endpoint added (if there is one); then $\{I'_n\}$ is an $\mathcal{H}$-cover of $A$, and $\sum_{n=1}^{\infty} \ell(I'_n) = \sum_{n=1}^{\infty} \ell(I_n)$; thus $\nu^*(A) \leq \lambda^*(A)$.

It is easily shown that the class $\mathcal{C}_f$ of bounded open intervals also induces Lebesgue outer measure, as do the classes $\mathcal{I}_f$ and $\mathcal{H}_f$: for any $\delta > 0$, the classes $\mathcal{C}_\delta$ of intervals of length $\leq \delta$ and $\mathcal{I}_\delta$, $\mathcal{H}_\delta$ also induce Lebesgue outer measure on $\mathbb{R}$ (Exercise ).

The next result is crucial, and shows that Lebesgue outer measure has the expected property of extending the interval length function. (In fact, without this theorem it is not even obvious that Lebesgue outer measure is not identically zero.) This result may seem “obvious” but is not, and the proof is somewhat delicate. Some references omit proving this entirely; the proof in [Fol99] (and in some other references) is described as “fussy.” We give a slick proof from [GP10], attributed to von Neumann.

III.3.2.4. Theorem. If $I$ is an interval in $\mathbb{R}$, then $\lambda^*(I) = \ell(I)$.

Proof: We have $\lambda^*(I) \leq \ell(I)$, since $\{I\}$ is a cover of $I$. To show the reverse inequality, first suppose $I = [a, b]$. Let $\epsilon > 0$, and let $(I_k)$ be a sequence of open intervals which cover $[a, b]$ with $\sum_{k=1}^{\infty} \ell(I_k) \leq \lambda^*(I) + \epsilon$ (so the $I_k$ are necessarily bounded). Since $[a, b]$ is compact, $(I_1, \ldots, I_n)$ covers $I$ for some $n$. Fix such an $n$.

If $J$ is a bounded interval in $\mathbb{R}$, write $\#(J)$ for the number of integers in $J$. We have

$$\ell(J) - 1 \leq \#(J) \leq \ell(J) + 1.$$
If $\alpha > 0$, then $\{\alpha I_1, \ldots, \alpha I_n\}$ covers $\alpha I$, so we have

$$\alpha \ell(I) - 1 = \ell(\alpha I) - 1 \leq \sum_{k=1}^{n} \#(\alpha I_k) \leq \sum_{k=1}^{n} \lfloor \ell(\alpha I_k) + 1 \rfloor = \alpha \left[ \sum_{k=1}^{n} \ell(I_k) \right] + n.$$  

Dividing by $\alpha$, we obtain

$$\ell(I) - \frac{1}{\alpha} \leq \left[ \sum_{k=1}^{n} \ell(I_k) \right] + \frac{n}{\alpha}.$$  

This is true for all $\alpha > 0$, so letting $\alpha \to +\infty$ we obtain

$$\ell(I) \leq \sum_{k=1}^{n} \ell(I_k) \leq \sum_{k=1}^{\infty} \ell(I_k) < \lambda^*(I) + \epsilon.$$  

Since $\epsilon > 0$ is arbitrary, $\ell(I) \leq \lambda^*(I)$.

Now suppose $I = (a, b)$. By subadditivity,

$$\ell(I) = b - a = \lambda^*((a, b)) \leq \lambda^*({a}) + \lambda^*({b}) = 0 + \lambda^*(I) + 0.$$  

If $I = (a, b)$ or $I = [a, b]$, then $(a, b) \subseteq I \subseteq [a, b]$, so by monotonicity $\lambda^*(I) = \ell(I)$.

If $I$ has infinite length, then either $(a, \infty) \subseteq I$ or $(-\infty, a) \subseteq I$ for some $a$. If $(a, \infty) \subseteq I$, then $(a, a+n) \subseteq I$ for all $n$, so by monotonicity

$$n = \lambda^*((a, a+n)) \leq \lambda^*(I)$$

for all $n$, and $\lambda^*(I) = \infty = \ell(I)$. The argument if $(-\infty, a) \subseteq I$ is similar.  

\* \* \*  

XIII.3.3. \ The Measure Induced by an Outer Measure

**XIII.3.3.1. Definition.** Let $\mu^*$ be an outer measure on a set $X$. A subset $A$ of $X$ is $\mu^*$-measurable if, for every $Y \subseteq X$,

$$\mu^*(Y) = \mu^*(Y \cap A) + \mu^*(Y \cap A^c) = \mu^*(Y \cap A) + \mu^*(Y \setminus A).$$

Intuitively in the case where $\mu^*$ comes from a set function by Method I, $A$ splits any set $Y$ into two pieces $Y \cap A$ and $Y \cap A^c$ which have “almost disjoint” covers.

Note that the inequality $\mu^*(Y) \leq \mu^*(Y \cap A) + \mu^*(Y \cap A^c)$ holds for any $Y$ and $A$ by subadditivity, so only the reverse inequality is needed for measurability of $A$. This reverse inequality is automatic if $\mu^*(Y) = \infty$, so we obtain:

**XIII.3.3.2. Proposition.** Let $\mu^*$ be an outer measure on a set $X$, and $A \subseteq X$.

(i) $A$ is $\mu^*$-measurable if and only if

$$\mu^*(Y) \geq \mu^*(Y \cap A) + \mu^*(Y \setminus A)$$

for every $Y \subseteq X$ with $\mu^*(Y) < \infty$.

(ii) $A$ is $\mu^*$-measurable if and only if, for every $Y \subseteq A$ and $Z \subseteq X \setminus A$ with $\mu^*(Y)$, $\mu^*(Z)$ finite,

$$\mu^*(Y \cup Z) \geq \mu^*(Y) + \mu^*(Z).$$
XIII.3.3.3.  **COROLLARY.** Let $\mu^*$ be an outer measure on a set $X$. If $A \subseteq X$ and $\mu^*(A) = 0$, then $A$ is $\mu^*$-measurable.

**Proof:** If $Y \subseteq X$, then by monotonicity we have $\mu^*(Y \cap A) = 0$, and

$$\mu^*(Y) \geq \mu^*(Y \cap A^c) = \mu^*(Y \cap A) + \mu^*(Y \cap A^c).$$

The name “measurable” for such sets explained in the introduction, and justified by the following theorem, which is the main result of this section and one of the fundamental theorems of measure theory:

XIII.3.3.4.  **THEOREM.**  [CARATHÉODORY] Let $\mu^*$ be an outer measure on a set $X$, and $\mathcal{M}$ the set of $\mu^*$-measurable subsets of $X$. Then

(i) $\mathcal{M}$ is a $\sigma$-algebra of subsets of $X$.

(ii) The restriction $\mu$ of $\mu^*$ to $\mathcal{M}$ is a measure (i.e. countably additive).

(iii) The measure space $(X, \mathcal{M}, \mu)$ is complete.

**Proof:** It is obvious from the definition of measurability that $\emptyset, X \in \mathcal{M}$ and that $A \in \mathcal{M}$ implies $A^c \in \mathcal{M}$. Let $A, B \in \mathcal{M}$. If $Y \subseteq X$, then

$$Y \cap (A \cup B) = [Y \cap (A \cap B)] \cup [Y \cap (A \cap B^c)] \cup [Y \cap (A^c \cap B)]$$

and so, by subadditivity,

$$\mu^*(Y \cap (A \cup B)) \leq \mu^*(Y \cap (A \cap B)) + \mu^*(Y \cap (A \cap B^c)) + \mu^*(Y \cap (A^c \cap B)).$$

Thus we have

$$\mu^*(Y) = \mu^*(Y \cap A) + \mu^*(Y \cap A^c)$$

$$= \mu^*(Y \cap A \cap B) + \mu^*(Y \cap A \cap B^c) + \mu^*(Y \cap A^c \cap B) + \mu^*(Y \cap A^c \cap B^c)$$

$$\geq \mu^*(Y \cap (A \cup B)) + \mu^*(Y \cap (A^c \cap B^c)) = \mu^*(Y \cap (A \cup B)) + \mu^*(Y \cap (A \cup B)^c)$$

so $A \cup B$ is $\mu^*$-measurable. Therefore $\mathcal{M}$ is an algebra.

Next suppose $A, B \in \mathcal{M}$ are disjoint. We have

$$\mu^*(A \cup B) = \mu^*((A \cup B) \cap A) + \mu^*((A \cup B) \cap A^c) = \mu^*(A) + \mu^*(B)$$

so $\mu^*$ is finitely additive on $\mathcal{M}$.

Now suppose $(A_n)$ is a pairwise disjoint sequence in $\mathcal{M}$, and set $B_n = \cup_{k=1}^n A_k$. Then $B_n \in \mathcal{M}$ for all $n$.

Set $B = \cup_{n=1}^\infty B_n = \cup_{n=1}^\infty A_n$. If $Y \subseteq X$, we have

$$\mu^*(Y) = \mu^*(Y \cap B_n) + \mu^*(Y \cap B_n^c) = \mu^*(Y \cap B_n \cap A_n) + \mu^*(Y \cap B_n \cap A_n^c) + \mu^*(Y \cap B_n^c)$$

$$= \mu^*(Y \cap A_n) + \mu^*(Y \cap B_n) + \mu^*(Y \cap B_n^c) = \cdots = \sum_{k=1}^n \mu^*(Y \cap A_k) + \mu^*(Y \cap B_n) \geq \sum_{k=1}^n \mu^*(Y \cap A_k) + \mu^*(Y \cap B_n^c)$$

1420
for every \( n \), and hence

\[
\mu^*(Y) \geq \sum_{k=1}^{\infty} \mu^*(Y \cap A_k) + \mu^*(Y \cap B^c) \geq \mu^*(Y \cap B) + \mu^*(Y \cap B^c) \geq \mu^*(Y)
\]

and thus all the inequalities are equalities. So \( B \in \mathcal{M} \) and \( \mathcal{M} \) is a \( \sigma \)-algebra (\( \mathcal{A} \)). Applying this last result to \( Y = B \), we obtain \( \mu^*(B) = \sum_{k=1}^{\infty} \mu^*(A_k) \), so \( \mu^* \) is countably additive on \( \mathcal{M} \).

The fact that \( (X, \mathcal{M}, \mu) \) is complete follows immediately from XIII.3.3.3.

XIII.3.3.5. The set \( \mathcal{M} \) of \( \mu^* \)-measurable subsets is more than just a \( \sigma \)-algebra; for example, unlike a general \( \sigma \)-algebra, it is also closed under the Suslin operation (XIII.3.6.7).

XIII.3.3.6. The definition of measurable set we have used is due to Carathéodory, and is now standard. Lebesgue’s definition of a measurable set (within a bounded interval \( I \) of \( \mathbb{R} \) with Lebesgue outer measure) was different and apparently less restrictive: \( A \subseteq I \) is measurable in Lebesgue’s sense if

\[
\lambda^*(A) + \lambda^*(I \setminus A) = \lambda^*(I) = \ell(I).
\]

The two notions are the same in good cases (XIII.3.5.24.), but not in general. Carathéodory’s definition is more generally useful, and even for finite measure spaces gives simpler proofs.

XIII.3.4. Lebesgue Measure on \( \mathbb{R} \)

[Prerequisite: (\( \mathcal{A} \))]

XIII.3.4.1. Definition. Let \( \mathcal{L} \) be the \( \sigma \)-algebra of \( \lambda^* \)-measurable subsets of \( \mathbb{R} \). \( \mathcal{L} \) is called the set of Lebesgue measurable sets in \( \mathbb{R} \). Write \( \lambda \) for the restriction of \( \lambda^* \) to \( \mathcal{L} \). Then \( \lambda \) is a measure on \( (\mathbb{R}, \mathcal{L}) \), called Lebesgue measure on \( \mathbb{R} \).

XIII.3.4.2. Proposition. \( (\mathbb{R}, \mathcal{L}, \lambda) \) is a complete measure space.

This is an immediate consequence of (\( \mathcal{A} \)).

XIII.3.4.3. Proposition. Every Borel set is \( \lambda^* \)-measurable, i.e. \( B \subseteq \mathcal{L} \).

Proof: This follows immediately from (\( \mathcal{A} \)). However, there is a quicker argument. It suffices to show that \( (a, \infty) \) is measurable for any \( a \in \mathbb{R} \) (actually just for \( a \) in a dense subset of \( \mathbb{R} \)), since such sets generate \( \mathcal{B} \). If \( Y \subseteq \mathbb{R} \) with \( \lambda^*(Y) < \infty \), we need to show that

\[
\lambda^*(Y) \geq \lambda^*(Y \cap (a, \infty)) + \lambda^*(Y \cap (-\infty, a]).
\]

Let \( \epsilon > 0 \), and let \( (I_n) \) be a sequence of intervals covering \( Y \) with

\[
\sum_{n=1}^{\infty} \ell(I_n) \leq \lambda^*(Y) + \epsilon.
\]

For each \( n \), let \( I_n' = I_n \cap (a, \infty) \) and \( I_n'' = I_n \cap (-\infty, a] \). Then the \( I_n' \) and \( I_n'' \) are intervals (some may be empty),

\[
\ell(I_n') + \ell(I_n'') = \ell(I_n), \quad (I_n') \text{ is a cover of } Y \cap (a, \infty), \quad \text{and } (I_n'') \text{ is a cover of } Y \cap (-\infty, a],
\]

so

\[
\lambda^*(Y \cap (a, \infty)) + \lambda^*(Y \cap (-\infty, a]) \leq \sum_{n=1}^{\infty} \ell(I_n') + \sum_{n=1}^{\infty} \ell(I_n'') = \sum_{n=1}^{\infty} \ell(I_n) \leq \lambda^*(Y) + \epsilon.
\]

1421
Proof: For each \( n \), \([-n, n]\) is Lebesgue measurable and \( \lambda([-n, n]) = 2n < \infty \), and \( \mathbb{R} = \bigcup_{n \in \mathbb{Z}} [-n, n] \).

It is not true that every Lebesgue measurable set is a Borel set. In fact, the cardinality of \( \mathcal{B} \) is \( 2^{2^{\aleph_0}} \); but every subset of the Cantor set \( K \) is Lebesgue measurable \((\ast)\), and \( \text{card}(K) = 2^{\aleph_0} \), so it follows that \( \text{card}(\mathcal{L}) = 2^{2^{\aleph_0}} \). For an explicit example of a Lebesgue measurable set which is not a Borel set, see \((\ast)\).

However:

XIII.3.4.4. **Corollary.** (\( \mathbb{R}, \mathcal{L}, \lambda \)) is a \( \sigma \)-finite measure space.

Proof: For every \( n \), \([-n, n]\) is Lebesgue measurable and \( \lambda([-n, n]) = 2n < \infty \), and \( \mathbb{R} = \bigcup_{n \in \mathbb{Z}} [-n, n] \).

For any \( \epsilon > 0 \), there is a sequence \( (I_{nm}) \) of open intervals covering \( A \) with
\[
\sum_{m=1}^{\infty} \ell(I_{nm}) < \lambda(A) + 2^{-\lceil |n| \rceil + 2} \epsilon.
\]

If \( U_n = \bigcup_{m=1}^{\infty} I_{nm} \), then \( U_n \) is open, \( A_n \subseteq U_n \), and
\[
\lambda(A_n) \leq \lambda(U_n) \leq \sum_{m=1}^{\infty} \ell(I_{nm}) < \lambda(A) + 2^{-\lceil |n| \rceil + 2} \epsilon
\]
and hence \( \lambda(U_n \setminus A_n) < 2^{-\lceil |n| \rceil + 2} \epsilon \) since \( \lambda(A_n) < \infty \).

Now let \( U = \bigcup_{n \in \mathbb{Z}} U_n \). Then \( U \) is open, \( A \subseteq U \), and \( U \setminus A \subseteq \bigcup_{n \in \mathbb{Z}} (U_n \setminus A_n) \), so
\[
\lambda(U \setminus A) \leq \sum_{n \in \mathbb{Z}} \lambda(U_n \setminus A_n) < \sum_{n \in \mathbb{Z}} 2^{-\lceil |n| \rceil + 2} \epsilon < \epsilon.
\]

(i): Let \( U \) be an open set containing \( A \) such that \( \lambda(U \setminus A^c) < \epsilon/2 \), and set \( E = U^c \). Then \( E \) is closed, \( E \subseteq A \), and \( A \setminus E = U \setminus A^c \), so \( \lambda(A \setminus E) < \epsilon/2 \). If \( \lambda(A) = \infty \), set \( F = E \). Suppose \( \lambda(A) < \infty \). For \( n \in \mathbb{N} \), set \( F_n = E \cap [-n, n] \). Then \( F_n \) is compact, and \( E = \bigcup_n F_n \), so \( A \setminus E = \bigcap_n A \setminus F_n \). This is a decreasing intersection of sets of finite measure, so \( \lambda(A \setminus E) = \inf_n \{ \lambda(A \setminus F_n) \} < \epsilon/2 \). There is thus an \( n \) so that \( \lambda(A \setminus F_n) < \epsilon \). Set \( F = F_n \) for this \( n \).

(ii): Let \( U \) be an open set containing \( A \) such that \( \lambda(U \setminus A) < \epsilon/2 \), and set \( E = U^c \). Then \( E \) is closed, \( E \subseteq A \), and \( A \setminus E = U \setminus A^c \), so \( \lambda(A \setminus E) < \epsilon/2 \). If \( \lambda(A) = \infty \), set \( F = E \). Suppose \( \lambda(A) < \infty \). For \( n \in \mathbb{N} \), set \( F_n = E \cap [-n, n] \). Then \( F_n \) is compact, and \( E = \bigcup_n F_n \), so \( A \setminus E = \bigcap_n A \setminus F_n \). This is a decreasing intersection of sets of finite measure, so \( \lambda(A \setminus E) = \inf_n \{ \lambda(A \setminus F_n) \} < \epsilon/2 \). There is thus an \( n \) so that \( \lambda(A \setminus F_n) < \epsilon \). Set \( F = F_n \) for this \( n \).

(iii): For each \( n \) let \( U_n \) be an open set containing \( A \) with \( \lambda(U_n \setminus A) < 1/n \), and set \( D = \cap_n U_n \).

(iv): For each \( n \) let \( F_n \) be a closed set contained in \( A \) with \( \lambda(A \setminus F_n) < 1/n \), and set \( E = \cup_n F_n \).
XIII.3.4.6. Thus every Lebesgue measurable set $A$ is “trapped between” a $G_\delta$ set $D$ and an $F_\sigma$ set $E$ (i.e. $E \subseteq A \subseteq D$) with $\lambda(D \setminus E) = 0$, and conversely by completeness any set which is trapped between such $D$ and $E$ is Lebesgue measurable. (Note, however, that for a given $A$ there is nothing unique about $D$ and $E$.)

XIII.3.5. Extending Premeasures from Semirings

XIII.3.5.1. We will now show that under some reasonable restrictions, a set function $\iota : \mathcal{C} \to [0, \infty]$ extends to a measure $\mu$ on a $\sigma$-algebra $\mathcal{A}$ containing $\mathcal{C}$. To motivate the restrictions on $\iota$, suppose an extension $\mu$ exists. Then a few moment’s thought shows that the following must be true:

(i) $\iota$ must be monotone on $\mathcal{C}$.

(ii) If $C_1, \ldots, C_n$ are disjoint sets in $\mathcal{C}$, and $C := \bigcup_{k=1}^n C_k \in \mathcal{C}$, then $\iota(C) = \sum_{k=1}^n \iota(C_k)$. (finite additivity).

(iii) If $C, C_1, C_2, \ldots \in \mathcal{C}$ and $C \subseteq \bigcup_{k=1}^\infty C_k$, then $\iota(C) \leq \sum_{k=1}^\infty \iota(C_k)$. (countable subadditivity).

(Note that (ii') does not necessarily imply (ii) unless $\emptyset \in \mathcal{C}$ and $\iota(\emptyset) = 0$.)

It is also reasonable to require that $\mathcal{C}$ be closed under enough set operations to make these restrictions on $\iota$ have some teeth. It turns out to be sufficient that $\mathcal{C}$ be a semiring; in fact, (i) will follow automatically from (ii) and (iii) in this case, and in the presence of (i), (ii') is equivalent to (ii) and (iii) combined.

XIII.3.5.2. Definition. Let $\mathcal{S}$ be a semiring of subsets of a set $X$. A premeasure on $\mathcal{S}$ is a set function $\iota : \mathcal{S} \to [0, \infty]$ with the properties that

(i) $\iota(\emptyset) = 0$.

(ii) If $C_1, \ldots, C_n$ are pairwise disjoint sets in $\mathcal{S}$, and $C := \bigcup_{k=1}^n C_k \in \mathcal{S}$, then $\iota(C) = \sum_{k=1}^n \iota(C_k)$ (finite additivity).

(iii) If $C, C_1, C_2, \ldots \in \mathcal{S}$ and $C \subseteq \bigcup_{k=1}^\infty C_k$, then $\iota(C) \leq \sum_{k=1}^\infty \iota(C_k)$ (countable subadditivity).

The premeasure $\iota$ is $\sigma$-finite if there are $C_1, C_2, \ldots \in \mathcal{S}$ with $\iota(C_n) < \infty$ for all $n$ and $\bigcup_{n=1}^\infty C_n = X$. If $\iota$ is $\sigma$-finite, then $\mathcal{S}$ is necessarily of countable type.

XIII.3.5.3. Examples. (i) Let $(X, \mathcal{A}, \mu)$ be any measure space, and $\mathcal{S}$ a semiring contained in $\mathcal{A}$. Then $\mu|_{\mathcal{S}}$ is a premeasure on $\mathcal{S}$.

(ii) Let $\mathcal{S}$ be any of the following semirings on $\mathbb{R}$:

- All intervals
  - All bounded intervals
  - For fixed $\delta > 0$, all intervals of length $\leq \delta$

(in all cases, include the degenerate intervals $\emptyset$ and singletons). Then $\iota$ is a $\sigma$-finite premeasure on $\mathcal{S}$ (cf. XIII.3.2.4., Exercise (i)).
XIII.3.5.4. **Note:** There is substantial nonuniformity of use of the term “premeasure,” and no consensus on the proper definition of the term. Some authors use it much more broadly than we have, and others more narrowly. I believe our definition of “premeasure” is the most useful one, since it is directly used not only in defining Lebesgue measure and Radon measures (finite Borel measures on $\mathbb{R}$ defined via cumulative distribution functions), but also naturally in defining product measures.

Measure extensions can be defined by more primitive data than a premeasure on a semiring; see [Kön97] for a study.

XIII.3.5.5. **Proposition.** A premeasure on a semiring is monotone.

**Proof:** Let $\mu$ be a premeasure on a semiring $\mathcal{S}$, and $C, D \in \mathcal{S}, C \subseteq D$. Then $D \setminus C$ is a disjoint union of $C_1, \ldots, C_n \in \mathcal{S}$, and

$$\mu(D) = \mu(C) + \sum_{k=1}^{n} \mu(C_k) \geq \mu(C)$$

since $\mu(C_k) \geq 0$ for all $k$.

Premeasures can be characterized alternatively by countable additivity, which is sometimes easier to check:

XIII.3.5.6. **Proposition.** Let $\mathcal{S}$ be a semiring of subsets of a set $X$, and $\mu : \mathcal{S} \to [0, \infty]$. Then $\mu$ is a premeasure if and only if $\mu$ satisfies

(i) $\mu(\emptyset) = 0$.

(ii') If $C_1, C_2, \ldots$ are pairwise disjoint sets in $\mathcal{S}$, and $C := \bigcup_{k=1}^{\infty} C_k \in \mathcal{S}$, then $\mu(C) = \sum_{k=1}^{\infty} \mu(C_k)$ (countable additivity).

Note that (ii') (countable additivity) does not trivially imply (iii) (countable subadditivity) on semirings, even on algebras, since countable additivity only applies to sequences whose union is in the semiring. The proposition is a consequence of XII.1.1.13. and XII.1.1.14., which insure that “sufficiently many” sets in a semiring are finite or countable disjoint unions of sets in the semiring.

**Proof:** Suppose $\mu$ satisfies (i) and (ii'). Then $\mu$ obviously satisfies (ii). Let $C, C_1, C_2, \ldots \in \mathcal{S}$ with $C \subseteq \bigcup_{n=1}^{\infty} C_n$. Then by XII.1.1.14. there are pairwise disjoint $B_k \in \mathcal{S}$, each contained in a unique $C_n$, only finitely many in each $C_n$, such that $C = \bigcup_{k} B_k$. For each $n$, let $D_n$ be the union of the $B_k$ which are in $C_n$. Then $C_n \setminus D_n$ is a finite disjoint union $A_{n1}, \ldots, A_{nm_n}$ of sets in $\mathcal{S}$ by XII.1.1.13.; hence we have

$$\mu(C_n) = \sum_{B_k \subseteq C_n} \mu(B_k) + \sum_{j=1}^{m_n} \mu(A_{nj}) \geq \sum_{B_k \subseteq C_n} \mu(B_k)$$

by (ii). Therefore we have by (ii')

$$\mu(C) = \sum_{k=1}^{\infty} \mu(B_k) = \sum_{n=1}^{\infty} \sum_{B_k \subseteq C_n} \mu(B_k) \leq \sum_{n=1}^{\infty} \mu(C_n)$$

1424
and thus $\iota$ satisfies (iii).

Conversely, if $\iota$ satisfies (i), (ii), and (iii), let $C_1, C_2, \ldots$ be pairwise disjoint sets in $S$ with $C = \bigcup_{n=1}^{\infty} C_n \in S$. We have $\iota(C) \leq \sum_{n=1}^{\infty} \iota(C_n)$ by (iii). On the other hand, if $D_n = \bigcup_{k=1}^{n} C_k$, we have that $C \setminus D_n$ is a finite disjoint union of sets $A_{n1}, \ldots, A_{nm}$ in $S$, so

$$\iota(C) = \sum_{k=1}^{n} \iota(C_k) + \sum_{j=1}^{m} \iota(A_{nj}) \geq \sum_{k=1}^{n} \iota(C_k)$$

for any $n$, i.e. $\iota(C) = \sum_{k=1}^{\infty} \iota(C_k)$.

Premeasures are technically simpler to work with if the domain is a ring instead of just a semiring. (In fact, some authors such as [Hal50] define a measure to be what we call a premeasure on a ring.) We do not make this restriction in the definition since many naturally occurring premeasures are only naturally defined on semirings. However, a premeasure on a semiring uniquely extends to a premeasure on the ring it generates, so there is no loss of generality for extension theory in considering just premeasures defined on rings (as some authors do):

**XIII.3.5.7.** **Theorem.** Let $\iota$ be a premeasure on a semiring $S$ of subsets of $X$, and let $R$ be the ring of subsets of $X$ generated by $S$. Then $\iota$ extends uniquely to a premeasure on $R$.

**Proof:** Recall () that $R$ consists of all finite disjoint unions of sets in $S$. If $\iota$ extends to a premeasure $\kappa$ on $R$, and $R \in R$ is a disjoint union of sets $C_1, \ldots, C_n \in S$, we must have $\kappa(R) = \sum_{k=1}^{n} \iota(C_k)$. We first need to show that this formula gives a well-defined function on $R$.

Suppose $R \in R$ has two representations $R = \bigcup_{k=1}^{n} C_k = \bigcup_{j=1}^{m} D_j$ as disjoint finite unions of sets in $S$. For each $k$ and $j$ set $E_{kj} = C_k \cap D_j$. Then each $E_{kj} \in S$ since $S$ is closed under finite intersections, and the $E_{kj}$ are pairwise disjoint. Thus

$$\sum_{k=1}^{n} \iota(C_k) = \sum_{k=1}^{n} \sum_{j=1}^{m} \iota(E_{kj}) = \sum_{j=1}^{m} \sum_{k=1}^{n} \iota(E_{kj}) = \sum_{j=1}^{m} \iota(D_j)$$

and so $\kappa$ is well defined.

To show that $\kappa$ is a premeasure, we must show (ii) and (iii). For (ii), suppose $R_1, \ldots, R_n \in R$ are pairwise disjoint and suppose $R := \bigcup_{k=1}^{n} R_k \in R$. For each $k$, write $R_k$ as a disjoint union $\bigcup_{j=1}^{m_k} C_{kj}$ with $C_{kj} \in S$. Then

$$\kappa(R) = \sum_{k=1}^{n} \sum_{j=1}^{m_k} \iota(C_{kj}) = \sum_{k=1}^{n} \kappa(R_k).$$

To show (iii), Suppose $R, R_1, R_2, \ldots \in R$ and $R \subseteq \bigcup_{k} R_k$. Write $R_k = \bigcup_{j=1}^{m_k} C_{kj}$ and $R = \bigcup_{i=1}^{r} D_i$ as disjoint unions with $C_{kj}, D_i \in S$. For each $i, j, k$, set $E_{ijk} = C_{kj} \cap D_i$. Then each $E_{ijk} \in S$ and, for each $i, j, k$,

$$\iota(D_i) \leq \sum_{k,j} \iota(E_{ijk}).$$

Then

$$\kappa(R) = \sum_{i=1}^{r} \iota(D_i) \leq \sum_{i,j,k} \iota(E_{ijk}) = \sum_{k=1}^{\infty} \sum_{j=1}^{m_k} \sum_{i=1}^{r} \iota(E_{ijk}) \leq \sum_{k=1}^{\infty} \iota(C_{kj}) = \sum_{k=1}^{\infty} \kappa(R_k).$$

1425
The model for constructing an extension of a premeasure to a measure is the construction of Lebesgue measure: begin with the premeasure \( \iota \), form the induced outer measure \( \mu^* \) and the \( \sigma \)-algebra \( \mathcal{M} \) of \( \mu^* \)-measurable subsets; the restriction of \( \mu^* \) to \( \mathcal{M} \) is the desired extension. The precise statement is the next theorem, which is the main result of this section, and another of the most important facts in measure theory:

**THEOREM. [Extension Theorem]** Let \( \mathcal{S} \) be a semiring on a set \( X \), \( \mathcal{A} \) the \( \sigma \)-algebra generated by \( \mathcal{S} \), and \( \iota \) a premeasure on \( \mathcal{S} \). Let \( \mu^* \) be the outer measure on \( X \) induced by \( \iota \), \( \mathcal{M} \) the \( \sigma \)-algebra of \( \mu^* \)-measurable subsets of \( X \), and \( \mu = \mu^*|_{\mathcal{M}} \). Then

(i) \( \mathcal{S} \subseteq \mathcal{M} \), i.e. every set in \( \mathcal{S} \) is \( \mu^* \)-measurable.

(ii) The restriction of \( \mu^* \) to \( \mathcal{S} \) is \( \iota \), i.e. \( \mu \) extends \( \iota \).

Thus \( \iota \) extends to a complete measure \( \mu \) on \( \mathcal{M} \), and hence to a measure \( \mu|_{\mathcal{A}} \) on \( \mathcal{A} \). If \( \mathcal{B} \) is a \( \sigma \)-algebra with \( \mathcal{A} \subseteq \mathcal{B} \subseteq \mathcal{M} \), the extension \( \mu|_{\mathcal{B}} \) is the largest extension of \( \iota \) to a measure on \( \mathcal{B} \), i.e. any extension \( \nu \) satisfies \( \nu \leq \mu \), and \( \nu \) agrees with \( \mu \) on sets of \( \sigma \)-finite \( \mu \)-measure. If \( \iota \) is \( \sigma \)-finite, then \( \mu \) is the unique extension of \( \iota \) to a measure on \( \mathcal{B} \), and \( (X, \mathcal{M}, \mu) \) is the completion of \( (X, \mathcal{A}, \mu|_{\mathcal{A}}) \).

**PROOF:** We first prove (ii). Let \( C \in \mathcal{S} \). Since \( \{C\} \) is a cover of \( C \), we have \( \mu^*(C) \leq \iota(C) \). For the opposite inequality, we may assume \( \mu^*(C) < \infty \). Let \( \epsilon > 0 \), and let \( (C_n) \) be a sequence of elements of \( \mathcal{S} \) with \( C \subseteq \bigcup_{n=1}^\infty C_n \) and \( \sum_{n=1}^\infty \iota(C_n) \leq \mu^*(C) + \epsilon \). Then, by (iii),

\[
\iota(C) \leq \sum_{n=1}^\infty \iota(C_n) \leq \mu^*(C) + \epsilon .
\]

Since \( \epsilon > 0 \) is arbitrary, \( \iota(C) \leq \mu^*(C) \).

(i): Now let \( C \in \mathcal{S} \), and let \( A \subseteq X \) with \( \mu^*(A) < \infty \). Fix \( \epsilon > 0 \), and let \( (C_n) \) be a sequence in \( \mathcal{S} \) with \( A \subseteq \bigcup_{n=1}^\infty C_n \) and \( \sum_{n=1}^\infty \iota(C_n) \leq \mu^*(A) + \epsilon \). Then \( A \cap C \subseteq \bigcup_{n=1}^\infty (C_n \cap C) \), and \( C_n \cap C \in \mathcal{S} \), so

\[
\mu^*(A \cap C) \leq \sum_{n=1}^\infty \mu^*(C_n \cap C) = \sum_{n=1}^\infty \iota(C_n \cap C) .
\]

Also, \( A \setminus C \subseteq \bigcup_{n=1}^\infty (C_n \setminus C) \). We have that \( C_n \setminus C \) is a finite disjoint union \( \bigcup_{k=1}^m D_{nk} \) for each \( n \), with \( D_{nk} \in \mathcal{S} \). So

\[
\mu^*(A \setminus C) \leq \sum_{n=1}^\infty \sum_{k=1}^m \mu^*(D_{nk}) = \sum_{n=1}^\infty \sum_{k=1}^m \iota(D_{nk}) .
\]

\[
\mu^*(A \cap C) + \mu^*(A \setminus C) \leq \sum_{n=1}^\infty \iota(C_n \cap C) + \sum_{n=1}^\infty \sum_{k=1}^m \iota(D_{nk}) = \sum_{n=1}^\infty \left( \iota(C_n \cap C) + \sum_{k=1}^m \iota(D_{nk}) \right) .
\]

1426
We have that, for each \( n \), \( C_n \) is the finite disjoint union of \( C_n \cap C \) and the \( D_{nk} \), so by (ii)

\[
\iota(C_n) = \iota(C_n \cap C) + \sum_{k=1}^{m_n} \iota(D_{nk})
\]

and thus

\[
\mu^*(A \cap C) + \mu^*(A \setminus C) \leq \sum_{n=1}^{\infty} \iota(C_n) \leq \mu^*(A) + \epsilon .
\]

Since \( \epsilon > 0 \) is arbitrary, \( \mu^*(A \cap C) + \mu^*(A \setminus C) \leq \mu^*(A) \). Thus \( C \) is \( \mu^* \)-measurable.

For the last part, suppose \( \nu \) is a measure extending \( \iota \) to a \( \sigma \)-algebra \( B \) with \( A \subseteq B \subseteq \mathcal{M} \). If \( B \in B \), \( \mu(B) < \infty \), let \( \epsilon > 0 \) and \( B \subseteq \cup_{n=1}^{\infty} C_n \) with \( C_n \in S \) and \( \sum_{n=1}^{\infty} \iota(C_n) \leq \mu(B) + \epsilon \). Then

\[
\nu(B) = \sum_{n=1}^{\infty} \nu(C_n) = \sum_{n=1}^{\infty} \iota(C_n) \leq \mu(B) + \epsilon .
\]

Since \( \epsilon \) is arbitrary, \( \nu(B) \leq \mu(B) \). On the other hand, let \( A = \cup_{n=1}^{\infty} C_n \in A \). Then \( \mu(A) \leq \sum_{n=1}^{\infty} \iota(C_n) < \infty \). Since \( \mu(A \setminus B) < \infty \), we have \( \nu(A \setminus B) \leq \mu(A \setminus B) \). Let \( D_1 = C_1 \) and \( D_n = C_n \setminus \cup_{k=1}^{n-1} C_k \). Then \( D_n \) is a finite disjoint union of sets in \( S \), so \( \nu(D_n) = \mu(D_n) \); and \( A \) is the disjoint union of the \( D_n \), so \( \nu(A) = \mu(A) \). Then

\[
\nu(B) = \nu(A) - \nu(A \setminus B) \geq \mu(A) - \mu(A \setminus B) = \mu(B) .
\]

So \( \nu(B) = \mu(B) \), and thus \( \mu = \nu \) for sets in \( B \) of finite \( \mu \)-measure. Then \( \nu = \mu \) also for sets of \( \sigma \)-finite \( \mu \)-measure, which can be written as countable disjoint unions of sets of finite \( \mu \)-measure; so if \( \iota \) is \( \sigma \)-finite, so is \( \mu \) and \( \nu = \mu \). In general, the only possible difference between \( \mu \) and \( \nu \) is that there could be a set \( B \) which is not of \( \sigma \)-finite \( \mu \)-measure, where \( \mu(B) = \infty \) but \( \nu(B) < \infty \). Thus \( \nu \leq \mu \).

For the last statement, let \( (C_n) \) be a sequence in \( S \) with \( \cup_{n=1}^{\infty} C_n = X \) and \( \iota(C_n) < \infty \) for all \( n \). Let \( M \in \mathcal{M} \). Fix \( n \in \mathbb{N} \); then for each \( m \in \mathbb{N} \) there is a sequence \( (D_{nmk}) \) in \( S \) with

\[
M \cap C_n \subseteq \bigcup_{k=1}^{\infty} D_{nmk}
\]

and

\[
\sum_{k=1}^{\infty} \iota(D_{nmk}) < \mu(M \cap C_n) + \frac{1}{m} .
\]

Set

\[
A_{nm} = \bigcup_{k=1}^{\infty} D_{nmk} .
\]

Then \( A_{nm} \in A \), \( M \cap C_n \subseteq A_{nm} \), and

\[
\mu(A_{nm}) < \mu(M \cap C_n) + \frac{1}{m} .
\]

Thus if

\[
A_n = C_n \cap \left( \bigcap_{m=1}^{\infty} A_{nm} \right)
\]

then
we have $A_n \in \mathcal{A}$, $M \cap C_n \subseteq A_n$, and $\mu(A_n) = \mu(M \cap C_n)$. Thus if $B_n = A_n \setminus (M \cap C_n)$, then $B_n \in \mathcal{M}$ and $\mu(B_n) = 0$. Set $A = \bigcup_{n=1}^{\infty} A_n$. Then $A \in \mathcal{A}$, and we have $M \subseteq A$ and

$$B = A \setminus M = \bigcup_{n=1}^{\infty} [A_n \setminus (M \cap C_n)] = \bigcup_{n=1}^{\infty} B_n$$

so $\mu(B) = 0$. Thus $M$ is the union of a set in $\mathcal{A}$ and a set $B$ of $\mu$-measure 0. Repeating the above argument for $M \cap C_n$, there is an $E \in \mathcal{A}$ with $B \subseteq E$ and $\mu(E) = 0$. Thus $M$ is the union of a set in $\mathcal{A}$ and a subset of a null set in $\mathcal{A}$.

There is an extremely important corollary of the uniqueness part:

**Corollary.** Let $\mathcal{S}$ be a semialgebra on $X$, and $\mathcal{A}$ the $\sigma$-algebra generated by $\mathcal{S}$. If $\mu$ and $\nu$ are measures on $\mathcal{A}$ which agree on $\mathcal{S}$ and are $\sigma$-finite on $\mathcal{S}$, then $\mu = \nu$ on $\mathcal{A}$.

Of course, it is enough to check that one of $\mu, \nu$ is $\sigma$-finite on $\mathcal{S}$. Note that it is not sufficient to check that $\mu = \nu$ on $\mathcal{S}$ and that $\mu$, say, is $\sigma$-finite on $\mathcal{A}$, unless we know that $\mu$ is the measure on $\mathcal{A}$ induced by $\mu|_{\mathcal{S}}$: there is an $\mathcal{S}$ on $\mathbb{R}$ which generates the Borel sets as a $\sigma$-algebra, with the property that every nonempty set in $\mathcal{S}$ has infinite Lebesgue measure (Exercise ()); Lebesgue measure is $\sigma$-finite on $\mathcal{B}$ but not on $\mathcal{S}$, and agrees on $\mathcal{S}$ with counting measure and the measure $\mu$ which is infinite on all nonempty sets ($\mu$ is the measure on $\mathcal{B}$ induced by $\lambda|_{\mathcal{S}}$).

**Theorems XIII.3.3.4. and XIII.3.5.8.** are often combined into a single theorem, which is called the **Carathéodory Extension Theorem**, and the construction called the **Carathéodory extension process**, even though **CARATHÉODORY** only proved XIII.3.3.4. (in addition to giving the definition of measurable set (XIII.3.3.1.)). Theorem XIII.3.5.8. was first proved by **FRÉCHET** []; the proof using XIII.3.3.4. is due independently to **HAHN** [] and **KOLMOGOROV** [].

**Theorem.** ([**CARATHÉODORY EXTENSION THEOREM**]) If $\iota$ is a premeasure on a semiring $\mathcal{S}$ of subsets of a set $X$, then there is an extension of $\iota$ to a complete measure $\mu$ on a $\sigma$-algebra $\mathcal{M}$ containing $\mathcal{S}$. If $\iota$ is $\sigma$-finite on $\mathcal{S}$, then the extension $\mu$ is unique if $\mathcal{M}$ is taken to be the $\sigma$-algebra generated by $\mathcal{S}$ and the null sets.

It is interesting to see what this construction gives when applied to the case where $\mathcal{S}$ is a $\sigma$-algebra and $\iota$ is a measure on $\mathcal{S}$:

**Proposition.** Let $(X, \mathcal{A}, \mu)$ be a measure space, and let $\mu^*$ be the outer measure induced by $\mu$, $\mathcal{M}$ the $\sigma$-algebra of $\mu^*$-measurable sets, and $\nu = \mu^*|_{\mathcal{M}}$. Then $(X, \mathcal{M}, \nu)$ is the saturation () of the completion (or the completion of the saturation) of $(X, \mathcal{A}, \mu)$. In particular, if $\mu$ is $\sigma$-finite, then $(X, \mathcal{M}, \nu)$ is the completion of $(X, \mathcal{A}, \mu)$.
Regular Outer Measures

Not every outer measure is induced by a premeasure. The ones that are can be characterized in a simple way:

XIII.3.5.13. Definition. An outer measure \( \mu^* \) on a set \( X \) is regular if, for every \( E \subseteq X \), there is a \( \mu^* \)-measurable set \( A \) with \( E \subseteq A \) and \( \mu^*(E) = \mu^*(A) \).

Not every outer measure is regular:

XIII.3.5.14. Examples. (i) If \( X = \{0,1\} \), set \( \mu^*(\emptyset) = 0 \), \( \mu^*(\{0\}) = \mu^*(\{1\}) = 1 \), and \( \mu^*(X) = \alpha \). If \( 1 \leq \alpha \leq 2 \), \( \mu^* \) is an outer measure. If \( \alpha < 2 \), the only \( \mu^* \)-measurable sets are \( \emptyset \) and \( X \); if \( 1 < \alpha < 2 \), \( \mu^* \) is not regular.

(ii) Let \( X = \mathbb{N} \). Set \( \mu^*(\emptyset) = 0 \), \( \mu^*(E) = 1 \) if \( E \) is nonempty and finite, and \( \mu^*(E) = 2 \) if \( E \) is infinite. The only \( \mu^* \)-measurable sets are \( \emptyset \) and \( \mathbb{N} \), and \( \mu^* \) is not regular.

XIII.3.5.15. There is a related property. If \( \mu^* \) is an outer measure on \( X \) and \( (E_n) \) is an increasing sequence of subsets of \( X \), with \( E = \bigcup_{n=1}^{\infty} E_n \), then \( \mu^*(E_1) \leq \mu^*(E_2) \leq \cdots \leq \mu^*(E) \) by monotonicity; thus

\[
\mu^*(E) \geq \lim_{n \to \infty} \mu^*(E_n) = \sup_n \mu^*(E_n).
\]

We do not have equality in general (XIII.3.5.17).

XIII.3.5.16. Definition. Let \( \mu^* \) be an outer measure on a set \( X \). Then \( \mu^* \) is monotone regular if, whenever \( (E_n) \) is an increasing sequence of subsets of \( X \), we have

\[
\mu^*(E) = \lim_{n \to \infty} \mu^*(E_n) = \sup_n \mu^*(E_n).
\]

XIII.3.5.17. Examples. The example of XIII.3.5.14.(ii) is not monotone regular: let \( E_n = \{1,\ldots,n\} \).

The example of XIII.3.5.14.(i) is monotone regular (as is any outer measure on a finite set) but not regular.

XIII.3.5.18. Proposition. A regular outer measure is monotone regular.

Proof: Let \( \mu^* \) be a regular outer measure on \( X \), and \( (E_n) \) an increasing sequence of subsets of \( X \), with \( E = \bigcup_{n=1}^{\infty} E_n \). It suffices to show that \( \mu^*(E) \leq \sup_n \mu^*(E_n) \). Let \( A_n \) be a \( \mu^* \)-measurable set with \( E_n \subseteq A_n \) and \( \mu^*(A_n) = \mu^*(E_n) \) for all \( n \). Set \( B_n = \cap_{k=n}^{\infty} A_k \). We have that \( E_n \subseteq A_k \) whenever \( n \leq k \), and hence \( E_n \subseteq B_n \subseteq B_{n+1} \) for all \( n \). Since \( B_n \subseteq A_n \), we have \( \mu^*(E_n) \leq \mu^*(B_n) \leq \mu^*(A_n) = \mu^*(E_n) \), so we have equality throughout. If \( B = \bigcup_{n=1}^{\infty} B_n \), then \( E \subseteq B \), so by () we have

\[
\mu^*(E) \leq \mu^*(B) = \sup_n \mu^*(B_n) = \sup_n \mu^*(E_n).
\]
**XIII.3.5.19.** Proposition. An outer measure induced by a premeasure is regular.

**Proof:** Suppose the outer measure \( \mu^* \) on \( X \) is induced by \( \nu : S \to [0, \infty] \), and let \( E \subseteq X \). If \( \mu^*(E) = \infty \), take \( A = X \). If \( \mu^*(E) < \infty \), by XIII.3.1.10, let \( A \in \mathcal{S}_\sigma \delta \) with \( E \subseteq A \) and \( \mu^*(A) = \mu^*(E) \).

**XIII.3.5.20.** Corollary. Lebesgue outer measure is a regular outer measure.

For the converse, we prove a more precise statement:

**XIII.3.5.21.** Proposition. Let \( \mu^* \) be an outer measure on \( X \), \( \mathcal{M} \) the set of \( \mu^* \)-measurable sets, and \( \mu^* \) the outer measure induced by \( \mu^*|_M \). Then \( \mu^* \) is a regular outer measure, \( \mu^* \geq \mu^* \), every set in \( \mathcal{M} \) is \( \mu^* \)-measurable, every \( \mu^* \)-measurable set of \( \sigma \)-finite \( \mu^* \)-measure is in \( \mathcal{M} \), and \( \mu^*|_M = \mu^*|_M \); \( \mu^* = \mu^* \) if and only if \( \mu^* \) is regular.

**Proof:** Most of this follows immediately from previous results. By XIII.3.5.8., setting \( \mathcal{S} = \mathcal{M} \) and \( \nu = \mu^*|_M \), every set in \( \mathcal{M} \) is \( \mu^* \)-measurable, and \( \mu^*|_M = \mu^*|_M \). The outer measure \( \mu^* \) is regular by XIII.3.5.19. We have that, for any \( E \subseteq X \),

\[
\mu^*(E) = \inf \{ \mu^*(A) : A \in \mathcal{M}, E \subseteq A \}
\]

and the infimum is attained \( () \) at some \( A \in \mathcal{M} \); for this \( A \) we have \( \mu^*(E) \leq \mu^*(A) = \mu^*(E) \). Thus \( \mu^* \geq \mu^* \).

If \( E \) is \( \mu^* \)-measurable and \( \mu^*(E) < \infty \), then there is a \( \mu^* \)-measurable set \( A \) with \( E \subseteq A \) and \( \mu^*(A) = \mu^*(E) \); then \( \mu^*(A) = \mu^*(A) = \mu^*(E) \), so \( \mu^*(A \setminus E) = 0 \). Since \( \mu^*(A \setminus E) \leq \mu^*(A \setminus E) \), \( \mu^*(A \setminus E) = 0 \) and \( A \setminus E \in \mathcal{M} () \). Thus \( E = A \setminus (A \setminus E) \in \mathcal{M} \). The case where \( E \) has \( \sigma \)-finite \( \mu^* \)-measure follows immediately.

Finally, if \( \mu^* \) is regular, let \( E \subseteq X \), and \( A \in \mathcal{M} \) with \( E \subseteq A \) and \( \mu^*(E) = \mu^*(A) \). Then \( \{ A \} \) is an \( \mathcal{M} \)-cover of \( E \), so \( \mu^*(E) \leq \mu^*(A) = \mu^*(E) \). Thus \( \mu^* \leq \mu^* \). So \( \mu^* = \mu^* \).

**XIII.3.5.22.** Example. [Rog70, p. 14] The \( \sigma \)-algebra of \( \mu^* \)-measurable sets can be strictly larger than \( \mathcal{M} \). Let \( X \) be a set of cardinality \( \aleph_2 \), and define \( \mu^* \) on \( X \) by setting \( \mu^*(E) = 0 \) if \( E \) is countable, \( \mu^*(E) = 1 \) if \( \text{card}(E) = \aleph_1 \), and \( \mu^*(E) = \infty \) if \( \text{card}(E) = \aleph_2 \). Then \( \mu^* \) is an outer measure on \( X \) which is not regular. The \( \sigma \)-algebra \( \mathcal{M} \) of \( \mu^* \)-measurable sets is the \( \sigma \)-algebra of countable and co-countable sets. Construct \( \mu^* \) as above from \( \mu^*|_M \). Then, for any \( E \subseteq X \), \( \mu^*(E) = 0 \) if \( E \) is countable and \( \mu^*(E) = \infty \) if \( E \) is uncountable, and every subset of \( X \) is \( \mu^* \)-measurable.

Putting the last two results together, we obtain:

**XIII.3.5.23.** Proposition. An outer measure is induced by a premeasure if and only if it is regular.

As a corollary of XIII.3.5.21., we can show that Lebesgue’s definition of measurability agrees with Carathéodory’s for finite regular outer measures:
XIII.3.5.24. Theorem. Let $\mu^*$ be a regular outer measure on a set $X$, with $\mu^*(X) < \infty$. Then $A \subseteq X$ is $\mu^*$-measurable if and only if $\mu^*(A) + \mu^*(X \setminus A) = \mu^*(X)$.

(Of course, $\mu^*(A) + \mu^*(X \setminus A) \geq \mu^*(X)$ is automatic; so only the reverse inequality needs to be checked.)

Proof: If $A$ is $\mu^*$-measurable, the equality holds by definition. Conversely, suppose $A \subseteq X$ and $\mu^*(A) + \mu^*(X \setminus A) = \mu^*(X)$. Let $B$ and $C$ be $\mu^*$-measurable subsets of $X$ with $A \subseteq B$, $\mu^*(B) = \mu^*(A)$, $(X \setminus A) \subseteq C$, $\mu^*(C) = \mu^*(X \setminus A)$. We have

$$\mu^*(B \setminus C) + \mu^*(B \cap C) + \mu^*(C \setminus B) = \mu^*(B \cup C) = \mu^*(X).$$

We also have

$$\mu^*(X) = \mu^*(A) + \mu^*(X \setminus A) = \mu^*(B) + \mu^*(C) = \mu^*(B \setminus C) + 2\mu^*(B \cap C) + \mu^*(C \setminus B)$$

and subtracting we get $\mu^*(B \cap C) = 0$. If $D = B \setminus A$, then $D = B \cap (X \setminus A) \subseteq (B \cap C)$, so $\mu^*(D) = 0$ and $D$ is $\mu^*$-measurable. Hence so is $A = B \setminus D$.

This result can fail for finite outer measures which are not regular (Exercise 1). It also usually fails for outer measures which are not finite: for example, there is a nonmeasurable subset $A$ of $\mathbb{R}$ with $\lambda^*(A) = \lambda^*(\mathbb{R} \setminus A) = \infty$.

Inner Measure

XIII.3.5.25. If $\mu^*$ is a finite regular outer measure on a set $X$, we can define the inner measure of a subset $A$ of $X$ by

$$\mu_+(A) = \mu^*(X) - \mu^*(X \setminus A).$$

Then the result of XIII.3.5.24. can be rephrased:

XIII.3.5.26. Corollary. Let $\mu^*$ be a finite regular outer measure on a set $X$, and $\mu_+$ the corresponding inner measure. Then $A \subseteq X$ is $\mu^*$-measurable if and only if $\mu^*(A) = \mu_+(A)$.

Generalizations of Regularity

XIII.3.5.27. The notion of regularity can be generalized. If $\mathcal{C}$ is a collection of subsets of a set $X$, and $\mu^*$ is an outer measure on $X$, then $\mu^*$ is $\mathcal{C}$-regular if every subset $Y$ of $X$ is contained in some $C \in \mathcal{C}$ with $\mu^*(C) = \mu^*(Y)$ (this implies that $X \in \mathcal{C}$). Normally this definition is applied only when $\mathcal{C} \subseteq \mathcal{M}$, where $\mathcal{M}$ is the set of $\mu^*$-measurable sets. Thus $\mu^*$ is regular if and only if it is $\mathcal{M}$-regular. If $\mu^*$ is a $\sigma$-finite outer measure induced from $\iota : \mathcal{C} \rightarrow [0, \infty]$, then $\mu^*$ is $\mathcal{C}_{\sigma\delta}$-regular (XIII.3.1.10.).

XIII.3.5.28. Proposition. Let $\mu^*$ be an outer measure on a set $X$, $\mathcal{M}$ the set of $\mu^*$-measurable subsets of $X$, and $\mathcal{A}$ a sub-$\sigma$-algebra of $\mathcal{M}$ such that $\mu^*|_{\mathcal{A}}$ is $\sigma$-finite. If $\mu^*$ is $\mathcal{A}$-regular, then $\mathcal{M}$ is the $\sigma$-algebra generated by $\mathcal{A}$ and the $\mathcal{A}$-null sets (subsets of sets in $\mathcal{A}$ of outer measure 0). In particular, if $(X, \mathcal{A}, \mu^*|_{\mathcal{A}})$ is complete and $\sigma$-finite, then $\mathcal{A} = \mathcal{M}$. 

1431
XIII.3.5.29. This does not mean that if \((X, A, \mu)\) is a \(\sigma\)-finite complete measure space, then it is not possible to extend \(\mu\) to a measure on a strictly larger \(\sigma\)-algebra; there are many examples where this is possible. See Exercise () for a simple example, and () for more natural and important ones. What XIII.3.5.28. does say is that if such a \(\mu\) is extended to a measure \(\nu\) on a larger \(\sigma\)-algebra \(B\), and \(\nu^*\) is the outer measure induced by \(\nu\), then \(\nu^*\) is not \(A\)-regular.

XIII.3.5.30. An important special case of regularity is when \(\mu^*\) is an outer measure on a topological space \(X\). Then \(\mu^*\) is Borel regular if it is \(B\)-regular, where \(B\) is the class of Borel sets in \(X\). This definition is usually reserved for Borel outer measures, i.e. ones where all Borel sets are \(\mu^*\)-measurable. The most important example is that Lebesgue outer measure is Borel regular (XIII.3.4.5., XIII.3.5.20.).

XIII.3.6. The Suslin Operation

XIII.3.6.1. There is a curious operation on sets called the Suslin operation (sometimes called the \(A\)-operation), which is reminiscent of the construction in the proof of XI.10.2.7.. For each finite sequence \((s_1, \ldots, s_n)\) of natural numbers, let \(A_{s_1, \ldots, s_n}\) be a subset of a set \(X\). The collection of finite sequences in \(N\) is countable, so there are countably many such sets in all. Define

\[
S(\{A_{s_1, \ldots, s_n}\}) = \bigcup_{s \in \mathcal{N}} \bigcap_{n=1}^{\infty} A_{s_1, \ldots, s_n}
\]

where \(\mathcal{N} = \mathbb{N}^\infty\) is the set of all sequences in \(\mathbb{N}\). Although the operation begins with a countable collection of sets, the union is over all sequences (uncountably many) in \(\mathcal{N}\).

If \(s = (s_1, s_2, \ldots) \in \mathcal{N}\), write \(s|n = (s_1, \ldots, s_n) \in \mathbb{N}^n\). These are called initial segments of \(s\). Take \(s|0\) to be the “empty string.” Thus

\[
S(\{A_{s_1, \ldots, s_n}\}) = \bigcup_{s \in \mathcal{N}} \bigcap_{n=1}^{\infty} A_{s|n}.
\]

XIII.3.6.2. More generally, if \(\mathcal{E}\) is a nonempty collection of subsets of a set \(X\), and all the \(A_{s_1, \ldots, s_n}\) are in \(\mathcal{E}\), the indexed collection \(\{A_{s_1, \ldots, s_n}\}\) is called a Suslin scheme in \(\mathcal{E}\). Denote by \(S(\mathcal{E})\) the collection \(\{S(\{A_{s_1, \ldots, s_n}\})\}\), for all Suslin schemes \(\{A_{s_1, \ldots, s_n}\}\) in \(\mathcal{E}\), along with \(\emptyset\) (we will automatically have \(\emptyset \in S(\mathcal{E})\) in many cases, e.g. if \(\emptyset\) is a countable intersection of sets in \(\mathcal{E}\)). The sets in \(S(\mathcal{E})\) are called the \(\mathcal{E}\)-Suslin sets (sometimes called the \(\mathcal{E}\)-analytic sets, but we reserve this term for sets defined differently in ()); the two classes of sets coincide in most natural settings. It is obvious that if \(\mathcal{E} \subseteq \mathcal{F}\), then \(S(\mathcal{E}) \subseteq S(\mathcal{F})\).

We typically take \(\mathcal{E}\) to be the collection of closed or compact sets in \(\mathbb{R}^n\) (or in a topological space), or a semialgebra (algebra, \(\sigma\)-algebra) of sets such as the Borel sets in \(\mathbb{R}^n\).

The sets in \(S(\mathcal{E})\) have a simpler explicit description than the sets in \(\sigma(\mathcal{E})\) (cf. ()). The collection \(S(\mathcal{E})\) is usually different from \(\sigma(\mathcal{E})\) although it has some of the same properties; it frequently happens that \(S(\mathcal{E})\) contains \(\sigma(\mathcal{E})\) (XIII.3.6.4.(iv)).

XIII.3.6.3. A Suslin scheme \(\{A_{s_1, \ldots, s_n}\}\) is monotone (or regular) if \(A_{s_1, \ldots, s_n, s_{n+1}} \subseteq A_{s_1, \ldots, s_n}\) for all \((s_1, \ldots, s_{n+1})\). If \(\mathcal{E}\) is closed under finite intersections (e.g. in one of the common situations described above), then for any Suslin scheme \(\{A_{s_1, \ldots, s_n}\}\) in \(\mathcal{E}\) there is a monotone Suslin scheme \(\{B_{s_1, \ldots, s_n}\}\) with \(S(\{B_{s_1, \ldots, s_n}\}) = S(\{A_{s_1, \ldots, s_n}\})\); just set

\[
B_{s_1, \ldots, s_n} = A_{s_1} \cap A_{s_1, s_2} \cap \cdots \cap A_{s_1, \ldots, s_n}
\]

1432
for each \((s_1, \ldots, s_n)\).

**XIII.3.6.4. Proposition.** Let \(E\) be a collection of subsets of a set \(X\). Then

(i) \(E \subseteq S(E)\).

(ii) \(S(S(E)) = S(E)\). Thus if \(E \subseteq F \subseteq S(E)\), then \(S(F) = S(E)\).

(iii) \(S(E)\) is closed under countable unions and countable intersections.

(iv) If the complement of every set in \(E\) is in \(S(E)\), then \(\sigma(E) \subseteq S(E)\).

**Proof:** (i): If \(A \in E\), set \(A_{s_1, \ldots, s_n} = A\) for all \((s_1, \ldots, s_n)\). Then \(\{A_{s_1, \ldots, s_n}\}\) is a Suslin scheme in \(E\), and 
\[S(\{A_{s_1, \ldots, s_n}\}) = A.\]

(ii): Let \(\phi : \mathbb{N}^2 \to \mathbb{N}\) be the bijection given by \(\phi(n, m) = 2^{n-1}(2m - 1)\). Let \(\alpha\) and \(\beta\) be the coordinate functions of the inverse map, i.e. \(\alpha(2^{n-1}(2m - 1)) = n\), \(\beta(2^{n-1}(2m - 1)) = m\). Define a bijection \(\psi : \mathbb{N} \times \mathbb{N}^\infty \to \mathbb{N}\) by
\[\psi(s, (t^{(k)})) = \phi(s, (t^{(\alpha(r))}))\]
where \(t^{(k)}_j\) is the \(j\)th term of the sequence \(t^{(k)}\). Note that if \(r = \phi(n, m)\), then \(\psi(s, (t^{(k)}))r\) completely determines \(s\) and \((t^{(n)})m\), i.e. if \((p_1, \ldots, p_r) \in \mathbb{N}^r\), then there are \((s_1, \ldots, s_n)\) and \((t_1, \ldots, t_m)\) such that whenever \(\psi(s, (t^{(k)}))r = (p_1, \ldots, p_r), s = (s_1, \ldots, s_n)\) and \((t^{(n)})m = (t_1, \ldots, t_m)\).

Now let \(B = \bigcup_{s \in \mathbb{N}} \bigcap_{p \in \mathbb{N}} B_{s, p} \in S(S(E))\), where \(\{B_{s, p}\}\) is a Suslin scheme in \(S(E)\), and suppose for each \((s_1, \ldots, s_n)\) we have \(B_{s_1, \ldots, s_n} = \bigcap_{s \in \mathbb{N}} A_{s_1, \ldots, s_n}^{(n)}\) with \(A_{s_1, \ldots, s_n}^{(n)} \in E\). For a finite sequence \((p_1, \ldots, p_r)\), let \((s_1, \ldots, s_n)\) and \((t_1^{(n)}, \ldots, t_m^{(n)})\) be the initial segments determined by \((p_1, \ldots, p_r)\) as above, and define
\[E_{p_1, \ldots, p_r} = A_{s_1, \ldots, s_n}^{(n)} = A_{s_1, \ldots, s_n}^{(n)}.\]
Then \(\{E_{p_1, \ldots, p_r}\}\) is a Suslin scheme in \(E\); set \(E = \bigcup_{p \in \mathbb{N}} \bigcap_{r \in \mathbb{N}} E_{p_1, \ldots, p_r} \in S(E)\).

We have that \(x \in B\) if and only if there is an \(s \in \mathbb{N}\) such that \(x \in B_{s, p}\) for all \(p\), i.e. if and only if for each \(n\) there is \(n \in \mathbb{N}\) such that \(x \in A_{s, n}^{(n)}\) for all \(m\). Set \(p = \psi(s, (t^{(n)}))\). Then, for any \(r\), \(E_{p_1, \ldots, p_r} = A_{s, n}^{(n)}\) where \(r = \phi(n, m)\), so \(x \in B\) if and only if \(x \in E_{p_1, \ldots, p_r}\) for all \(p\), for some \(p \in \mathbb{N}\), i.e. if and only if \(x \in E\). Thus \(B = E \in S(E)\). So \(S(S(E)) \subseteq S(E)\), and the opposite inclusion follows from (i).

(iii): By (ii), it suffices to show that \(S(E)\) contains all countable unions and countable intersections of sets in \(E\). Suppose \((E_n)\) is a sequence of sets in \(E\). For each \((s_1, \ldots, s_n)\), set \(A_{s_1, \ldots, s_n} = E_{s_1}\). Then \(\{A_{s_1, \ldots, s_n}\}\) is a Suslin scheme in \(E\), and \(S(\{A_{s_1, \ldots, s_n}\}) = \bigcup_{n=1}^\infty E_n\). Similarly, set \(A_{s_1, \ldots, s_n} = E_{s_1}\) for all \((s_1, \ldots, s_n)\); then \(S(\{A_{s_1, \ldots, s_n}\}) = \bigcap_{n=1}^\infty E_n\).

(iv): Follows immediately from **XIII.3.10.11.** (cf. **XIII.3.10.11.**), since \(E \subseteq S(E) \cap \widehat{S(E)}\) which is a \(\sigma\)-algebra.

**XIII.3.6.5.** \(S(E)\) is not closed under complements in general, even if \(E\) is a \(\sigma\)-algebra. For example, if \(B\) is the \(\sigma\)-algebra of Borel sets in \(\mathbb{R}\), then \(S(B)\) is not closed under complements ( ).
XIII.3.6.6. Let $\mathcal{K}$ be the collection of compact subsets of $\mathbb{R}^n$, $\mathcal{F}$ the collection of closed subsets, and $\mathcal{B}$ the collection of Borel sets. The complement of every compact set is open, hence a countable union of compact sets; thus by XIII.3.4.4(iv) $\sigma(\mathcal{K}) = \mathcal{B} \subseteq \mathcal{S}(\mathcal{K})$. Thus by (ii) $\mathcal{S}(\mathcal{K}) = \mathcal{S}(\mathcal{F}) = \mathcal{S}(\mathcal{B})$, i.e. every $\mathcal{B}$-Suslin set is $\mathcal{K}$-Suslin. These sets are called the Suslin sets in $\mathbb{R}^n$. See also Exercise XIII.3.10.9.

The next theorem is the main result of this subsection.

XIII.3.6.7. **Theorem.** Let $\mu^*$ be an outer measure on a set $X$, $\mathcal{M}$ the $\sigma$-algebra of $\mu^*$-measurable sets, and $\mu = \mu^*|_\mathcal{M}$. Then

(i) $\mathcal{M}$ is closed under the Suslin operation, i.e. $\mathcal{S}(\mathcal{M}) = \mathcal{M}$.

(ii) Suppose $\mu^*$ is monotone regular. Let $\mathcal{E}$ be a subset of $\mathcal{M}$ which is closed under finite unions and countable intersections, and such that $\mu(E) < \infty$ for all $E \in \mathcal{E}$. Then, for every $A \in \mathcal{S}(\mathcal{E})$ with $\mu(A) < \infty$, we have

$$\mu(A) = \sup \{ \mu(E) : E \in \mathcal{E}, E \subseteq A \} .$$

Combining XIII.3.6.7. with XIII.3.5.12., we obtain:

XIII.3.6.8. **Corollary.** Let $(X, \mathcal{A}, \mu)$ be a complete $\sigma$-finite measure space. Then $\mathcal{A}$ is closed under the Suslin operation. (“$\sigma$-finite” can be replaced by “saturated.”)

XIII.3.6.9. The conclusion of this corollary can be false if the measure is not complete. In fact, the $\sigma$-algebra of Borel sets on $\mathbb{R}$ is not closed under the Suslin operation ().

We now prove Theorem XIII.3.6.7.

**Proof:** ([Rog70], [Bog07]) We first prove (i) and (ii) in the case where $\mu^*$ is monotone regular. Let $A = \mathcal{S}\{\{A_{s_1, \ldots, s_n}\} \in \mathcal{S}(\mathcal{M})$, where $\{A_{s_1, \ldots, s_n}\}$ is a Suslin scheme in $\mathcal{M}$ which we may assume is monotone since $\mathcal{M}$ is closed under finite intersections. For (ii), we take the $A_{s_1, \ldots, s_n}$ to be in $\mathcal{E}$. To show that $A \in \mathcal{M}$, we use the criterion of XIII.3.3.2.(ii). So let $Y \subseteq A$ and $Z \subseteq X \setminus A$ with $\mu^*(Y), \mu^*(Z) < \infty$; in (ii) we take $Y = A$ (and in this case we can take $Z = \emptyset$). For (i) we must show that $\mu^*(Y \cup Z) \geq \mu^*(Y) \cdot \mu^*(Z)$. We will show that for any $\epsilon > 0$ there is an $E \in \mathcal{M}$, $E \subseteq A$, with $\mu^*(Y \cap E) \geq \mu^*(Y) - \epsilon$, and $E \in \mathcal{E}$ in case (ii); (ii) will then follow immediately, and (i) will also follow since then $Z \subseteq X \setminus E$, so

$$\mu^*(Y \cup Z) \geq \mu^*(Y \cap E \cup Z) = \mu^*(Y \cap E) \cdot \mu^*(Z) \geq \mu^*(Y) - \epsilon + \mu^*(Z)$$

and since $\epsilon > 0$ is arbitrary, $\mu^*(Y \cup Z) \geq \mu^*(Y) + \mu^*(Z)$.

Fix $\epsilon > 0$. For $m \in \mathbb{N}$, set

$$B_m = Y \cap \bigcup_{s \in \mathcal{N}_m} \bigcap_{k \geq 1} A_{s_{1:k}}$$

where $\mathcal{N}_m = \{s \in \mathcal{N} : s_1 \leq m\}$. Then the $B_m$ increase with $m$, and $\bigcup_m B_m = Y$. So

$$\mu^*(Y) = \sup_m \mu^*(B_m)$$

1434
since $\mu^*$ is monotone regular. Thus there is an $m_1$ such that

$$\mu^*(B_{m_1}) > \mu^*(Y) - \epsilon.$$  

Proceed inductively. Suppose $m_1, \ldots, m_n$ have been defined and

$$B_{m_1, \ldots, m_n} = Y \cap \bigcup_{s \in \mathcal{N}_{m_1, \ldots, m_n}} \bigcap_k A_{s[k]}$$

where $\mathcal{N}_{m_1, \ldots, m_n} = \{s \in \mathcal{N} : s_1 \leq m_1, \ldots, s_n \leq m_n\}$ and

$$\mu^*(B_{m_1, \ldots, m_n}) > \mu^*(Y) - \epsilon.$$  

For $m \in \mathcal{N}$, set

$$B_{m_1, \ldots, m_n, m} = Y \cap \bigcup_{s \in \mathcal{N}_{m_1, \ldots, m_n, m}} \bigcap_k A_{s[k]}$$

where $\mathcal{N}_{m_1, \ldots, m_n, m} = \{s \in \mathcal{N} : s_1 \leq m_1, \ldots, s_n \leq m_n, s_{n+1} \leq m\}$ Then the $B_{m_1, \ldots, m_n, m}$ increase in $m$, and

$$\mu^*(B_{m_1, \ldots, m,n+1}) > \mu^*(Y) - \epsilon.$$  

Now for each $n$ set

$$E_n = \bigcup_{s \in \mathcal{N}_{m_1, \ldots, m_n}} A_{s[n]}.$$  

This is a finite union, so $E_n \in \mathcal{M}$ for all $n$, and $E_n \in \mathcal{E}$ in case (ii). We have $B_{m_1, \ldots, m_n} \subseteq Y \cap E_n$ for all $n$. We also have $E_{n+1} \subseteq E_n$ for all $n$. Set $E = \cap_n E_n$.  

We claim that $\mu^*(E) \geq \mu^*(Y) - \epsilon$. This is obvious from downward continuity () in case (ii) since $\mu$ is finite on $\mathcal{E}$ and $\mu^*(E_n) \geq \mu^*(B_{m_1, \ldots, m_n}) > \mu^*(Y) - \epsilon$ for all $n$. For case (i), define a new outer measure $\mu_Y$ on $X$ by

$$\mu_Y(S) = \mu^*(Y \cap S)$$

for $S \subseteq X$. Then every set in $\mathcal{M}$ is $\mu_Y$-measurable by (), and we have

$$\mu^*(E) \geq \mu_Y^*(E) = \inf_n \mu^*(E_n) = \inf_n \mu^*(Y \cap E_n) \geq \inf_n \mu^*(B_{m_1, \ldots, m_n}) \geq \mu^*(Y) - \epsilon$$

where the first equality is downward continuity for the finite measure $\mu_Y$.

Finally, we show $E \subseteq A$. Let $x \in E$. Write

$$\mathbb{N}_{m_1, \ldots, m_n}^n = \{(s_1, \ldots, s_n) : s_1 \leq m_1, \ldots, s_n \leq m_n\} \subseteq \mathbb{N}^n$$

for each $n$. If $k > n$, say $(s_1, \ldots, s_n) \in \mathbb{N}_{m_1, \ldots, m_n}^n$ is extendible to $k$ if there are $s_{n+1}, \ldots, s_k$ such that $(s_1, \ldots, s_n, s_{n+1}, \ldots, s_k) \in \mathbb{N}_{m_1, \ldots, m_n}^k$, and $x \in A_{s_1, \ldots, s_k}$. Since $x \in E_k$ for all $k$, there is for every $k$ an $s_1$ for which $(s_1)$ is extendible to $k$. Since there are only finitely many $s_1 \leq m_1$, there is an $s_1$ such that $(s_1)$ is extendible to arbitrarily large $k$. Similarly, for this $s_1$ there is an $s_2$ such that $(s_1, s_2)$ is extendible to arbitrarily large $k$. Continuing inductively, a sequence $s = (s_1, s_2, \ldots)$ is generated such that $x \in A_{s[n]}$ for all $n$, i.e. $x \in \cap_n A_{s[n]} \subseteq A$.

This completes the proof of (ii), and of (i) if $\mu^*$ is monotone regular.
For (i) in the case of general $\mu^*$, let $A, Y, Z$ be as above. Form the outer measure $\mu^*_W$, where $W = Y \cup Z$. Then every set in $\mathcal{M}$ is $\mu^*_W$-measurable. We also have that $\mu^*_W(X \setminus W) = 0$, hence $X \setminus W$ and also $W$ are $\mu^*_W$-measurable. Let $\iota$ be the restriction of $\mu^*_W$ to the $\mu^*_W$-measurable sets, and $\nu^*$ the outer measure on $X$ induced by $\iota$. Then $\nu^*$ is a regular outer measure, hence monotone regular (XIII.3.5.18.), and every $\mu^*_W$-measurable set is $\nu^*$-measurable (XIII.3.5.21.); in particular, $W$ and all sets in $\mathcal{M}$ are $\nu^*$-measurable. So

$$\nu^*(W) = \iota(W) = \mu^*_W(W) = \mu(W).$$

We also have $\nu^*(S) \geq \mu^*_W(S)$ for all $S \subseteq X$ (XIII.3.5.21.); in particular, $\nu^*(Y) \geq \mu^*_W(Y) = \mu^*(Y)$ and $\nu^*(Z) \geq \mu^*_W(Z) = \mu^*(Z)$. By the first part of the proof, $A$ is $\nu^*$-measurable, so

$$\mu^*(Y \cup Z) = \mu^*(W) = \nu^*(W) = \nu^*(W \cap A) + \nu^*(W \cap A^c) = \nu^*(Y) + \nu^*(Z) \geq \mu^*(Y) + \mu^*(Z)$$

and it follows that $A$ is $\mu^*$-measurable.

This completes the proof of XIII.3.6.7.

---

XIII.3.7. Radon Measures on $\mathbb{R}$

XIII.3.8. Lebesgue Measure and Radon Measures on $\mathbb{R}^n$

XIII.3.9. Nonmeasurable Subsets of $\mathbb{R}$

An interesting and rather subtle question is whether every subset of $\mathbb{R}$ is Lebesgue measurable. Using the Axiom of Choice, we construct a family of nonmeasurable subsets. This construction is due to Vitali.

**XIII.3.9.1.** Define a relation $R$ on $\mathbb{R}$ by $xRy$ if $y - x \in \mathbb{Q}$. It is easily checked that $R$ is an equivalence relation. If $a \in \mathbb{R}$, then the equivalence class of $a$ is

$$[a] = a + \mathbb{Q} = \{a + q : q \in \mathbb{Q}\}.$$

Thus the equivalence classes are countable and dense. (They are exactly the cosets of $\mathbb{Q}$ in the additive group $\mathbb{R}$.) As for any equivalence relation, the equivalence classes are pairwise disjoint and their union is $\mathbb{R}$.

**XIII.3.9.2.** **Definition.** (AC) Let $P$ be a subset of $(0, 1)$ which contains exactly one element of each equivalence class of $R$. If $q \in \mathbb{Q}$, set $P_q = P + q$.

Since each equivalence class is dense, it has nonempty intersection with $(0, 1)$. The existence of such a set $P$ is then guaranteed by the Axiom of Choice. (Any other actual interval could be used in place of $(0, 1)$.)

**XIII.3.9.3.** **Proposition.** The sets $\{P_q : q \in \mathbb{Q}\}$ are pairwise disjoint, and $\cup_{q \in \mathbb{Q}} P_q = \mathbb{R}$.

**Proof:** If $x \in (P + q_1) \cap (P + q_2)$, then $x = p_1 + q_1 = p_2 + q_2$ for $p_1, p_2 \in P$. Then $p_2 - p_1 = q_1 - q_2 \in \mathbb{Q}$, so $p_1 R p_2$ and hence $p_1 = p_2$ since $P$ contains only one element from any equivalence class. Thus also $q_1 = q_2$. If $x \in \mathbb{R}$, then $xRp$ for some $p \in P$. Set $q = x - p \in \mathbb{Q}$; then $x = p + q \in P_q$.

Now let $J = \mathbb{Q} \cap (-1, 1)$, and set $N = \cup_{q \in J} P_q$. 1436
XIII.3.9.4. Proposition. We have \((0,1) \subseteq N \subseteq (-1,2)\). Thus \(1 \leq \lambda^*(N) \leq 3\).

Proof: Since \(P \subseteq (0,1)\), it is obvious that \(P_q \subseteq (-1,2)\) for any \(q \in J\). For the other containment, let \(x \in (0,1)\). Then \(x = p + q\) for some \(p \in P\), \(q \in \mathbb{Q}\) by XIII.3.9.3.. Then \(q = x - p \in (-1,1)\), so \(x \in N\). \(\Diamond\)

XIII.3.9.5. Theorem. \(P\) is not Lebesgue measurable.

Proof: Suppose \(P\) is measurable. Then \(P_q\) is measurable for all \(q\), and \(\lambda(P_q) = \lambda(P)\); so \(N\) is measurable. If \(\lambda(P) = 0\), then \(\lambda(N) = \sum_{q \in J} \lambda(P_q) = 0\), contradicting XIII.3.9.4.. And if \(\lambda(P) > 0\), then \(\lambda(N) = \sum_{q \in J} \lambda(P_q) = \infty\) since \(J\) is infinite, again contradicting XIII.3.9.4..

In fact, we can do better:

XIII.3.9.6. Proposition. If \(A\) is a Lebesgue measurable subset of \(P\), then \(\lambda(A) = 0\).

Proof: Let \(B = \bigcup_{q \in J} (A + q)\). The sets \(A + q\) are pairwise disjoint since \(A \subseteq P\). Since \(\lambda(A + q) = \lambda(A)\) for all \(q\), and \(J\) is infinite, we would have \(\lambda(B) = \infty\) if \(\lambda(A) > 0\). But \(B \subseteq N \subseteq (-1,2)\), so \(\lambda(B) \leq 3\). Thus we must have \(\lambda(A) = 0\) (and hence \(\lambda(B) = 0\)). \(\Diamond\)

XIII.3.9.7. Theorem. (AC) Let \(Y \subseteq \mathbb{R}\). If \(\lambda^*(Y) > 0\), then \(Y\) contains a subset which is not Lebesgue measurable.

Proof: For \(q \in \mathbb{Q}\), let \(Y_q = Y \cap P_q\). Then the \(Y_q\) are pairwise disjoint and \(Y = \bigcup_{q \in \mathbb{Q}} Y_q\) by XIII.3.9.3.. If \(Y_q\) is measurable, then \(\lambda(Y_q) = 0\) by XIII.3.9.6.. Thus, if all the \(Y_q\) are measurable, then \(\lambda^*(Y) \leq \sum_{q \in \mathbb{Q}} \lambda^*(Y_q) = 0\). \(\Diamond\)

This result is only interesting if \(Y\) is Lebesgue measurable, since it is trivial otherwise. The important consequence is that every measurable set of positive measure contains a nonmeasurable subset.

There is an interesting corollary for Lebesgue measurable functions:

XIII.3.9.8. Theorem. (AC) The inverse image of a Lebesgue measurable set under a Lebesgue measurable function is not necessarily Lebesgue measurable. In fact, there is a strictly increasing continuous function (homeomorphism) \(f: \mathbb{R} \to \mathbb{R}\) and a measurable subset \(A \subseteq \mathbb{R}\) such that \(f^{-1}(A)\) is not Lebesgue measurable.

Proof: Let \(K\) be the Cantor set, and \(K_\alpha\) the generalized Cantor set of positive measure from (). There is a strictly increasing continuous function \(f: \mathbb{R} \to \mathbb{R}\) with \(f(K_\alpha) = K\). By XIII.3.9.7., there is a nonmeasurable subset \(B\) of \(K_\alpha\). Let \(A = f(B)\); since \(A \subseteq K\) and \(\lambda(K) = 0\), \(A\) is measurable and \(\lambda(A) = 0\). But \(B = f^{-1}(A)\) is nonmeasurable. \(\Diamond\)

1437
XIII.3.9.9. So homeomorphisms of \( \mathbb{R} \) do not necessarily preserve Lebesgue measurability, i.e. Lebesgue measurability of subsets of \( \mathbb{R} \) is not a topological property, although it is a metric property (in fact, see (\).

Note that the property of being a Borel set is a topological property.

XIII.3.9.10. The Axiom of Choice was used in an essential way in the definition of \( P \), so all results of this subsection depend on AC. In fact, R. Solovay showed \([]\) that (assuming that the existence of an inaccessible cardinal is consistent with ZFC; cf. (\)) the existence of a nonmeasurable subset of \( \mathbb{R} \) cannot be proved in ZF, i.e. it is consistent with ZF to assume that every subset of \( \mathbb{R} \) is Lebesgue measurable. Specifically, he showed that if an inaccessible cardinal exists, then there is a model for ZF in which every subset of \( \mathbb{R} \) is Lebesgue measurable; this model satisfies DC, but of course not AC. Thus even ZF+DC is not sufficient to prove the existence of a subset of \( \mathbb{R} \) which is not Lebesgue measurable.

But the full Axiom of Choice is not needed to obtain a set which is not Lebesgue measurable. The argument only requires a choice function for the set of cosets of \( \mathbb{Q} \) in \( \mathbb{R} \), hence existence of a choice function for \( \mathcal{P}(\mathbb{R}) \) suffices, which will be automatic if \( \mathbb{R} \) can be well ordered. Thus the Continuum Hypothesis is sufficient (but not necessary) to obtain Vitali’s example (\). For another example of a Lebesgue nonmeasurable set based on the CH, see XIV.6.3.1.\(]\).

Actually, assuming AC and some weak version of the CH, there is no finite continuous measure at all on \((\{0,1\}, \mathcal{P}([0,1]))\). See (\) for a discussion. It is also known that ZF+(Hahn-Banach Theorem) suffices to prove existence of a Lebesgue nonmeasurable set \([\]\), and the Hahn-Banach Theorem is strictly weaker than the Axiom of Choice (\).

Bernstein’s Nonmeasurable Set

There is another construction of a nonmeasurable subset of \( \mathbb{R} \), due to F. Bernstein. This construction uses more machinery than Vitali’s, but works in great generality.

XIII.3.9.11. The general setting is an outer measure \( \mu^* \) on a set \( X \), for which there is a collection \( \mathcal{C} = \{C_i : i \in I\} \) of subsets of \( X \), with the following properties:

(i) \( |I| \leq 2^{\aleph_0} \).

(ii) \( |C_i| = 2^{\aleph_0} \) for all \( i \).

(iii) \( \mu^*(C_i) > 0 \) for all \( i \).

(iv) If \( A \) is any \( \mu^* \)-measurable subset of \( X \) with \( \mu^*(A) > 0 \), then \( C_i \subseteq A \) for some \( i \).

Actually, \( 2^{\aleph_0} \) can be replaced by any other infinite cardinal here; the case of \( 2^{\aleph_0} \) is just the important one for applications.

XIII.3.9.12. Lebesgue outer measure on \( \mathbb{R} \) has such a \( \mathcal{C} \): the collection of closed subsets of \( \mathbb{R} \) with positive Lebesgue measure. There are \( 2^{\aleph_0} \) closed subsets of \( \mathbb{R} \) in all (\) (and \( 2^{\aleph_0} \) closed intervals, each of positive measure). Each closed set of positive measure is uncountable, hence has cardinality \( 2^{\aleph_0} \) by (\). Condition (iv) is satisfied by XIII.3.4.5..
XIII.3.9.13. Theorem. Let $\mu^*$ be an outer measure on a set $X$ for which there is a $\mathcal{C}$ satisfying (i)–(iv). If $Y$ is any subset of $X$ with $\mu^*(Y) > 0$, there is a subset of $Y$ which is not $\mu^*$-measurable.

Proof: Put a well ordering on $I$ such that the set of predecessors of any $i \in I$ has cardinality strictly less than $2^{80}$ (the Axiom of Choice guarantees that this can be done, by putting $I$ in one-one correspondence with the cardinal $\text{card}(I)$). Inductively choose for each $i$ two distinct elements $x_i$ and $y_i$ of $C_i$ such that $x_i$ and $y_i$ are also distinct from the set $\{x_j, y_j : j < i\}$; this is possible since the cardinality of this set is strictly smaller than the cardinality of $C_i$. Let $A = \{x_i : i \in I\}$.

Let $Y \subseteq X$ with $\mu^*(Y) > 0$. To show that $Y$ contains a subset which is not $\mu^*$-measurable, we may assume that $Y$ is $\mu^*$-measurable (since otherwise $Y$ itself is the desired subset). We claim $A \cap Y$ is not $\mu^*$-measurable. If $A \cap Y$ (and hence also $Y \setminus A$) is $\mu^*$-measurable, we cannot have $\mu^*(A \cap Y) > 0$, since then $C_i \subseteq (A \cap Y)$ for some $i$; but $y_i \in C_i \setminus A$, a contradiction. Thus $\mu^*(A \cap Y) = 0$. Similarly, we cannot have $\mu^*(Y \setminus A) > 0$, so $\mu^*(Y \setminus A) = 0$. But then $\mu^*(Y) = \mu^*(A \cap Y) + \mu^*(Y \setminus A) = 0$, contradicting the assumption that $\mu^*(Y) > 0$.

Note that AC is used twice: well ordering $I$ and choosing the $x_i$ and $y_i$.

XIII.3.9.14. This result applies more generally to any purely nonatomic Borel regular Borel outer measure on a Polish space, whose restriction to the Borel sets is $\sigma$-finite: an infinite Polish space has $2^{80}$ Borel sets ($\mathcal{B}$), and an uncountable Borel set in a Polish space has cardinality $2^{80}$ ($\mathcal{B}$). Compare with XI.13.9.14.

XIII.3.10. Exercises

(a) There is a sequence $(S_i)$ of pairwise disjoint Borel subsets of $[1, \infty)$, each of infinite Lebesgue measure. [Let $(N_i)$ be a sequence of pairwise disjoint infinite subsets of $N$, e.g. by identifying $N$ with $\mathbb{N} \times \mathbb{N}$. Let $S_i = \cup_{n \in N_i} [n, n + 1]$.

(b) Let $\mathcal{F}$ be the set of finite subsets of $\mathbb{N}$. $\mathcal{F}$ is countable; let $i$ be a bijection from $\mathcal{F}$ to $\mathbb{N}$.

(c) Arrange the bounded open intervals in $\mathbb{R}$ with rational endpoints into a sequence $(J_n)$, with each interval appearing infinitely often in the sequence.

(d) For each $n$, let

$$A_n = J_n \cup \left[ \bigcup_{n \in F} S_i(F) \cap [n, \infty) \right]$$

(i.e. the union runs over all sets $F \in \mathcal{F}$ with $n \in F$) and let $\mathcal{S}$ be the set of finite intersections of the $A_n$ and their complements. Then $\mathcal{S}$ is a semi-algebra ($\mathcal{A}$). Show that every nonempty set in $\mathcal{S}$ has infinite Lebesgue measure. [If $E = A_{n_1} \cap \cdots \cap A_{n_k} \cap A_{m_1} \cap \cdots \cap A_{m_l}$, if $n_i = m_j$ for some $i, j$, then $E = \emptyset$, and otherwise $S_{i=(n_1, ..., n_k)} \cap [p, \infty] \subseteq E$, where $p = \max\{n_1, ..., n_k\}$. Note that $S_i \cap [p, \infty]$ has infinite Lebesgue measure for every $i$ and $p$.]

If $\mathcal{A}$ is the algebra generated by $\mathcal{S}$, then $\mathcal{A}$ consists of finite disjoint unions of sets in $\mathcal{S}$ ($\mathcal{A}$), and hence every nonempty set in $\mathcal{A}$ has infinite Lebesgue measure.

(e) If $J$ is a bounded open interval with rational endpoints, then there is an infinite sequence $(n_k)$ such that $J_{n_k} = J$ for all $k$. Then $\bigcap_{k=1}^{\infty} A_{n_k} = J$. Thus $J$ is in the $\sigma$-algebra generated by $\mathcal{S}$ ($\mathcal{B}$). Since such intervals generate $\mathcal{B}$ as a $\sigma$-algebra, the $\sigma$-algebra generated by $\mathcal{S}$ ($\mathcal{A}$) is $\mathcal{B}$.

(f) The restriction of $\lambda$ to $\mathcal{S}$ ($\mathcal{A}$) is not $\sigma$-finite, and $\lambda$ is not the measure induced on $\mathcal{B}$ from $\lambda|_{\mathcal{S}}$ or $\lambda|_{\mathcal{A}}$ by the Carathéodory extension process.
(g) If \((X, \mathcal{B}, \mu)\) is a measure space with \(\mu(X) = \infty\), is there always an algebra \(\mathcal{A}\) in \(\mathcal{B}\) which generates \(\mathcal{B}\) as a \(\sigma\)-algebra, with the property that \(\mu(A) = \infty\) for every nonempty \(A \in \mathcal{A}\)?

**XIII.3.10.2.** Let \(X = \{x_1, x_2, x_3\}\) be a set with three elements. If \(A \subseteq X\), let \(\mu^*(A) = 0\) if \(A = \emptyset\), \(\mu^*(A) = 1\) if \(|A| = 1\) or if \(|A| = 2\), and \(\mu^*(A) = 2\) if \(|A| = 3\).

(a) Show that \(\mu^*\) is an outer measure on \(X\) which is not regular.

(b) If \(A = \{x_1, x_2\}\), show that \(\mu^*(A) + \mu^*(X \setminus A) = \mu^*(X)\), but \(A\) is not \(\mu^*\)-measurable. [Consider \(Y = \{x_1, x_3\}\).]

**XIII.3.10.3.** Prove the following generalization of (a). Let \(\mu^*\) be an outer measure on a set \(X\), and \(\mathcal{M}\) the \(\sigma\)-algebra of \(\mu^*\)-measurable sets.

(a) If \((A_n)\) is a pairwise disjoint sequence of sets in \(\mathcal{M}\) with \(A = \bigcup_{n=1}^{\infty} A_n\), and \(Y\) is any subset of \(X\), then \(\mu^*(Y \cap A) = \sum_{n=1}^{\infty} \mu^*(Y \cap A_n)\).

(b) If \(B_1 \subseteq B_2 \subseteq \cdots\) is an increasing sequence in \(\mathcal{M}\) with \(B = \bigcup_{n=1}^{\infty} B_n\), and \(Y\) is any subset of \(X\), then \(\mu^*(Y \cap B) = \sup_n \mu^*(Y \cap B_n)\).

(c) If \(C_1 \supseteq C_2 \supseteq \cdots\) is a decreasing sequence in \(\mathcal{M}\) with \(C = \bigcap_{n=1}^{\infty} C_n\), and \(Y\) is any subset of \(X\) with \(\mu^*(Y \cap C_1) < \infty\), then \(\mu^*(Y \cap C) = \inf_n \mu^*(Y \cap C_n)\).

**XIII.3.10.4.** If \(\mu^*\) is an outer measure on \(X\) and \(A, Y \subseteq X\) with \(A\) \(\mu^*\)-measurable, show that
\[
\mu^*(A \cup Y) + \mu^*(A \cap Y) = \mu^*(A) + \mu^*(Y) .
\]

**XIII.3.10.5.** Let \(\mu^*\) be a regular outer measure on a set \(X\). If \(A, B \subseteq X\) with \(A \cup B\) \(\mu^*\)-measurable and \(\mu^*(A \cup B) = \mu^*(A) + \mu^*(B) < \infty\), show that \(A\) and \(B\) are \(\mu^*\)-measurable.

**XIII.3.10.6.** Let \(X\) and \(Y\) be sets, \(f : X \to Y\) a function, and \(\mu^*\) an outer measure on \(X\). For \(B \subseteq Y\), set \(\nu^* = \mu^* \circ (f^{-1})\). Show that \(\nu^*\) is an outer measure on \(Y\). This outer measure is usually denoted \(f_*(\mu^*)\).

**XIII.3.10.7.** Let \(\{\mu^*_i\}\) be a collection of outer measures on a set \(X\), and let \(\mu^* = \sup \mu^*_i\). Show that \(\mu^*\) is an outer measure.

**XIII.3.10.8.** Let \(X = (0, 2], \mathcal{A} = \{\emptyset, [0, 1], (1, 2], (0, 2]\}\). Let \(\mu\) be the restriction of Lebesgue measure to \(\mathcal{A}\), and \(\mu^*\) the induced outer measure on \(X\).

(a) Describe \(\mu^*(Y)\) for a general \(Y \subseteq X\), and compare it to \(\lambda^*(Y)\). Find the \(\sigma\)-algebra of \(\mu^*\)-measurable subsets of \(X\).

(b) Show that \((X, \mathcal{A}, \mu)\) is a finite complete measure space, but that \(\mu\) extends to a measure (e.g. \(\lambda\)) on a strictly larger \(\sigma\)-algebra. Show that \(\lambda^*\) is not \(\mathcal{A}\)-regular.

**XIII.3.10.9.** Let \(\mathcal{U}\) be the collection of open sets in \(\mathbb{R}^n\), and let \(\mathcal{Q}\) be the set of bounded open intervals with rational endpoints. Show that \(\mathcal{S}(\mathcal{U}) = \mathcal{S}(\mathcal{Q})\) and that this collection of sets is the same as \(\mathcal{S}(\mathcal{K}), \mathcal{S}(\mathcal{F})\), and \(\mathcal{S}(\mathcal{B})\) of XIII.3.6.6. These sets are usually just called the Suslin subsets of \(\mathbb{R}^n\).
XIII.3.10.10. Show that the collection $S(Q)$ of Suslin subsets of $\mathbb{R}^n$ (Exercise XIII.3.10.9.) has cardinality $2^{\aleph_0}$. [Show that there are exactly $2^{\aleph_0}$ Suslin schemes in $Q$.] Since $B \subseteq S(Q)$, this gives a cleaner proof than ( ) that $B$ has cardinality $2^{\aleph_0}$.

XIII.3.10.11. Let $E$ be a nonempty collection of subsets of a set $X$.

(a) If $A = S(E) \cap \widehat{S(E)}$ is nonempty, it is a $\sigma$-algebra and the largest $\sigma$-algebra contained in $S(E)$ (cf. XII.1.5.2.).

(b) Show that $S(E) \cap \widehat{S(E)}$ can be empty.

In probability, $P$ is usually used for a measure instead of $\mu$. Thus $P(E)$ is the probability (measure) of $E$, and $E(X) = \int X \, dP$ is the expectation (integral) of $X$. 
XIII.4. Measures on Metric Spaces

Many important outer measures (e.g. Lebesgue outer measure) are defined on metric spaces, and behave nicely relative to the topology of the space.

XIII.4.1. Metric Outer Measures and Borel Measures

XIII.4.1.1. Definition. Let \((X, \rho)\) be a metric space, and let \(\mu^*\) be an outer measure on \(X\). The outer measure \(\mu^*\) is a metric outer measure on \(X\) (with respect to \(\rho\)) if, whenever \(A, B \subseteq X\) and \(\rho(A, B) > 0\), we have \(\mu^*(A \cup B) = \mu^*(A) + \mu^*(B)\).

XIII.4.1.2. Example. By Exercise (), Lebesgue outer measure is a metric outer measure on \(\mathbb{R}\) with the usual metric.

XIII.4.1.3. Proposition. Let \((X, \rho)\) be a metric space, and \(\mu^*\) an outer measure on \(X\) for which every closed set is \(\mu^*\)-measurable. Then \(\mu^*\) is a metric outer measure.

Proof: If \(A, B \subseteq X\) with \(\rho(A, B) > 0\), then \(B \cap \bar{A} = \emptyset\). Since \(\bar{A}\) is closed, we have

\[
\mu^*(A \cup B) = \mu^*((A \cup B) \cap \bar{A}) + \mu^*((A \cup B) \cap (\bar{A})^c) = \mu^*(A) + \mu^*(B) .
\]

The main theorem of this subsection is the converse:

XIII.4.1.4. Theorem. Let \((X, \rho)\) be a metric space, and \(\mu^*\) a metric outer measure on \(X\) with respect to \(\rho\). Then every Borel set in \(X\) is \(\mu^*\)-measurable.

Proof: Since the collection of \(\mu^*\)-measurable sets is a \(\sigma\)-algebra, it suffices to show that every closed set \(F\) in \(X\) is \(\mu^*\)-measurable. Fix \(E \subseteq X\) with \(\mu^*(E) < \infty\), and let \(A = E \cap F\), \(B = E \cap F^c\). It suffices to show that \(\mu^*(E) \geq \mu^*(A) + \mu^*(B)\).

For \(n \in \mathbb{N}\), set

\[
B_n = \left\{ x \in B : \rho(x, F) \geq \frac{1}{n} \right\} .
\]

We have \(B = \bigcup_{n=1}^\infty B_n\) since \(F\) is closed; and we have \(\mu^*(A \cup B_n) = \mu^*(A) + \mu^*(B_n)\) for each \(n\) since \(\mu^*\) is a metric outer measure.

If \(\mu^*\) were known to be monotone regular, the proof would be trivial:

\[
\mu^*(E) = \mu^*(A \cup B) = \sup_n \mu^*(A \cup B_n) = \sup_n \left[ \mu^*(A) + \mu^*(B_n) \right] = \mu^*(A) + \sup_n \mu^*(B_n) = \mu^*(A) + \mu^*(B) .
\]

In general, we must show that \(\mu^*\) has enough vestiges of monotone regularity to get the conclusion.
For each \( n \) let \( D_n = B_{n+1} \setminus B_n \). We have \( \rho(D_{n+1}, B_n) \geq \frac{1}{n} - \frac{1}{n+1} = \frac{1}{n(n+1)} \) by the triangle inequality, and thus \( \mu^*(B_n \cup D_{n+1}) = \mu^*(B_n) + \mu^*(D_{n+1}) \) for all \( n \); since \( B_n \cup D_{n+1} \subseteq B_{n+2} \), we have \( \mu^*(B_n) + \mu^*(D_{n+1}) \leq \mu^*(B_{n+2}) \) for all \( n \) (this also holds for \( n = 0 \) if we set \( B_0 = \emptyset \)). Inductively, we get

\[
\sum_{k=1}^{n} \mu^*(D_{2k-1}) \leq \mu^*(B_{2n}) \leq \mu^*(E) < \infty 
\]

for all \( n \). Similarly,

\[
\sum_{k=1}^{n} \mu^*(D_{2k}) \leq \mu^*(B_{2n+1}) \leq \mu^*(E) < \infty 
\]

for all \( n \). Thus \( \sum_{k=1}^{\infty} \mu^*(D_k) \) converges; hence, for any \( \epsilon > 0 \) there is an \( n \) such that \( \sum_{k=1}^{\infty} \mu^*(D_k) < \epsilon \). By countable subadditivity we then have for this \( n \) that

\[
\mu^*(B) \leq \mu^*(B_n) + \sum_{k=n+1}^{\infty} \mu^*(D_k) < \mu^*(B_n) + \epsilon 
\]

Thus \( \mu^*(B) = \sup_n \mu^*(B_n) \). We then have

\[
\mu^*(E) \geq \sup_n \mu^*(A \cup B_n) = \sup_n [\mu^*(A) + \mu^*(B_n)] = \mu^*(A) + \sup_n \mu^*(B_n) = \mu^*(A) + \mu^*(B) 
\]

Borel Measures

**XIII.4.1.5.** DEFINITION. Let \( X \) be a topological space. A Borel measure on \( X \) is a measure on \((X, B)\), where \( B \) is the \( \sigma \)-algebra of Borel subsets of \( X \).

**XIII.4.1.6.** Suppose \( X \) is a metrizable topological space, and \( \rho \) is a metric on \( X \) giving the topology. If \( \mu^* \) is an outer measure on \( X \) which is a metric outer measure with respect to \( \rho \), then \( \mu^* \) defines a Borel measure on \( X \) by **XIII.4.1.4.** Conversely, a Borel measure \( \mu \) on \( X \) defines a (regular) outer measure \( \mu^* \) on \( X \) by (), which is a metric outer measure for \( \rho \) by **XIII.4.1.3.** Thus every Borel measure arises this way from a (regular) metric outer measure.

**XIII.4.2.** Method II Construction of Outer Measures

The standard construction of an outer measure from a set function (e.g., a premeasure) described in () is sometimes called the Method I construction, particularly in Geometric Measure Theory. On a metric space, there is another construction of outer measures which is more roundabout, but gives interesting examples such as Hausdorff measures.

It is customary in Geometric Measure Theory to use upper-case script letters such as \( \mathcal{M} \) to denote outer measures. (The reader is also cautioned that in much of the literature for Geometric Measure Theory, an outer measure is called a “measure.” The outer measures of Geometric Measure Theory are typically metric outer measures and are applied only to Borel sets, where they are indeed countably additive.)

Method II uses covers of sets which are “fine” in the sense that every point is contained in a set in the cover of arbitrarily small diameter:

1443
XIII.4.2.1. Definition. Let \((X, \rho)\) be a metric space, and \(E \subseteq X\). A Vitali cover of \(E\) is a collection \(\mathcal{V}\) of subsets of \(X\) such that, for every \(x \in E\) and \(\epsilon > 0\), there is a \(V \in \mathcal{V}\) with \(x \in V\) and \(\text{diam}(V) < \epsilon\).

XIII.4.2.2. The notion of Vitali cover depends on \(\rho\). It is easily checked that if \(\sigma\) is another metric on \(X\) uniformly equivalent to \(\rho\), then a collection \(\mathcal{V}\) of subsets of \(X\) is a Vitali cover for \(E\) with respect to \(\rho\) if and only if it is a Vitali cover with respect to \(\sigma\). However, this is not necessarily true if \(\rho\) and \(\sigma\) are just equivalent. To denote the dependence on \(\rho\) where necessary, we will use the terminology "\(\rho\)-Vitali cover."

XIII.4.2.3. The sets in a Vitali cover are not required to be of any particular form. But note that if \(\mathcal{V}\) is a Vitali cover of \(E\), then

\[
\widehat{\mathcal{V}} = \{ \widehat{V} : V \in \mathcal{V} \}
\]

is a Vitali cover of \(E\) consisting of closed sets. Thus we may work with Vitali covers consisting of closed sets, which is often convenient.

XIII.4.2.4. Examples. (i) The power set of \(X\) is a Vitali cover of any subset of \(X\).
(ii) The collection of open balls in \((X, \rho)\) is a Vitali cover of any subset \(E\) of \(X\).
(iii) The collection of closed balls in \((X, \rho)\) is a Vitali cover of any subset \(E\) of \(X\).
(iv) In (ii) and (iii), we may restrict to balls of rational radius and/or with centers in \(E\).
(v) If \(\mathcal{V}\) is a Vitali cover of \(E\) and \(\delta > 0\), then

\[
\mathcal{V}_\delta = \{ V \in \mathcal{V} : \text{diam}(V) < \delta \}
\]

are also Vitali covers of \(E\).
(vi) A Vitali cover of \(E\) is also a Vitali cover of any subset of \(E\). In particular, a Vitali cover of \(X\) is a Vitali cover of any subset of \(X\).

XIII.4.2.5. Fix a metric space \((X, \rho)\) and a Vitali cover \(\mathcal{V}\) of \(X\). We may assume \(\emptyset \in \mathcal{V}\). Let \(\iota\) be a function from \(\mathcal{V}\) to \([0, +\infty]\) with \(\iota(\emptyset) = 0\). For any \(\delta > 0\), define \(\mathcal{M}_\delta^\iota\) to be the outer measure on \(X\) defined by the restriction of \(\iota\) to \(\mathcal{V}_\delta\) (XIII.4.2.4.(v)) as in (i), i.e. for \(E \subseteq X\) define

\[
\mathcal{M}_\delta^\iota(E) = \inf \left\{ \sum_{k=1}^{\infty} \iota(V_k) : E \subseteq \bigcup_{k=1}^{\infty} V_k, V_k \in \mathcal{V}, \text{diam}(V_k) < \delta \right\}
\]

(with \(\mathcal{M}_\delta^\iota(E) = +\infty\) if there are no countable covers of \(E\) by sets in \(\mathcal{V}_\delta\)). As usual, since \(\emptyset \in \mathcal{V}\) and \(\iota(\emptyset) = 0\), finite as well as countably infinite covers are allowed in computing \(\mathcal{M}_\delta^\iota\).

As \(\delta\) decreases, there are fewer such covers, so \(\mathcal{M}_\delta^\iota\) increases. Define

\[
\mathcal{M}^\iota = \sup_{\delta > 0} \mathcal{M}_\delta^\iota
\]

and note that \(\mathcal{M}^\iota\) is an outer measure by (i). \(\mathcal{M}^\iota\) is called the outer measure defined by \(\mathcal{V}\) and \(\iota\) by Method II.

The outer measure \(\mathcal{M}^\iota\) does depend on \(\mathcal{V}\) in general, but the standard notation does not reflect this since in reasonable cases (e.g. (i)) it is independent of \(\mathcal{V}\). It is most common to take \(\mathcal{V}\) to be the entire power set of \(X\).
XI.4.2.6. Use of a strict inequality in the diameters of the sets used is arbitrary. We could have also used the covers $\mathcal{V}_\delta$ to obtain outer measures $\mathcal{M}_\delta^\ast$, where

$$\mathcal{M}_\delta^\ast(E) = \inf \left\{ \sum_{k=1}^{\infty} \iota(V_k) : E \subseteq \bigcup_{k=1}^{\infty} V_k, V_k \in \mathcal{V}, diam(V_k) \leq \delta \right\}$$

and then obtained

$$\mathcal{M}^\ast = \sup_{\delta>0} \mathcal{M}_\delta^\ast$$

since we have

$$\mathcal{M}_\delta^\ast(E) \leq \mathcal{M}_\delta^\ast(E) \leq \mathcal{M}_\delta^\ast(E)$$

for any $E$ and any $0 < \delta < \delta'$. 

XI.4.2.7. In the most commonly used special case where $\mathcal{V} = \mathcal{P}(X)$, we may also restrict to covers by closed sets:

$$\mathcal{M}_\delta^\ast(E) = \inf \left\{ \sum_{k=1}^{\infty} \iota(V_k) : E \subseteq \bigcup_{k=1}^{\infty} V_k, V_k \text{ closed}, diam(V_k) < \delta \right\}$$

since $diam(A) = diam(A)$ for any $A \subseteq X$. In some cases, one can also restrict to covers by open sets (cf. XIII.4.3.6.).

XI.4.2.8. It is the passage to the limit as $\delta \to 0$ which gives Method II outer measures some nice properties making them useful. The idea is very similar to the way arc length for curves is defined: short chords and a passage to a limit are necessary to truly give an appropriate notion of length for curves. See () for more on this.

The first example of a nice property of Method II outer measures is:

XI.4.2.9. Proposition. For any $\mathcal{V}$ and $\iota$, $\mathcal{M}^\ast$ is a metric outer measure.

Proof: Suppose $A, B \subseteq X$ and $\rho(A, B) > 0$. If $\delta < \frac{\rho(A, B)}{2}$, then covers of $A$ and $B$ by sets in $\mathcal{V}_\delta$ are disjoint, so any cover of $A \cup B$ by sets in $\mathcal{V}_\delta$ breaks into a disjoint union of a cover of $A$ and a cover of $B$, and every pair of covers of $A$ and $B$ arises this way. It follows that

$$\mathcal{M}_\delta^\ast(A \cup B) = \mathcal{M}_\delta^\ast(A) + \mathcal{M}_\delta^\ast(B)$$

by taking infima. Then taking supremum over such small $\delta$ gives

$$\mathcal{M}^\ast(A \cup B) = \mathcal{M}^\ast(A) + \mathcal{M}^\ast(B) .$$

XI.4.2.10. So by XIII.4.1.4., $\mathcal{M}^\ast$ defines a Borel measure on $X$, also denoted $\mathcal{M}^\ast$. 

1445
XIII.4.3. Hausdorff Measure

Perhaps the most important example of the Method II construction of outer measures is Hausdorff measure. Hausdorff measure is most commonly considered on \( \mathbb{R}^n \), but it can be equally well defined on any metric space. It gives a metric notion of “dimension” for subsets of the space, which need not be an integer. Actually, we will get a more refined and flexible notion of metric dimension than just a number.

We first consider a class of functions:

XIII.4.3.1. Definition. Let \( \mathcal{H} \) be the set of all nondecreasing, right continuous functions from \([0, +\infty]\) to \([0, +\infty]\). Let \( \mathcal{H}_0 \) be the set of functions \( h \in \mathcal{H} \) with \( h(0) = 0 \) (and hence \( \lim_{t \to 0^+} h(t) = 0 \)).

If \((X, \rho)\) is any metric space, we will define a Hausdorff measure on \((X, \rho)\) corresponding to each \( h \in \mathcal{H} \). (Unfortunately, there are many \( h \)'s in the standard notation for Hausdorff measure, which must be carefully distinguished; it will be impossible to stick to the recommendations of II.1.3.14. if standard notation is used.)

XIII.4.3.2. Definition. Let \((X, \rho)\) be a metric space, and \( h \in \mathcal{H} \). Define the Hausdorff measure \( \mathcal{H}^h \) on \( X \) by \( \mathcal{H}^h = \mathcal{M} \), the Method II outer measure on \( X \) using \( V = \mathcal{P}(X) \) and \( \iota(V) = h(\text{diam}(V)) \) (set \( \iota(\emptyset) = 0 \)). Thus \( \mathcal{H}^h = \sup_{\delta > 0} \mathcal{H}_\delta^h \), where for \( E \neq \emptyset \) we have

\[
\mathcal{H}_\delta^h(E) = \inf \left\{ \sum_{k=1}^{\infty} h(\text{diam}((V_k)) : E \subseteq \bigcup_{k=1}^{\infty} V_k, V_k \subseteq X, \text{diam}(V_k) < \delta \right\}
\]

(with \( \mathcal{H}_\delta^h(E) = +\infty \) if there are no countable covers of \( E \) by sets of diameter \( < \delta \)).

We will use the notation \( \mathcal{H}^h \) for both the outer measure and the associated Borel measure. When the dependence on the metric \( \rho \) is relevant, we will write \( \mathcal{H}_\rho^h \).

The most important case is when \( h \) is a power function:

XIII.4.3.3. Definition. Let \( s > 0 \). Then \( s \)-dimensional Hausdorff measure \( \mathcal{H}^{(s)} \) on a metric space \((X, \rho)\) is \( \mathcal{H}^h \), where \( h(t) = t^s \). In other words, \( \mathcal{H}^{(s)} = \sup_{\delta > 0} \mathcal{H}_\delta^{(s)} \), where \( E \neq \emptyset \) we have

\[
\mathcal{H}_\delta^{(s)}(E) = \inf \left\{ \sum_{k=1}^{\infty} (\text{diam}((V_k))^s : E \subseteq \bigcup_{k=1}^{\infty} V_k, V_k \subseteq X, \text{diam}(V_k) < \delta \right\}
\]

(with \( \mathcal{H}_\delta^{(s)}(E) = +\infty \) if there are no countable covers of \( E \) by sets of diameter \( < \delta \)).

We also define \( \mathcal{H}^{(0)} \) to be \( \mathcal{H}^h \), where \( h \) is the constant function 1.

XIII.4.3.4. Proposition. The measure \( \mathcal{H}^{(0)} \) is counting measure on \( X \).

Proof: Suppose \( E \) is a finite subset of \( X \) with \( n \) elements. If \( \delta \) is smaller than the minimum distance between distinct points of \( E \), any cover of \( E \) by sets of diameter \( < \delta \) must have at least \( n \) elements, so \( \mathcal{H}_\delta^{(0)}(E) = n \). A similar argument applies in the case where \( E \) is infinite: for any \( n \), we have \( \mathcal{H}_\delta^{(0)}(E) > n \) for sufficiently small \( \delta \).
In the definition of Hausdorff measure, we can also use the outer measures $H^h$, where

$$H^h(E) = \inf \left\{ \sum_{k=1}^{\infty} h(\text{diam}(V_k)) : E \subseteq \cup_{k=1}^{\infty} V_k, V_k \subseteq X, \text{diam}(V_k) \leq \delta \right\}$$

(cf. XIII.4.2.6.).

In computing $H^h(E)$, we may restrict to covers by closed sets by XIII.4.2.7. We may also use open covers (this is the place where right continuity of $h$ is used):

**Proposition.** Let $(X, \rho)$ be a metric space, $h \in \mathcal{H}$, and $\delta > 0$. Then

$$H^h(E) = \inf \left\{ \sum_{k=1}^{\infty} h(\text{diam}(V_k)) : E \subseteq \cup_{k=1}^{\infty} V_k, V_k \subseteq X \text{ open}, \text{diam}(V_k) < \delta \right\}$$

for any $E \subseteq X$.

**Proof:** We clearly have

$$H^h(E) \leq \inf \left\{ \sum_{k=1}^{\infty} h(\text{diam}(V_k)) : E \subseteq \cup_{k=1}^{\infty} V_k, V_k \subseteq X \text{ open}, \text{diam}(V_k) < \delta \right\}.$$

For the reverse inequality, there is nothing to prove if $H^h(E) = +\infty$, so assume $H^h(E) < +\infty$. Let $\epsilon > 0$, and fix a cover $\{V_k\}$ of $E$ with $\text{diam}(V_k) < \delta$ for all $k$ and

$$\sum_{k=1}^{\infty} h(\text{diam}(V_k)) < H^h(E) + \frac{\epsilon}{2}.$$

For each $k$, let $U_k$ be an open set containing $V_k$ such that $\text{diam}(U_k) < \delta$ and $h(\text{diam}(U_k)) \leq h(\text{diam}(V_k)) + \frac{\epsilon}{2k^r}$; $U_k$ can be taken to be $U_k = \{x \in X : \rho(x, V_k) < r\}$ for some sufficiently small $r > 0$, using the right continuity of $h$. Then

$$\sum_{k=1}^{\infty} h(\text{diam}(U_k)) \leq \sum_{k=1}^{\infty} h(\text{diam}(V_k)) + \frac{\epsilon}{2} < H^h(E) + \epsilon$$

and since $\epsilon > 0$ is arbitrary, we obtain the reverse inequality.

The Hausdorff measures $\mathcal{H}^h$, even the $s$-dimensional Hausdorff measures $\mathcal{H}^{(s)}$, depend strongly on the choice of metric. If $\sigma$ is uniformly equivalent to $\rho$, . . .
Many slight variations on Hausdorff measure are possible. One variation is to take $V$ to be the set of balls in $(X, \rho)$ (in metric spaces such as $\mathbb{R}^n$ where each closed ball is the closure of an open ball of the same diameter, it does not matter whether one uses open balls, closed balls, or arbitrary balls in between; note that in a general metric space the diameter of a ball of radius $r$ may be strictly smaller than $2r$). The measures made in the same way are sometimes called spherical measures and denoted $S^h$ or $S^{(s)}$.

The measure $S$ is not the same as $H^h$ since a set of diameter $d$ is not necessarily contained in a ball of diameter $d$ (cf. $();$ it is clearly contained in a ball of diameter $\leq 2d$). We have $H^h(E) \leq S^h(E)$ for any $h$ and $E$. For power functions we have $H^s(E) \leq S^s(E)$ for any $s$ and $E$.

Hausdorff Dimension

As $s$ increases, the Hausdorff measure $H^{(s)}(E)$ of a subset $E$ of a metric space $(X, \rho)$ jumps suddenly down from $+\infty$ to $0$. The critical value where this occurs is called the Hausdorff dimension of $E$. More generally, there are typically functions $h \in H$ whose rate of convergence to 0 describe the boundary between infinite and zero Hausdorff measure.

**Proposition.** Suppose $g, h \in H$ and $\lim_{t \to 0^+} \frac{g(t)}{h(t)} = 0$. Let $(X, \rho)$ be a metric space, and $E \subseteq X$.

(i) If $H^h(E) < +\infty$, then $H^g(E) = 0$.

(ii) If $H^g(E) > 0$, then $H^h(E) = +\infty$.

**Proof:** Statement (ii) is the contrapositive of (i). To prove (i), let $\epsilon > 0$, and choose $\eta > 0$ such that $g(t) \leq \frac{\epsilon}{H^h(E) + 1} h(t)$ for $t < \eta$. If $0 < \delta < \eta$, there is a cover $(V_k)$ of $E$ with $\text{diam}(V_k) < \delta$ for all $k$, such that

$$\sum_{k=1}^{\infty} h(\text{diam}(V_k)) < \frac{\epsilon}{H^h(E) + 1} \sum_{k=1}^{\infty} h(\text{diam}(V_k)) < \epsilon$$

and for this cover we have

$$\sum_{k=1}^{\infty} g(\text{diam}(V_k)) \leq \frac{\epsilon}{H^h(E) + 1} < \epsilon$$

so we have $H^g(E) < \epsilon$. Taking the supremum over such $\delta$, we have $H^g(E) \leq \epsilon$. Since $\epsilon > 0$ is arbitrary, $H^g(E) = 0$. $\Box$
XIII.4.3.11. Corollary. Let $0 \leq s < t$. Let $(X, \rho)$ be a metric space, and $E \subseteq X$. Then

(i) If $\mathcal{H}^s(E) < +\infty$, then $\mathcal{H}^t(E) = 0$.

(ii) If $\mathcal{H}^t(E) > 0$, then $\mathcal{H}^s(E) = +\infty$.

XIII.4.3.12. Corollary. Let $(X, \rho)$ be a metric space, and $E$ an infinite subset of $X$. Then

$$\sup\{s \geq 0 : \mathcal{H}^s(E) = \infty\} = \inf\{t > 0 : \mathcal{H}^t(E) = 0\}$$

(set $\inf(\emptyset) = +\infty$).

XIII.4.3.13. Definition. The common value in XIII.4.3.12. is called the Hausdorff dimension of $E$ in $(X, \rho)$, denoted $\dim_H(E)$. We also define the Hausdorff dimension of a finite set to be 0.

XIII.4.3.14. So the Hausdorff dimension of $E$ is the critical value $s$ where the Hausdorff measure $\mathcal{H}^s(E)$ jumps from $+\infty$ to 0. Examples show that if $s = \dim_H(E)$, then $\mathcal{H}^s(E)$ can be 0, $+\infty$, or any finite positive number.

XIII.4.3.15. If only power functions are considered, for a given $E$ there is an exact boundary between the functions $h$ for which $\mathcal{H}^h(E) = +\infty$ and the $h$ for which $\mathcal{H}^h(E) = 0$. But if all functions in $\mathcal{H}$ are considered, there is not such a clean boundary. Still, if there is an $h \in \mathcal{H}$ for which $0 < \mathcal{H}^h(E) < +\infty$, it can be considered a reasonable boundary: for any $g \in \mathcal{H}$ with $\lim_{t \to 0+} \frac{g(t)}{h(t)} = 0$, we have $\mathcal{H}^g(E) = 0$, and for any $g \in \mathcal{H}$ with $\lim_{t \to 0+} \frac{g(t)}{h(t)} = +\infty$, we have $\mathcal{H}^g(E) = +\infty$. Such an $h$ is not generally unique, however; but dividing $\mathcal{H}$ into those $h$ for which $\mathcal{H}^h(E) < +\infty$ and those $h$ for which $\mathcal{H}^h(E) = +\infty$ (or, almost equivalently, those $h$ for which $\mathcal{H}^h(E) = 0$ and those $h$ for which $\mathcal{H}^h(E) > 0$) is an illuminating partition.

XIII.4.3.16. Because of XIII.4.3.8., the same phenomenon works for spherical measures and gives the same $s$ as the transition point. Thus Hausdorff dimension can be calculated using spherical measures, i.e. covering with balls. For more general $h$ the phenomenon is not quite the same or so simple.

XIII.4.4. Hausdorff Measure on $\mathbb{R}^n$

XIII.4.4.1. Hausdorff measures and Hausdorff dimension were originally defined and studied for subsets of $\mathbb{R}^n$, and are still of most interest there.

Unfortunately, there is no consistency in references about the exact definition of Hausdorff measure in $\mathbb{R}^n$. It appears that most references define the measures in the same way up to a constant factor, which can vary from reference to reference. There are two predominant definitions used in the literature: the “unnormalized Hausdorff measure,” primarily used in the theory of fractals, and the “normalized Hausdorff measure,” primarily used in Geometric Measure Theory (only $s$-dimensional Hausdorff measure can be reasonably normalized, and usually only integer values of $s$ are used). The normalized version has nicer properties for most purposes in analysis, since it exactly coincides with Lebesgue measure and arc length/surface area/surface measure in appropriate dimensions. Thus we will concentrate on the normalized case. The
distinction is not important for many purposes: the crucial distinction is often simply whether a set has zero, infinite, or finite nonzero measure. For example, both versions give the same Hausdorff dimension for subsets of \( \mathbb{R}^n \).

**Unnormalized Hausdorff Measure**

**XIII.4.4.2.** **Definition.** Let \( h \in \mathcal{H} \). Unnormalized Hausdorff \( h \)-measure \( \mathcal{H}^h \) on \( \mathbb{R}^n \) is \( \mathcal{H}^h \) on \( \mathbb{R}^n \) with the usual Euclidean metric \( \rho_2 \). If \( 0 \leq s \), unnormalized \( s \)-dimensional Hausdorff measure \( \mathcal{H}^s \) on \( \mathbb{R}^n \) is \( \mathcal{H}^s \) for \( (\mathbb{R}^n, \rho_2) \).

As usual, we will use the same notation for the outer measure and the Borel measure.

**Normalized Hausdorff Measure**

**XIII.4.4.3.** **Definition.** If \( 0 \leq s \), normalized \( s \)-dimensional Hausdorff measure \( \mathcal{L}^s \) on \( \mathbb{R}^n \) is \( \mathcal{H}^s \) for \( (\mathbb{R}^n, \rho_2) \), where

\[
\alpha_s = \frac{\pi^{n/2}}{2^s \Gamma(\frac{n}{2} + 1)}
\]

is a normalizing constant (\( \Gamma \) is the Gamma function).)

**XIII.4.4.4.** If \( s \) is an integer, \( \alpha_s \) is the \( s \)-dimensional “volume” of a ball in \( \mathbb{R}^s \) of diameter 1 (radius \( 1/2 \)). Thus \( \alpha_1 = 1 \), \( \alpha_2 = \frac{\pi}{4} \), \( \alpha_3 = \frac{1}{8} \left( \frac{4}{3} \pi \right) = \frac{\pi}{6} \), etc.; see (n).

**XIII.4.4.5.** The notation \( \mathcal{L}^s \) for normalized Hausdorff measure is nonstandard; it is most commonly called \( \mathcal{H}^s \). But this notation is also used by some authors to mean unnormalized Hausdorff measure, which is consistent with its use in general metric spaces, so we use \( \mathcal{H}^s \) to mean unnormalized Hausdorff measure. We have chosen the notation \( \mathcal{L}^s \) for normalized Hausdorff measure since for appropriate \( s \) it coincides with usual Lebesgue measure or standard variants. Note that we do not define normalized Hausdorff measure for general \( h \in \mathcal{H} \).

**XIII.4.4.6.** Hausdorff measure on \( \mathbb{R}^n \) can be defined in other ways too. For example, in [7] it is defined using the metric \( \rho_\infty \). Hausdorff measure defined in this way is not a constant multiple of the usual Hausdorff measure in most cases, but it is an equivalent measure and gives the same theory of Hausdorff dimension, and is technically simpler in some respects.

**XIII.4.5. Hausdorff Measure and Hausdorff Dimension for Self-Similar Sets**

**XIII.4.6. Packing Measure and other Geometric Measures**

Hausdorff measure, or more precisely spherical measure (XIII.4.3.8.), which is equivalent and hence gives the same dimension, uses good coverings by balls. There is a “dual” notion which uses dense packings by disjoint balls, not surprisingly called packing measure. Packing measure is a much more recent development than Hausdorff measure, being defined by Tricot in 1982 [1].

The definition of packing measure involves yet another level of approximation:
XIII.4.6.1. **Definition.** Let \((X, \rho)\) be a metric space, and \(s \geq 0\). Let \(E \subseteq X\). For each \(\delta > 0\) set
\[
\mathcal{P}_\delta^{(s)}(E) = \sup \left\{ \sum_{k=1}^{\infty} (\text{diam}(B_k))^s \right\}
\]
where the supremum is over all sequences \((B_k)\) of pairwise disjoint open balls of radii \(\leq \delta\) with centers in \(E\) (empty balls are allowed, i.e. finite sequences of \(B_k\) are allowed). Set
\[
\mathcal{P}_0^{(s)}(E) = \inf_{\delta > 0} \mathcal{P}_\delta^{(s)}(E)
\]
(note that \(\mathcal{P}_\delta^{(s)}(E)\) decreases as \(\delta\) decreases) and
\[
\mathcal{P}^{(s)}(E) = \inf \left\{ \sum_{k=1}^{\infty} \mathcal{P}_0^{(s)}(E_k) : E \subseteq \bigcup_{k=1}^{\infty} E_k \right\}
\]
i.e. \(\mathcal{P}^{(s)}\) is the outer measure defined by the set function \(\mathcal{P}_0^{(s)}()\). \(\mathcal{P}^{(s)}\) is called \(s\)-dimensional packing measure on \((X, \rho)\).

XIII.4.6.2. Note that “packing measure” is actually an outer measure. But it is easily seen to be a metric outer measure, so all Borel sets are measurable and it is truly a measure on Borel sets. \(\mathcal{P}_\delta^{(s)}\) is an outer measure for any \(\delta > 0\), but \(\mathcal{P}_0^{(s)}\) is not an outer measure in general, so the last step is necessary even though it makes packing measure harder to compute.

A routine argument shows that disjoint closed balls can be used instead of disjoint open balls in the definition of packing measure, since the diameter of an open ball is the supremum of the diameters of the closed balls contained in it, and two open balls are disjoint if and only if all pairs of closed balls contained in them are disjoint.

It is also easily verified that \(\mathcal{P}^{(0)}\) is counting measure on \((X, \mathcal{P}(X))\).

XIII.4.6.3. **Proposition.** Let \((X, \rho)\) be a metric space, and \(s \geq 0\). Then \(\mathcal{H}^{(s)} \leq \mathcal{P}^{(s)}\) on \(X\). Thus \(\mathcal{H}^{(s)} \leq \mathcal{P}^{(s)}\) on \(X\).

Packing measure behaves in a similar way to Hausdorff measure as \(s\) varies:

XIII.4.6.4. **Proposition.** Let \(0 \leq s < t\). Let \((X, \rho)\) be a metric space, and \(E \subseteq X\). Then
(i) If \(\mathcal{P}^{(s)}(E) < +\infty\), then \(\mathcal{P}^{(t)}(E) = 0\).
(ii) If \(\mathcal{P}^{(t)}(E) > 0\), then \(\mathcal{P}^{(s)}(E) = +\infty\).

**Proof:** If \((B_k)\) is a sequence of pairwise disjoint balls of radius \(\leq \delta\) with centers in \(E\), then \(\sum_{k=1}^{\infty} (\text{diam}(B_k))^t \leq (2\delta)^{t-s} \sum_{k=1}^{\infty} (\text{diam}(B_k))^s\). Taking the infimum over all such sequences, we obtain \(\mathcal{P}^{(t)}(E) \leq (2\delta)^{t-s} \mathcal{P}^{(s)}(E)\). Taking the infimum over all \(\delta\), if \(\mathcal{P}_0^{(s)}(E) < +\infty\), then \(\mathcal{P}_0^{(t)}(E) = 0\). Now suppose \(\mathcal{P}^{(s)}(E) < +\infty\). Then
there is a sequence \((E_k)\) with \(E \subseteq \bigcup_{k=1}^{\infty} E_k\) and \(\sum_{k=1}^{\infty} \mathcal{P}_0^{(s)}(E_k) < +\infty\). Then \(\mathcal{P}_0^{(s)}(E_k) < +\infty\) for all \(k\), so \(\mathcal{P}_0^{(1)}(E_k) = 0\) for all \(k\), and thus
\[
\mathcal{P}^{(1)}(E) \leq \sum_{k=1}^{\infty} \mathcal{P}_0^{(1)}(E) = 0.
\]

Statement (ii) is the contrapositive of (i).

XIII.4.6.5. **COROLLARY.** Let \((X, \rho)\) be a metric space, and \(E\) an infinite subset of \(X\). Then
\[
\sup\{s \geq 0 : \mathcal{P}^{(s)}(E) = \infty\} = \inf\{t > 0 : \mathcal{P}^{(t)}(E) = 0\}
\]
(set \(\inf(\emptyset) = +\infty\)).

XIII.4.6.6. **DEFINITION.** The common value in XIII.4.6.5. is called the **packing dimension** of \(E\) in \((X, \rho)\), denoted \(\text{dim}_P(E)\). We also define the packing dimension of a finite set to be 0.

XIII.4.6.7. So the packing dimension of \(E\) is the critical value \(s\) where the packing measure \(\mathcal{P}^{(s)}(E)\) jumps from \(+\infty\) to 0. Examples show that if \(s = \text{dim}_P(E)\), then \(\mathcal{P}^{(s)}(E)\) can be 0, \(+\infty\), or any finite positive number.

XIII.4.6.8. It is an immediate corollary of XIII.4.6.3. that \(\text{dim}_H(E) \leq \text{dim}_P(E)\) for any \(E \subseteq X\). The Hausdorff and packing dimensions of a subset can differ (), although for well-behaved subsets they frequently coincide; when they do, the “fractal dimension” of the set is well defined as the common value.

XIII.4.6.9. A variation of the diameter-based packing measure we have considered is **radius-based packing measure**: use twice the radius of \(B_n\) in place of \(\text{diam}(B_n)\) in the definition. This makes no difference in Euclidean space since the diameter of any ball is exactly twice the radius, but this is false in general metric spaces, even subsets of Euclidean space with the restricted metric. The radius-based \(s\)-dimensional packing measure of a subset of a general metric space can differ significantly from the diameter-based packing measure (the radius-based one is larger), and even the radius-based and diameter-based packing dimensions of a subset can be different. Some references use radius-based packing measure. See [] for a discussion.

XIII.4.6.10. There is also a question of interpretation of the diameter of a ball: is it the diameter in \(X\), or the diameter of the intersection of the ball with the subset? In fact, there is a potential ambiguity in packing measure: is the packing measure or packing dimension of a subset \(E\) of \(X\) the same whether \(E\) is regarded as a subset of \(X\) or just as a metric space with the restricted metric? More generally, if \(Y\) is a subset of \(X\) with the restricted metric, and \(E \subseteq Y\), is the packing measure or packing dimension of \(E\) as a subset of \(Y\) the same as it is as a subset of \(X\)? Note that this problem does not occur with radius-based packing measure or dimension.

XIII.4.6.11. There are some other notions of fractal dimension generally intermediate between Hausdorff and packing dimension, e.g. upper and lower box-counting dimension and modified upper and lower box-counting dimensions, which do not arise from measures and which are not as nicely behaved, and some others which are more subtle and variable. These are defined and discussed in [Fal14].
Integralgeometric Measure

$\mathcal{H}$ is Hausdorff measure
$\mathcal{P}$ is packing measure
$\mathcal{I}$ is integralgeometric measure
$\mathcal{L}$ is Lebesgue measure

XIII.4.7. Radon Measures on Metric Spaces

XIII.4.8. Exercises

XIII.4.8.1. (a) Let $\rho$ be a metric on $\mathbb{R}^n$ coming from a norm. Show that $\mathcal{H}_\rho^{(n)}$ is a scalar multiple $\alpha \mathcal{L}^{(n)}$, where $\alpha$ is the reciprocal of the Lebesgue measure of the unit ball for $\rho$.

(b) Show that unless $\rho$ is a constant multiple of the usual Euclidean distance, $\mathcal{H}_\rho^{(s)}$ for $0 < s < n$ is not a constant multiple of $\mathcal{L}^{(s)}$. [For $s = 1$ consider horizontal and diagonal line segments.]
XIII.5. Measures on Product Spaces

In this section, we will discuss a natural way of constructing a Cartesian product of two or more measure spaces.

XIII.5.1. Product $\sigma$-Algebras

XIII.5.1.1. Suppose $(X, A)$ and $(Y, B)$ are measurable spaces. If $A \subseteq X$ and $B \subseteq Y$, then $A \times B$ is called a rectangle in $X \times Y$. If $A \in A$ and $B \in B$, then $A \times B$ is called a measurable rectangle (technically, $(A, B)$-measurable rectangle). It is natural that such subsets of $X \times Y$ should be regarded as measurable sets.

XIII.5.1.2. Definition. The product $\sigma$-algebra of $(A, B)$, denoted $A \otimes B$, is the $\sigma$-algebra on $X \times Y$ generated by the measurable rectangles.

Although some authors use the notation $AB$ for the product $\sigma$-algebra, we will use the symbol $A \otimes B$ since $A \otimes B$ is much larger than just the set of measurable rectangles in general; we will use $AB$ to denote the set of measurable rectangles. (The symbol $\otimes$ is normally used for “tensor product” in abstract algebra; there is a close analogy between our use of the symbol here and algebraic tensor products.)

XIII.5.1.3. Examples.

(i) If $X$ and $Y$ are sets, and at least one is countable, then it is easily checked that $\mathcal{P}(X) \otimes \mathcal{P}(Y) = \mathcal{P}(X \times Y)$ (Exercise (i)). In particular, $\mathcal{P}(\mathbb{N}) \otimes \mathcal{P}(\mathbb{N}) = \mathcal{P}(\mathbb{N}^2)$. But this result does not hold if $X$ and $Y$ are of large cardinality (Exercise (i)).

(ii) If $B$ is the $\sigma$-algebra of Borel sets in $\mathbb{R}$, then $B \otimes B = \mathcal{B}^{(2)}$, the $\sigma$-algebra of Borel sets in $\mathbb{R}^2$. Neither inclusion is completely obvious. To show that $B \otimes B \subseteq \mathcal{B}^{(2)}$, it suffices to show that every measurable rectangle is in $\mathcal{B}^{(2)}$. But $\mathcal{B}_x = \{ B \times \mathbb{R} : B \in \mathcal{B} \}$ is a $\sigma$-algebra which is generated by $\{ U \times \mathbb{R} : U \text{ open} \}$, and $U \times \mathbb{R}$ is open in $\mathbb{R}^2$, hence in $\mathcal{B}^{(2)}$; thus $\mathcal{B}_x \subseteq \mathcal{B}^{(2)}$. Similarly, $\mathcal{B}^{(2)} = \{ \mathbb{R} \times B : B \in \mathcal{B} \} \subseteq \mathcal{B}^{(2)}$. So if $A, B \in \mathcal{B}$, then $A \times B = (A \times \mathbb{R}) \cap (\mathbb{R} \times B) \in \mathcal{B}^{(2)}$, so $B \otimes B \subseteq \mathcal{B}^{(2)}$. For the other inclusion, it suffices to show that every open set in $\mathbb{R}^2$ is in $\mathcal{B} \otimes \mathcal{B}$. But it is a simple exercise (i) that every nonempty open set in $\mathbb{R}^2$ is a (countable) union of open rectangles of the form $(a, b) \times (c, d)$ with $a, b, c, d \in \mathbb{Q}$. (This example generalizes to the Borel sets in any product of second countable topological spaces; see (ii).)

Although the set of measurable rectangles is not a $\sigma$-algebra or even an algebra because it is not closed under complements or finite unions (except in trivial cases), we have:

XIII.5.1.4. Proposition. Let $(X, A)$ and $(Y, B)$ be measurable spaces. Then the set

$A \times B = \{ A \times B : A \in A, B \in B \}$

of measurable rectangles is a semialgebra.

Proof: We have $X \times Y$ and $\emptyset = \emptyset \times \emptyset$ in $A \times B$. If $\{ A_k \times B_k : 1 \leq k \leq n \}$ is a finite collection in $A \times B$, then

$\bigcap_{k=1}^{n} (A_k \times B_k) = \left( \bigcap_{k=1}^{n} A_k \right) \times \left( \bigcap_{k=1}^{n} B_k \right) \in A \times B$. 

1454
so $A \times B$ is closed under finite intersections (in fact, the same argument shows that $A \times B$ is closed under countable intersections). And if $A \times B \in A \times B$, then

$$(A \times B)^c = (A \times B^c) \cup (A^c \times Y)$$

so $(A \times B)^c$ is a disjoint union of two sets in $A \times B$.

\[\Box\]

XIII.5.1.5. PROPOSITION. Let $(X, \mathcal{A})$, $(Y, \mathcal{B})$, and $(Z, \mathcal{C})$ be measurable spaces. Let $\pi_X$ and $\pi_Y$ be the projections from $X \times Y$ to $X$ and $Y$ respectively, i.e. $\pi_X(x, y) = x$, $\pi_Y(x, y) = y$. Then

(i) $\pi_X$ is an $(\mathcal{A} \otimes \mathcal{B}, \mathcal{A})$-measurable function and $\pi_Y$ is an $(\mathcal{A} \otimes \mathcal{B}, \mathcal{B})$-measurable function.

(ii) If $f : Z \to (X \times Y)$ is a function, then $f$ is $(\mathcal{C}, \mathcal{A} \otimes \mathcal{B})$-measurable if and only if $\pi_X \circ f : Z \to X$ is $(\mathcal{C}, \mathcal{A})$-measurable and $\pi_Y \circ f : Z \to Y$ is $(\mathcal{C}, \mathcal{B})$-measurable.

PROOF: (i): If $A \in \mathcal{A}$, then $\pi_X^{-1}(A) = A \times Y \in \mathcal{A} \otimes \mathcal{B}$, so $\pi_X$ is measurable. The argument for $\pi_Y$ is similar.

(ii): If $f$ is measurable, then $\pi_X \circ f$ and $\pi_Y \circ f$ are measurable by XIII.1.4.3. Conversely, if $\pi_X \circ f$ is measurable, then $f^{-1}(A \times Y) = [\pi_X \circ f]^{-1}(A) \in \mathcal{C}$ for all $A \in \mathcal{A}$. Similarly, if $\pi_Y \circ f$ is measurable, then $f^{-1}(X \times B) \in \mathcal{C}$ for all $B \in \mathcal{B}$. Since $\{A \times Y : A \in \mathcal{A}\} \cup \{X \times B : B \in \mathcal{B}\}$ generates $\mathcal{A} \otimes \mathcal{B}$ as a $\sigma$-algebra, $f$ is measurable by XIII.1.4.10. \[\Box\]

XIII.5.2. Product Measures

Now suppose that $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ are measure spaces. We want to obtain a reasonable measure $\mu \times \nu$ on $(X \times Y, \mathcal{A} \otimes \mathcal{B})$. It is natural to want the measure of a measurable rectangle $A \times B$ to be $\mu(A)\nu(B)$. It turns out that it is possible to obtain such a measure through the Carathéodory extension process.

XIII.5.2.6. THEOREM. Let $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ be measure spaces. For $A \times B$ in the semialgebra $\mathcal{C}$ of measurable rectangles (XIII.5.1.4.), set $\iota(A \times B) = \mu(A)\nu(B)$ (where $0 \cdot \infty = \infty \cdot 0 = 0$ by convention). Then $\iota$ is a premeasure on $\mathcal{C}$, and hence $\iota$ extends to a measure on $(X \times Y, \mathcal{A} \otimes \mathcal{B})$ denoted $\mu \times \nu$ by the Carathéodory extension process. If $\mu$ and $\nu$ are $\sigma$-finite, then $\mu \times \nu$ is the unique extension of $\iota$ to a measure on $(X \times Y, \mathcal{A} \otimes \mathcal{B})$, and is also $\sigma$-finite.

PROOF: We verify that $\iota$ satisfies (i), (ii'), and (iii) of XIII.3.5.2. and XIII.3.5.6. (note that (ii') $\Rightarrow$ (ii) since $\emptyset \in \mathcal{A} \times \mathcal{B}$). Condition (i) is obvious. We prove (ii') and (iii) simultaneously since the arguments are almost identical (we could simplify the argument slightly by using the somewhat nontrivial result XIII.3.5.6. to avoid proving (iii), but this is not necessary). Suppose $A_1 \times B_1, A_2 \times B_2, \ldots$ is a sequence of measurable rectangles and

$$\bigcup_{k=1}^{\infty} (A_k \times B_k) \supseteq A \times B \in \mathcal{A} \times \mathcal{B}$$

1455
(for (ii'), assume the $A_k \otimes B_k$ are pairwise disjoint and $\bigcup_{k=1}^{\infty} (A_k \times B_k) = A \times B$). We must show $\mu(A)\nu(B) \leq \sum_{k=1}^{\infty} \mu(A_k)\nu(B_k)$, with equality for (ii'). We may assume $A$ and $B$ are nonempty. Set

$$\phi = \mu(A)\chi_B, \quad \psi = \sum_{k=1}^{\infty} \mu(A_k)\chi_{B_k}$$

(where the convention $\infty \cdot 0 = 0$ is followed). Then $\phi$ and $\psi$ are extended real-valued measurable functions on $(Y, \mathcal{B})$. We claim $\phi \leq \psi$, with equality in (ii'). If $y \notin B$, then $\phi(y) = 0$, and in case (ii') also $\psi(y) = 0$. If $y \in B$, set

$$I_y = \{k \in I : y \in B_k\} \subseteq \mathbb{N}.$$  

If $x \in A$, then $(x, y) \in A \times B$, so $(x, y) \in A_k \times B_k$ for at least one $k$ (exactly one $k$ in case (ii')), i.e. $x \in A_k$ for at least one $k \in I_y$ (exactly one in case (ii')). Thus $A$ is contained in the union of $\{A_k : k \in I_y\}$. In case (ii'), if $x \notin A$, then for every $k \in I_y$, $(x, y) \notin A_k \times B_k$; since $y \in B_k$, we have $x \notin A_k$ for every $k \in I_y$, i.e. $A$ is the disjoint union of $\{A_k : k \in I_y\}$. Thus

$$\phi(y) = \mu(A) \leq \sum_{k \in I_y} \mu(A_k) = \sum_{k \in I_y} \mu(A_k)\chi_{B_k}(y)$$

$$= \sum_{k \in \mathbb{N}} \mu(A_k)\chi_{B_k}(y) = \psi(y)$$

(with equality in case (ii')), where the first equality in the last line is because the additional terms are zero. Thus $\phi \leq \psi$, with equality in case (ii'). So

$$\mu(A)\nu(B) = \int_Y \phi \, d\nu \leq \int_Y \psi \, d\nu = \int_Y \left[ \sum_{k=1}^{\infty} \mu(A_k)\chi_{B_k} \right] \, d\nu$$

$$= \sum_{k=1}^{\infty} \mu(A_k) \left[ \int_Y \chi_{B_k} \, d\nu \right] = \sum_{k=1}^{\infty} \mu(A_k)\nu(B_k)$$

(with equality in case (ii')), where interchange of the sum and integral is justified by the MCT (XIV.4.5.5.). Thus $\iota$ satisfies (ii') and (iii) and is a premeasure.

The other conclusions then follow from XIII.3.5.8.. }

XIII.5.2.7. **DEFINITION.** The measure $\mu \times \nu$ is called the product measure of $\mu$ and $\nu$.

Completeness

XIII.5.2.8. There is a slight ambiguity in XIII.5.2.7. By the Extension Theorem, the $\sigma$-algebra $\mathcal{M}$ of $(\mu \times \nu)$-measurable sets contains the $\sigma$-algebra $\mathcal{A} \otimes \mathcal{B}$. But $(X \times Y, \mathcal{M}, \mu \times \nu)$ is a complete measure space and $\mathcal{M}$ is strictly larger than $\mathcal{A} \otimes \mathcal{B}$ in general. By slight abuse of notation, we will write $\mu \times \nu$ for the measure on $(X \times Y, \mathcal{A} \otimes \mathcal{B})$ and its extension on $(X \times Y, \mathcal{M})$ when a distinction is unimportant.

1456
If $\mu$ and $\nu$ are $\sigma$-finite, then $(X \times Y, \mathcal{M}, \mu \times \nu)$ is precisely the completion of $(X \times Y, \mathcal{A} \otimes \mathcal{B}, \mu \times \nu)$ XIII.3.5.8. If $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ are the completions of $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ respectively, then the outer measures induced by $\iota$ on $\mathcal{A} \times \mathcal{B}$ and $\iota$ on $\mathcal{A} \times \mathcal{B}$ coincide (Exercise XIV.6.3.2); so if $\mathcal{M}$ is the $\sigma$-algebra of $(\mu \times \nu)$-measurable sets, then $\mathcal{M} = \mathcal{M}$. Thus in the $\sigma$-finite case we can also identify the completion of $(X \times Y, \mathcal{A} \otimes \mathcal{B}, \mu \times \nu)$ with $(X \times Y, \mathcal{M}, \mu \times \nu)$, i.e. the completions of $(X \times Y, \mathcal{A} \otimes \mathcal{B}, \mu \times \nu)$ and $(X \times Y, \mathcal{A} \otimes \mathcal{B}, \mu \times \nu)$ coincide, and in particular $\mathcal{A} \otimes \mathcal{B} = \mathcal{A} \otimes \mathcal{B}$.

**Products of Finitely Many Spaces**

**XIII.5.2.9.** The results about products of two measure spaces can easily be generalized to products of finitely many. If $(X_1, \mathcal{A}_1), \ldots, (X_n, \mathcal{A}_n)$ are measurable spaces, then a set of the form $A_1 \times \cdots \times A_n$ with $A_i \subseteq X_i$, is called a rectangle, a measurable rectangle if $A_i \in \mathcal{A}_i$ for each $i$. Then $\mathcal{A}_1 \otimes \cdots \otimes \mathcal{A}_n$ is the $\sigma$-algebra generated by the measurable rectangles in $X_1 \times \cdots \times X_n$. If $I = \{1, \ldots, n\}$, $\mathcal{A}_1 \otimes \cdots \otimes \mathcal{A}_n$ is often denoted $\bigotimes_{i \in I} \mathcal{A}_i$ or $\bigotimes_{i=1}^n \mathcal{A}_i$.

The next proposition shows that the product $\sigma$-algebra can be defined also by successive products of two $\sigma$-algebras, using any convenient grouping:

**XIII.5.2.10.** Proposition. Let $(X, \mathcal{A})$, $(Y, \mathcal{B})$, and $(Z, \mathcal{C})$ be measurable spaces. If $X \times Y \times Z$ is identified with $(X \times Y) \times Z$ and $X \times (Y \times Z)$ in the standard way, we have $\mathcal{A} \otimes \mathcal{B} \otimes \mathcal{C} = (\mathcal{A} \otimes \mathcal{B}) \otimes \mathcal{C} = \mathcal{A} \otimes (\mathcal{B} \otimes \mathcal{C})$.

The proof is routine, and is left as an exercise.

**XIII.5.2.11.** Corollary. Let $(X_1, \mathcal{A}_1), \ldots, (X_n, \mathcal{A}_n)$ be measurable spaces, and let $I_1, I_2$ be disjoint subsets of $I = \{1, \ldots, n\}$ with $I = I_1 \cup I_2$. If $\prod_{i \in I} X_i$ is identified with $\left(\prod_{i \in I_1} X_i\right) \times \left(\prod_{i \in I_2} X_i\right)$ in the standard way, then

$$\bigotimes_{i \in I} \mathcal{A}_i = \left(\bigotimes_{i \in I_1} \mathcal{A}_i\right) \otimes \left(\bigotimes_{i \in I_2} \mathcal{A}_i\right).$$

There is then an analog of XIII.5.1.5. This can be proved directly in the same way as XIII.5.1.5., or by repeated application of XIII.5.1.5. and XIII.5.2.10.

**XIII.5.2.12.** Theorem. Let $(X_1, \mathcal{A}_1), \ldots, (X_n, \mathcal{A}_n)$ and $(Z, \mathcal{C})$ be measurable spaces. Let $\pi_k$ $(1 \leq k \leq n)$ be the projections from $X_1 \times \cdots \times X_n$ to $X_k$, i.e. $\pi_k(x_1, \ldots, x_n) = x_k$. Then

(i) $\pi_k$ is an $(\mathcal{A}_1 \otimes \cdots \otimes \mathcal{A}_n, \mathcal{A}_k)$-measurable function.

(ii) If $f : Z \to (X_1 \times \cdots \times X_n)$ is a function, then $f$ is $(\mathcal{C}, \mathcal{A}_1 \otimes \cdots \otimes \mathcal{A}_n)$-measurable if and only if $\pi_k \circ f : Z \to X$ is $(\mathcal{C}, \mathcal{A}_k)$-measurable for each $k$, $1 \leq k \leq n$.

We also have the analog of XIII.5.1.4., which can also either be proved directly in the same way as XIII.5.1.4. or by repeated application of XIII.5.1.4. and XIII.5.2.10.
XIII.5.2.13. Proposition. Let \((X_1, \mathcal{A}_1), \ldots, (X_n, \mathcal{A}_n)\) be measurable spaces. Then the set \(\mathcal{C} = \{ A_1 \times \cdots \times A_n : A_i \in \mathcal{A}_i \}\) of measurable rectangles is a semialgebra.

XIII.5.2.14. If \((X_1, \mathcal{A}_1), \cdots, (X_n, \mathcal{A}_n, \mu_n)\) are measure spaces, we can form a product measure \(\mu_1 \times \cdots \times \mu_n\) on \((\prod_{i=1}^n X_i, \bigotimes_{i=1}^n \mathcal{A}_i)\) such that \((\mu_1 \times \cdots \times \mu_n)(A_1 \times \cdots \times A_n) = \mu_1(A_1) \mu_2(A_2) \cdots \mu_n(A_n)\) for any \(A_i \in \mathcal{A}_i\). The proof of the next theorem is an adaptation of the proof of (\(\)) and is left as an exercise (\(\)).

XIII.5.2.15. Theorem. Let \(\{(X_i, \mathcal{A}_i, \mu_i) : 1 \leq i \leq n\}\) be measure spaces. For \(\prod_{i=1}^n \mathcal{A}_i\) in the semialgebra \(\mathcal{C}\) of measurable rectangles (XIII.5.2.13.), set \(\tau(\prod_{i=1}^n A_i) = \mu_1(A_1) \cdots \mu_n(A_n)\). Then \(\tau\) is a premeasure on \(\mathcal{C}\), and hence \(\tau\) extends to a measure on \((\prod_{i=1}^n X_i, \bigotimes_{i=1}^n \mathcal{A}_i)\) denoted \(\mu_1 \times \cdots \times \mu_n\) or \(\chi^n_{i=1} \mu_i\), by the Caratheodory extension process. If all \(\mu_i\) are \(\sigma\)-finite, then \(\chi^n_{i=1} \mu_i\) is the unique extension of \(\tau\) to a measure on \((\prod_{i=1}^n X_i, \bigotimes_{i=1}^n \mathcal{A}_i)\).

The next fact is immediate from the uniqueness in the \(\sigma\)-finite case, but holds in general. The proof in the general case is routine but somewhat tedious, and the result in the non-\(\sigma\)-finite case is of limited interest, so we omit the details.

XIII.5.2.16. Proposition. Let \((X_1, \mathcal{A}_1, \mu_1), \ldots, (X_n, \mathcal{A}_n, \mu_n)\) be measure spaces, and let \(I_1, I_2\) be disjoint subsets of \(I = \{1, \ldots, n\}\) with \(I = I_1 \cup I_2\). If \(\prod_{i \in I} X_i\) is identified with \((\prod_{i \in I_1} X_i) \times (\prod_{i \in I_2} X_i)\) in the standard way, then \(\chi_{i \in I_1} \mu_i = (\chi_{i \in I_1} \mu_i) \times (\chi_{i \in I_2} \mu_i)\).

XIII.5.3. Lebesgue Measure on \(\mathbb{R}^n\)

XIII.5.4. Infinite Product Spaces

It is also possible to define an infinite Cartesian product of measure spaces provided that all (or all but finitely many) of the measures are probability measures.

XIII.5.4.1. Suppose that \(\{(X_i, \mathcal{A}_i) : i \in I\}\) is an indexed collection of measurable spaces. A rectangle in \(\prod_i X_i\) is a finite set \(I_0 = \{i_1, \ldots, i_n\}\) of coordinates, and for each \(i_k\) a subset \(A_{i_k}\) of \(X_{i_k}\). The corresponding set

\[\{\cdots x_i \cdots \} \in \prod_i X_i : x_{i_k} \in A_{i_k} \text{ for all } k, 1 \leq k \leq n\]

is often denoted \(A_{i_1} \times \cdots \times A_{i_n}\), although it should more correctly be denoted \(\prod_{i \in I_0} A_i \times \prod_{i \not\in I_0} X_i\). Such a rectangle is a measurable rectangle if each \(A_{i_k}\) is in \(\mathcal{A}_{i_k}\).

If \(A_i\) is a subset of \(X_i\) for each \(i\), then the subset

\[\prod_i A_i = \{\cdots x_i \cdots \} \in \prod_i X_i : x_i \in A_i \text{ for all } i \in I\]

is called a box, and, if each \(A_i \in \mathcal{A}_i\), a measurable box. Note that a [measurable] box is not a [measurable] rectangle in general if \(I\) is infinite, unless \(A_i = X_i\) for all but finitely many \(i\).
XIII.5.4.2. Definition. The product $\sigma$-algebra $\bigotimes_{i \in I} A_i$ is the $\sigma$-algebra on $\prod_i X_i$ generated by the measurable rectangles.

XIII.5.4.3. Proposition. If $I$ is countable, then every measurable box is in $\bigotimes_{i \in I} A_i$.

XIII.5.4.4. This statement is false in general if $I$ is uncountable. We say that a subset $A$ of $\prod_i X_i$ depends only on the coordinates in $J \subseteq I$ if, whenever $x = (\cdots x_i \cdots)$ and $y = (\cdots y_i \cdots)$ are elements of $\prod_i X_i$, and $x_j = y_j$ for all $j \in J$, then $x \in A$ if and only if $y \in A$. A subset $A$ of $\prod_i X_i$ depends on finitely many countably many coordinates if it depends only on some finite countable set of coordinates. Thus every rectangle depends only on finitely many coordinates.

XIII.5.4.5. Proposition. Every set in $\bigotimes_{i \in I} A_i$ depends only on countably many coordinates.

Proof: It is easily checked that the collection of all sets which depend on only countably many coordinates is a $\sigma$-algebra.

XIII.5.4.6. Corollary. A nonempty measurable box $\prod_i A_i$ is in $\bigotimes_{i \in I} A_i$ if and only if $A_i = X_i$ for all but countably many $i$.

Infinite product measures are particularly important in probability. The next example is a good illustration of an infinite product measure which has a nice probabilistic interpretation.

XIII.5.4.7. Example. Let $X = \{0, 1\}$, and for each $n$ let $(X_n, A_n) = (X, \mathcal{P}(X))$. Put a measure $\mu$ on $(X, \mathcal{P}(X))$ by $\mu(\{0\}) = \mu(\{1\}) = 1/2$, and let $\mu_n$ be the corresponding measure on $(X_n, A_n)$. Let $X^n = \prod_{n \in \mathbb{N}} X_n$, $A^n = \bigotimes_{n \in \mathbb{N}} A_n$, and $\mu^n = \times_{n \in \mathbb{N}} \mu_n$. $(X, \mathcal{P}(X), \mu)$ is not a very interesting or complicated measure space, but $(X^n, A^n, \mu^n)$ is quite interesting and nontrivial. Elements of $X^n$ are, of course, all sequences of 0’s and 1’s.

If instead of $\{0, 1\}$ we take $X = \{H, T\}$, we may interpret $(X, \mathcal{P}(X), \mu)$ as the sample space of the experiment of tossing a fair coin once. Then $(X^n, A^n, \mu^n)$ can be interpreted as the sample space of the experiment of tossing a fair coin infinitely many times. Probabilists use this measure space to analyze such things as the likelihood of long runs and other details in a sequence of coin tosses. This is a good example of a stochastic process, the study of which is an entire branch of probability theory.

This example also has other interpretations not closely connected with probability. The product measure can be interpreted as a measure on the Cantor set (or as Haar measure on a certain compact topological group $(\cdot)$). There is also a close connection with Lebesgue measure on the unit interval $(\cdot)$.

The example could be modified by taking $\mu_\alpha(\{0\}) = \alpha$, $\mu_\alpha(\{1\}) = 1 - \alpha$ for some fixed $\alpha$, $0 < \alpha < 1$ (the original $\mu$ is $\mu_{1/2}$). The measure $\mu_\alpha$ could be interpreted probabilistically (using $\{H, T\}$ for $\{0, 1\}$) as tossing an unfair coin with probability of heads equal to $\alpha$. It turns out that the $\mu^n_\alpha$ are mutually singular continuous probability measures on $(X^n, A^n)$ as $\alpha$ ranges over $(0, 1)$ $(\cdot)$. One could even similarly define $\mu_0$ and $\mu_1$; $\mu^n_0$ is then the point mass at the constant sequence of 0’s, and $\mu^n_1$ the point mass at the constant sequence of 1’s.
XIII.5.4.8. One might try to construct the infinite product of \( \{ (X_i, A_i, \mu_i) : i \in I \} \) (where \( \mu_i(X_i) = 1 \) for all \( i \)) as follows. For each finite subset \( F \) of \( I \), let \( A_F \) be the \( \sigma \)-algebra on \( X = \prod X_i \) generated by the measurable rectangles depending only on \( F \), and \( \mu_F \) the measure on \( (X, A_F) \) which is effectively \( \times_{i \in F} \mu_i \) using the obvious identification of \( A_F \) with \( \otimes_{i \in F} A_i \) on \( \prod_{i \in F} X_i \). Then \( B = \cup_F A_F \) is an algebra of subsets of \( X \), and the \( \mu_F \) give a well-defined function \( \iota \) from \( B \) to \( [0, 1] \). The \( \sigma \)-algebra generated by \( B \) is \( \otimes_{i \in I} A_i \), and \( \times_{i \in I} \mu_i \) is an extension of \( \iota \) to \( \otimes_{i \in I} A_i \), so one might try to obtain \( \times_{i \in I} \mu_i \) directly from \( \iota \) by the Caratheodory extension process.

The difficulty in this approach is showing that \( \iota \) is a premeasure on \( B \). This is not automatic: it is not true in general that if \( (X, A_n, \nu_n) \) is a compatible family of probability measures on an increasing sequence \( (A_n) \) of \( \sigma \)-algebras, that the function \( \nu \) defined by the \( \nu_n \) on the algebra \( \cup_n A_n \) is a premeasure. For example, let \( X = \mathbb{N} \), \( A_n \) the \( \sigma \)-algebra of all subsets of \( \{1, \ldots, n\} \) and their complements in \( \mathbb{N} \), and \( \nu_n \) the measure on \( (\mathbb{N}, A_n) \) with \( \nu_n(A) = 0 \) if \( A \subseteq \{1, \ldots, n\} \) and \( \nu_n(A) = 1 \) if \( \mathbb{N} \setminus A \subseteq \{1, \ldots, n\} \). Then the function \( \nu \) is not a premeasure on \( \cup_n A_n \).

XIII.5.5. Exercises

XIII.5.5.1. Let \( X \) and \( Y \) be sets, and \( E \subseteq X \times Y \). For each \( x \in X \), set

\[
E_x = \{ y \in Y : (x, y) \in E \} \subseteq Y
\]

\[S_X(E) = \{ E_x : x \in X \} \subseteq \mathcal{P}(Y) .\]

\( S_X(E) \) is the set of “vertical cross-sections” of the set \( E \). The \( X \)-variety of \( E \) is \( var_X(E) = card(S_X(E)) \), the “number” of different sets occurring as vertical cross sections of \( E \). Similarly, for \( y \in Y \) define

\[
E^y = \{ x \in X : (x, y) \in E \} \subseteq X
\]

\[S_Y(E) = \{ E^y : y \in Y \} \subseteq \mathcal{P}(X) \]

and the \( Y \)-variety of \( E \) to be \( var_Y(E) = card(S_Y(E)) \).

(a) Prove that \( C_X = \{ E \subseteq X \times Y : var_X(E) \leq 2^{|Y|} \} \) is a \( \sigma \)-algebra of subsets of \( X \times Y \) containing \( \mathcal{P}(X) \otimes \mathcal{P}(Y) \). Similarly, \( C_Y = \{ E \subseteq X \times Y : var_Y(E) \leq 2^{|X|} \} \) is a \( \sigma \)-algebra containing \( \mathcal{P}(X) \otimes \mathcal{P}(Y) \).

(b) If \( card(X) > 2^{|X|} \) and \( card(Y) \geq 2^{|Y|} \), then \( \mathcal{P}(X) \otimes \mathcal{P}(Y) \neq \mathcal{P}(X \times Y) \). [Let \( \kappa = min(card(X), 2^{|X|}) \). Construct an \( E \subseteq X \times Y \) with \( var_X(E) = \kappa \). (What is really needed is a function from \( X \) to \( \mathcal{P}(Y) \) whose range has cardinality greater than \( 2^{|X|} \); AC is needed in general to insure that \( card(X) \) is comparable with \( 2^{|X|} \).)]

(c) Is it true that \( \mathcal{P}(X) \otimes \mathcal{P}(Y) = C_X \cap C_Y \) for all \( X, Y \)?
